MANILA HEMP, the most valuable of all fibres for cordage, is the produce of the leaf-stalks of *Musa textilis*, a native of the Philippine Islands. The plant, called *abaca* by the islanders, throws up a spurious stem from its rhizome, consisting of a cluster of sheathing leaf-stalks which rise to a height of from 20 to 30 feet, and spread out into a crown of huge undivided leaves characteristic of the various species of *Musa* (plantain, banana, &c.). In its native regions the plant is rudely cultivated solely as a source of fibre; it requires little attention, and when about three years old develops flowers on a central stem, at which stage it is in the most favourable condition for yielding fibre. The stock is then cut down, and the sheathing stalks torn asunder and reduced to small strips. These strips in their fresh succulent condition are drawn between a sharp knife-edged instrument and a hard wooden block to which it is fixed, and by repeated scraping in this way the soft cellular matter which surrounds the fibre is removed, and the fibre so cleaned has only to be hung up to dry in the open air, when, without further treatment, it is ready for use. Each stock yields, on an average, a little under 1 lb of fibre; and two natives cutting down plants and separating fibre will prepare not more than 25 lb per day. The fibre yielded by the outer layer of leaf-stalks is hard, fully developed, and strong, but the produce of the inner stalks is increasingly thin, fine, and weak. The finer fibre is used by the natives, without spinning or twisting (the ends of the single fibres being knotted together), for making exceedingly fine, light, and transparent yet comparatively strong textures, which they use as articles of dress and ornament. The hemp exported for cordage purposes is a somewhat woody fibre, of a bright brownish-white colour, and possessing great durability and strain-resisting power. It contains a very considerable amount of adherent pectinous matter, and an unusually large proportion, as much as 12 per cent., of water in a dry condition. In a damp atmosphere the fibre absorbs moisture so freely that it has been found to contain not less than 40 per cent. of water, a circumstance which dealers in the raw fibre should bear in mind. The plant has been introduced into many tropical lands; but the cheapness of labour in its native regions, and its abundance there, prevent its being a profitable substance for general cultivation. The entire supply comes from Manila and Cebu in the Philippine Islands, where its cultivation and preparation must give employment to a very large population. The exports, which are increasing with great rapidity, amounted in 1881 to about 400,000 bales of $2\frac{1}{2}$ cwts. each, almost the whole of which goes to the United Kingdom, the United States, and the Australian colonies. The quantity imported into the United Kingdom in 1881 was 346,908 cwts., valued at £678,514. The fibre is now so valuable that manila hemp cordage is freely adulterated by manufacturers, chiefly by admixture of phormium (New Zealand flax) and Russian hemp.

MANILIUS, a Roman poet, was the author of a poem in five books called *Astronomica.* Nothing is recorded of the author; he is neither quoted nor mentioned by any ancient writer. His very name is uncertain, but was probably Marcus Manilius. From the work itself it may be gathered with much probability that the writer lived under Augustus or Tiberius, and that he was a citizen of and resident in Rome. He bears the name of a distinguished plebeian family. His work is one of great learning; he had studied his subject in the best writers, and generally represents the most advanced views of the ancients on astronomy. It is, however, destitute of poetical or literary merit. It is difficult to explain how a work of such learning on a subject which was studied with such interest by the ancients should have remained so neglected. Firmicus, who wrote in the time of Constantine, has so many points of resemblance with the work of Manilius that he must either have used him or have followed some work that Manilius also followed. As Firmicus says that hardly any Roman except Cæsar, Cicero, and Fronto had treated the subject, it is probable that he did not know the work of Manilius. The latest event referred to in the poem is the great defeat of 9 A.D.

MANIN, DANIELE (1804–1857), president of the Venetian republic in 1848–49, and one of the principal founders of Italian independence, was born in Venice on the 13th May 1804. He studied at Padua, graduating as doctor of laws when only seventeen years of age, and soon after translated Pothier's large treatise *Sur le Droit Romain.* To his father, an eminent barrister, he was indebted not only for much of his skill in jurisprudence but for his strong republican bias, having as a boy constantly heard him denounce indignantly the injustice of Bonaparte in handing Venice over to Austria by the scandalous treaty of Campio Formio. In 1830 Manin commenced practice as an advocate, but only to become conscious of the harsh restrictions laid by Austria upon the administration of law. That and the following year showed some stirrings of political life in Italy; and Manin, already the leading spirit in Venetia of the new national party, strove to train his countrymen to united purpose and action. The question of a railway to Milan, for instance, or whether the Indian mail should go by Venice, was utilized to quicken the patriotic instinct by thwarting the Government, and that without neglecting the great principle "legality and publicity"—which till 1848 was his unswerving rule of conduct.

In 1847 he spoke ably on political economy at the scientific congress held in Venice, and soon after presented two petitions to the "congregation,"—a shadowy deliberative assembly which was tolerated by Austria. His principal demands were—separate government of Venice and Lombardy, revision of the code, an annual budget, freedom of the press, and religious equality. On the 18th January 1848, soon after Radetsky's cruel treatment of Milan, he was arrested, but only to intensify the patriotic enthusiasm of the people. The population of Venice marched past his prison silently and mournfully, every head uncovered. The carnival (that year spent in gloom) was scarcely over, however, when the glad news from Sicily, Naples, and Paris so worked upon their minds that the Austrian authorities were forced to feel that the revolutionary wave had reached Venice. On the 17th March Manin was carried in triumph to the Place St Mark, and virtually declared dictator. Now that the moment for action was come he immediately formed a civic guard, and by his energy and earnestness inspired all classes of the citizens to act as one man. On the 22d the dictator became president of the new republic of St Mark, to cope alone with all the difficulties of administration, organization, and finance. In March 1849, on the defeat of King Charles Albert, Venice had to prepare herself resolutely for defence; and on the 2d April there was passed in the palace of the Doges a decree in two clauses:— "(1) Venice will resist the Austrians at whatever cost; (2) the president Manin is invested with unlimited powers." On the 26th May one outlying fort was taken, but on the 3d July, when Rome and Mazzini had succumbed to the French, Venice and Manin were still strenuous in their heroic defence. Only when cholera had also attacked them, when food and ammunition were spent and people were dying of hunger, when every house not burned down was riddled by the shot and shell of the bombardment, and no gleam of hope from without was visible, was the capitulation signed, 24th August, on terms of amnesty to all except the president and thirty-nine other citizens.

Leaving Venice on the 27th, with his wife and two children, Manin spent the rest of his life in Paris, where he maintained a modest independence by teaching his native language. His energies were still devoted to the unification of Italy, so that, whether as a republic or as a kingdom, she might be freed from Austrian domination. He died of heart disease on the 22d September 1857, and was buried in the family tomb of Ary Scheffer. In 1868 the remains were removed to Venice, and honoured with a public funeral.

See Henri Martin, *D. Manin*, 1859, and *L'Unité Italienne*, 1861 (Martin also wrote the article in the *Biogr. Universelle*); C. L. Chassin, *Manin et l'Italie*; Errera's *Vita di D. Manin*, Venice, 1872; P. de La Faye's *Documents, &c., de D. Manin*, 1860. Other writers are Ernest Legouvé, A. de La Forge, and Edmund Flagg (New York).

MANIOC or MANDIOC. See CASSAVA and ARROWROOT.

MANIPUR, a native state in north-eastern India, lying between 24° 35′ and 24° 48′ 30″ N. lat., and between 93° and 94° 40′ E. long., is bounded on the N. by the Nága country and the hills overlooking the Assam valley, on the W. by Cáchár district, and on the E. by Independent Burmah. On the south the boundary is undefined, and abuts on the country inhabited by various independent wild hill tribes of Lushais, Kukis, &c. The state consists of an extensive valley, estimated at about 650 square miles in extent, and a large surrounding unsurveyed tract of difficult mountainous country stretching between Assam, Cáchár, Burmah, and Chittagong. The total area is estimated at about 7600 square miles. The population of the Manipur valley and the surrounding hills is supposed to be about 74,000 hill-men and 65,000 Manipuris. The hill ranges generally run north and south, with occasional connecting spurs and ridges of lower elevation between. Their greatest altitude is in the north, where they reach to upwards of 8000 feet above sea-level. The principal geographical feature in the valley is the Logtak Lake, an irregular sheet of water of considerable size, but said to be yearly growing smaller. The valley is watered by numerous rivers, the Bárak being the most important. The hills are densely clothed with tree jungle and large forest timber. There are large herds of wild elephants, as well as tigers, leopards, bears, buffaloes, &c. The country seems to be singularly free from poisonous snakes; the cobra does not appear to exist in the valley, but the boa constrictor is found in the dense forests to the south.

The first relations of the British with Manipur date from 1762, when the rájá solicited British aid to repel a Burmese invasion, and a treaty was entered into. The force was recalled, and but little communication between the two countries took place until 1824, on the outbreak of the first British Burmese war. British assistance was again invoked by the rájá, and the Burmese were finally expelled both from the Assam and Manipur valleys. A political agent acts as a means of communication between the state and the British Government. Manipur valley appears to have been originally occupied by several tribes which came from different directions. Although their general facial characteristics are Mongolian, there is a great diversity of feature among the Manipuris, some of them showing a regularity approaching the Aryan type. In the valley the people are chiefly Hindus, that religion being apparently of recent introduction. They have a caste system of their own, different from that of India, and chiefly founded on what is known as the system of *lallûp* or forced labour. Every male between the ages of seventeen and sixty is obliged to place his services at the disposal of the state for a certain number of days each year, and to different classes of the people different employments are assigned. About four hundred Mohammedan families, descendants of settlers from Bengal, reside to the east of the capital. The aboriginal hill-men belong to one of the two great divisions of Nágas and Kukis, and are subdivided into innumerable clans and sections with slight differences in language, customs, or dress. The state is noted for the excellence of its breed of ponies. The now popular English game of polo was introduced from Manipur, where it forms a great national pastime. The trade is but small, owing chiefly to the want of means of transport, none of the roads being available for wheeled carts.

MANIS. See PANGOLIN.

MANISA, or MANISSA, a town of Asia Minor or Anatolia, situated on the north side of Mount Sipylus, 28 miles northeast of Smyrna. This town was anciently called *Magnesia ad Sipylum* (see MAGNESIA). It is situated on the banks of the Hermus, and is noted as being one of the neatest and cleanest cities in Asia Minor. It contains above twenty mosques, two of which are adorned on the exterior with double minarets, and in the inside with paintings and other articles. The Armenians, Greeks, and Jews have also their respective places of worship. There is also a fine khan, and a citadel, which stands on a lofty rock, and commands an extensive view. The surrounding country is rich and productive, especially of saffron, which is exported. The town is the seat of some considerable trade, and many of the inhabitants are employed in the manufacture of cotton and silk goods and goats' hair shawls. Population about 40,000. The town is now connected with Smyrna by a railway, which is continued on to Ala-Shehr (Philadelphia). A few miles from Manisa is a colossal statue cut in the rock, which is generally supposed to be the figure of Niobe, alluded to by ancient authors.

MANISTEE, a city of the United States, the county seat of Manistee county, Michigan, is situated 135 miles north-west of Lansing, on the east side of Lake Michigan, at the mouth of the Manistee river, which is navigable for vessels drawing 10 to 12 feet of water for the distance of $1\frac{1}{2}$ miles to Manistee Lake. It is a great seat of the lumber trade, shipping annually 200,000,000 feet of timber, and having a score of saw-mills and about as many shingle mills, the latter of which produce in the year 400,000,000 shingles,—the largest quantity made at any one place in the world. Planing-mills and foundries are also maintained; and, in consequence of the discovery in 1881 of a bed of solid salt 30 feet thick, extensive salt factories are being built. The surrounding district is especially adapted for fruit-growing; and sportsmen are attracted to the Manistee river and its tributaries by the abundance of the rarely found grayling. The population, 3373 in 1870, was 7080 in 1880.

MANITOBA, one of the western provinces of the Dominion of Canada, is situated midway between the Atlantic and the Pacific coasts of the Dominion, about 1090 miles due west of Quebec (see vol. iv. plate xxxv.). It is bounded on the S. by the parallel 49° N. lat., which divides it from the United States; on the W. by 101° 20′ W. long; on the N. by 52° 50′ N. lat.; and on the E. by the western boundary of Ontario. Manitoba formerly belonged to the HUDSON'S BAY COMPANY (*q.v.*), and was, after the transfer of their territory to Canada, admitted in 1870 as the fifth province of the Dominion. At that time the infant province had an area of 13,500 square miles, and some 12,000 people, chiefly Indian half-breeds. In 1881 the limits were increased to the extent indicated above, and now contain, taking the Lake of the Woods as the eastern boundary, upwards of 80,000 square miles, an area only 8782 square miles less than that of England and Scotland together, extending 264 miles from north to south and upwards of 300 from east to west. The old district of Assiniboia, the result of the efforts in colonization by the earl of Selkirk in 1811 and succeeding years, was the nucleus of the province. Manitoba was so called by the Dominion parliament after the lake of that name; the designation is usually considered to be a compound of the Ojibway words, Manito, great spirit, and Waba, straits between lakes, or a word meaning echo.

The drainage of Manitoba is entirely north-eastward to Hudson's Bay. The three lakes—whose greatest lengths are 250, 150, and 130 miles respectively—are Winnipeg, Winnipegoosis, and Manitoba. They are all of a very varying and irregular shape, but average respectively 30, 18, and 10 miles in width. They are fresh, shallow, and tideless. Winnipegoosis and Manitoba at high water, in spring time, discharge their overflow through small streams into Winnipeg. The chief rivers emptying into Lake Winnipeg are the Winnipeg, the Red, and the Saskatchewan. The Assiniboine river, with its source in the province, and navigable from 250 to 350 miles for steamers of light draught, enters the Red river 45 miles from Lake Winnipeg, and at the confluence of the rivers ("The Forks") is situated the city of Winnipeg. The Winnipeg, which flows from the territory lying southeast of Lake Winnipeg, is a noble river some 200 miles long, that after leaving Lake of the Woods, dashes with its clear water over many cascades, and traverses very beautiful scenery. At its falls from Lake of the Woods is one of the greatest and most easily utilized water-powers in the world. Like most rivers in the New World, the Red river is at intervals of years subject to freshets. In the seventy years' experience of the Selkirk colonists there have been four "floods." The highest level of the site of the city of Winnipeg is said to have been under 5 feet of water for several weeks in May and June in 1826, under $2\frac{1}{2}$ feet in 1852, not covered in 1861, and only under water on the lowest levels in 1882. The extent of overflow has thus on each occasion been less. The loose soil on the banks of the river is every year carried away in great masses, and the channel has so widened as to render the recurrence of an overflow unlikely. The Saskatchewan, though not in the province, empties into Lake Winnepeg less than half a degree from the northern boundary. It is a mighty river, rising in the Rocky Mountains, and crossing eighteen degrees of longitude. Near its mouth are the Grand Rapids. Above these, steamers ply to Fort Edmonton, a point upwards of 800 miles north-west of the city of Winnipeg. Steamers run from Grand Rapids, through Lake Winnipeg, up Red river to the city of Winnipeg.

Geologically Manitoba may be said to be the resumption of the Secondary rocks left behind in the fertile portions of Ontario. The whole north-east of North America, running from Labrador, crossing the Ottawa, and skirting the Georgian Bay and Lake Superior, is a region of Laurentian or Primary rocks—containing copper, silver, and probably gold-bearing rocks. From Lake Superior north-westward to within 40 miles of Red river and up to the eastern shore of Lake Winnipeg the same region continues for about 500 miles, including near its western limits the Lake of the Woods. This barren region left behind, the fertile plains of Manitoba begin—a district resting on Silurian limestones. For 100 or 150 miles these rocks continue. This is the first prairie steppe. At very few points does an outcrop of limestone occur. A range of hills running from south-east to north-west bounds this region on the west. These are Pembina Mountains, Riding Mountains, and Duck Mountain, varying from 200 to 700 feet in height. Before the Riding Mountains are reached, on the shores and islands of Lakes Manitoba and Winnipegoosis are found a few buff-coloured Devonian limestones. From this line of hills westward spreads out the second prairie steppe, extending some 400 or 500 miles. Beyond this for an equal distance, at a still higher elevation, is the third prairie steppe, till the Rocky Mountains are reached. From the Pembina and Riding Mountains to the Rocky Mountains, say 1000 miles, Cretaceous beds underlie the plains and crop out at long intervals. The most striking feature of this formation, of which only the eastern 100 or 150 miles are within Manitoba, is the presence of coal. It is, like most of the Tertiary varieties, a lignite; a specimen analysed gives water 7·82 per cent., volatile combustible matter 31·35 per cent., fixed carbon 54·97 per cent., and ash 5·86 per cent. The supply of this coal is, according to Professor Selwyn, practically inexhaustible. Mr G. M. Dawson, Government explorer, has figured exposures of lignite 1 foot, 7 feet, and even 18 feet in thickness in the Souris valley, 250 miles south-west of Winnipeg. As a fuel for domestic purposes, this coal in general answers very well. The drift deposit on the first and second prairie levels varies from 20 to 100 feet, and consists of clay and boulders. A clay lying near the surface is used for making the white brick of which Winnipeg is built. The most recent geologic deposit is a rich vegetable mould, sometimes 4 feet in thickness. It is this that gives the reputation for fertility which the soil of the province enjoys.

The surface of Manitoba is somewhat level and monotonous. It is chiefly a prairie region, with treeless plains of from 5 to 40 miles extent, covered in summer with an exuberant vegetable growth, which dies every year. The river banks are, however, fringed with trees, and in the more undulating lands the timber belts vary from a few hundreds of yards to 5 or 10 miles in width, forming at times forests of no inconsiderable size. The chief trees of the country are the aspen (*Populus tremuloides*), the ash-leaved maple (*Negundo aceroides*), oak (*Quercus alba*), elm (*Ulmus americana*), and many varieties of willow. The strawberry, raspberry, currant, plum, cherry, and grape are indigenous.

The climate of Manitoba, being that of a region of wide extent and of similar conditions, is not subject to frequent variations. Winter, with cold but clear and bracing weather, usually sets in about the middle of November, and ends with March. In April and May the rivers have opened, the snow has disappeared, and the opportunity has been afforded the farmer of sowing his grain. The month of June is often wet, but most favourable for the springing crops; July and August are warm, but, excepting two or three days at a time, not uncomfortably so; while the autumn months of August and September are very pleasant. Harvest generally extends from the middle of August to near the end of September. The chief crops of the farmer are wheat (which from its flinty hardness and full kernel is the specialty of the Canadian north-west), oats, barley, and pease. Hay is made of the native prairie grasses, which grow luxuriantly. From the richness and mellowness of the soil potatoes and all tap-roots reach a great size. Heavy dews in summer give the needed moisture after the rains of June have ceased. The traveller and farmer are at times annoyed by the mosquito. This troublesome insect is chiefly found near swampy ground or on the uncultivated prairie. It usually continues through June and July.

The population of the province is very mixed. In 1870 there were 2000 whites and 10,000 Indian half-breeds. Of the latter, one half are of English-speaking parentage, and chiefly of Orkney origin; the remainder are known as Metis or Bois-brûlés, and are descended from French-Canadian voyageurs. In 1875 a number of Russian Mennonites (descendants of the Anabaptists of the Reformation) came to the country. Some fifty years ago they originally emigrated from Germany to the plains of southern Russia, but came over to Manitoba to escape the conscription. They number nearly 8000. About 4000 French Canadians, who had emigrated from Quebec to the United States, have also made the province their home, as well as a number of Icelanders. The remainder of the population is chiefly made up of English-speaking people from the other provinces of the Dominion, from the United States, from England and Scotland and the north of Ireland. Though somewhat difficult to estimate, the population of Manitoba is estimated by competent authorities at upwards of 120,000 in 1882.

In 1881 the religious opinions of the people were as follows:—Episcopalians, 22 per cent; Presbyterians, 22; Roman Catholics, 19; Methodists, 14; Baptists, 2½; Lutherans, 1½ per cent.

There is a system of primary and secondary free school education for Protestants, and another for Roman Catholics. For the higher education there are the three colleges of St Boniface (Roman Catholic), St John's (Episcopalian), and Manitoba College (Presbyterian). These are affiliated to the university of Manitoba, which is an examining and degree-conferring body.

Like other provinces of the Dominion, Manitoba is under a lieutenant-governor, with a council of five ministers responsible to the local legislature, which again is composed of thirty-one members. The province is represented by three senators in the Dominion senate, and by five members in the Dominion house of commons. There are three judges of the superior court, and a number of county court judges. The whole province is divided into municipalities, each of which chooses a warden and six councillors annually.

The city of Winnipeg, the provincial centre of government, law, education, and religion, had in 1882 upwards of 20,000 inhabitants. The trade of the country has chiefly grown up since Winnipeg was connected in 1878 with the United States railroad system, and it has received a further impulse from the construction of the Canadian Pacific Railway, which traverses the territory. (G. BR.)

MANITOWOC, a city of the United States, the county seat of Manitowoc county, Wisconsin, is situated on the west side of Lake Michigan, at the mouth of Manitowoc river, 77 miles north of Milwaukee by the Milwaukee, Lake Shore, and Western Railway. It has a good harbour, and is the seat of an active trade in lumber, leather, and wheat. Shipbuilding is also extensively carried on. Population in 1870, 3059; in 1880, 6367.

MANKATO, a city of the United States, the county seat of Blue Earth county, Minnesota, is situated in the midst of a good agricultural district on the right bank of the Minnesota river, and is a station on the Chicago, Milwaukee, and St Paul, the Chicago and North Western, and the Chicago, St Paul, Minneapolis, and Omaha railways. From St Paul it is distant 86 miles. Besides carrying on an extensive trade Mankato manufactures woollen goods, linseed oil, flour, beer, carriages and waggons, iron wares, and furniture. It has a fine park and fair ground, three public halls, a public library, and a State normal school. The population increased from 3482 in 1870 to 5550 in 1880.

MANLEY, MARY DE LA RIVIER (1672–1724), dramatist, political writer, and novelist, the most eminent female "wit" of the reign of Queen Anne, was the daughter of a studious and literary royalist, Sir Roger Manley, governor of the Channel Islands, part author of *The Turkish Spy*, and author of several military histories. Mrs Manley is herself the chief authority for such particulars of her private life as are known. Towards the close of Anne's reign, finding that Curll had announced *The Adventures of Rivella, or the History of the Author of Atalantis*, and suspecting this to be the work of an enemy, she contrived with dexterous tact to supplant Curll's author, and wrote her own biography under the announced title. Her mother died when she was a child, her father when she was a girl of sixteen. A kinsman, already married, took advantage of her position, went through a mock ceremony of marriage, and deserted her basely three years afterwards. She was patronized for a short time by the duchess of Cleveland, and in 1696 made good a position among writers of established reputation by two plays, a comedy and a tragedy. The dialogue of the comedy, *The Lost Lover*, is extremely brilliant and witty, overflowing with high animal spirits; in freedom of speech it goes almost beyond the most licentious male writers of comedy in that generation. The play was at once published. In the preface she thanks the town for not keeping her long in suspense: her comedy was damned with promptitude. A similar fate befel her tragedy, *The Royal Mischief*, though great literary power was shown in it. The splendid energy of the characters, and the hyperbolical vigour of their language, may be compared with the undisciplined youth of the Elizabethan drama; but it was not without reason that even contemporary critics complained of the "warmth" of certain passages. She pleaded in defence the example of Dryden; but Dryden in his most indecent moments falls short of it. From 1696 Mrs Manley was a favourite member of witty and fashionable society; she admits that she never had any pretensions to beauty, but the charms of her eyes and her conversation made her very fascinating. She achieved her principal triumph as a writer by her *Secret Memoirs of Several Persons of Quality*, a scandalous chronicle "from the New Atalantis, an island in the Mediterranean," published in 1709. Henceforth she was known as "the author of *Atalantis*." The *Atalantis* had a political purpose. Mrs Manley was a warm Tory partisan, and she sought in this scandalous narrative to expose the private vices of the ministers whom Swift, Bolingbroke, and Harley combined to drive from office. There are many references to her in Swift's *Journal to Stella*. "She has very good principles for one of her sort, and a great deal of good sense and invention." Mrs Manley was in fact one of the most romantically public-spirited and disinterested politicians of that corrupt time, and next to Swift the most effective writer on the side of Harley and Bolingbroke. During the keen political campaign in 1711 she wrote several pamphlets, and many numbers of the *Examiner*, criticizing persons and policy with equal vivacity. After the accession of George, she wrote a tragedy *Lucius* (1717)—a failure, and two so-called novels, *Bath Intrigues*, and *A Stage-Coach Journey to Exeter*. The story in these novels is told in letters between the principal characters.

MANLIUS is the name of a Roman gens, chiefly patrician, but, in later times at least, also containing plebeian families. The Roman historians represent them as intrepid, but stern even to cruelty.

I. Marcus Manlius Capitolinus, a brave and distinguished soldier, was one of the garrison of the Capitol while besieged by the Gauls; when they attempted to scale the rock by night, Manlius, aroused by the cackling of the sacred geese, rushed to the spot and threw down the foremost. Several years after, seeing a centurion led to prison for debt, he freed him with his own money, and even sold his estate to relieve other poor debtors, while he accused the senate of embezzling public money. He was charged with aspiring to kingship, and condemned by the comitia, but not until the assembly had adjourned to a place without the walls, where they could no longer see the Capitol which he had saved. His house on the Capitol was razed, and the Manlii resolved that no patrician Manlius should henceforth bear the name of Marcus.

II. Titus Manlius Imperiosus Torquatus went to the tribune Pomponius, who had brought his father to trial for overstepping the limits of his office, and threatened to kill him unless he desisted from the accusation (365 B.C.). Shortly after he slew a gigantic Gaul in single combat, and took from him a torques or neck-ornament, whence his surname is said to have been derived. When the Latins demanded an equal share in the government of the confederacy, Manlius vowed to kill with his own hand the first Latin he saw in the senate-house. The Latins and Campanians revolted, and Manlius, consul for the third time, marched into Campania and gained two great victories, near Vesuvius (where Decius his colleague devoted himself to gain the day), and at Trifanum. In this campaign Manlius executed his own son, who had killed an enemy in single combat, and thus disobeyed the express command of the consuls.

Both these Manlii belong to a great extent to legend, much of which is probably due to attempts to explain their surnames.

III. Titus Manlius Torquatus in his first consulship (235 B.C.) subjugated Sardinia, recently acquired from the Carthaginians; he was consul again (224) during the Gallic war. In 216 he opposed the ransoming of the Romans taken prisoners at Cannæ; and in 215 he was sent to Sardinia and defeated a Carthaginian attempt to regain possession of the island.

IV. Cnæus Manlius Vulso, consul in 189 B.C., received Asia as his province. Starting from Ephesus in the spring, he marched into Pamphylia, levying enormous contributions. He then attacked the Celts of Galatia on the pretext that they had aided Antiochus. They took refuge in Mounts Olympus and Magaba, but the missiles of the Roman light troops won each position with great slaughter. In the winter, assisted by ten delegates sent from Rome, he settled the terms of peace with Antiochus. He returned to Rome in 187, and triumphed after much opposition. The discipline of his army was loose, and his soldiers brought into Rome many foreign luxuries.

MANN, Horace, one of the best-known of American educationists, was born at Franklin, Massachusetts, May 4, 1796, and died at Yellow Springs, Ohio, August 2, 1859. His childhood and youth were passed in great poverty. "It was the misfortune of his family that it belonged to the smallest district, had the poorest schoolhouse, and employed the cheapest teachers, in a town which was itself small and poor." His health was early injured by hard manual labour, which left him no time for recreation either in summer or winter. He lost his father at the age of thirteen. He was from his childhood an eager reader; but his only means of gratifying this desire was a very small library in his native town. Up to the age of fifteen he had never been able to attend school for more than eight or ten weeks in any one year. He remained at home, working for his mother and the rest of the family, till the age of twenty. At that age he was taught the rudiments of Latin and Greek and a little English grammar by an itinerant schoolmaster, and entered the junior classes in Brown University in the year 1816. Symptoms of consumption, poverty, the necessity of supporting himself while at college, and other circumstances interfered with his studies. He, however, graduated in 1819. In 1821 he entered the school of law at Litchfield, Connecticut, and was called to the bar in 1823. In 1827 he was elected to the State legislature of Massachusetts, and in 1833 he was returned to the upper house. He suggested and organized the State lunatic asylum of Worcester. In 1837 the legislature appointed a board of education to revise and reorganize the common school system of the State; and Mann was appointed secretary. To give his whole time to the work, he gave up his profession and also his seat in the senate. He was secretary for twelve years. For these twelve years he worked fifteen hours a day, held teachers' conventions, gave lectures, and carried on an enormous correspondence. He started a periodical, *The Common School Journal*, in which he explained his views on education. He also published a series of *Annual Reports*; these American critics call "a classic on the subject." His seventh annual report gave the substance of his observations in Europe, and compared the systems of instruction followed in Prussia with those in use in Massachusetts, much to the disadvantage of the latter.[1]

In 1848 Mann was elected to Congress to fill the vacancy caused by the death of John Quincy Adams. He tried to induce the Government to establish a bureau of education at Washington, but this was not done till much later. He resigned his seat in Congress in 1853, and became the first president of Antioch College, at Yellow Springs,—a college for the combined education of men and women. Mann's chief work in American education is the reform which he brought about in the common and normal school system of Massachusetts; and this reform is largely due to his twelve annual reports.

Mann's other works are—*Lectures on Education*, 1848; *A Few Thoughts for a Young Man*, 1850; *Slavery, Letters and Speeches*, 1851; *Powers and Duties of Women*, 1853, &c. A complete edition of his writings, with a biography, was published in Cambridge, Massachusetts, in 1867; and a selection, under the title of *Thoughts Selected from the Writings of Horace Mann*, in 1869.

MANNA, a concrete saccharine exudation obtained by making incisions in the trunk of the flowering or manna ash tree, *Fraxinus Ornus*, L. At the present day the manna of commerce is collected exclusively in Sicily from cultivated trees, chiefly in the districts around Capaci, Carini, Cinisi, and Favarota, small towns 20 to 25 miles west of Palermo, and in the townships of Geraci, Castelbuono, and other places in the district of Cefalù, 50 to 70 miles east of Palermo. In the *frassinetti* or plantations the trees are placed about 7 feet apart, and after they are eight years old, and the trunk at least 3 inches in diameter, the collection of manna is begun. This operation is performed in July or August during the dry weather, by making transverse incisions $1\frac{1}{2}$ to 2 inches long, and about 1 inch apart, through the bark, one cut being made each day, the first at the bottom of the tree, another directly above the first, and so on. In succeeding years the process is repeated on the untouched sides of the trunk, until the tree has been cut all round and exhausted. It is then cut down, and a young plant arising from the same root takes its place. The finest or flaky manna appears to have been allowed to harden on the stem. A very superior kind, obtained by allowing the juice to encrust pieces of wood or straws inserted in the cuts, and called *manna a cannolo*, is not found in commerce in England. The fragments adhering to the stem after the finest flakes have been removed are scraped off, and form the small or Tolfa manna of commerce. That which flows from the lower incisions is often collected on tiles or on a concave piece of the prickly pear (*Opuntia*), but is less crystalline and more glutinous, and is less esteemed.

Manna of good quality dissolves at ordinary temperatures in about 6 parts of water, forming a clear liquid. Its chief constituent is mannite or manna sugar, a hexatomic alcohol, $C_6H_8(OH)^6$, which likewise occurs, in much smaller quantity, in certain species of *Fucus* and in plants of several widely separated natural orders. Of this substance the best manna contains 70 to 80 per cent. It crystallizes in shining rhombic prisms from its solution in boiling alcohol. Manna possesses mildly laxative properties, and on account of its sweet taste is employed as a mild aperient for children. It is less used in England now than formerly, but is still largely consumed in South America. In Italy mannite is prepared for sale in the shape of small cones resembling loaf sugar in shape, and is frequently prescribed in medicine instead of manna.

The manna of the present day appears to have been unknown before the 15th century, although a mountain in Sicily with the Arabic name Gibelman, *i.e.*, "manna mountain," appears to point to its collection there during the period that the island was held by the Saracens, 827–1070. In the 16th century it was collected in Calabria in Italy, and until recently was produced in the Tuscan Maremma, but neither from that locality nor from the States of the Church is any now brought into commerce, although the name of Tolfa, a town near Civita Vecchia, is still applied to an inferior variety of the drug.

Various other kinds of manna are known, but none of these have been found to contain mannite. Alhagi manna (Persian and Arabic *tar-angubín*) is the produce of *Alhagi camelorum*, Fisch., a small, spiny, leguminous plant, growing in Persia, Afghanistan, and Baluchistan. This manna occurs in the form of small, roundish, hard, dry tears, varying from the size of a mustard seed to that of a coriander, of a light-brown colour, sweet taste, and senna-like odour. The spines and pods of the plant are often mixed with it. It is collected near Kandahar and Herat, and imported into India from Cabul and Kandahar to the extent of about 2000 ℔. annually, and is valued, at about thirty shillings per ℔. Tamarisk manna (Persian *gaz-angubín*, tamarisk honey) exudes in June and July from the slender branches of *Tamarix gallica*, var. *mannifera*, Ehrenb., in the form of honey-like drops, which, in the cool temperature of the early morning, are found in the solid state. This secretion is caused by the puncture of an insect, *Coccus manniparus*, Ehrenb. In the valleys of the peninsula of Sinai, especially in the Wády el-Sheikh, this manna (Arabic *man*) is collected by the Arabs and sold to the monks of St Catherine, who supply it to the pilgrims visiting the convent. It is found also in Persia and the Punjab, but does not appear to be collected in any quantity. This kind of manna seems to be alluded to by Herodotus (vii. 31). Under the same name of *gaz-angubín* there are sold commonly in the Persian bazaars round cakes, of which a chief ingredient is a manna obtained to the south-west of Ispahan, in the month of August, by shaking the branches or scraping the stems of *Astragalus florulentus* and *A. adscendens*, Boiss. and Hausskn.[2] *Shírkhist*, a kind of manna known to writers on materia medica in the 16th century, is still found in the bazaars of north-west India, being imported from Afghanistan and Turkestan to a limited extent. Haussknecht states that it is the produce of *Cotoneaster nummularia*, Fisch. and Mey. (*Rosaceæ*), and *Atraphaxis spinosa*, L. (*Polygonaceæ*), and that it is brought chiefly from Herat.

Oak manna, according to Haussknecht, is collected from the twigs of *Quercus Vallonea*, Kotschy, and *Q. persica*, Jaub. and Spach, on which it is produced by the puncture of an insect during the month of August. This manna occurs in the state of agglutinated tears, and forms an object of some industry among the wandering tribes of Kurdistan at the present day. It is collected before sunrise, by shaking the grains of manna on to linen cloths spread out beneath the trees, or by dipping the small branches in hot water and evaporating the solution thus obtained. A substance collected by the inhabitants of Laristan from *Pyrus glabra*, Boiss., strongly resembles oak manna in appearance.

Australian manna is found on the leaves of *Eucalyptus viminalis*, Lab.; the Lerp manna of Australia is of animal origin.

Briançon manna is met with on the leaves of the common LARCH (*q.v.*), and a kind of manna was at one time obtained from the cedar, but none of these are now collected for commercial purposes.

The manna of Scripture, notwithstanding the miraculous circumstances which distinguish it in the Biblical narrative from anything now known, answers in its description very closely to the tamarisk manna.

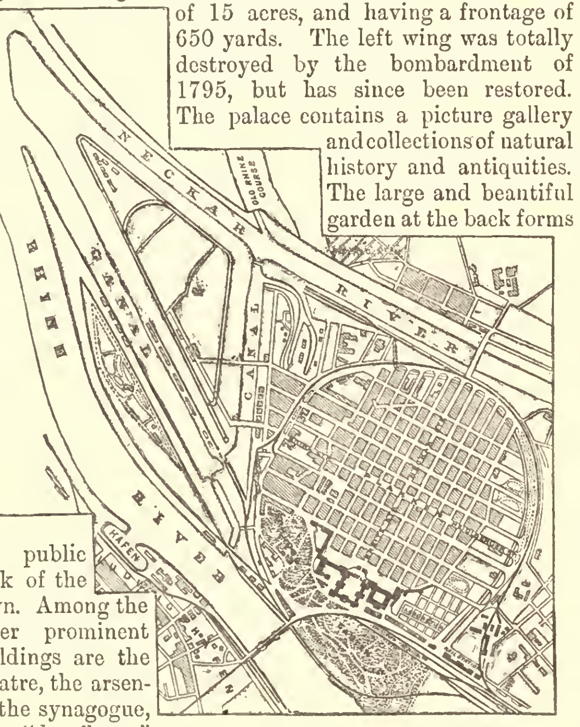
MANNHEIM, the most populous town and the second capital of the grand-duchy of Baden, lies on the right bank of the Rhine, in the triangular piece of low-lying ground enclosed between that river and the Neckar. It

[1] This report has been published and edited, with preface and notes, by Dr W. B. Hodgson, under the title of *Report of an Educational Tour in Germany, France, Holland, and parts of Great Britain and Ireland*, London, 1846.

[2] See *Bombay Lit. Tr.*, vol. i. art. 16, for details as to the gaz-angubín. A common Persian sweetmeat consists of wheat-flour kneaded with manna into a thick paste.

is the most regularly built town in Germany, consisting of twelve parallel streets intersected at right angles by ten others, which cut it up into about 130 square sections of equal size. These blocks are distinguished, after the American fashion, by letters and numerals. Except on the south side all the streets debouch on the promenade, which forms a circle round the town on the site of the old ramparts. Outside this ring are the suburbs of Schwetzinger Gärten to the south and Neckargärten to the north. Mannheim is connected by a handsome bridge with Ludwigshafen, a rapidly growing commercial and manufacturing town on the left bank of the Rhine, in Bavarian territory. The Neckar is spanned by a suspension bridge. In 1880 Mannheim contained 53,545 inhabitants, of whom about 4500 were Jews, and the rest Roman Catholics and Protestants in nearly equal proportions. Ludwigshafen contained 15,012 inhabitants.

Nearly the whole of the south-west side of the town is occupied by the palace, built in 1720–29, and formerly the residence of the elector of the Palatinate. It is one of the largest buildings of the kind in Germany, covering an area of 15 acres, and having a frontage of 650 yards. The left wing was totally destroyed by the bombardment of 1795, but has since been restored. The palace contains a picture gallery and collections of natural history and antiquities. The large and beautiful garden at the back forms the public park of the town. Among the other prominent buildings are the theatre, the arsenal, the synagogue, the "kaufhaus," the town-hall, the railway station, and the observatory. The only noteworthy church is that of the old Jesuit college, the interior of which is lavishly decorated with marble and painting. The square in front of the theatre is embellished with statues of Schiller, Iffland the actor, and Dalberg, intendant of the theatre in the time of Schiller. Mannheim is the chief commercial town on the upper Rhine, and yields in importance to Coblentz and Cologne alone among the lower Rhenish towns. The staple commodities of its trade are tobacco, grain, petroleum, hops, timber, and coffee. Its new harbour, constructed at a cost of £650,000, and measuring 2300 yards in length, is the most extensive inland harbour in Germany. It is entered annually by 3000 river craft, carrying nearly 700,000 tons of goods. The railway goods station and warehouses in connexion with the harbour cover 100 acres of ground. The principal industrial products of Mannheim are machinery, iron, brass, india-rubber, sugar, mirrors, chemicals, wall-paper, and cigars. The manufactories of Ludwigshafen produce aniline dyes, soda, tartaric acid, alum, artificial manures, and lime. Mannheim is the seat of the central board for the navigation of the Rhine, of a chamber of commerce, and of the supreme court of Baden. Ten or twelve different countries are represented here by their consuls. The schools and public institutions of Mannheim include a gymnasium, a "realschule," an industrial school, a high school for girls, a public library, a large poorhouse, three hospitals, and an orphanage.



Plan of Mannheim.

History.—The name of Mannheim was connected with its present site as early as the 8th century, when a small village belonging to the abbey of Lorsch lay in the marshy district between the Neckar and the Rhine. To the south of this village, on the Rhine, was the castle of Eicholzheim, which acquired some celebrity as the place of confinement assigned to Pope John XXIII. by the council of Constance. The history of the modern Mannheim begins, however, with the opening of the 17th century, when Elector John Frederick IV. founded a town here, which he peopled chiefly with Protestant refugees from Holland. The strongly fortified castle which he erected at the same time had the unfortunate result of making the infant town an object of contention in the Thirty Years' War, during which it was five times taken and retaken. In 1689 Mannheim, which had in the meantime recovered from its former disasters, was captured by the French under Melac, and ruthlessly destroyed. Ten years later it was rebuilt on an extended scale and provided with fortifications. For its subsequent importance it was indebted to Elector Charles Philip, who, owing to ecclesiastical disputes, transferred his residence from Heidelberg to Mannheim in 1720. It remained the capital of the Palatinate for nearly sixty years. In 1794 Mannheim fell into the hands of the French, and in the following year it was retaken by the Austrians after a severe bombardment, which left scarcely a single building uninjured. In 1802 it was assigned to the grand-duke of Baden, who caused the fortifications to be razed. Ludwigshafen, originally only the *tête-du-pont* of Mannheim, received its present name in 1843, and became a town in 1859. Towards the end of last century Mannheim attained great celebrity in the literary world as the place where Schiller's early plays were performed for the first time. It was at Mannheim that Kotzebue was assassinated in 1819.

See Feder, *Geschichte der Stadt Mannheim*, 1875; and Unglenk, *Praktischer Führer durch Mannheim*, 1880.

MANNING, Robert, commonly known as Robert of Brunne, a monk of the priory of Brunne or Bourne in Lincolnshire, wrote in the beginning of the reign of Edward III. a metrical history of England from the landing of the imaginary Brute to the end of the reign of Edward I. The work has no independent historical value; it professedly follows Peter of Langtoft's *Chronicle* from the Anglo-Saxon or "Inglis" invasion downwards, and Wace for the previous "British" story. It is a lively narrative, written "not for the lered bot for the lewed," and it has a certain interest as a landmark, not only in the history of the English language, but also in the history of national sentiment. Manning is warm in praise of the deeds and the character of Edward I., "Edward of Inglond," although he deplores the Norman Conquest as a "bondage," and says concerning the death of Harold that "our freedom that day for ever took the leave." The old monk is our first avowedly "popular" historian. He wrote for the entertainment of men who knew neither Latin nor French, and in his prologue comments humorously on the "quaint English" and subtle rhymes of his predecessors, claiming for himself purity of language and simplicity of metre. A passage in this prologue has often been quoted as bearing on the authorship of the romance of *Sir Tristram*. Manning also translated William of Waddington's *Manuel des Pechiez* under the title of *Handlying Synne*, in 1303, and is plausibly conjectured to be the author of *Medytacyuns of the Soper of oure Lorde Ihesu*, translated from Bonaventura's *Vita Christi*. He is not a bald rhymester, but uses language with skill and effect, and in some places where he departs from his originals shows genuine poetical rapture.

MANOMETER, or Pressure Gauge, is an instrument for measuring the hydrostatic pressure exerted by gases, vapours, or liquids against the sides of the closed vessels in which they are confined,—as, for instance, the pressure of steam in a steam-boiler.

The simplest and at the same time most accurate form of manometer is that known as the "mercury manometer," sometimes also called the "free-air manometer," and represented in fig. 1. It consists essentially of two vertical communicating tubes. One of these, AB, open at both ends, and made of thick glass, with a narrow uniform bore, is fixed hermetically in the neck of a large wrought-iron cylinder C, its lower end dipping below the surface of mercury contained in the cylinder. The other tube, EF, is attached at its lower end to the cylinder by the cross pipe D, and at its upper end can be put in communication with the vessel the pressure in which is to be ascertained. Usually the tube EF, the cross pipe D, and the space above the mercury in C are filled with water. At first the tube EF is left open to the atmosphere, and the height of the mercury in AB noted. When EF is then put in communication with the vessel in which the pressure (above atmospheric) is to be determined, the mercury in AB rises, and from the height to which it rises the pressure is deduced. For accurate work corrections must be made for the fall of the mercury in C as it rises in AB, and for the temperature and the height of the barometer at the time of the experiment.

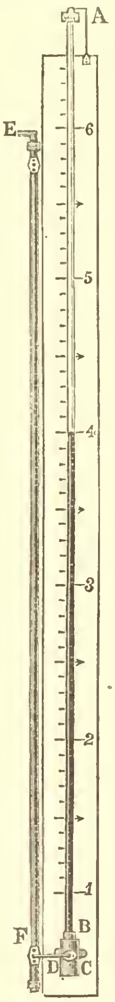


FIG. 1.—Mercury Manometer.

The great drawback to the employment of the simple mercury manometer for measuring very great pressures is the mechanical difficulty of obtaining a sufficiently long column of mercury. E. H. M. Amagat, however, has lately (1880) worked with a column *one-fifth of a mile* high. His experiments were undertaken to find out how the various gases, nitrogen, oxygen, air, hydrogen, &c., departed from Mariotte's law when subjected to enormous pressures. At the bottom of a coal-mine at Verpilleux, near St Étienne, which had a depth of 327 metres, was placed the glass manometer tube containing the compressed gas, while the mercury tube (made of steel) extended up the shaft, being gradually built up in sections. See *Nature*, vol. xxii. pp. 62, 63. By means of Amagat's tables of the volume and corresponding pressure of the several gases, and with special forms of manometer to suit particular circumstances, accurate and delicate measures of enormous pressures can now be obtained. Professor Tait, for instance, has recently applied these tables along with a manometer of his own devising for testing the behaviour of the thermometers supplied to the "Challenger" expedition under a pressure of as much as 10 tons to the square inch.

"Regnault's manometer" is shown in fig. 2. AB is a strong metal tube, closed at the lower end, and carrying at the upper a bent pipe for admitting the compressed gas and a stop-cock R pierced with holes in a T form. DE and FG are two graduated glass tubes communicating at their lower ends by a narrow passage in the metal block to which they are hermetically fixed. DE and AB also communicate at the upper ends by a passage in a metal piece attached hermetically to them. By the stop-cock R′, having radial holes at right angles to each other, DE can communicate either with AB or with the atmosphere at O; and by the stop-cock R″ it can communicate either with FG or with the open air. The three tubes are surrounded by a cylinder MM′ containing water to keep the temperature constant. The tube AB is filled with the compressed gas whose pressure is to be ascertained. The stop-cock R′ being then placed as in fig. 2, mercury is poured into FG till it fills DE and runs out at O. The stop-cocks R and R′ are then turned as in fig. 2*a*, so that AB and DE communicate with each other. Part of the compressed gas flows over into DE, and the mercury in FG rises. By manipulating the stop-cock R″ as shown in fig. 2*b*, part of the mercury is allowed to run out of DE till a conveniently measurable difference of level between the mercury surfaces in DE and FG is attained.

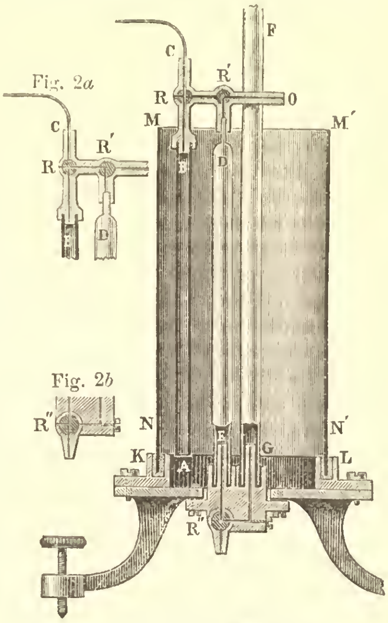

FIG. 2.—Regnault's Manometer.

Let h be this difference. Also let x be the pressure of the gas originally filling the volume V of AB, V′ the additional volume occupied by the expanded gas, and H be the height of the barometer at the time; then we have by Mariotte's law

$$xV = (V + V')(H + h),$$

from which

$$x = \frac{V + V'}{V}(H + h) \quad . \quad . \quad . \quad . \quad . \quad . \quad (1).$$

V′ is determined by weighing the mercury required to fill the space it occupies, and V can be calculated from (1) when AB is filled with dry air at pressure H.

In Regnault's apparatus the length of AB and DE was 1 metre, the diameter of AB 5 mm. and of DE 20 mm. The section of DE was thus sixteen times that of AB, and in this way a very great pressure could be measured by a comparatively small difference of level between the mercury surfaces in FG and DE. The instrument, however, is subject to errors, arising chiefly from the difficulty of measuring accurately the volumes V and V′.

The "compressed air manometer" (fig. 3) consists of a strong graduated glass tube of uniform narrow bore, closed at the top and fixed hermetically into the neck of a wide iron cylinder. The tube contains dry air, and its lower end dips below the surface of mercury contained in the cylinder. Attached to the side of the cylinder is a tube A, with a stop-cock, to afford communication with the vessel the pressure in which is to be measured. When the manometer is attached to the vessel containing compressed gas the mercury rises in the glass tube till the pressure of the air confined in the tube (reckoned in millimetres of mercury) plus the height of the mercury column above the level of the mercury in the cylinder is equal to the pressure on the surface of mercury in the cylinder.

FIG. 3.—Compressed Air Manometer.

"Desgoffe's manometer" depends upon the same principle as the hydraulic press, and can be employed to measure the enormous pressure reached in the cylinder of that instrument. It is represented in perspective in fig. 4 and in section in fig. 5. V is a strong circular iron vessel, in which moves up and down for a short distance a flat piston D attached to a cylindrical plug T. The lower part of V contains mercury which has free communication with a graduated vertical glass tube AB fixed hermetically into the side of V. Above the mercury in V is placed a thin layer of water, and above that is stretched a thin membrane of india-rubber bolted down water-tight by an iron ring. The chamber C contains a cavity in which the plug T moves water-tight. By means of the tube t the instrument can be put in communication with the vessel containing the fluid whose pressure is to be measured. The compressed fluid acting upon T depresses the piston D and causes the mercury to rise in AB.

Let p be the pressure of the fluid per unit of area, s the area of T, and S the area of D; also let P be the pressure per unit of area as recorded by the height of the mercury in AB. Thus evidently we have

$$ps = PS, \text{ or } p = \frac{S}{s}P.$$

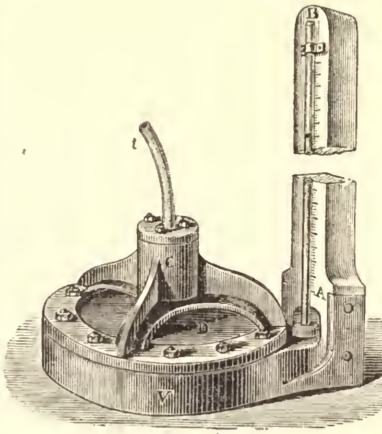

Fig. 4.—Desgoffe's Manometer.

Hence by making S very great and s very small a very great pressure can be measured by a comparatively short column of mercury in AB. As part of the pressure p is employed to stretch the india-rubber membrane, the ratio $S:s$ should be made very great, so that D will only sink a very short distance. Cailletet, who employed this manometer in his experiments on the compressibility of fluids, had it so arranged that (neglecting the stretching of the india-rubber) the mercury in AB rose 4·3 metres while the piston in D sunk only one-eighth of a millimetre.

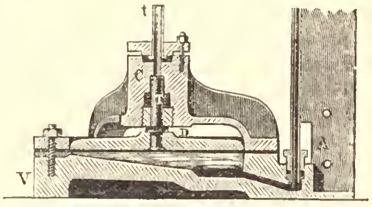

Fig. 5. Section of Desgoffe's Manometer.

Metallic manometers depend on the principle exemplified in the aneroid barometer. Suppose a long tube, preferably of elliptic section, and having thin walls of elastic material, to be closed at one end and either bent or coiled up in the form of a spiral. Let the open end be attached to an apparatus whereby the pressure inside the tube can be either increased or diminished. If the pressure inside the tube be made greater than that outside, the tube has a tendency to straighten or uncoil itself, but if the pressure outside be greater than that inside the tube has a tendency to bend or coil itself up farther. Fig. 6 represents an early form of metallic manometer made on this principle by Bourdon, the first to construct such instruments. A metallic tube ab, closed at b, is coiled in a spiral and rigidly attached at the open end a to a tube with stop-cock m, whereby it can communicate with the compression apparatus. A light index e is attached to b and moves over a graduated scale. The scale is graduated by applying known pressures inside the tube. This form of manometer is very convenient for rough practical work, but has no pretensions to scientific accuracy, as changes of temperature affect the elasticity of the tube in a way which is difficult to discover and allow for. Various forms of metallic manometers have been recently invented, the best-known of which are perhaps those of Bourdon and Schäfer, in which the index is moved by a train of wheels actuated by the free end of the elastic tube.

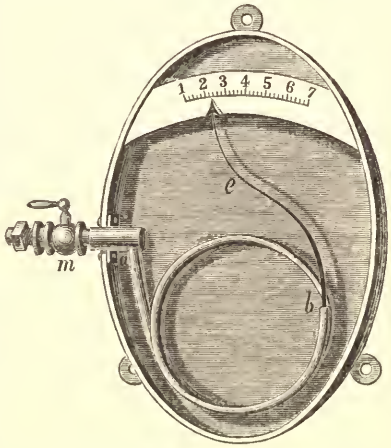

Fig. 6.—Bourdon's Metallic Manometer.

Air-pump Manometer.—For measuring pressures less than that of the atmosphere, as in the receiver of an air-pump, a special form of mercury manometer is employed, consisting of a glass U tube with each leg over 30 inches long and half filled with mercury. One leg communicates by an air-tight communication with the receiver of the air-pump, and the other is left open. As the exhaustion proceeds, the mercury falls in the open leg and rises in the other. When only considerable degrees of exhaustion are to be measured, the instrument takes the form of a short U tube closed at one end and open at the other, and has its closed leg completely filled with mercury, the mercury being held up by the atmospheric pressure. The whole is enclosed in a wide glass tube closed at the top and hermetically fixed at the lower end to a brass piece, provided with a stop-cock, whereby it can be screwed on to the sole plate of the air-pump. The difference of level in the two legs gives the degree of exhaustion obtained.

See Ganot's *Physics*; Wüllner's *Lehrbuch der Experimentalphysik*; Amagat in *Annales de Chemie et de Physique*, March 1880; *Report of H.M.S. Challenger*, in regard to pressure corrections supplied by thermometers, by Professor Tait. (J. BL.)

MANOR, in English law, is an estate in land, to which is incident the right to hold certain courts called courts baron. It might be described as the unit of tenure under the feudal system, and it is historically connected with the territorial divisions of the mark and the parish or township.[1] The legal theory of the origin of manors refers them to a grant from the crown, as stated in the following extract from Perkins's *Treatise* on the laws of England:—"The beginning of a manor was when the king gave a thousand acres of land, or a greater or lesser parcel of land, unto one of his subjects and his heirs, which tenure is knight's service at the least. And the donor did perhaps build a mansion house upon parcel of the same land, and of 20 acres, parcel of that which remained, or of a greater or lesser parcel before the statute of *Quia Emptores* did enfeoff a stranger to hold of him and his heirs to plow 10 acres of land, parcel of that which remained in his possession, and did enfeoff another of another parcel thereof to go to war with him against the Scots, &c., and so by continuance of time made a manor." It is still, as Mr Joshua Williams terms it, a "fundamental rule" that all lands were originally derived from the crown, and that the queen is lady paramount mediate or immediate of all the land in the realm. A manor then arises where the owner of a parcel so granted or supposed to have been granted by the crown (and who is called in relation thereto the lord) has in turn granted portions thereof to others who stand to him in the relation of tenants. Of the portion reserved by the lord for his own use (his demesne) part was occupied by villeins, with the duty of cultivating the rest for the lord's use. These were originally tenants at will, and in a state of semi-serfdom, but they became in course of time the copyhold tenants of the later law. (See Copyhold.) It is of the essence of copyhold that it should be regulated by the custom of the manor; and that, according to some authorities, is one reason why a manor cannot be created at the present day. "Length of time being of the very essence of a manor, such things as receive their perfection by the continuance of time come not within the compass of a king's prerogative" (Scriven, *Copyholds*, chap. i.). But the effect of the statute of *Quia Emptores* was to make the creation of manors henceforward impossible, inasmuch as it enacted "that upon all sales or feoffments of land, the feoffee shall hold the same, not of his immediate feoffor, but of the chief lord of the fee of whom such feoffor himself held it." The statute did not apply to the king's tenants *in capite*, who might have aliened their land under a licence. Accordingly it is assumed that all existing manors are "of a date prior to the statute of *Quia Emptores*, except perhaps some which may have been created by the king's tenants *in capite* with licence from the crown" (Williams, *Real Property*, chap. iv.; see also Scriven, *Copyholds*, chap. i.). When a great baron had granted out smaller

[1] Laveleye (*Primitive Property*, chap. xviii.) observes that in the 10th century, even before the Norman Conquest, the mark had already been transformed into the manor, although the term was not yet in use. The country was covered with a great number of domains (*maneria*), of very different extent, from the maneriolum of one plough to the latifundium of fifty ploughs.

manors to others, the seignory of the superior baron was frequently termed an honour.

MANRESA, a town of Catalonia, Spain, 39 miles north-west of Barcelona, with a population of 15,264. It was formerly Bacasis, one of the cities of the Jaccetani, the most important of the small tribes at the foot of the Pyrenees. It lies on the left bank of the Cardonero, 2 miles above its junction with the Llobregat, in the midst of a fertile and well-irrigated district, and its chief manufactures are cloth, cotton, silk, gunpowder, and brandy. Building stone is quarried near the town. The Cardonero is crossed by two bridges,—one ancient, the other erected in 1804. The two principal sights of Manresa are the collegiate church, El Seo, commenced in 1328, and finished in the 15th century, and the Cueva de San Ygnacio. The late Mr G. E. Street has minutely described the church in his *Gothic Architecture of Spain*. Among its greatest treasures he specializes a magnificent altar frontal as "the most beautiful work of its age." It is 10 feet long by 2 feet 10 inches in height, and is divided into nine compartments, at the bottom of which is the inscription in Lombardic characters :—GERI : LAPI : RECHAMATORE : MEFECIT : INFLORENTIA. In the Cueva de San Ygnacio, Ignatius Loyola lived for a year, fasting and submitting himself to the severest penances, constantly gazing at the shrine of the Virgin of Montserrat, who, he asserted, encouraged him in his austerities. A great monastery surrounds the cave, which is visited by thousands of pilgrims, and from the esplanade there is a magnificent view of the "pinnacles, spires, turrets, sugar-loaves, and pyramids of faint grey rocks," constituting the famous mountain of Montserrat. At Cardona, a little more than 20 miles to the north-west of Manresa, there is a remarkable hill of rock-salt 3 miles in circumference, and 350 feet in height, which is estimated to contain 400 million cubic yards of salt.

MANS, LE, a town of France, formerly capital of Maine and now of the department of Sarthe, lies 118 miles (131 by rail) W.S.W. from Paris, near the confluence of the Sarthe and the Huisne, on an elevation rising from the left bank of the former river. Three bridges besides that of the railway connect the town with the quarter on the right bank. Of the wide and commodious thoroughfares which are gradually superseding the old winding and narrow streets, the most worthy of notice is the tunnel by which the Place des Jacobins is connected with the river side. The principal building is the cathedral, originally founded by St Julian, to whom it is dedicated. Rebuilt in the 6th century by St Innocent, in the 9th by St Aldric, and a third or fourth time in the 11th by Vulgrin, who was at once architect and bishop, it was completed by the addition of two towers in the 12th. Destroyed by two fires, the roof was reconstructed in the Gothic style, and the transept and south portal were added. In the 13th century the choir was enlarged in the grandest and boldest style of that magnificent period. Finally a new transept and a bell tower were added in the 15th century. In the large window of the west front the ten divisions which have for their subject the legend of St Julian are the oldest extant specimens of stained glass in France (end of 11th century). The side portal (12th century) is richly decorated, and its statuettes exhibit many interesting costumes of the period. The aisles have ten bays, but the nave only five; the transept is much higher; from it rises the only tower of the building. The austere simplicity of the nave is in striking contrast with the lavish richness of the ornamentation in the choir and apse. The former is 115 feet in height, and has twelve chapels besides the sacristy; its windows almost entirely date from the middle of the 13th century. The glass of the north transept is of the 15th century, and represents the Last Judgment; it contains many historical figures. The cathedral has also curious tapestries and some remarkable tombs, including that of Berengaria, queen of Richard Cœur de Lion. The entire length of the building is 427 feet. Close to the western wall is a megalithic monument nearly 15 feet in height. The church of La Couture, which belonged to an old abbey founded in the 7th century by St Bertrand or Bertram, has a remarkable porch of the 13th century; the rest of the building is older. Of the other churches of Le Mans, none require special mention except that of Notre Dame du Pré, on the right bank of the Sarthe. Of the secular buildings may be mentioned the hôtel de ville, built about a century ago on the site of the former castle of the counts of Maine, and the prefecture, occupying the site of the monastery of La Couture (1760). The latter contains the library (50,000 volumes, 700 MSS.), the communal archives, and the museum of paintings, archæology, and natural history. Other prominent buildings are the general hospital, the lyceum, the seminary, the palais de justice, and the cavalry barracks; the house occupied by Scarron is still pointed out, and there are considerable remains of the old Gallo-Roman enceinte. The principal promenades are those of the Jacobins, of the horticultural garden, Du Greffier (on the right bank of the river), and Des Sapins (on the road to Tours). The industries of Le Mans, which are carried on chiefly in the faubourg of Pontlieue, include metal-working, the manufacture of agricultural implements, and weaving. For some years there has been a Government tobacco factory. A local specialty is the fattening of poultry. The population in 1876 was 50,175 (including 5282 representing the garrison, &c.). Le Mans is an important railway junction.

As the capital of the Aulerci Cenomani, Le Mans was called Suindinum or Vindinum. The Romans surrounded it with walls in the 3d century; it was evangelized by St Julian in the 4th. The countship of Maine was made hereditary by Hugh Capet in the 10th century. Le Mans was seized by William the Conqueror, but his son Robert was unable to retain it. Having chosen the side of Richard Cœur-de-Lion, it was taken by Philip Augustus, recaptured by John, subsequently confiscated, and afterwards ceded to the widow of Richard. Maine was next held by Margaret, the wife of St Louis, who gave it to his brother Charles of Anjou. Le Mans was five times besieged during the Hundred Years' War, and was subsequently devastated by the Huguenots in 1562. In 1793 it was seized by the Vendeans, who were expelled by Marceau after a sanguinary battle in the streets of the town. In 1799 it was again occupied by the Chouans; and in January 1871 the second army of the Loire sustained in the neighbourhood of Le Mans a defeat which made the relief of Paris impossible. The town is the birthplace of Henry II. of England, of John the Good, king of France, and of Chappe, the inventor of the aerial telegraph.

MANSEL, HENRY LONGUEVILLE (1820–1871), metaphysician and theologian, was born at Cosgrove, Northamptonshire (where his father was rector) in 1820, and educated at Merchant Taylors' School and St John's College, Oxford. He succeeded to a fellowship in 1842, graduated in 1843, and became tutor of his college. He was appointed reader in moral and metaphysical philosophy at Magdalen College in 1855, becoming Waynflete professor in 1859. In 1867 he succeeded Dean Stanley as professor of ecclesiastical history, and in the following year was appointed dean of St Paul's. He died July 31, 1871.

The philosophy of Mansel, like that of his older contemporary Sir W. Hamilton of Edinburgh, was mainly due to three sources,—the works of Aristotle, the speculations of Kant, and the philosophy of Reid. Like Hamilton, Mansel maintained the purely formal character of logical science, the duality of consciousness as testifying to both self and the external world, and the limitation of knowledge to the finite and "conditioned." His logical doctrines were developed in his edition of Aldrich's *Artis Logicæ Rudimenta* (1849)—his chief contribution to the reviving study of Aristotle—and in his *Prolegomena Logica,—an Inquiry into the Psychological Character of Logical Processes* (1851), in which the limits of logic as the "science of formal thinking" are rigorously determined. In his Bampton Lectures on *The Limits of Religious Thought* (1858) he applied to Christian theology the metaphysical agnosticism which seemed to result from Kant's criticism, and which had been developed in Hamilton's *Philosophy of the Unconditioned*. Showing the contradictions which arise when we attempt to conceive God under the categories of substance or cause, Mansel contends that we can have no positive conception either of the metaphysical or moral attributes of the Absolute and Infinite Being, though we are compelled to believe in His existence, the religious consciousness being built up by reflexion from the feeling of dependence and the conviction of moral obligation. Hence he infers the invalidity of all objections to revelation from its alleged inconsistency with the Divine character, maintaining the dependence of its claim to acceptance upon the evidences accompanying it. While denying all knowledge of the supersensuous, Mansel deviated from Kant in contending that cognition of the ego as it really is is itself a fact of experience. Consciousness, he held,—agreeing thus with the doctrine of "natural realism" which Hamilton developed from Reid,—implies knowledge both of self and of the external world. The latter Mansel's psychology reduces to consciousness of our organism as extended; with the former is given consciousness of free-will and moral obligation. These views and a summary of his whole philosophy are contained in his article "Metaphysics" contributed to the 8th edition of the *Encyclopædia Britannica* (separately published, 1860). Mansel was also the author of an essay on *The Philosophy of the Conditioned* (1866) in reply to Mill's criticism of Hamilton, of other controversial and occasional writings republished in *Letters, Lectures, and Reviews* (1873), and of lectures on *The Gnostic Heresies* (edited by J. B. Lightfoot, 1875).

MANSFELD, COUNT ERNEST OF (1585–1626), a natural son of Peter Ernest, governor of Luxemburg and Brussels, was born in 1585. Trained by his godfather, the archduke Ernest of Austria, in the Roman Catholic religion, he devoted himself to the service of the king of Spain in the Netherlands, and to that of the emperor in Hungary. The emperor Rudolf II. conferred on him the rights of legitimate birth, and promised to put him in possession of his father's lands in the Netherlands. As this promise was not fulfilled, he joined the Reformed Church, and in 1610 formally associated himself with the Protestant princes. From the outbreak of the Thirty Years' War in 1618 he fought steadily on behalf of the elector of the Palatinate both in Bohemia and in the Rhine country. In 1625 he was able to collect a powerful force with which he intended to attack the hereditary territories of Austria, but, on the 25th of April 1626, he was defeated by Wallenstein at Dessau. He pressed forward to effect a junction with Bethlen Gabor, prince of Transylvania, but as the latter changed his policy Mansfeld had no alternative but to disband his army. When preparing to go to England by Venice, he became ill at a village near Zara, and died on the 20th of November 1626. He was a man of great courage and resource, and ranks among the most brilliant generals of his age.

See Reuss, *Graf Ernst von Mansfeld im böhmischen Kriege* 1618–21 (1865); Villermont, *Ernest de Mansfeld* (1866); and Graf Uetterodt zu Scharffenberg, *Ernest Graf zu Mansfeld, historische Darstellung* (1867).

MANSFIELD, a market-town in the county of Nottingham, England, is situated in Sherwood Forest, near the north bank of the river Mann or Maun, 17 miles north-west from Nottingham, and 140 north-north-west of London by rail. The town is built of stone, with regular streets radiating from the market place, and several good houses. The church of St Peter is partly Early Norman and partly Perpendicular. There is a grammar school founded by Queen Elizabeth in 1561, for which new buildings have lately been erected at a cost of £10,000. Twelve almshouses were founded by Elizabeth Heath in 1693, and to these six were afterwards added. In addition there are a number of other charities. The other principal buildings are the town-hall, the mechanics' institute, and the public baths. In the market place there is a monument to Lord George Bentinck. The industries of the town are the manufacture of lace thread, cotton hose, machines, engines, and bricks and tiles, iron-founding, and brewing. In the neighbourhood there are quarries of limestone, sandstone, and freestone. Population in 1871, 11,824; in 1881, 13,651.

From coins found at Mansfield and the remains of a Roman villa in the neighbourhood, it is believed to have been a Roman station. During the heptarchy it was occasionally the residence of the Mercian kings, and it was afterwards a favourite resort of Norman sovereigns. By Henry VIII. the manor was granted to the earl of Surrey. Afterwards it went by exchange to the duke of Newcastle, and from the Newcastles to the Portland family. The town obtained a fair from Richard II. in 1377.

MANSFIELD, the county seat of Richland county, Ohio, U.S., pleasantly situated on high ground, 54 miles south of Sandusky, in the midst of a prosperous farming district. It is the terminus of the North-Western Ohio Railroad, and is at the junction of the Baltimore and Ohio, the Pittsburgh, Fort Wayne, and Chicago, and the New York, Pennsylvania, and Ohio lines. It possesses a flourishing trade, and extensive manufactories of agricultural implements, machinery, flour, boilers, carriages, and household furniture, with many minor industries. Mansfield has public water-works on the "Holly" system, a public library, and an opera-house. The population was 8029 in 1870 and 9859 in 1880.

MANSFIELD, WILLIAM MURRAY, EARL OF (1705–1793), was born at Scone, in Perthshire, on 2d March 1705. He was the eleventh child and fourth son of David, fifth Viscount Stormont, a nobleman whose family possessions had shrunk within so narrow limits that he had to bring up his numerous family with exceedingly strict economy. The family was Jacobite in its politics, and the second son, being apparently mixed up in some of the plots of the time, joined the court of the Pretender at the accession of George I., and was created by him earl of Dunbar. William Murray was sent first to the grammar school at Perth, where he remained until he was thirteen, and at that age was sent to Westminster at the suggestion of his exiled brother, who had been in close relation with Atterbury (then dean of Westminster), and probably desired to bring the boy under his influence. He was elected a king's scholar a year after his entrance, and in 1723 was first on the list of scholars sent on the foundation to Christ Church, where he remained for nearly four years. It had been originally intended that he should enter the English church, as, although his own inclination while at school pointed strongly towards the bar, the circumstances of his family seemed to forbid the expense of a legal education. But this obstacle was removed by the kindness of the father of one of his schoolfellows, and he was entered at Lincoln's Inn. Soon after he went to Oxford. In 1727 he took chambers in Lincoln's Inn, and in 1730 was called to the bar. His studies from the time he left Westminster seem to have been steadily directed towards his future profession, but in a manner far more liberal than was then usual among lawyers. He had made himself at Westminster and Oxford an admirable classical scholar; he paid particular attention to English composition and to the art of debate; his historical studies were extensive, and in the more strictly professional sphere his wide view of the education necessary for a lawyer was shown by the knowledge he acquired of Roman law and of the juridical writers of Scotland and France. At the same time he enjoyed the advantage of mixing extensively with the best literary society. He had early become an intimate friend of Pope, and his own ability and accomplishments soon made him everywhere a man of mark.

For two or three years he made little or no progress at the bar, but at length his appearance in some important Scotch appeal cases brought him into notice, and in Scotland at least he acquired an immense reputation by his appearance for the city of Edinburgh when it was threatened with disfranchisement for the affair of the Porteous mob. His English business had as yet been scanty, but in 1737 a single speech in a jury trial of note may be said to have placed him at the head of the bar, and from this time he enjoyed a great business. In 1738 he married Lady Elizabeth Finch, daughter of the earl of Winchelsea. His political career commenced in 1742 with his appointment as solicitor-general. Probably his political opinions were not of a marked party character; he had been bred a Jacobite, and many of his earlier associates belonged to the high Tory camp, but his calm sense and temper disinclined him to extreme factions, and indeed his interest in politics seems at all times to have been subordinate to the love of his profession. He had kept entirely aloof during the struggles which preceded the fall of Sir Robert Walpole; he refused any purely political appointment, and only took office as solicitor when he felt assured of the permanence of the new administration. During the next fourteen years Murray was one of the most conspicuous figures in the parliamentary history of the time. Although holding an office of subordinate rank, and not sharing, nominally at least, in the councils of the administration, he was the chief defender of their measures in the House of Commons, and during the time that Pitt was in opposition had to bear the brunt of his attacks. He was especially conspicuous in the great debates on the employment of the Hanoverian troops, the treaty of Aix-la-Chapelle, and the Regency Bill. In 1754 he became attorney-general, and for the next two years acted as leader of the House of Commons under the administration of the duke of Newcastle. During these years he had to defend a weak Government against the incessant, vehement assaults of Pitt, and, according to the testimony of contemporaries, acquitted himself brilliantly in the contest. But in 1756, when the Government was evidently approaching its fall, an unexpected vacancy occurred in the chief justiceship of the king's bench, and he claimed the office. Newcastle made every effort to retain him in the House of Commons, feeling as he did that his departure would hasten the fall of the Government, but Murray was inexorable. He seems to have been thoroughly tired of his parliamentary life, and to have long looked forward to the bench as the proper sphere of his work. He was at the same time raised to the peerage as Baron Mansfield.

From this time the chief interest of his career lies in his judicial work, but he did not wholly dissever himself from politics. He became by a singular arrangement, only once repeated subsequently in the case of Lord Ellenborough, a member of the cabinet, and remained in that position through various changes of administration for nearly fifteen years, and, although he persistently refused the chancellorship, he acted as speaker of the House of Lords while the great seal was in commission. During the time of Pitt's ascendency he took but little part in politics, but while Lord Bute was in power his influence was very considerable, and seems mostly to have been exerted in favour of a more moderate line of policy. He was on the whole a supporter of the prerogative, but within definite limits. Macaulay terms him, justly enough, "the father of modern Toryism, of Toryism modified to suit an order of things in which the House of Commons is the most powerful body in the state." In this spirit he continued to act a conspicuous though not a foremost part in political life during the rest of his career. During the stormy session of 1770 he came into violent collision with Lord Chatham and Lord Camden in the questions that arose out of the Middlesex election and the trials for political libel, and in the subsequent years he was made the subject of the bitter attacks of Junius, in which his early Jacobite connexions, and his apparent leanings to arbitrary power, were used against him with extraordinary ability and virulence. In 1776 he was created earl of Mansfield. In 1783, although he declined to re-enter the cabinet, he acted as speaker of the House of Lords during the coalition ministry, and with this his political career may be said to have closed. He continued to act as chief justice until his resignation in June 1788, and after five years spent in quiet retirement died peacefully on 20th March 1793. He left no family, but his title had been re-granted (in 1792) with a direct remainder to his nephew, Lord Stormont.

Lord Mansfield's great reputation rests chiefly on his judicial career. The political trials in which he presided, although they gave rise to numerous accusations against him, were conducted with singular fairness and propriety. He was accused with especial bitterness of favouring arbitrary power by the law which he laid down in the trials for libel which arose out of the publications of Junius and Horne Tooke, and which at a later time he reaffirmed in the case of the dean of St Asaph (see LIBEL). But, although his political opinions led him to look with disfavour on the popular view, and although it was unquestionably unfortunate that in some of these instances he was a member of the cabinet which directed the proceedings, we must remember that his view of the law was concurred in by the great majority of the judges and lawyers of that time, and was supported by undoubted precedents. In other instances, when the Government were equally concerned, he was wholly free from suspicion. He supported Lord Camden's decision against general warrants, and reversed the outlawry of Wilkes. While on the whole he leaned in opinion to a view of the law which we should now call oppressive, there is no instance in which he can justly be accused of wresting it, and in every instance he treated the accused with a fairness and decency which had not always been shown by his predecessors. In another way he came into conflict with popular prejudices. He was always ready to protect the rights of conscience, whether they were claimed by Dissenters or Catholics, and the popular fury which led to the destruction of his house during the Gordon riots was directed against him very much because a Catholic priest, who was accused of saying mass, had escaped the penal laws by his charge to the jury. His chief celebrity, however, is founded upon the consummate ability with which he discharged the civil duties of his office. He has always been recognized as the founder of English mercantile law. The common law as it existed before his time was wholly inadequate to cope with the new cases and customs which arose with the increasing development of commerce. The facts were left to the jury to decide as best they might, and no principle was ever extracted from them which might serve as a guide in subsequent cases. Lord Mansfield found the law in this chaotic state, and left it in a form that was almost equivalent to a code. Working patiently with the guildhall juries, whom he trained to act in thorough understanding with him, he defined almost every principle that governed commercial transactions in such a manner that his successors had only to apply the rules he had laid down. His knowledge of Roman and foreign law, and the general width of his education, freed him from the danger of relying too exclusively upon narrow precedents, and afforded him a storehouse of principles and illustrations, while the grasp and acuteness of his intellect enabled him to put his judgments in a form which almost always commanded assent. A similar influence was exerted by him in other branches of the common law; and although, after his retirement, a reaction took place, and he was regarded for a while as one who had corrupted the ancient principles of English law, these prejudices passed rapidly away, and the value of his work in bringing the older law in harmony with the needs of modern society has long been fully recognized.

The chief defect of Lord Mansfield's character was a certain coldness and want of moral courage. He had no very warm attachment either to persons or opinions, although invariably kindly and considerate in his demeanour. Even his greatest speeches owe their impressiveness to a certain intellectual nobleness and breadth of view. His attachment to justice was not impassioned, but of the type which is bred from highest professional custom, and from the kind of intellectual taste which led him so frequently to the ethical writings of Cicero. He could not always face the enthusiasm of Chatham, and we cannot feel certain that his courage would have sustained him through any very perilous stand for righteousness. But in the sphere in which he was chiefly famous these defects were scarcely disadvantages. His sense of duty and of personal dignity was amply sufficient to bear him perfectly unstained through life. No suitor had ever to complain of delay or neglect. His want of strong feeling only permitted him to use his magnificent intellect with greater impartiality; and, if at any time he was affected by personal prejudice, no trace of it was ever allowed to appear. Nothing ever disturbed the perfect dignity and propriety of his judicial conduct, which is apparent in every trial at which he presided. He impressed himself on the mind of his contemporaries as one of the best examples of what a great judge ought to be, and from that estimate a closer examination of his claims will scarcely lead us to differ. (A. GI.)

MANSLAUGHTER. See MURDER.

MANSON, GEORGE (1850–1876), a Scottish water-colour painter, was born in Edinburgh on the 3d of December 1850. When about fifteen he was apprenticed as a woodcutter with Messrs W. & R. Chambers, with whom he remained for over five years, designing and engraving vignettes distinguished by singular rightness and directness of technical method, diligently employing all his spare time in the study and practice of art, and producing in his morning and evening hours water-colours of much delicacy and beauty, like the Milking Time and the Cottage Door. In 1871 he left the Messrs Chambers, and devoted himself exclusively to painting. His subjects were derived from humble Scottish life—especially child life, varied occasionally by portraiture, by landscape, and by views of picturesque architecture. In 1873 he visited Normandy, Belgium, and Holland; in the following year he spent several months in Sark; and in 1875 he resided at St Lô, and in Paris, where he mastered the processes of etching. He afterwards produced a series of plates which promised excellence in the art. Meanwhile in his water-colour work he had been adding more of breadth and power to the tenderness and richness of colour which distinguished his early pictures, and he was planning more complex and important subjects. But his health had been gradually failing, and he was ordered to Lympstone in Devonshire, where he died on the 27th of February 1876. Among his chief productions are the High School Wynd; the Companions—a gipsy girl and her donkey; Waiting for the Boats; What is It?—a child examining an antique clock; and his own portrait as a Sark fisherman. Since his death several exhibitions of his works have been held in London and Edinburgh, and a volume of photographs from his water-colours and sketches, with a memoir by J. M. Gray, was published in 1880. For an account of Manson's technical method as a wood engraver see P. G. Hamerton's *Graphic Arts*, p. 311.

MANSUR, MANSOOR, or more properly, with the article, AL-MANṢÚR, "the victorious," a surname (*laḳab*) assumed by not a few Mohammedan princes. Among the personages commonly referred to by this title the following may be noticed.

1. Abú Ja'far ibn Mohammed, second caliph of the house of 'Abbás, who reigned 754–775 A.D. See MOHAMMEDAN EMPIRE.

2. Abú Ṭáhir Isma'íl ibn Al-Ḳáim, third Fatimite caliph of Africa (946–953). Under Al-Ḳáim, his father, the Fatimites, already weakened by their conflict with the Omayyads of Spain, were threatened with utter ruin by a Berber rising under Abú Yezíd, a poor nonconformist ('Ibáḍí) schoolmaster, who appeared as a religious reformer, and gathered round him the Sunnites, who detested the Fatimites. In 944 Abú Yezíd conquered the capital Ḳairawán, and recognized the spiritual headship of the Spanish caliph. While the Spanish caliph and his vassals stripped the Fatimite of his remoter possessions, Abú Yezíd pressed him at home, and during the siege of Súsa Al-Ḳáim died, and was succeeded by Al-Manṣúr. Then the fortunes of war rapidly turned. Abú Yezíd alienated many of his followers by lapsing into habits of arrogant luxury and by treachery towards the Sunnites. At length he lost all he had won, fell into the hands of Al-Manṣúr, and was put to death (947). The caliph built the city of Manṣúríyah on the field of the decisive battle and made it his residence; the empire was rapidly restored, and the Spanish vassals driven from Africa. Al-Manṣúr died at Manṣúríyah, and was succeeded by Al-Mo'izz, the conqueror of Egypt (see vol. vii. p. 750 *sq.*).

3. Ibn Abí 'Ámir Mohammed, commonly called Almanzor by European writers, of an ancient but not illustrious Arab family, which had its seat at Torrox near Algeciras, was born 939 A.D., and began life as a lawyer at Cordova. In 967 he obtained a place at the court of Ḥakam II., the Andalusian caliph, and by an unusual combination of the talents of a courtier with administrative ability and address in dealing with men, rapidly rose to distinction, enjoying in particular the powerful support of Subḥ, the favourite of the caliph and mother of his heir Hishám. On the death of Ḥakam (976) the accession of a minor gave fresh scope to the genius of Ibn Abí 'Ámir, who threaded his way with consummate but unscrupulous talent through the intrigues of the court, and in 978 became prime minister. He now aimed at absolute dominion. The weak young caliph, absorbed in exercises of piety, was easily reduced to a cipher, but at first Ibn Abí 'Ámir had to share the power with his father-in-law Ghálib, the best general of Andalusia, and his chief aid, along with the mother of Hishám, in the steps that had raised him to power. At last a rupture took place between the two ministers, and ended in a war in which Ghálib professed himself the champion of the caliph and called in the aid of the Christians of Leon. But his rival had anticipated the struggle; he had long before found means to add military to administrative reputation, and since he rose to the direction of affairs had remodelled the army so as to make it more formidable and more devoted to his cause. Ghálib fell in battle (981); a victorious campaign chastised the Leonese; and on his return to Cordova the victor assumed the regal surname of Al-Manṣúr billah, and became practically sovereign of Andalusia. The caliph was a mere prisoner of state, holding a nominal dignity, and Al-Manṣúr ultimately assumed the title as well as the prerogatives of king (996). Unscrupulous in the means by which he rose to power, he wielded the sovereignty nobly. His strict justice and the enlightened excellence of his internal administration were not less notable than his military prowess. But it is by the latter that he is best known. His arms were the terror of the Christians, and raised the Moslem power in Spain to a pitch it had never before attained. He fought more than

fifty campaigns, all glorious, and destroyed many cities, including the three capitals of Leon, Pampeluna, and Barcelona, and the sacred shrine of Santiago de Compostella. In Africa his armies were for a time hard pressed by the revolt of Zírí, viceroy of Mauretania, but before his death this enemy had also fallen. Al-Mansúr died at Medinaceli 10th August 1002, and was succeeded by his son Modaffar.[1]

4. Abú Yúsuf Ya'kúb ibn Yusuf (Jacob Almanzor), of the Moorish dynasty of the Almohades, the conqueror of Alphonso III. in the great battle of Alarcos (1195), reigned 1184-99.

MANTEGNA, Andrea (1431–1506), one of the chief heroes in the advance of painting in Italy, was born in or near Padua, of very humble parentage. It is said that in his earliest boyhood Andrea was, like Giotto, put to shepherding or cattle-herding; but this can have lasted only a very short while, as his natural genius for art developed with singular precocity, and excited the attention of Francesco Squarcione, who entered him in the guild of painters before he had completed his eleventh year.

Squarcione, whose original vocation was tailoring, appears to have had a remarkable enthusiasm for ancient art, and a proportionate faculty for acting, with profit to himself and others, as a sort of artistic middleman; his own performances as a painter were merely mediocre. He travelled in Italy, and perhaps in Greece also, collecting antique statues, reliefs, vases, &c., forming the largest collection then extant of such works, making drawings from them himself, and throwing open his stores for others to study from, and then undertaking works on commission for which his pupils no less than himself were made available. As many as one hundred and thirty-seven painters and pictorial students passed through his school, established towards 1440, which became famous all over Italy. Mantegna was, as he deserved to be, Squarcione's favourite pupil. Squarcione adopted him as his son, and purposed making him the heir of his fortune. Andrea was only seventeen when he painted, in the church of St Sophia in Padua, a Madonna picture of exceptional and recognized excellence. He was no doubt fully aware of having achieved no common feat, as he marked the work with his name and the date, and the years of his age. This painting was destroyed in the 17th century.

The affectionate relation between Squarcione and Mantegna was not destined to continue long. As the youth progressed in his studies, he came under the influence of Jacopo Bellini, a painter considerably superior to Squarcione, father of the celebrated painters Giovanni and Gentile, and of a daughter Niccolosia; and at some date, which may have been towards 1450, Jacopo gave Niccolosia to Andrea in marriage. This connexion of Andrea with the pictorial rival of Squarcione is generally assigned as the reason why the latter became alienated from the son of his adoption, and always afterwards hostile to him. Another suggestion, which rests, however, merely on its own internal probability, is that Squarcione had at the outset used his pupil Andrea as the unavowed executant of certain commissions, but that after a while Andrea began painting on his own account, thus injuring the professional interests of his chief, and incurring his animosity. The remarkably definite and original style formed by Mantegna may be traced out as founded on the study of the antique in Squarcione's atelier, followed by a diligent application of principles of work exemplified by Paolo Uccello and Donatello, with the practical guidance and example of Jacopo Bellini in the sequel.

Among the other early works of Mantegna are the fresco of two saints over the entrance-porch of the church of S. Antonio in Padua, 1452, and an altarpiece of St Luke and other saints for the church of St Justina, now in the Brera Gallery in Milan, 1453. It is probable, however, that before this time some of the pupils of Squarcione, including Mantegna, had already begun that series of frescos in the chapel of St Christopher, in the church of S. Agostino degli Eremitani, by which the great painter's reputation was fully confirmed, and which remain to this day conspicuous among his finest achievements.[2] The now censorious Squarcione found much to carp at in the earlier works of this series, illustrating the life of St James; he said the figures were like men of stone, and had better have been coloured stone-colour at once. Andrea, conscious as he was of his great faculty and mastery, and of the transcendent display he had here made of these, seems nevertheless to have felt that there was something in his old preceptor's strictures; and the later subjects, from the legend of St Christopher, combine with his other excellences more of natural character and vivacity. Trained as he had been in the study of marbles and the severity of the antique, and openly avowing that he considered the antique superior to nature as being more eclectic in form, he now and always affected precision of outline, dignity of idea and of figure, and he thus tended towards rigidity, and to an austere wholeness rather than gracious sensitiveness of expression. His draperies are tight and closely folded, being studied (as it is said) from models draped in paper and woven fabrics gummed. Figures slim, muscular, and bony, action impetuous but of arrested energy, tawny landscape, gritty with littering pebbles, mark the athletic hauteur of his style. He never changed, though he developed and perfected, the manner which he had adopted in Padua; his colouring, at first rather neutral and undecided, strengthened and matured. There is throughout his works more balancing of colour than fineness of tone. One of his great aims was optical illusion, which he carried out by a mastery of perspective that, though not always impeccably correct, nor absolutely superior in principle to the highest contemporary point of attainment, was worked out by himself with strenuous labour, and an effect of actuality astonishing in those times.

Successful and admired though he was in Padua, Mantegna left his native city at an early age, and never afterwards resettled there; the hostility of Squarcione has been assigned as the cause. The rest of his life was passed in Verona, Mantua, and Rome—chiefly Mantua; Venice and Florence have also been named, but without confirmation.

It may have been in 1459 that he went to Verona; and he painted, though not on the spot, a grand altarpiece for the church of S. Zenon, a Madonna and angels, with four saints on each side. The Marquis Lodovico Gonzaga of Mantua had for some time been pressing Mantegna to enter his service; and the following year, 1460, was perhaps the one in which he actually established himself at the Mantuan court, residing at first from time to time at Goito, but, from December 1466 onwards, with his family in Mantua itself. His engagement was for a salary of 75 lire (about £30) a month, a sum so large for that period as to mark conspicuously the high regard in which his art was held. He was in fact the first painter of any eminence

[1] His life is brilliantly described in vol. iii. of Dozy, *Histoire des Musulmans d'Espagne.*

[2] His fellow-workers were Bono of Ferrara, Ansuino of Forlì, and Niccolò Pizzolo, to whom considerable sections of the fresco-paintings are to be assigned. The acts of St James and St Christopher are the leading subjects of the series. St James Exorcising may have been commenced by Pizzolo, and completed by Mantegna. The Calling of St James to the Apostleship appears to be Mantegna's design, partially carried out by Pizzolo; the subjects of St James baptizing, his appearing before the judge, and going to execution, and most of the legend of St Christopher, are entirely by Mantegna.

ever domiciled in Mantua. He built a stately house in the city, and adorned it with a multitude of paintings. The house remains, but the pictures have perished. Some of his early Mantuan works are in that apartment of the Castello which is termed the Camera degli Sposi,—full compositions in fresco, including various portraits of the Gonzaga family, and some figures of genii, &c. In 1488 he went to Rome at the request of Pope Innocent VIII., to paint the frescos in the chapel of the Belvedere in the Vatican; the duke of Mantua created him a cavaliere before his departure. This series of frescos, including a noted Baptism of Christ, was ruthlessly destroyed by Pius VI. in laying out the Museo Pio-Clementino. The pope treated Mantegna with less liberality than he had been used to at the Mantuan court; but on the whole their connexion, which ceased in 1490, was not unsatisfactory to either party. Mantegna then returned to Mantua, and went on with a series of works—the nine tempera-pictures, each of them 9 feet square, of the Triumph of Cæsar—which he had probably begun before his leaving for Rome, and which are now in Hampton Court. These superbly invented and designed compositions, gorgeous with all splendour of subject-matter and accessory, and with the classical learning and enthusiasm of one of the master-spirits of the age, have always been accounted of the first rank among Mantegna's works. They were sold in 1628 along with the bulk of the Mantuan art treasures, and were not, as is commonly said, plundered in the sack of Mantua in 1630. They are now greatly damaged by patchy repaintings. Another work of Mantegna's later years was the so-called Madonna della Vittoria, now in the Louvre. It was painted in tempera about 1495, in commemoration of the battle of Fornovo, which Gonzaga found it convenient to represent to his lieges as an Italian victory, though in fact it had been a French victory; the church which originally housed the picture was built from Mantegna's own design. The Madonna is here depicted with various saints, the archangel Michael and St Maurice holding her mantle, which is extended over the kneeling Francesco Gonzaga, amid a profusion of rich festooning and other accessory. Though not in all respects of his highest order of execution, this counts among the most obviously beautiful and attractive of Mantegna's works,—from which it must be said that the qualities of beauty and attraction are often excluded, in the stringent pursuit of those other excellences more germane to his severe genius, tense energy passing into haggard passion.

Vasari eulogizes Mantegna for his courteous, distinguished, and praiseworthy deportment, although there are indications of his having been not a little litigious in disposition. With his fellow-pupils at Padua he had been affectionate; and for two of them, Dario da Trevigi and Marco Zoppo, he retained a steady friendship. That he had a high opinion of himself was natural, for no artist of his epoch could produce more manifest vouchers of high and progressive attainment. He became very expensive in his habits, fell at times into difficulties, and had to urge his valid claims upon the duke's attention. After his return to Mantua from Rome his prosperity was at its height, until the death of his wife. He then formed some other connexion, and became at an advanced age the father of a natural son, Giovanni Andrea; and at the last, although he continued launching out into various expenses and schemes, he had serious tribulations, such as the banishment from Mantua of his son Francesco, who had incurred the duke's displeasure. Perhaps the aged master and connoisseur regarded as barely less trying the hard necessity of parting with a beloved antique bust of Faustina. Very soon after this transaction he died in Mantua, on 13th September 1506 In 1517 a handsome monument was set up to him by his sons in the church of S. Andrea, where he had painted the altarpiece of the mortuary chapel.

We have spoken as yet of Mantegna as a painter and architect; he was no less eminent as an engraver, and is reported to have been a sculptor and poet as well, though we are not aware that any verses of his are extant, or that his sculptural practice extended beyond making a drawing for a statue of Virgil. As an engraver his history is somewhat obscure, partly because he never signed or dated any of his plates, unless in one single disputed instance, 1472. The account which has come down to us is that Mantegna began engraving in Rome, prompted by the engravings produced by Baccio Baldini of Florence after Sandro Botticelli; nor is there anything positive to invalidate this account, except the consideration that it would consign all the numerous and elaborate engravings made by Mantegna to the last sixteen or seventeen years of his life, which seems a scanty space for them. To get over this difficulty, it has been suggested, but without any evidence, that he began engraving while still in Padua, under the tuition of a distinguished goldsmith, Niccolò. He engraved about fifty plates, according to the usual reckoning; some thirty of them are indisputable—often large, full of figures, and highly studied. Among the principal examples are Roman Triumphs (not the same compositions as the Hampton Court pictures), A Bacchanal Festival, Hercules and Antæus, Marine Gods, Judith with the Head of Holophernes, the Deposition from the Cross, the Entombment, the Resurrection, the Man of Sorrows, the Virgin in a Grotto. Mantegna has sometimes been credited with the important invention of engraving with the burin on copper. This claim cannot be sustained on a comparison of dates, but at any rate he introduced the art into upper Italy. Several of his engravings are supposed to be executed on some metal less hard than copper. The technique of himself and his followers is characterized by the strongly marked forms of the design, and by the oblique formal hatchings of the shadows. The prints are frequently to be found in two states, or editions. In the first state, the prints have been taken off with the roller, or even by hand-pressing, and they are weak in tint; in the second state, the printing press has been used, and the ink is stronger.

The influence of Mantegna on the style and tendency of his age was very marked, and extended not only to his own flourishing Mantuan school, but over Italian art generally. His vigorous perspectives and trenchant foreshortenings pioneered the way to other artists: in solid antique taste, and the power of reviving the aspect of a remote age with some approach to system and consistency, he distanced all contemporary competition. He did not, however, leave behind him many scholars of superior faculty. His two legitimate sons were painters of only ordinary ability. His favourite pupil was known as Carlo del Mantegna; Caroto of Verona was another pupil, Bonsignori an imitator. Giovanni Bellini, in his earlier works, obviously followed the lead of his brother-in-law Andrea.

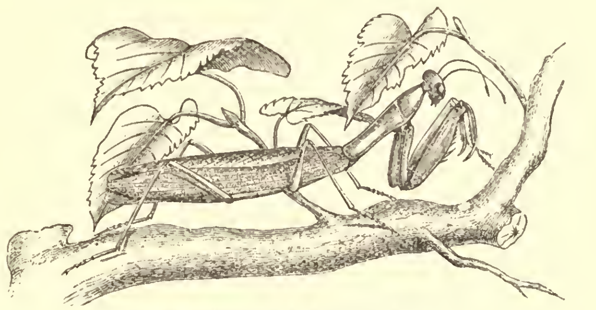
The works painted by Mantegna, apart from his frescos, are not numerous; thirty-three or thereabouts are regarded as fully authenticated. We may name, besides those already specified—in the Naples museum, St Euphemia, a fine early work; in Casa Melzi, Milan, the Madonna and Child with Chanting Angels, 1461; in the Tribune of the Uffizi, Florence, three pictures remarkable for scrupulous finish; in the Berlin Museum, the Dead Christ with two Angels; in the Louvre, the two celebrated pictures of mythic allegory—Parnassus, and Minerva Triumphing over the Vices; in the London National Gallery, the Virgin and Child enthroned, with the Baptist and the Magdalen, a late example; the monochrome of Vestals, lately bought from Hamilton Palace; the Triumph of Scipio (or Phrygian Mother of the Gods received by the Roman Commonwealth), a tempera in chiaroscuro, painted only a few months before the master's death; in the Brera, Milan, the Dead Christ, with the two Maries weeping, a remarkable *tour de force* in the way of foreshortening, which, though it has a stunted appearance, is in correct technical perspective as seen from all points of view. With all its exceptional merit, this is an eminently ugly picture. It remained in Mantegna's studio unsold at his death, and was disposed of to liquidate debts. (W. M. R.)

MANTELL, Gideon Algernon (1790–1852), born in 1790 at Lewes, Sussex, rose to eminence as a popular exponent of geology, and contributed many original papers to the literature of the science. Educated for the medical profession, he first practised in his native town, afterwards in Brighton, and finally at Clapham, near London. While devoting himself with industry and success to the duties of a medical man, he yet found time to prosecute researches in the palæontology of the Secondary rocks, particularly in Sussex—a region which he has made for ever classical in the history of discovery. While he was still a country doctor at Lewes his eminence as a geological investigator was fully recognized on the publication of his work on *The Fossils of the South Downs*, 1822. His most remarkable discoveries were made in the Wealden formations, whence he brought to light and described the remarkable Dinosaurian reptiles known as *Iguanodon*, *Hylæosaurus*, *Pelorosaurus*, and *Regnosaurus*. The memoirs in which he sketched the structure of these strange creatures, and pointed out the probable conditions in which they lived, were recognized by the Geological Society as deserving of its highest honour—the Wollaston medal. The Royal Society also awarded him a Royal medal. Besides these and other contributions to the literature of palæontology and geology, he published from time to time various popular works which had a large sale and did much to spread a knowledge of and interest in the science.[1] Towards the end of his life Dr Mantell retired to London. Though for many years suffering from a severe spinal disease, the result of an accident, he continued with unabated enthusiasm the prosecution of his favourite scientific pursuits, sparing neither pains nor expense towards the attainment of his objects, and kindling in others a spirit of eager desire to further the cause of science. He wrote with great clearness and attractiveness, so that his general works were deservedly popular. As a lecturer also he was almost unrivalled for fluency and eloquence. His name appeared on the list of membership of many learned societies both at home and abroad. He died in 1852.

MANTINEIA was one of the most famous cities of Arcadia. It was situated in the long narrow valley, running north and south, which is now called after the chief town Tripolitza. Tegea was in the same valley, about 10 miles south of Mantineia, and the two cities continually disputed the supremacy of the valley. In every great war we find them ranged on opposite sides, except when superior force constrained both. In the Peloponnesus the disputes between Argos and Sparta lasted for centuries; and Mantineia was always an ally of the former. In the war between Sparta and Athens, Mantineia was at first forced to be an ally of Sparta, but in 421 it joined Argos in making an alliance with Athens. The city is said by Strabo to have been founded under Argive instigation, by the union of several villages of the valley; there can be no doubt that this was done in order to maintain a party in the valley hostile to Tegea and Sparta. It is impossible here to trace the varying history of the town. It was one of the chief members of the Arcadian league that helped Epaminondas to break the power of Sparta. It was one of the original members of the Achæan league, but deserted it for the Ætolian. The Achæans and Antigonus Doson captured the city in 222 B.C., and changed its name to Antigoneia, but the emperor Hadrian restored the ancient name. The worship and mysteries of Cora at Mantineia were famous. The valley in which the city lies has no opening to the coast, and the water finds its way, often only with much care and artificial aid, through underground passages (*catabothra*) to the sea. It is bounded on the west by Mount Mænalus, on the east by Mount Artemision. The river Ophis flowed through the city. The position of the town in the centre of this valley route made it of great military importance, and five important battles were fought beside it: in 418 B.C. Sparta defeated the alliance above mentioned; in 362 Epaminondas defeated the Spartans and lost his own life; in 295 Demetrius Poliorcetes defeated the Spartans; in 242 Aratus defeated the Spartans; in 207 Philopœmen defeated the Spartans. In the beginning of the 4th century B.C. Mantineia had 3000 citizens capable of bearing arms.

[1] Of these the following may be enumerated—*The Wonders of Geology*, 2 vols.; *The Medals of Creation*, 2 vols.; *Thoughts on a Pebble, or First Lessons in Geology*; *A Geological Excursion round the Isle of Wight*; *Pictorial Atlas of Fossil Remains*; *Thoughts on Animalcules, or a Glimpse at the Invisible World as revealed by the Microscope*; *Petrifactions and their Teachings*.

MANTIS. Probably no other insect has been the subject of so many and widespread legends and superstitions as the common "praying mantis," *Mantis religiosa*, L. (see INSECTS, *Orthoptera*, fam. *Mantidæ*, vol. xiii. p. 152). The ancient Greeks endowed it with supernatural powers (μάντις, "a diviner"); the Turks and Arabs hold that it prays constantly with its face turned towards Mecca; the Provençals call it *Prega-Diou* (*Prie-Dieu*); and numerous more or less similar names—preacher, saint, nun, mendicant, soothsayer, &c.,—are widely diffused throughout southern Europe. Children ask it to show them the way, and Mouffet assures us that it rarely or never deceives them; and it is even recorded that one specimen, which alighted on the hand of St Francis Xavier, and which he commanded to sing the praise of God, loudly intoned a very beautiful canticle. In Nubia it is held in great esteem, and the Hottentots, if not indeed worshipping the local species (*M. fausta*), as one traveller has alleged, at least appear to regard its alighting upon any person both as a token of saintliness and an omen of good fortune.



Praying Mantis (*Mantis religiosa*).

Yet these are "not the saints, but the tigers, of the insect world." The front pair of limbs are very peculiarly modified,—the coxa being greatly elongated, while the strong third joint or femur bears on its curved underside a channel armed on each edge by strong movable spines. Into this groove the stout tibia is capable of closing like the blade of a penknife, its sharp, serrated edge being adapted to cut and hold. The arrangement is essentially similar to the sub-chela of *Squilla* and Amphipods among CRUSTACEA (*q.v.*), as well as to the chelicerae of spiders (see ARACHNIDA). Thus armed, with head raised upon the much-elongated and semi-erect prothorax, and with the half-opened fore limbs held outwards in the characteristic devotional attitude, it rests motionless upon the four posterior limbs waiting for prey, or occasionally stalks it with slow and silent movements, finally seizing it with its knife-blades and devouring it. Although apparently not daring to attack ants, these insects destroy great numbers of flies, grasshoppers, and caterpillars, and the larger South-American species even attack small frogs, lizards, and birds. They are very pugnacious, fencing with their sword-like limbs "like hussars with sabres," the larger frequently devouring the smaller, and the females the males. The Chinese keep them in bamboo cages, and match them like fighting cocks.

The elytra of the common mantis have been compared to a withering willow leaf, a circumstance which not improbably aids in concealing them from their prey. Some of the tropical forms exhibit as perfect mimicry of the leaves as the leaf insects proper (*Phasmidæ*). Bates found a mantis on the Amazon which exactly resembled the white ants it preyed upon, while Wallace mentions a Javanese species which mimics a pink orchid flower, and "is said to feed largely on butterflies,—so that it is really a living trap, and forms its own bait!"

The common species fixes its somewhat nut-like egg capsules on the stems of plants in September. The young are hatched in early summer, and resemble the adults, but are without wings.

See Westwood's *Introd. Mod Class. of Insects*, 1840, and forthcoming monograph of the family.

MANTUA (Italian, *Mantova*), a fortified city of Italy, the chief town of a province, the see of a bishop, and the centre of a military district, lies 95 miles east-south-east of Milan, and 25 miles by rail south of Verona on the way to Modena, occupying, at the height of 88 feet above the level of the Adriatic, an almost insular site in the midst of the swampy lagoons of the Mincio, with their vast reaches of reeds and bulrushes. As the belt of marshy ground along the south side can be laid under water at pleasure, the site of the city proper, exclusive of the considerable suburbs of Borgo di Fortezza to the north and Borgo di San Giorgio to the east, may still be said to consist, as it formerly did more distinctly, of two islands separated by a narrow channel and united by a number of bridges. On the west side lies Lago Superiore, on the east side Lago Inferiore —the boundary between the two being marked by the *Argine del Mulino*, a long covered wooden bridge stretching northward from the north-west angle of the city. As approached from the north by the old road, Mantua presents a beautiful prospect with its "towers and walls and waters." On the highest ground in the city rises the cathedral, built after his death according to the plans of Giulio Romano on the site of the ancient church of Sts Peter and Paul; it has double aisles, a dome-covered transept, and a large tower, popularly assigned to the Roman governor Arius. Architecturally much more important is the church of St Andrew, built towards the close of the 15th century, after plans by Leon Battista Alberti, and consisting of a single barrel-vaulted nave 350 feet long by 62 feet wide. It has a noble façade, with a deeply recessed portico, and a brick campanile of earlier date than the main building. The interior is richly decorated with 18th century frescos. S. Maria delle Grazie, consecrated in 1399 as an act of thanksgiving for the cessation of the plague, has a curious collection of *ex voto* pictures and the tombs of the Gonzaga family. The old ducal palace—one of the largest buildings of its kind in Europe—was commenced in 1302 for Guido Bonaccolsi, and probably completed in 1328 for Ludovico Gonzaga; but many of the accessory apartments are of much later date, and the interior decorations are for the most part the work of Giulio Romano and his pupils. Outside of the city, to the south of Porta Pusterla, stands the Palazzo del Te, Giulio's architectural masterpiece, erected for Frederick Gonzaga; of the numerous fresco-covered chambers which it contains, perhaps the most celebrated is the Sala dei Giganti, where, by a combination of mechanical with artistic devices, the rout of the Titans still contending with artillery of uptorn rocks against the pursuit and thunderbolts of Jove appears to rush downwards on the spectator. Among the educational institutions in Mantua are an academy of arts and sciences (*Accademia Vergiliana*) occupying a fine building erected by Piermarini, a public library founded in 1780 by Maria Theresa, a museum of antiquities dating from 1779, a good botanical garden, and an observatory. The Monte di Pietà was established in 1484, the civil hospital in 1449. Oil, beer, leather, and playing cards are the chief products of the limited local industry. The population increased from 26,687 in 1871 to 28,048 in 1881. As a fortress Mantua was long one of the most formidable in Europe, a force of thirty to forty thousand men finding accommodation within its walls; but it had two serious defects—the marshy climate told heavily on the health of the garrison, and effective sorties were almost impossible.

Mantua was originally an Etruscan town, and had still a strong Etruscan element in its population during the Roman period. It was a Roman municipium; but Martial calls it little Mantua, and, had it not been for Virgil's interest in his native place and in the expulsion of a number of the Mantuans from their lands in favour of Octavian's soldiers, we should probably have heard almost nothing of its existence. In 568 the Lombards found Mantua a walled town of some strength; recovered from their grasp in 590 by the exarch of Ravenna, it was again captured by Agilulf in 601. The 9th century was the period of episcopal supremacy, and in the 11th the city formed part of the vast possessions of Bonifacio, marquis of Canossa. From him it passed to Geoffrey, duke of Lorraine, and afterwards to the Countess Matilda, whose support of the pope led to the conquest of Mantua by the emperor Henry IV. in 1090. Reduced to obedience by Matilda in 1113, the city obtained its liberty on her death, and instituted a communal government of its own, *salva imperiali justitia*. It afterwards joined the Lombard League; and the unsuccessful attack made by Frederick II. in 1236 brought it a confirmation of its privileges. But after a period of internal discord Ludovico Gonzaga attained to power (1328), and was recognized as imperial vicar (1329); and from that time till the death of Ferdinando Carbo in 1708 the Gonzagas were masters of Mantua (see GONZAGA, vol. x. p. 772). Under Gian Francesco II., Ludovico, and Federico II., the first duke of Mantua, the city rose rapidly into importance as a seat of industry and culture. Claimed in 1708 as a fief of the empire by Joseph I., it was governed for the greater part of the century by the Austrians. In June 1796 it was besieged by Napoleon; but in spite of terrific bombardments it held out till February 1797. A three days' bombardment in 1799 again placed Mantua in the hands of the Austrians; and, though restored to the French by the peace of Lunéville (1801), it became Austrian once more from 1814 till 1866. In the years between 1849 and 1859 the city was the scene of violent political persecution.

Besides Virgil, Mantua counts among its celebrities Sordello the Provençal poet, Castiglioni, Folengo the writer of macaronics, and Pomponazzi the philosopher; and it has a long roll of local historians—Donesmondi (ecclesiastical affairs), Possevino, Daino, Amedei, Visi, Tonelli, and Count Carlo d'Arco.

Gaet. Susani, *Nuovo prospetto delle pitture, &c., di Mantova*, Mantua, 1830; Carlo d'Arco, *Delle arti e degli artefici di Mantova*, Mantua, 1857, and *Storia di Mantova*, Mantua, 1874.

MANUCODE, from the French, an abbreviation of *Manucodiata*, and the Latinized form of the Malay *Manuk-dewata*, meaning, says Crawfurd (*Malay and Engl. Dictionary*, p. 97), the "bird of the gods," and a name applied for more than two hundred years apparently to Birds-of-paradise in general. In the original sense of its inventor, Montbeillard (*Hist. Nat. Oiseaux*, iii. p. 163), *Manucode* was restricted to the King Bird-of-paradise and three allied species; but in English it has curiously been transferred[1] to a small group of species whose relationship to the *Paradiseidæ* has been frequently doubted, and must be considered uncertain. These Manucodes have a glossy steel-blue plumage of much beauty, but are easily distinguished from other birds of similar coloration by the outer and middle toes being united for some distance, and they are very remarkable for the extraordinary convolution of the trachea, in the males at least, with which singular structure is correlated the loud and clear voice of the birds. The convoluted portion of the trachea lies on the breast, between the skin and the muscles, much as is found in the females of the genus *Rhynchæa*, in the males of the Curassows (*Cracidæ*), and in a few other birds, but wholly unknown elsewhere among the *Passeres*. The Manucodes are peculiar to the Papuan Sub-region (including therein

[1] *Manucodiata* was used by Brisson (*Ornithologie*, ii. p. 130) as a generic term equivalent to the Linnæan *Paradisea*. In 1783 Boddaert, when assigning scientific names to the birds figured by Daubenton, called the subject of one of them (*Pl. enlum.* 634) *Manucodia chalybea*, the first word being apparently an accidental curtailment of the name of Brisson's genus to which he referred it. Nevertheless some writers have taken it as evidence of an intention to found a new genus by that name, and hence the importation of *Manucodia* into scientific nomenclature, and the English form to correspond.

the peninsula of Cape York), and comprehend, according to Mr Sharpe (*Cat. B. Brit. Museum*, iii. p. 164), two genera, for the first of which, distinguished by the elongated tufts on the head, he adopts Lesson's name *Phonygama*, and for the second, having no tufts, but the feathers of the head crisped, that of *Manucodia*; and Mr W. A. Forbes (*Proc. Zool. Society*, 1882, p. 349) observes that the validity of the separation (which has not yet been generally acknowledged) is confirmed by what is now known of their tracheal formation. Of *Phonygama* Mr Sharpe recognizes three species, *P. keraudreni* (the type) and *P. jamesi*, both from New Guinea, and *P. gouldi*, the Australian representative species; but the first two are considered by Mr Elliot (*Ibis*, 1878, p. 56) and Count Salvadori (*Ornitol. della Papuasia*, ii. p. 510) to be inseparable. There is a greater unanimity in regard to the species of the so-called genus *Manucodia* proper, of which four are admitted—*M. chalybeata* or *chalybea* from north-western New Guinea, *M. comriei* from the south-eastern part of the same country, *M. atra* of wide distribution within the Papuan area, and *M. jobiensis* peculiar to the island which gives it a name. Little is known of the habits of these birds, except that they are as already mentioned remarkable for their vocal powers, which, in *P. keraudreni*, Lesson describes (*Voy. de la Coquille*, Zoologie, i. p. 638) as enabling them to pass through every note of the gamut. Mr Wallace (*Ann. Nat. History*, ser. 2, xx. p. 476) remarked that *M. atra* was very powerful and active, clinging suspended to the smaller branches of trees, on the fruits of which alone it appears to feed. *M. gouldi*, according to an informant quoted by Mr Forbes (*ut supra*), frequents in pairs the dense palm-forests, perching high up, uttering a very deep and loud guttural note; it is graceful in its movements, evincing more curiosity than timidity on being approached. As with members of the *Paradiseidæ* generally, the nidification of the Manucodes is still shrouded in mystery. (A. N.)

MANUEL I., COMNENUS, emperor of Constantinople from 1143 to 1184, was the fourth son of John II. (Calo-Joannes), and was born about the year 1120. He succeeded to the imperial crown on April 8, 1143, having for his martial qualities been nominated by John to the inheritance in preference to his elder surviving brother. During his reign of thirty-seven years he was involved in almost perpetual war, in which he displayed much more of the courage of a soldier than of the prudence and skill of a commander. In 1144 the imperial general Demetrius Branas brought back Raymond, the Latin prince of Antioch, to his allegiance, and in 1145 Manuel in person drove out the Turks who had invaded Isauria, and compelled them to accept peace on his own terms. In 1147 he granted a passage through his dominions to the crusaders under Louis VII. of France and Conrad III. of Germany, but secretly harassed them by every means in his power, and sent word to the Turks of their approach. In the following year he became involved, along with the Venetians, in a war with Roger of Sicily, who had taken Corfu and invaded Greece; an episode of the campaign towards its beginning was his repulse beyond the Danube of the Patzenegues, of whom he took hostages for their future good behaviour. Disembarking his host at Corfu before the end of the year, he invested the fortress in co-operation with the Venetian army; the inhabitants, after a long siege, in which he displayed prodigies of personal strength and valour, surrendered in 1149. Manuel was now prevented from invading Sicily by a diversion made by the Servians and Hungarians on the Danube, who were not completely vanquished until 1152. In that year Manuel was repulsed by the Turks in Cilicia, but in the west his troops obtained possession of Bari, Brundisium, and other places of importance in Apulia and Calabria. The course of Italian politics, however, deprived him of the means on which he had reckoned for enabling him to reunite southern Italy with the Byzantine empire, and after the defeat of his fleet at Negropont he concluded a peace with William, Roger's successor, in 1155. The next important war of Manuel's reign was waged against the Hungarians from 1163 to 1168; it came to an end in the latter year with the hard-won victory of the Byzantine arms at Zeugminum (Semlin). Less successful was the expedition under Andronicus Contostephanus against Egypt in 1169, when the combined forces of Manuel and King Amalric were compelled to withdraw from before Damietta. From 1171 to 1174 Manuel had a war with the Venetians; and in 1176 he led in person an expedition against Kilidj Arslan, the sultan of Iconium when he sustained a disastrous defeat at Myriocephalus, and was compelled to sign a dishonourable peace. This disgrace, although partially retrieved by a somewhat more successful expedition in 1177, so preyed upon the spirit of Manuel that he ultimately succumbed to a slow fever on September 24, 1180. He was first married to Bertha (Irene), a relative of Conrad III. of Germany, and afterwards to Maria (Xene), daughter of Raymond of Antioch; Alexis II., his son by the latter, succeeded him.

MANUEL II., PALÆOLOGUS, emperor of Constantinople, was born in 1348, and succeeded his father, John VI. (with whom he had been associated since 1375), in 1391. At the time he was a hostage at the court of Bajazet at Nicæa, but succeeded in making his escape; he was forthwith besieged in Constantinople by the sultan, whose victory over the Christians at Nicopolis, however (September 28, 1395), did not secure for him the capital. Manuel subsequently set out in person to seek help from the West, and for this purpose visited Italy, France, and Germany, but without material success; the victory of Timur in 1402, and the death of Bajazet in the following year, were the first events to give him a genuine respite from Ottoman oppression. He stood on friendly terms with Mahomet I., but was again besieged in his capital by Amurath II. in 1422. He died in 1425, and was succeeded by his son, John VII.

MANUEL I., emperor of Trebizond, surnamed the Great Captain (ὁ στρατηγικώτατος), was the second son of Alexius I., first emperor of Trebizond, and ruled from 1238 to 1263. Whatever may have been his military skill, or his personal character for bravery, he was unable to deliver his empire from vassalage first to the Seljuks and afterwards to the Mongols. He was the founder of the church and monastery of St Sophia at Trebizond. His predecessor was John I., Axuchus, and his eldest son, Andronicus II., succeeded him.

Manuel II., the descendant of Manuel I., reigned only a few months in 1322–33. Manuel III. reigned from 1390 to 1417, but the only interest attaching to his name arises from his connexion with Timur, whose vassal he was.

See Finlay, *Mediæval Greece and Trebizond*, 1851.

MANURE. The term "manure," though formerly applied only to the excrements of animals, either alone or mixed with straw, is now more widely used, and is given to all substances, or mixtures of substances, which are added to the soil in order to increase its productiveness or to restore the natural fertility lost by repeated cropping.

The subject of manures and their application involves a prior consideration of plant life and its requirements. The plant, growing as it does in the soil, and surrounded by the atmosphere, derives from these two sources its nourishment and means of growth through the various stages of its development. From these sources, each equally indispensable, the plant obtains the materials which it has the power of elaborating and building up to form its own structure.

Chemical analysis has shown that plants are composed of water, organic or combustible matters, and inorganic, incombustible, or mineral matters. These last are left as the ash when the plant is burnt. The elements forming the organic portion of plants are carbon, hydrogen, oxygen, and nitrogen; the mineral portion, or ash, consists principally of lime, magnesia, potash, soda, oxide of iron, phosphoric acid, sulphuric acid, chlorine, and silica.

The atmosphere is the great storehouse of organic plant-food. The carbonic acid always present in the air is, as is well known, eagerly taken up by the leaves of plants, all of which have the power of decomposing carbonic acid, giving off its oxygen, and assimilating its carbon. Roughly speaking, three-fourths of the dry substance of all plants is derived from the atmosphere.

Under conditions of natural growth and decay, when no crops are gathered in, or consumed on the land by live stock, the herbage on dying down and decaying returns to the atmosphere and the soil the elements taken from them during life; but under cultivation a succession of crops deprives the land of the constituents which are essential to healthy and luxuriant growth. Without an adequate return to the land of the matters removed in the produce, its fertility cannot be maintained for many years. In newly-opened countries, where old forests have been cleared and the land brought into cultivation, the virgin soil often possesses at first a high degree of fertility, but gradually its productive power decreases from year to year. Generally speaking, it is more convenient to clear fresh forest land than to improve more or less exhausted virgin land by the application of manure, labour, and skill. In all densely peopled countries where such a mode of cultivation cannot be followed it is necessary to resort to artificial means to restore the natural fertility of the land and maintain and increase its productiveness.

The researches of Liebig, Wiegmann, Polstorff, and others have proved beyond doubt the important functions of the mineral constituents of the soil in relation to plant life. The gradual removal of phosphate of lime in the tillage of dairy districts, or the removal of other mineral matters essential to the healthy growth of farm crops, certainly impoverishes the land. The exhaustion of the soil is caused in a much more marked way, however, by the rapid loss in available nitrogenous plant food which soils sustain when under cultivation without manure.

Agricultural improvements manifest themselves in two different directions—the mechanical and the chemical. Under mechanical improvement the physical condition of the soil is bettered and its latent stores of plant food brought into action by mechanical means, such as ploughing, subsoiling, steam cultivation, &c. The introduction of new and superior agricultural implements, good systems of drainage, and intelligent division of labour characterize the first stage of progress in agriculture. The second stage is marked by the application of chemical principles to practical agriculture, an application shown by the introduction of a rational system of feeding, a proper rotation of crops, and chiefly the use of chemical, or artificial, manures for the purpose of restoring the natural fertility of the soil and increasing its productive powers.

The aid which chemistry has rendered during the last twenty-five or thirty years to practical agriculture has greatly promoted agricultural improvements; and farming, which is in a large measure dependent for success upon an economical use of manures, is now being carried on much more rationally than in former times. The proper application of various kinds of manures is one of the most prominent features of successful modern farming.

In considering the economical use of manures on the land, regard must be had to the following points:—(1) the requirements of the crops intended to be cultivated; (2) the physical condition of the soil; (3) the composition of the soil; and (4) the composition of the manure. Briefly stated, the guiding principle of manuring economically and profitably is to meet the requirements of the crops intended to be cultivated, by incorporating with the soil, in the most efficacious states of combination, the materials in which it is deficient, or which the various crops usually grown on the farm do not find in the land in a sufficiently available condition to ensure an abundant harvest.

Soils vary greatly in composition, and hence it will be readily understood that in one locality or on one particular field a certain manure may be used with great benefit, while in another field the same manure has little or no effect upon the produce. Although increased attention has of recent years been paid to the chemical composition and properties of soils, there is still much room left for improvement, for many farmers disregard almost altogether the composition of their fields in buying artificial manures.

It has been pointed out by Sir John Lawes that in actual English farm-practice there is, speaking practically, a standard of natural produce which varies within certain limits, as influenced by seasons and management, and which cannot be permanently increased or reduced by cultivation; and further, when land is spoken of as being in "good condition," reference is made only to the temporary rise of fertility by means of the manures employed, while by land "out of condition" is signified the exhaustion of the manures by the removal of crops, loss by drainage, &c., and that the soil has merely gone back to its standard of natural productiveness. Some soils, indeed, contain in their natural condition hardly a sufficient proportion of available elements of plant food to yield remunerative crops; such soils are naturally barren, and, although by the constant use of manures they may be improved and may attain some degree of fertility, they will, if left unmanured, speedily revert to their former natural unproductive state.

The principal constituents of manures are—nitrogen, in the form of ammonia, nitrates, and nitrogenous organic matters; organic matters not containing nitrogen (humus); phosphoric acid, potash, soda, lime, magnesia, silica, sulphuric acid, and chlorine. Of these constituents by far the most important are the nitrogen, phosphoric acid, and potash, and these will be considered more in detail.

1. *Nitrogen.*—Nothing so much affects the productiveness of soils as nitrogen, when it is supplied to plants in a form in which it can be assimilated by them, and nothing is more readily removed from the land, either in the crop grown or, in the form of nitrates, by drainage. The "good condition" of land, to which allusion has been made already, is, in a great measure, the fertility which has been imparted to the soil by the nitrogen supplied to it, while the "natural productiveness" may be taken as that due to the phosphoric acid, potash, and other mineral constituents of the soil.

Supply of Nitrogenous Plant Food.—In the case of a crop growing under natural conditions, and not removed from the land, the mineral constituents taken from the soil, and carbonaceous as well as some nitrogenous organic matter, principally derived from the atmosphere, are returned to the land, and a rich carbonaceous soil or humus is produced in the course of years. Such a soil is capable of supplying for a considerable number of years, when under cultivation, the nitrogen needed by the crops grown on the land. This supply of nitrogen, however, gradually becomes exhausted by repeated cropping. The atmosphere, in addition to free nitrogen gas, which constitutes about four-fifths of its volume, contains but very little combined nitrogen in the forms of ammonia or nitric acid.

M. Boussingault's experiments clearly show that plants do not possess the power of taking up by their leaves and of assimilating the free nitrogen of the air. This conclusion has been verified by the extensive researches of Messrs Lawes, Gilbert, and Pugh. The nitrogen contained as nitric acid and ammonia in the air, and descending upon the land in the shape of rain, dew, or snow, though, without doubt, adding to the supply of nitrogen in the soil, is altogether insufficient to meet the requirements of remunerative crops. The experiments of Messrs Lawes and Gilbert and Professor Way show that the average proportion of nitrogen deposited annually upon one acre of land at Rothamsted, St Albans, amounts to 7·21 lb, of which quantity 6·46 lb occur as ammonia and ·75 lb as nitric acid.

The further investigations of Dr Voelcker, Professor Frankland, and Messrs Lawes and Gilbert upon the drainage water from cultivated soils show that a considerable quantity of nitrogen in the shape of nitric acid passes into land drainage, and that this loss of nitrogen is much greater than the total amount supplied to the land by the rain and dew. The results which Messrs Lawes and Gilbert obtained in their experiments on the continuous growth of barley at Rothamsted from 1852 to 1875 afford, as is shown in the following table (I.), direct evidence of the insufficiency of the atmospheric supply of nitrogen, and of that present in the soil in the form of nitrogenous organic matter.

8. Farmyard manure (14 tons every year)	46⅝	50¾	48¾	53¼	55½	54⅜	27⅞	29⅝	28¾

The Rothamsted soil is a moderately stiff one, of considerable depth, and contains naturally the mineral elements of plant food in abundance; thus it has been possible to grow corn crops for over twenty-five years without any manure (Plots 1). The crops in the second period of twelve years were, however, less than those of the first period, and in neither case were full crops obtained. While the application of mineral manures alone (Plots 2) produced only a slight increase in the case of the wheat, and rather better, though poor, results with barley, nitrogenous manures, applied to the land either in the shape of ammonia salts or nitrate of soda, produced a strikingly large increase. The experiments further show that while good crops, both of wheat and barley, can be grown by the annual application of 14 tons of farmyard manure per acre, the best results are obtained by the use of a mixture of mineral and nitrogenous manures.

In Messrs Lawes and Gilbert's experiments the amount of nitrogen removed in different crops was determined with the following results:—over a period of thirty-two years (to 1875), wheat yielded an average of 20·7 lb of nitrogen per acre per annum without any manure, but the annual yield has decreased from an average of over 25 lb in the first eight to less than 16 lb in the last twelve years, and since 1875 it has been still less; over a period of twenty-four years, barley, when unmanured, yielded an average of 18·3 lb nitrogen per acre per annum, but with a decline from 22 lb in the first twelve to 14·6 in the last twelve years. Experiments similar to those on wheat and barley have been made on oats, root crops, leguminous and grass crops, all showing the gradual decline in produce when grown continuously without nitrogenous manures, and proving that the soil and not the atmosphere is the chief source of nitrogen in plants. In face of these results the "mineral theory" of Liebig, which attached but small value to nitrogen applied to the soil in the form of nitrogenous manures, and maintained the sufficiency of the ammonia of the atmosphere for supplying the needs of the plant, cannot be accepted without reserve.

Notwithstanding the great effect produced by the nitrogenous manures, two-thirds of the nitrogen supplied was unrecovered in the increase of crops when the ammonia salts were supplied to wheat in autumn. When, however, nitrate of soda was used, which is always applied in the spring, the quantity left unrecovered was not much more than half that supplied.

The following table (II.), by Messrs Lawes and Gilbert, shows the amount of nitrogen recovered, and the amount not recovered, in the increase of the crop for 100 supplied in manure, to wheat and to barley respectively, the result being in each case the average over a period of twenty years:—

[1] Previous cropping:—1839, turnips with farmyard manure; 1840, barley; 1841, pease; 1842, wheat; 1843, oats; the last four crops unmanured. First experimental wheat crop in 1844. Wheat every year since; and, with some exceptions, nearly the same description of manure on the same plots each year—especially during the last twenty-six years (1852 and since). Unless otherwise stated, the manures are sown in the autumn before the seed. Area under experiment about 13 acres.

[2] Previous cropping:—1847, swedish turnips with dung and superphosphate of lime, the roots carted off; 1848, barley; 1849, clover; 1850, wheat; 1851, barley manured with ammonia salts. First experimental crop in 1852. Barley every year since.

TABLE II.

Manuring quantities per Acre per Annum.	Wheat. 20 Years 1852–71. Recovered in Increase.	Wheat. 20 Years 1852–71. Not recovered in Increase.	Barley. 20 Years 1852–71. Recovered.	Barley. 20 Years 1852–71. Not recovered.

Farmyard manure (about 200 lb of nitrogen)	14·6	85·4	10·7	89·3

The question will naturally be raised, What becomes of the one-half or two-thirds of the nitrogen which is not recovered in the increase of the crops? The examination of some seventy samples by Dr Voelcker, and a number of independent determinations by Dr Frankland, of the drainage-water from the experimental wheat plots which yielded the above results throw much light on this loss. The following table (III.) contains a summary of some of the more important results obtained.

TABLE III.—*Nitrogen as Nitrates and Nitrites, per* 100,000 *parts of Drainage Water from Plots differently Manured, in the Experimental Wheat-field at Rothamsted, Wheat every year, commencing* 1844.

Mean of Dr Voelcker's and Dr Frankland's Results.	Experiments.	Nitrogen.
Farmyard manure	6	1·264
Without manure	11	0·353
Complex mineral manure	11	0·428
Do. and 41 lb nitrogen as ammonia	11	0·823
Do. and 82 lb nitrogen as ammonia	11	1·439
Do. and 123 lb nitrogen as ammonia	11	1·815
Do. and 82 lb nitrogen as nitrate	10	1·437

These experiments show how great may be the loss of nitrogen by drainage when ammonia salts or nitrates are liberally applied to the land in autumn, should there be much wet weather in winter, or even when applied in spring if there be much heavy rain; also, that the quantity of nitrogen in drainage water as nitrates is increased in proportion to the amounts of ammonia or nitrate employed on the land. Assuming that from one-quarter to nearly one-half the annual rainfall descends more than 40 inches below the surface, every inch of rain passing through the drains and carrying with it one part of nitrogen in 100,000 of water, there will be a loss of 2½ lb of nitrogen per acre from the manure. Dr Voelcker's analysis of the drainage water of a wheat field manured in autumn by ammonia salts supplying 82 lb of nitrogen per acre shows that for every inch of rain passing through the drains in January a loss took place of about 8½ lb of nitrogen, costing about 1s. per lb as manure. The loss of nitrogen thus is very large, and shows that by far the largest proportion of the nitrogen of manure which is not recovered in the crop is lost in drainage. In addition to the nitrogen removed in the crop and to that lost in drainage, some small proportion is found by analysis to be retained in the soil itself. The nitrogen may be of advantage to crops grown subsequently, according to the source from which it was derived; for while ammonia salts and nitrates yield but very small residues, and exert little or no effect beyond the first year, from bones, cake, and other such materials we get large residues of nitrogen in the soil, which tell markedly on future crops. The experiments on drainage water have further shown the absorbent power of soils, and that manuring matters when in contact with soils undergo remarkable changes, being taken up by plants, not in the simple state in which they are applied, but in quite different kinds of combination. Professor Way has the merit of having first proved that all soils possess, in different degrees, the power of absorbing ammonia from its solution in water, and that in passing solutions of salts of ammonia through soils the ammonia alone is absorbed, and the acids of the ammonia salts pass through in combination, generally with lime, or, if lime be deficient, with magnesia or other mineral bases of the soil.

In the drainage investigations at Rothamsted, it was found that, although large quantities of ammonia salts were applied to some of the plots, the drainage water from them contained mere traces of ammonia, but at all times of the year nitrates were present in quantity; from this it would appear that it is chiefly, if not solely, from nitrates that crops build up their nitrogenous organic constituents. Before leaving the subject of drainage water it is worthy of note here that phosphoric acid and potash, the most valuable mineral fertilizing constituents of the manures, passed but little into the drainage water, but were retained almost entirely in the land, while the more abundant and less important mineral matters, such as lime, magnesia, soda, chlorine, sulphuric acid, and soluble silica, passed in large quantities into the drainage water. It follows from these investigations, first, that much more nitrogenous material must be applied to the land than would be needed to produce a given increase in the crop, supposing all the nitrogen to be recoverable; and secondly, that nitrogenous organic matters when applied to the land undergo decomposition, and are gradually resolved into ammonia compounds, which, after being retained a short time by the soil, are finally oxidized into nitrates, in which form they are most available and beneficial to plants, but are not absorbed by the soil, and are readily washed out by rain. Nitrogen has great forcing properties, and is most beneficial when applied to crops in their early stages. Grass land on which nitrate of soda has been put as a top dressing shows very rapidly and markedly the effects of the manure.

Nitrate of soda, unless applied just at the time the crop is ready to take it up, will be largely wasted in drainage; hence it is usual to apply nitrate of soda as a top dressing in spring. Ammoniacal manures, such as Peruvian guano, soot, sulphate of ammonia, &c., when used for winter wheat, are best applied in autumn, either before the wheat is sown or when it is fairly above ground. On light land they are often used as top dressings for wheat early in spring. The gradual decomposition of farmyard manures gives a more constant supply of nitrogen than the manures already noticed, and as the fermentation of dung proceeds but slowly it is best to apply it, when quite fresh, in autumn or winter, allowing it to decompose in the land and to yield nitrogen as nitrates when required in spring by the fresh growth of vegetation. In the case of nitrogenous organic materials, such as wool or hair refuse, which take even longer than farmyard manure to decompose, it is necessary to apply them some three or four months before the seed is sown.

2. *Phosphoric Acid.*—Next in value to nitrogen as a constituent of manures comes phosphoric acid. Of all the mineral or ash constituents of plants, this is the most important, for the simple reason that it occurs in most soils in comparatively small proportions, and is required alike by corn and forage crops in larger quantities than lime, magnesia, and other mineral matters, which occur in most soils in almost inexhaustible quantities, or which, if deficient, can be easily and cheaply incorporated with the land.

Phosphoric acid occurs in soils principally in combination with lime as phosphate of lime, a constituent which enters largely into the composition of recent and fossil bones, coprolites, and guano, and of a variety of phosphatic minerals, such as Norwegian and Canadian apatite, Sombrero and Curaçoa rock phosphate, South Carolina phosphate, Spanish and Portuguese phosphorite, &c. These and other phosphatic materials are now used largely in the manufacture of superphosphate and other artificial manures.

Phosphate of lime is so sparingly soluble in pure water that, for all practical purposes, it may be considered to be insoluble in water; it is, however, attacked by the natural agencies at work in the soil, and rendered available as plant food. According to the more or less porous condition of the phosphatic manuring materials, phosphate of lime is rendered more or less readily assimilable. Thus, while bone dust and guano, on account of their porous condition, may be used with good effect as suppliers of phosphoric acid to the soil, others, such as hard and crystalline Canadian or Norwegian apatite, produce but little or no result when used as manures merely in a powdered state. It was in 1840 that Liebig suggested the treatment of bones with sulphuric acid in order to make their action more rapid. This treatment of bones by acid converts the phosphate of lime into a soluble lime salt called superphosphate, or, speaking chemically, transforms the original tribasic phosphate of lime into the monocalcic phosphate, sulphate of lime being at the same time produced. Following on this, Mr (now Sir) John Lawes treated mineral phosphates similarly with sulphuric acid, and with results which led to the establishment of a new industry, the manufacture of superphosphate and other artificial manures. The yearly importation of phosphatic minerals, &c., into England for this manufacture alone exceeds 500,000 tons.

The acid or soluble phosphate of lime in superphosphate, when applied to the soil, is first dissolved by the rain, and equally distributed in a portion of the soil, in which it must be precipitated and rendered insoluble before it can be assimilated by the plant. It is this intimate distribution and subsequent precipitation in a most finely divided state that would seem to constitute the beneficial effects of superphosphate, and its superiority over undissolved phosphates. It supplies at once phosphoric acid, lime, and sulphuric acid to the soil, and is much used in conjunction with nitrogenous materials. Superphosphates are manufactured of various strengths, the percentage of tribasic phosphate of lime, rendered soluble by acid, being taken as the basis of valuation.

3. *Potash.*—The next to rank after phosphoric acid as a valuable constituent of manures is potash. It enters largely into the composition of all crops, especially root crops. Sandy soils, as a rule, are poor in potash, for which reason they are benefited to a greater extent by the application of potash salts than most clay soils, which contain sufficient potash to meet the requirements of farm crops. In clay soils potash mainly occurs in the form of insoluble silicate of potash together with other silicates. By autumn cultivation, subsoiling, and similar means of facilitating the free access of the air to clay-land potash is gradually liberated from the insoluble silicates and is rendered available as plant food. Lime also seems to be an important agent in the liberation of potash. Potash also occurs in farmyard manure, urine, all excrements, in oil cakes, and largely in wood ashes.

Most potash salts are very soluble in water; this explains their greater abundance in the liquid than the solid excrements of animals. On this account it is a matter of importance, in making farmyard manure, to preserve the urine, and not lose the benefit of the potash salts it contains. On most soils in a good agricultural condition the addition of potash manures produces little or no effect, but on poor sandy soils or worn-out pasture land the use of potash salts, in conjunction with superphosphate, dissolved bones, and guano, is followed by most beneficial results. Potash salts as an addition to manures for potatoes have been found advantageous, while their effect on pasture seems to be to improve the quality of the herbage rather than to increase the yield of grass per acre.

4. *Soda.*—Most soils contain in abundance all the soda that farm crops require. With the exception of chloride of sodium (common salt), which occasionally is applied with more or less benefit to light sandy soils, and of nitrate of soda, which is employed as a nitrogenous manure, soda salts are not used for manuring purposes.

5. *Lime.*—Lime is essential for the production of healthy crops. Experience has shown that, when a soil is deficient in lime, farmyard manure, Peruvian guano, and other manures, though used in abundance, produce comparatively but little effect. Again, on poor sandy soils, lime, marl, or chalk not unfrequently produces better crops than farmyard or expensive artificial manures. Lime not only supplies an essential constituent of plants, but also prevents the loss by drainage of fertilizing matters such as potash, ammonia, and phosphoric acid. One of the functions of lime in the soil is to combine with the acids of the potash and ammoniacal salts of guano and of farmyard and other manures, and to liberate potash and ammonia, which are retained in the land, while the inexpensive lime salts pass into the land drainage.

Lime is used in agriculture in the form of quicklime, chalk (carbonate of lime), gypsum (sulphate of lime), marl, and shell-sand. For liming purposes gas-lime also is frequently employed, and, if well exposed to the air before being put on the land, may be used with safety and advantage.

6. *Magnesia.*—Magnesia is of but slight importance in manures; it occurs with potash in kainite and other potash salts, and the sulphate is sometimes used in making up artificial manures, but apparently without benefit.

7. *Silica.*—Silica is a constituent of the ashes of all plants, and occurs specially in large proportion in the straw of cereal crops. All soils contain such an abundance of silica that no necessity exists of supplying it artificially.

8. *Chlorine, Sulphuric Acid, and Oxide of Iron.*—These ash constituents are of little practical importance, inasmuch as most soils contain a sufficiency of them to meet the requirements of the crops usually cultivated on the farm. It may be observed, however, that chlorine has been found to be essential to plant life, and that iron is necessary for imparting to plants their green colour.

9. *Organic Matter or Humus.*—The importance of organic matter in manures was formerly much exaggerated. It has been conclusively proved that the carbon of which the bulk of the dry substance of all agricultural produce consists is derived from the carbonic acid of the atmosphere, and not from humus of the soil or the non-nitrogenous organic matters supplied in the manure. The organic matters present in dung in the shape of more or less decomposed or rotten straw exert a beneficial effect by improving the physical condition of both light and heavy land.

Farmyard Manure.—Farmyard manure is composed of the urine and solid excrements of animals collected in the stalls or yards, together with the straw used as litter. Its

composition varies greatly, according to the quantity of straw used as an absorbent, the nature of the animals, the food they have consumed to produce it, the length of time and way in which it has been kept, &c. The analysis by Dr Voelcker of well-made farmyard manure from horses, cows, and pigs, given in Table IV., p. 509, will show its approximate composition.

This analysis shows that farmyard manure contains all the constituents, without exception, which are required by cultivated crops to bring them to perfection, and hence it may be called a perfect manure. Dung, it will be observed, contains a great variety of organic and inorganic compounds of various degrees of solubility, and this complexity of composition—difficult, if not impossible, to imitate by art—is one of the reasons which render farmyard manure a perfect as well as a universal manure.

The excrements of different kinds of animals vary in composition, and those of the same animal will vary according to the nature and quantity of the food given, the age of the animal, and the way it is generally treated. Thus a young animal which is growing needs food to produce bone and muscle, and voids poorer dung than one which is fully grown and only has to keep up its condition. The solid and liquid excrements differ much in composition, for, while the former contains a good deal of phosphoric acid, lime, magnesia, and silica, and comparatively little nitrogen, the urine is almost destitute of phosphoric acid, and abounds in alkaline salts and nitrogenous organic matters, which on decomposition yield ammonia. Unless, therefore, the two kinds of excrements are mixed, a perfect manure supplying all the needs of the plant is not obtained; care must accordingly be taken to absorb all the urine by the litter. Farmyard manure, it is well known, is much affected by the length of time and the way in which it has been kept. Fresh dung is soluble in water only to a limited extent, and in consequence it acts more slowly on vegetation, and the action lasts longer than when dung is used which has been kept some time; fresh dung is therefore generally used in autumn or winter, and thoroughly rotten dung in spring, when an immediate forcing effect is required.

The changes which farmyard manure undergoes on keeping are illustrated by the following table of analyses, by Professor Wolff of Hohenheim in Würtemberg, of farmyard manure in its different stages of decomposition :—

TABLE V.—*Average Percentage Composition of Farmyard Manure.*

	Fresh.	Moderately Rotten.	Thoroughly Rotten.
Water	71·0	75·0	79·0
Organic matters	24·6	19·2	14·5
Ash	4·4	5·8	6·5
	100·0	100·0	100·0
Potash	·52	·63	·50
Soda	·15	·19	·13
Lime	·57	·70	·88
Magnesia	·14	·18	·18
Phosphoric acid	·21	·26	·30
Sulphuric acid	·12	·16	·13
Chlorine	·15	·19	·16
Silica	1·25	1·68	1·70
Nitrogen	·45	·50	·58

These figures represent the composition of farmyard manure of rather poor quality. Well-made good dung, produced by fattening cattle fed upon a fair allowance of cake, roots, hay, and straw, on an average may be said to contain—

Potash	·50 per cent.	
Phosphoric acid	·53	,,
Nitrogen	·64	,,

Forty tons of dung, according to this estimate, contain in round numbers 448 lb of potash, 475 of phosphoric acid, and 573 of nitrogen.

During the fermentation of dung a large proportion of the non-nitrogenous organic matters disappears in the form of carbonic acid and water, while another portion is converted into humic acids which effectually fix the ammonia gradually produced from the nitrogenous constituents of the solid and liquid excrements. The mineral matters remain behind entirely in the rotten dung, if care be taken to prevent loss by drainage.

Well-fermented dung, it will be noticed from the preceding table, is more concentrated and consequently more efficacious than fresh farmyard manure. Neither fresh nor rotten dung contains any appreciable quantity of volatile ammonia, and hence there is no necessity for applying gypsum, dilute acid, green vitriol, or other substances recommended as fixers of ammonia. If dung is carted out into the field and spread out at once it may be left for weeks together before it is ploughed in without the slightest risk of sustaining loss in fertilizing matter by evaporation, for dung does not lose ammonia by evaporation on exposure to the air, and any mineral soluble salts will be washed into the soil where they are wanted. If, however, dung is kept for a length of time in shallow heaps, or in open straw-yards and exposed to rain, it loses by drainage a considerable proportion of its most valuable soluble fertilizing constituents.

With a view to ascertaining the loss in fertilizing substances which farmyard manure sustains when it is kept for a long time exposed in open yards to the deteriorating influences of rain, Dr Voelcker spread a weighed quantity of fresh dung of known composition in an open yard, and after a period of twelve months again weighed the dung and submitted it to analysis, when the results shown in Table VI. were obtained :—

TABLE VI.—*Showing the Loss which Dung sustains by Drainage in Open Yards.*

		Fresh Manure.		After 12 Months' Exposure.
Weight of the manure		1652		793·65
Amount of water in the manure		1093		622·80
,, dry substances		559		170·85
The dry substances consist of—				
A. Soluble organic matters		40·97		3·95
B. Soluble mineral matters		25·43		5·52
C. Insoluble organic matters		425·67		94·45
D. Insoluble mineral matters		66·93		66·93
Whereof		559·00		170·85
A contains nitrogen		3·28		·32
Equal to ammonia	3·98		·39	
B contains nitrogen		6·21		3·56
Equal to ammonia	7·54		4·25	
Total amount of nitrogen in manure		9·49		3·88
Equal to ammonia	11·52		4·64	
The whole manure contained—				
Ammonia in free state		·55		·0055
Ammonia in the form of salts readily decomposed by quicklime		1·45		·28
Total amount of organic matters		466·64		98·40
,, ,, mineral matters		92·36		72·45

These tabulated results showed that the manure lost 69·8 per cent. of its fertilizing matters; or, in round numbers, two-thirds of the dung was wasted and only one-third left behind. Thus, after twelve months' exposure to the weather, nearly all the soluble nitrogen and 78·2 per cent. of the soluble mineral matters were lost by drainage. To prevent this loss, farmyard manure, as had been already pointed out, should, when possible, be carted into the field, spread out at once, and ploughed in at the convenience of the farmer. It is, however, not always practicable to apply farmyard manure just at the time it is made, and, as the manure heap cannot be altogether dispensed with, it is necessary to see how the manure may best be kept. For proper decomposition both air and moisture are requisite, while extreme dryness or too much water will arrest it. Farmyard manure is either prepared in dung-pits, which are put in a separate place, or is accumulated under the animal in the feeding-boxes; of the two plans the latter is the better, the urine being more thoroughly absorbed, and, owing to the box manure being more compact through constant treading on it, air enters less freely and the decomposition goes on less rapidly, the volatile matters in consequence not being so readily lost. External agents, such as rain, wind, sun, &c., do not affect it as they would in the case of dung-pits. If farmyard manure must be stored in heaps, care should be taken to have the bottom and sides of the pit impermeable to water, and the bottom slightly inclined to allow any liquid manure which collects to run off into a tank below, from which, by means of a pump, it may be again poured over the heap. A concrete bottom for the pit is best, or, failing that, one of thick clay or well-beaten earth. The manure heap should be kept as compact as possible, and always moist. The advantage of farmyard manure lies, not only in its supplying all the constituents of plant food, but also in the improved physical condition of the soil through its application, as the land is kept porous, and air is allowed free access. While, however, farmyard manure has these advantages, experience has shown that artificial manures, properly selected to meet the requirements of the crops intended to be grown, due regard being had to the chemical composition of the soil, may be employed to greater advantage. In farmyard manure about two-thirds of the weight is water and one-third dry matter; a large bulk thus contains only a small proportion of fertilizing substances, and expense is incurred for carriage of much useless matter when dung has to be carted to distant fields. When a plentiful supply of good farmyard manure can be produced on the farm or bought at a moderate price in the immediate neighbourhood, it is economy to use it either alone or in conjunction with artificial manures; but when food is dear and fattening does not pay, or farmyard manure is expensive to buy, it will be found more economical to use artificial manures.

Manures from Feeding Stuffs.—The investigations of Messrs Lawes, Gilbert, and Mure have shown that, in estimating the value of animal manure, 90 per cent. of the nitrogen of the food may be reckoned to be recovered in the case of feeding cakes, pulse, and other highly nitrogenous feeding stuffs; 85 per cent. in the case of foods comparatively poor in nitrogen, such as cereals and roots; and less than 65 per cent. in the case of bulky feeding stuffs, such as hay and straw. As a source of manure, the value of fattening foods is greater the more nitrogen they contain. Practically speaking, the whole of the mineral constituents and about nine-tenths of the nitrogen of the food are recovered in the dung and urine. For the same weight of dry substance consumed, oxen void more manure than sheep, and sheep more than pigs. The composition of the different foods given to fattening animals being well known, it is easy to calculate the amounts of nitrogen, phosphoric acid, and potash of the food which will be recovered in the manure. Each constituent having its market value as a manuring constituent, the money value of the manure obtained from the consumption of a ton of any ordinary food of which the composition is known can be determined. Assuming ammonia to be worth 8d. per lb, potash 2d. per lb, and phosphate of lime 1d. per lb, the money value of the manure produced by the consumption of a ton of various foods is given by Mr Lawes in the following table (VII.), which also shows the general composition of the different foods as far as their manurial value is concerned.

In these estimates it is presumed that the manure can be put on the land without loss, but in practice some loss is unavoidable; it may be but slight, as, for instance, when sheep are fed on the land, or when the manure is made in feeding-boxes, but it will be considerable when the food has been consumed in open yards in a very rainy season. Allowances must thus be made for the circumstances under which the manure was produced.

TABLE VII.—*Composition of Ordinary Feeding Stuffs in* 1000 *parts, and their Manuring Value per Ton.*

	Dry Matter.	Nitrogen.	Potash.	Phosphoric Acid.	Money value of the Manure from One Ton of each Food.

Artificial Manures.—By some a distinction has been drawn between those manures which, like superphosphate, dissolved bones, &c., are manufactured in chemical works and those which are produced naturally, such as guano, nitrate of soda, &c. However, the term artificial manure is generally applied to all manures, natural or manufactured, which are not produced on the farm, as distinguished from farmyard manure and manure from purchased foods, which are essentially farm products. The value of all manures mainly depends on their chemical composition.

As compared with farmyard manure, artificial manures have the disadvantage that they, unlike it, do not improve the physical condition of the soil. Artificial manures have, on the other hand, the advantage over farmyard manure that they can supply in a small compass, and even if used in small quantity, the needed nitrogen, phosphoric acid, and potash, &c., which crops require, and which farmyard manure has but in small proportion; they present the expensive fertilizing matters in a concentrated form, and by their application save expense in labour and carriage.

The following are the principal artificial manures in use:—

1. *Nitrogenous Manures.—Peruvian Guano.*—This is a natural manure, valuable on account of the ammonia, phosphoric acid, and potash it contains. It is the excrement, &c., of sea birds accumulated in parts where no rain falls. The earliest deposits found contained as much as 14 to 17 per cent. of ammonia, *e.g.*, Chinchas Island guano; those now (1882) imported seldom exceed 8 per cent., and generally vary from 4 to 8 per cent., of ammonia. In using guano it should be mixed with earth, &c., to prevent injury to the seeds or plants. Peruvian guano is also treated with sulphuric acid, which renders the phosphates soluble and fixes the ammonia, thereby preventing any loss of it; this constitutes dissolved guano, and is frequently sold upon a guarantee of 20 per cent. of soluble phosphates, 4 per cent. of insoluble phosphates, and 9 per cent. of ammonia. Peruvian guano is used as a top dressing for wheat and barley; in addition to insoluble phosphates, it contains soluble phosphates of the alkalies.

Ammonia Salts.—The principal one is sulphate of ammonia, largely produced in gas works by neutralizing gas liquor with sulphuric acid; it is usually sold on a basis of 24 to 25 per cent. of ammonia.

Soot is valuable on account of the sulphate of ammonia it contains; the percentage of ammonia varies from 1½ to 4.

Nitrate of soda is a natural deposit; it is greatly used as a top dressing for wheat and barley. It usually contains common salt, and when purified is sold on a basis of 95 per cent. of pure nitrate.

Organic Nitrogenous Substances.—Wool, hair, fish, flesh, horn, blood, rape cake, damaged cotton cake and other oil cakes. Wool refuse (shoddy), according to its quality, contains from 4 to 8 per cent. of nitrogen, flesh 14 to 15 per cent., blood (dried) 13 to 15 per cent., rape cake 4 to 5 per cent., linseed cake about 4 per cent., cotton cake (undecorticated) nearly 4 per cent., and cotton cake (decorticated) over 6 per cent. of nitrogen.

2. *Phosphatic Manures.*—(*a*) The following phosphatic minerals are used for the manufacture of superphosphate of various strengths, and of compound manures:—coprolites (Cambridge, Suffolk, and Bedfordshire), containing 50 to 55 per cent. of phosphate of lime; phosphorite (Spanish and Portuguese); apatite (Norwegian and Canadian), containing often as much as 80 per cent. phosphate of lime; South Carolina (land and river) phosphate, 52 to 56 per cent. phosphate of lime; French phosphate; Sombrero phosphate, 70 per cent. phosphate of lime; Curaçoa phosphate, 80 per cent. phosphate of lime; Navassa phosphate; Aruba phosphate, &c.

(*b*) *Bones.*—Raw bones, as ½ inch and ¼ inch bones; bone meal; bone dust, having about 48 per cent. phosphate of lime and 4½ per cent. of ammonia; boiled bones, with 60 per cent. phosphate of lime and about 1·8 per cent. of ammonia; dissolved bones; bone ash, with 70 per cent. phosphate of lime; animal charcoal, with 70 to 80 per cent. phosphate of lime.

(*c*) *Phosphatic Guanos.*—Lacepede Island guano; Mexillones guano; Malden Island guano; Fanning Island guano; and many others varying in composition from 60 to 90 per cent. phosphate of lime.

3. *Saline Materials.*—Potash salts (chloride and sulphate); kainite, with 20 to 25 per cent. sulphate of potash, and also sulphate of magnesia and common salt; wood ashes, with about 10 per cent. of potash; common salt.

4. *Calcareous Manures.*—Lime, chalk, marl, gypsum, shell sand, gas lime, coal ashes, road scrapings, &c.

5. *Carbonaceous Manures.*—Sawdust, peat, sea-weed, vegetable refuse, &c.

6. *Special and Compound Manures.*—The basis of these is superphosphate, which is mixed with other manuring materials to meet the special requirements of particular crops and soils.

The foregoing remarks made on the application of manures to different kinds of crops may now in conclusion be summed up. Farmyard manure, in order to be most beneficial, should be applied as quickly as possible after it is made, the best time being in autumn or early winter. Nitrate of soda should be applied as a top dressing early in spring; its effect will be seen in the first season only. Ammonia salts, guano, dung, &c., are best applied to heavy land in autumn or winter, either before the seed is sown, or after the plant is fairly above ground, but in the case of light land early in spring. The effect of bones in the various form of dissolved bones, bone dust, raw bones, &c., will last two or more seasons according to the quantities used and their respective solubility. Lastly, it may be observed that the presence of lime is essential to the economical use of manures.

As regards cereal crops, it has been found that mineral manures alone, whether simple or complex, do not produce appreciable increase of crop, but that nitrogenous manures, whether as ammonia salts, nitrate of soda, or farmyard manure, greatly benefit the crop; that nitrate of soda does rather better than ammonia salts; and that, while on fairly heavy land farmyard manure will yield good crops, the best results are obtained by using mineral and nitrogenous manures together. On clay soils a top dressing of nitrate of soda often answers all practical purposes, but on light soils nitrate of soda or ammonia salts should not be used without mineral manures, while it is advisable even on heavy land to use superphosphate as well.

For root crops, on cold clays nothing answers so well as mineral superphosphate alone, but on light land dissolved bones, bone dust, precipitated phosphate, or a compound artificial manure will be found to be much preferable to superphosphate. Bone meal mixed with mineral superphosphate makes, for instance, a good manure for roots; for mangolds Peruvian guano and common salt in addition are useful, and for potatoes potash salts with phosphatic and nitrogenous manures.

For pasture land the use of artificial manures is, as a rule, not economical; nitrogenous manures raise the quantity and phosphatic and potash manures improve the quality of the herbage, while, for worn-out pastures, potash with dissolved bones or superphosphate or superphosphate and guano will do much good. The most economical way of manuring pasture land is to apply farmyard manure liberally, or feed it off with cattle, giving cotton cake in addition.

The employment of artificial manures in a judicious manner has shown the occupier of land that it is not necessary for him to be bound down to any system of rotation of crops which may be practised in his particular district, but that he has the means of pursuing the course of cropping, system of manuring, and general management of his farm which will yield him the best returns. No more striking instance of this could be put forward than the experience of Mr Prout, who at Sawbridgeworth, Herts, has grown with much success cereal crops, year after year, on heavy clay land, selling the whole of the growing crops, and restoring the fertility of the soil by artificial manures. The land was purchased in 1861, and up to the present time (1882) the crops have been as good as ever, and the land has not been deteriorated, but on the other hand improved, by continuous corn growing. The experiments of Messrs Lawes and Gilbert at Rothamsted and of Dr Voelcker at Woburn have been thus verified on a large scale in the experience of Mr Prout, and have shown beyond all possibility of doubt the efficacy and economy of a liberal use of artificial manures. (A. V.)

MANUSCRIPTS, ANCIENT. See DIPLOMATICS and PALÆOGRAPHY.

MANUTIUS. I. ALDUS MANUTIUS (1450–1515). Teobaldo Mannucci, better known as Aldo Manuzio, the founder of the Aldine press, was born in 1450 at Sermoneta in the Papal States. He received a scholar's training, studying Latin at Rome under Gasparino da Verona, and Greek at Ferrara under Guarino da Verona. Having qualified himself for the career of a humanist, according to the custom of the century, he went in 1482 to reside at Mirandola with his old friend and fellow-student, the illustrious Giovanni Pico. There he stayed two years, prosecuting his studies in Greek literature. Before Pico removed to Florence, he procured for Aldo the post of tutor to his nephews Alberto and Lionello Pio, princes of Carpi. To Alberto Pio the world owes a debt of gratitude, inasmuch as he supplied Aldo with funds for starting his printing press, and gave him lands at Carpi. It was Aldo's ambition to secure the literature of Greece from further accident by committing its chief masterpieces to type; and the history of his life is the record of the execution of this gigantic task. Before his time four Italian towns had won the honours of Greek publications:—Milan, with the grammar of Lascaris, Æsop, Theocritus, a Greek Psalter, and Isocrates, between 1476 and 1493; Venice, with the *Erotemata* of Chrysoloras in 1484; Vicenza, with reprints of Lascaris's grammar and the *Erotemata*, in 1488 and 1490; Florence, with Alopa's Homer, in 1488. Of these works, only three, the Milanese Theocritus and Isocrates and the Florentine Homer, were classics. Aldo selected Venice as the most appropriate station for his labours. He settled there in 1490, and soon afterwards gave to the world editions of the *Hero and Leander* of Musæus, the *Galeomyomachia*, and the Greek Psalter. These have no date; but they are the earliest tracts issued from his press, and are called by him "Precursors of the Greek Library."

At Venice Aldo gathered an army of Greek scholars and compositors around him. His trade was carried on by Greeks, and Greek was the language of his household. Instructions to type-setters and binders were given in Greek. The prefaces to his editions were written in Greek. Greeks from Crete collated MSS., read proofs, and gave models of calligraphy for casts of Greek type. Not counting the craftsmen employed in merely manual labour, Aldo entertained as many as thirty of these Greek assistants in his family. His own industry and energy were unremitting. In 1495 he issued the first volume of his Aristotle. Four more volumes completed the work in 1497–98. Nine comedies of Aristophanes appeared in 1498. Thucydides, Sophocles, and Herodotus followed in 1502; Xenophon's *Hellenics* and Euripides in 1503; Demosthenes in 1504. The troubles of Italy, which pressed heavily on Venice at this epoch, suspended Aldo's labours for a while. But in 1508 he resumed his series with an edition of the minor Greek orators; and in 1509 appeared the lesser works of Plutarch. Then came another stoppage. The league of Cambray had driven Venice back to her lagoons, and all the forces of the republic were concentrated on a struggle to the death with the allied powers of Europe. In 1513 Aldo reappeared with Plato, which he dedicated to Leo X. in a preface eloquently and earnestly comparing the miseries of warfare and the woes of Italy with the sublime and tranquil objects of the student's life. Pindar, Hesychius, and Athenæus followed in 1514.

These complete the list of Aldo's prime services to Greek literature. · But it may be well in this place to observe that his successors continued his work by giving Pausanias, Strabo, Æschylus, Galen, Hippocrates, and Longinus to the world in first editions. Omission has been made of Aldo's reprints, in order that the attention of the reader might be concentrated on his labours in editing Greek classics from MSS. Other presses were at work in Italy; and, as the classics issued from Florence, Rome, or Milan, Aldo took them up, bestowing in each case fresh industry upon the collation of codices and the correction of texts. Nor was the Aldine press idle in regard to Latin and Italian classics. The *Asolani* of Bembo, the collected writings of Poliziano, the *Hypnerotomachia Poliphili*, Dante's *Divine Comedy*, Petrarch's poems, a collection of early Latin poets of the Christian era, the letters of the younger Pliny, the poems of Pontanus, Sannazzaro's *Arcadia*, Quintilian, Valerius Maximus, and the *Adagia* of Erasmus were printed, either in first editions, or with a beauty of type and paper never reached before, between the years 1495 and 1514. For these Italian and Latin editions Aldo had the elegant type struck which bears his name. It is said to have been copied from Petrarch's handwriting, and was cast under the direction of Francesco da Bologna, who has been identified by Panizzi with Francia the painter.

Aldo's enthusiasm for Greek literature was not confined to the printing-room. He burned with a humanist's enthusiasm for the books he printed; and we may well pause astonished at his industry, when we remember what a task it was in that age to prepare texts of authors so numerous and so voluminous from MSS. Whatever the students of this century may think of Aldo's scholarship, they must allow that only vast erudition and thorough familiarity with the Greek language could have enabled him to accomplish what he did. In his own days Aldo's learning won the hearty acknowledgment of ripe scholars. To his fellow workers he was uniformly generous, free from jealousy, and prodigal of praise. His stores of MSS. were as open to the learned as his printed books were liberally given to the public. While aiming at that excellence of typography which renders his editions the treasures of the book-collector, he strove at the same time to make them cheap. We may perhaps roughly estimate the current price of his pocket series of Greek, Latin, and Italian classics, begun in 1501, at 2s. per volume of our present money. The five volumes of the Aristotle cost about £8. His great undertaking was carried on under continual difficulties, arising from strikes among his workmen, the piracies of rivals, and the interruptions of war. When he died, bequeathing Greek literature as an inalienable possession to the world, he was a poor man. In order to promote Greek studies, Aldo founded an academy of Hellenists in 1500 under the title of the New Academy. Its rules were written in Greek. Its members were obliged to speak Greek. Their names were Hellenized, and their official titles were Greek. The biographies of all the famous men who were enrolled in this academy must be sought in the pages of Didot's *Alde Manuce*. It is enough here to mention that they included Erasmus and the English Linacre.

In 1499 Aldo married Maria, daughter of Andrea Torresano of Asola. Andrea had already bought the press established by Nicholas Jenson at Venice. Therefore Aldo's marriage combined two important publishing firms. Henceforth the names Aldus and Asolanus were associated on the title pages of the Aldine publications; and after Aldo's death in 1515, Andrea and his two sons carried on the business during the minority of Aldo's children. The device of the dolphin and the anchor, and the motto *festina lente*, which indicated quickness combined with firmness in the execution of a great scheme, were never wholly abandoned by the Aldines until the expiration of their firm in the third generation.

II. PAULUS MANUTIUS (1512–1574). By his marriage with Maria Torresano, Aldo had three sons, the youngest of whom, Paolo, was born in 1512. He had the misfortune to lose his father at the age of two. After this event his grandfather and two uncles, the three Asolani, carried on the Aldine press, while Paolo prosecuted his early studies with unremitting industry at Venice. Excessive application hurt his health, which remained weak during the rest of his life. At the age of twenty-one he had acquired a solid reputation for scholarship and learning. In 1533 Paolo undertook the conduct of his father's business, which had latterly been much neglected by his uncles. In the interregnum between Aldo's death and Paolo's succession (1514–33) the Asolani continued to issue books, the best of which were Latin classics. But, though their publications count a large number of first editions, and some are works of considerable magnitude, they were not brought out with the scholarly perfection at which Aldo aimed. The Asolani attempted to perform the whole duties of editing, and to reserve all its honours for themselves, dispensing with the service of competent collaborators. The result was that some of their editions, especially their Æschylus of 1518, are singularly bad. Paolo determined to restore the glories of the house, and in 1540 he separated from his uncles. The field of Greek literature having been well-nigh exhausted, he devoted himself principally to the Latin classics. He was a passionate Ciceronian, and perhaps his chief contributions to scholarship are the corrected editions of Cicero's letters and orations, his own epistles in a Ciceronian style, and his Latin version of Demosthenes. Throughout his life he combined the occupations of a student and a printer, winning an even higher celebrity in the former field than his father had done. Four treatises from his pen on Roman antiquities deserve to be commemorated for their erudition no less than for the elegance of their Latinity. Several Italian cities contended for the possession of so rare a man; and he received tempting offers from the Spanish court. Yet his life was a long struggle with pecuniary difficulties. To prepare correct editions of the classics, and to print them in a splendid style, has always been a costly undertaking. And, though Paolo's publications were highly esteemed, their sale was slow. In 1556 he received for a time external support from the Venetian Academy, founded by Federigo Badoaro. But Badoaro failed disgracefully in 1559, and the academy was extinct in 1562. Meanwhile Paolo had established his brother, Antonio, a man of good parts but indifferent conduct, in a printing office and book shop at Bologna. Antonio died in 1559, having been a source of trouble and expense to Paolo during the last four years of his life. Other pecuniary embarrassments arose from a contract for supplying fish to Venice, into which Paolo had somewhat strangely entered with the Government. In 1561 Pope Pius IV. invited him to Rome, offering him a yearly stipend of 500 ducats, and undertaking to establish and maintain his press there. The profits on publications were to be divided between Paolo Manuzio and the apostolic camera. Paolo accepted the invitation, and spent the larger portion of his life, under three papacies, with varying fortunes, in the city of Rome. Ill health, the commercial interests he had left behind at Venice, and the coldness shown him by Pope Pius V., induced him at various times and for several reasons to leave Rome. But of these excursions it is not necessary to take particular notice. As was natural, his editions after his removal to Rome were mostly Latin works of theology and Biblical or patristic literature.

Paolo married his wife, Caterina Odoni, in 1546. She brought him three sons and one daughter. His eldest son, the younger Aldus, succeeded him in the management of the Venetian printing house when his father settled at Rome in 1561. Paolo had never been a strong man, and his health was overtaxed with studies and commercial worries. Yet he lived into his sixty-second year, and died at Rome in 1574.

III. ALDUS MANUTIUS, JUNIOR (1547-1597). The younger Aldo, born in the year after his father Paolo's marriage, cradled in scholarship, and suckled as it were with printer's ink, proved what is called an infant prodigy. When he was nine years old, his name was placed upon the title page of the famous *Eleganze della lingua Toscana e Latina.* What his share was in that really excellent selection cannot be ascertained; but it is hardly possible that a boy of nine could have compiled it without assistance. The *Eleganze* was probably a book made for his instruction and in his company by his father. In 1561, at the age of fourteen, he produced a work upon Latin spelling, called *Orthographiæ Ratio.* During a visit to his father at Rome in the next year, he was able to improve this treatise by the study of inscriptions, and in 1575 he completed his labours in the same field by the publication of an *Epitome Orthographiæ.* Whether Aldo was the sole composer of the work on spelling, in its first edition, may be doubted; but he appropriated the subject and made it his own. Probably his greatest service to scholarship is this analysis of the principles of orthography in Latin.

Aldo remained at Venice, prosecuting studies in literature and superintending the Aldine press. But in these days of early manhood he was not satisfied with the career of scholarship and business. At one time he hankered after the more worldly honours of the law, at another he built a country house at Asola, perplexing his father, who had given him too easy independence, with the humours of his age. A marriage came to make these matters straight. The Giunta family had been steadily rising in the world as printers, in proportion as the Aldi declined through want of concentration upon commerce. In 1572 Aldo took for his wife Francesca Lucrezia, daughter of Bartolommeo Giunta, and great-grandchild of the first Giunta, who founded the famous printing house in Venice. This was an alliance which augured well for the future of the Aldines, especially as the young husband, in the midst of distractions, had recently found time to publish a new revised edition of Velleius Paterculus. Two years later the death of his father at Rome placed Aldo at the head of the firm. In concert with his new relatives, the Giunta, he now edited an extensive collection of Italian letters, and in 1576 he appeared again before the public as a critic with his commentary upon the *Ars Poetica* of Horace. Printing, in this case, as in the case of his father, went hand in hand with original authorship. About the same time, that is to say, about the year 1576, he was appointed professor of literature to the Cancelleria at Venice. The Aldine press continued through this period to issue books, but none of signal merit; and in 1585 Aldo determined to quit his native city for Bologna, where he occupied the chair of eloquence for a few months. In 1587 he left Bologna for Pisa, and there, in his quality of professor, he made the curious mistake of printing Alberti's comedy *Philodoxius* as a work of the classic Lepidus. Sixtus V. drew him in 1588 from Tuscany to Rome; and at Rome he hoped to make a permanent settlement as lecturer. But his public lessons were ill attended, and he soon fell back upon his old vocation of publisher under the patronage of a new pope, Clement VIII. In the tenth year of his residence at Rome, that is, in 1597, he died, leaving children, but none who cared or had capacity to carry on the Aldine press. Aldo himself, though a precocious student, a scholar of no mean ability, and a publisher of some distinction, was the least remarkable of the three men who gave books to the public under the old Aldine ensign. Times had changed in Italy since Aldo the elder conceived the great idea of reaping for the press the harvest of Greek literature. And his posterity had changed with the times for the worse. This does not of necessity mean that we should adopt Scaliger's critique of the younger Aldo without reservation. Scaliger called him "a poverty-stricken talent, slow in operation; his work is very commonplace; he aped his father." What is true in this remark lies partly in the fact that scholarship in Aldo's days had flown beyond the Alps, where a new growth of erudition, on a basis different from that of the Italian Renaissance, had begun.

Renouard's *Annales de l'Imprimerie des Aldes*, Paris, 1834, and Didot's *Alde Manuce*, Paris, 1873, contain all necessary information regarding the lives of the Manutii and their publications. (J. A. S.)

MANZONI, ALESSANDRO FRANCESCO TOMMASO ANTONIO (1785-1873), founder of the romantic school in Italian literature, was born at Milan, March 7, 1785. Don Pietro, his father, then about fifty, represented an old family settled near Lecco, but originally feudal lords of Barzio, in the Valsassina, where the memory of their violence is still perpetuated in a local proverb, comparing it to that of the mountain torrent. The poet's maternal grandfather, Cesare Beccaria, was a well-known author, and his mother Giulia a woman of some literary ability. Manzoni's intellect was slow in maturing, and at the various colleges where his school days were passed he ranked among the dunces. At fifteen, however, he developed a passion for poetry, and wrote two sonnets of considerable merit. On the death of his father in 1805, he joined his mother at Auteuil, and spent two years there, mixing in the literary set of the so-called "idealogues," philosophers of the 18th century school, among whom he made many friends, notably Claude Fauriel. There too he imbibed the negative creed of Voltairianism, and only after his marriage, and under the influence of his wife, did he exchange it for that fervent Catholicism which coloured his later life. In 1806-7, while at Auteuil, he first appeared before the public as a poet with two pieces, one entitled *Urania*, in the classical style, of which he became later the most conspicuous adversary, the other an elegy in blank verse, on the death of Count Carlo Imbonati, from whom, through his mother, he inherited considerable property, including the villa of Brusuglio, thenceforward his principal residence.

Manzoni's marriage in 1808 to Henriette Blondel, daughter of a Genevese banker, proved a most happy one, and he led for many years a retired domestic life, divided between literature and the picturesque husbandry of Lombardy. His intellectual energy at this period was devoted to the composition of the *Inni Sacri*, a series of sacred lyrics, and a treatise on Catholic morality, forming a task undertaken under religious guidance, in reparation for his early lapse from faith. In 1818 he had to sell his paternal inheritance, as his affairs had gone to ruin in the hands of a dishonest agent. The beautiful villa Il Galeotto, where he had spent his childish years amid the scenery he afterwards immortalized, then passed from his hands, to his great regret. His characteristic generosity was shown on this occasion in his dealings with his peasants, who on settling their accounts were found heavily indebted to him. He not only cancelled on the spot the record of all sums owing to him, but bade them keep for themselves the whole of the coming maize harvest.

In 1819 Manzoni published his first tragedy, *Il Conte di Carmagnola*, which, boldly violating all classical conventionalisms, excited a lively controversy. It was severely criticized in the *Quarterly Review*, in an article to which Goethe replied in its defence, "one genius," as Count de Gubernatis remarks, "having divined the other." The death of Napoleon in 1821 inspired Manzoni's powerful stanzas *Il Cinque Maggio*, the most popular lyric in the Italian language.

The political events of that year, and the imprisonment of many of his friends, weighed much on Manzoni's mind, and the historical studies in which he sought distraction during his subsequent retirement at Brusuglio, suggested his great work. Round the episode of the *Innominato*, historically identified with Bernardino Visconti, *I Promessi Sposi* began to grow into shape, and was completed in September 1822. The work when published, after revision by friends in 1825-27, at the rate of a volume a year, at once raised its author to the first rank of literary fame. In the interim of its composition in 1822, Manzoni published his second tragedy *Adelchi*, turning on the overthrow by Charlemagne of the Lombard domination in Italy, and containing many veiled allusions to the existing Austrian rule.

With these works Manzoni's literary career was practically closed. The end of the poet's long life was saddened by domestic sorrows. The loss of his wife in 1833 was followed by that of several of his children, and of his mother, to whom he was fondly attached. In 1837 he married his second wife, Teresa Borri, widow of Count Stampa, whom he also survived, while of nine children born to him in his two marriages, all but two preceded him to the grave. The death of his eldest son, Pier Luigi, on April 28, 1873, was the final blow which hastened his end; he fell ill immediately, and died of cerebral meningitis, May 22, aged eighty-eight. His country mourned him with almost royal pomp, and his remains, after lying in state for some days, were followed to the cemetery of Milan by a vast cortége, including the royal princes and all the great officers of state. But his noblest monument was Verdi's *Requiem*, specially written to honour his memory.

Manzoni's position in literature is unique; for, while the romantic Renaissance produced in other countries a galaxy of genius, in Italy it remained embodied in him alone, since none of his disciples came near enough to be classed with him. Scott declared *I Promessi Sposi* the finest novel ever written; and, if we take as our standard loftiness of aim combined with ingenuous simplicity of style, and Titianesque power of character painting relieved by an undercurrent of subtle irony giving point to every trivial incident, we need scarcely dispute his verdict. It occupies the same place in Italian as *Don Quixote* in Spanish literature, overshadowing in similar fashion the whole field of subsequent fiction. Manzoni's poetry cannot be classed so high, and, despite its nervous diction and epigrammatic intensity of thought, it is as a great master of Italian prose that he will go down to posterity.

Of exalted private character, Manzoni furnishes an almost solitary instance of a poet whose life contains no note of discord with the loftiest standard presented by his works. The highest genius, disciplined by still higher moral self-control, produced in him the rare spectacle of a perfect equilibrium of forces in a powerful mind. His presence was impressive, and his speech, though retarded by a slight impediment, so full of wisdom that Tommaseo declared he had learned more from his conversation than from all the books he had ever read. At the same time he had that exquisite courtesy in listening which gave to those who addressed him the sense of having spoken well. No man ever attained to greater honour from his contemporaries, or sought it less, and few have joined such rare intellectual gifts to so much gracious humility of mind and manners. His warmth of affection, tenderness of sympathy, and universal benevolence endeared him to his friends and fellow-citizens, while by his countrymen at large he was revered as the sage and patriarch of Italian letters.

In addition to the works already named, he wrote *La Storia della Colonna Infame*, and a small treatise on the Italian language. *I Promessi Sposi*, laboriously revised by the author in accordance with the Tuscan idiom, has gone through 118 Italian, 19 French, 17 German, and 10 English editions.

Biographical sketches of Manzoni have been recently published by Cesare Cantù (1882), Benedetto Prina, Giulio Carcano, Angelo de Gubernatis, Antonio Stoppani (his early years), and others. Some of his letters have been published by Giovanni Sforza, and a work entitled, *Commento Storico su I Promessi Sposi*, by Cesare Cantù. MAP. 1. *First Essays in Map-making.*—As each man stands in the centre of his horizon and the portion of the earth's surface which lies within his range of vision has the appearance of a disk, the whole world was in ancient times conceived as a disk surrounded by the sea. It was consequently not uncommon for a people to imagine—as was the case we know with the Chinese, the Hindus, the Chaldæans, the Jews, the Arabs, and even the ancient Peruvians—that it occupied the middle part of the world. The wider a people's range of vision, the wider was the disk of the world represented. A circular surface is thus the simplest form for a *mappa mundi* or map of the world; and it is met with both in antiquity and in the Middle Ages. The extent of the circle of vision depends among uncivilized peoples on their way of life. Wandering tribes have seen more of the world than settled tribes; and hunters, fishers, and seamen make the widest excursions. Among them consequently we find the beginnings of map-making; and Eskimo, Indians, and Polynesians, for example, show in this matter astonishing quickness of apprehension, while among the settled Negro tribes, on the other hand, there are no maps. A map drawn by an Eskimo woman enabled Sir Edward Parry to discover Fury and Hecla Strait; M'Clintock during his endeavours to clear up the fate of the Franklin expedition repeatedly got the Eskimo to draw coast-maps of the Arctic lands; and many similar instances are given by Andree, "Beginnings of Cartography," *Globus*, xxxi. pp. 24-27, 37-43.

Turning to civilized peoples, it is among the Egyptians that we find the earliest recorded examples of cartographic representation. Apollonius of Rhodes (born 230 B.C.) reports in his *Argonautica* (iv. 279) that the Egyptians of Colchis, a colony dating from the time of Ramses II. (?), had preserved as heirlooms certain wooden tablets (κύρβεις) on which land and sea, roads and highways, were accurately indicated; Eustathius, in his commentary on Dionysius Periegetes, mentions that Sesostris the Egyptian king caused route-maps to be prepared; and Strabo also refers to certain old maps in the library of Eratosthenes in which Meroe and the south end of the peninsula of India were placed on the same parallel of latitude. These statements have been confirmed by the actual discovery of such maps and plans on old Egyptian papyrus-rolls. Birch has, for instance, identified a drawing on a papyrus in the Turin Museum as the topographical map of a gold-mining district in Nubia. The perspective in this case is very childish: in order to show that the road leads between two mountain-chains, the mountains on one side of the road are inverted (comp. Lepsius, *Urkundenbuch*, pl. xxii.). This map is one thousand years older than that of Anaximander, who was considered by the Greeks as the inventor of cartography. On another sheet appears a representation of the victorious return of Sethos I. (1443–1392 B.C.) from Asia, showing the road from Pelusium by Leontopolis to Heroopolis, Lake Timsah with fish in it, the canal from the Nile with crocodiles, and at Heroopolis a bridge over the canal. Similar picture-maps were discovered by Layard in Assyria (*Nineveh and Babylon*, p. 231 *sq.*, 1867). The ancient Babylonians have also the high distinction of having divided space and time in a way that allowed scientific measurements to be made after the still customary method. It was they who originated the division of the ecliptic into twelve signs and later into 360 degrees; and the division of the circle into 360 degrees with 60 minutes to the degree and 60 seconds to the minute, as well as the corresponding division of the hour, was the outcome of their sexagesimal system of numeration. This method of division was introduced among the Greeks by Hipparchus (150 B.C.), and obtained general currency through the geographer Ptolemy (150 A.D.). By this means were provided the elements necessary for the astronomical determination of geographical position. Among the Egyptians and Babylonians map-making remained in its first infantile stage; its scientific development was received at the hands of the Greeks.

2. *Development of Map-making among the Greeks.*—In Homer the "circumfluent ocean" represents the horizon which bounds the disk of the world; the scientific treatment of geography and map-making has its origin among the Ionic Greeks of Asia Minor. Anaximander, a pupil of Thales (about 560 B.C.), sketched the first map (γεωγραφικὸς πίναξ), and was the first who sought to determine the compass of the earth (the world-disk) and the sea. As the Greeks gradually extended their journeys as far as India in the East and the Atlantic in the West, the conviction gained ground that the world-disk could not be bounded by a regular circular outline. About one hundred years after Anaximander, Democritus of Abdera ventured to draw a new map on the basis of his own observations (for in his extensive wanderings he had been as far as Persia and perhaps even India); and in opposition to the circular form of the Ionians he gave the world an oblong shape, and taught that from east to west it was half as long again as from north to south. Although after the time of Aristotle the tabular or flat-surface theory of the figure of the earth was expelled by the spherical or globe theory, the portion of the earth's surface which was really known retained the same oblong shape which it had with Democritus; and hence we still speak of longitude and latitude, that is, length and breadth. It was on this basis also that the far-travelled Hecatæus of Miletus, who wrote his Γῆς περίοδος between 520 and 500 B.C., drew up his map; for the representation of the world on a brazen tablet, which was shown by Aristagoras, tyrant of Miletus, to King Cleomenes of Sparta, was probably nothing else than the world-map of Hecatæus. The first application of astronomy to geography was made by the famous Arctic navigator Pytheas of Marseilles, about 326 B.C.; it is from him that we obtain the first observation of latitude, and, what is of some importance, this is for Marseilles. His voyage to the extreme North (Thule) was undertaken partly for the purpose of satisfying himself in regard to the figure and size of the earth. Dicæarchus of Messana in Sicily, a pupil of Aristotle's (310 B.C.), made the first approach to a projection. He divided the inhabited (*i.e.*, the known) world, which he reckoned to be one and a half times as long as it was broad, into a northern and a southern half by means of what he considered a straight line drawn from the pillars of Hercules, through Sicily, the Peloponnesus, Caria, Lycia, Pamphylia, Cilicia, and across the Taurus to the Imaus (Himalaya). He thus drew the first parallel of latitude, and upon this basis he prepared maps which were to be publicly exhibited in a hall (Agathem., § 5; Strabo, p. 105). The name διάφραγμα τῆς οἰκουμένης, *i.e.*, partition of the inhabited world, was given to the base-line. For the next material improvement we are indebted to the famous astronomer and geographer Eratosthenes of Cyrene, the keeper of the Alexandrian library (276–196 B.C.). He was the first to make a rational geodetic measurement for the purpose of determining the size of the earth, and he collected in his Γεωγραφικά the whole geographical learning of his time. This work has unfortunately been lost, but from the numerous fragments that have been preserved, especially by Strabo, it is possible to form an idea of this the first systematic geography. Starting with the spherical form and the size of the world, it gave a description of the οἰκουμένη, discussed the space relations of the world-island, and estimated its extent in longitude and latitude. On the basis of the diaphragm of Dicæarchus, the course of which was more precisely indicated, a series of seven parallels and as many meridians cutting the diaphragm at right angles were drawn, and by this means the inhabited world was divided to the north and the south of the diaphragm into a certain number of regular divisions to which the name of sphragidia or seals was given. Then follows a description of the countries in the several "seals," beginning with India. In this arrangement we may recognize the first attempt to construct a network or system of degrees. As numerous data in regard to distances were already at his command, Eratosthenes greatly improved on the old maps in the matter of correctness; but, as the number of astronomical determinations of latitude was still small, and the intervals between the parallels and the meridians were unequal and conditioned by the available data in regard to distance, his network of lines was far from being an exact mathematical system. Hipparchus of Nicæa in Bithynia, the greatest astronomer of the ancient world (about 150 B.C.), consequently rejected the geography of Eratosthenes because it only partially utilized the abundant resources provided by the high development of contemporary mathematics and astronomy. Instead of the uncertain estimates of distance and direction furnished by travellers, only astronomical determinations of latitude and longitude should, he maintained, have been employed. He does not appear, however, to have himself written a geography or constructed a map. About the same time Crates of Mallus made the first globe. On this he extended the Atlantic Ocean southward to the south pole, placed a corresponding ocean on the other hemisphere, and, in the belief that the torrid zone could be occupied by nothing but water, ran an Oceanic belt along the line of the equator (fig. 1). In the four segments thus produced he set four semicircular land-areas, only one of which was known to the ancient world. This systematic figure maintained its place down into the Middle Ages, as

appears from the ornamentation of the globe that forms part of the insignia of royalty.

Marinus of Tyre (about 150 A.D.) was the first who sought to give effect to the demand made by Hipparchus for a trustworthy representation of the countries of the world. His work unfortunately has been lost; and we know of its existence only from his successor Claudius Ptolemy. Without Marinus, however, Ptolemy's work would have been impossible; and neither of them was able really to carry out Hipparchus's idea of determining the latitude and longitude for every place; for observations of latitude were known only for Marseilles, Syene, Alexandria, Rhodes, and perhaps a few other places, and all other positions were obtained by reducing distances to degrees. The determination of longitudes was even more difficult. Ptolemy possessed only the contemporary observation of the lunar eclipse in Arbela and Carthage of the year 331 B.C., from which he calculated a difference of meridian of 45° 10′ instead of 34° 2′. The longer axis of the Mediterranean was consequently a third too great, 62 degrees of the meridian being assumed instead of $41\frac{2}{3}$, and from this there resulted an exaggeration of all the Mediterranean countries, which was corrected only by the compass-maps of the later Middle Ages. Ptolemy, however (availing himself of the stereographic projection devised by Hipparchus), corrected an important blunder which Marinus had committed through neglecting to take account of the sphericity of the earth and constructing a rectangular system of degrees. Like Marinus, he counted his meridians from the Canaries (the Fortunate Islands). No maps appear to have been drawn by Ptolemy himself; those to be found in the oldest editions of his work are by Agathodæmon (a mathematician of the 5th (?) century after Christ), though accurately based, it is true, on Ptolemy's data. The oldest MS. of Ptolemy is that found in the Vatopedi monastery of Mount Athos, and published by Victor Langlois in 1867 along with careful reproductions of the maps. It dates from the 12th or 13th century. Besides the exaggeration of the Mediterranean, the greatest blunders of Ptolemy are the following:—the European continent between the Black Sea and the Baltic is too narrow; India is not represented as a peninsula; Ceylon (Taprobane) is made much too large; and the Indian Ocean is bounded by lands towards the south (Plate VII.). But in spite of all this the scientific method pursued in the representation was perfectly correct. It was not till the Renaissance that a return was made to the rational treatment of cartography inaugurated by Ptolemy; and he then became the teacher of the modern world.

3. *Map-making among the Romans.*—The Romans contributed nothing to the development of the scientific method of the Greeks, and did not apply astronomy to the purposes of cartography. They valued maps according to their practical utility as implements of political administration; and they accordingly attached most importance to the route-map, from which they could learn the roads, the stations, and the distances. If we may judge by the few examples which have been preserved, these sketches may, distortions apart, be compared with our railway maps. Cicero and Seneca mention general and topographical maps. In their time the military routes were already divided into stages, furnished with milestones, and consequently measured. During the reign of Augustus a survey of the whole Roman empire was carried out. The routes were marked on parchment rolls for the purposes of military and civil administration. A map of the world was painted in a portico at Rome; a map of Italy was to be seen in the temple of Tellus. Particularly celebrated was Agrippa's map. Pliny must plainly have been in possession of maps to keep himself right in regard to the great number of names which he records. A map of the Roman empire was drawn up under Domitian. The emperors of the 2d, 3d, and 4th centuries caused maps to be constructed and painted on the walls of public buildings in the cities of Gaul, as for example in Augustodunum (Autun); but of this class unfortunately none has been preserved. The only Roman map, indeed, of the imperial epoch which has come down to us is the *Tabula Peutingeriana*, which takes its modern name from Conrad Peutinger of Augsburg, who possessed it in the 16th century. It is now preserved in the Imperial Library of Vienna. Its origin as a map goes back at least to the 3d century of the Christian era,—to the time, that is, of Alexander Severus; but the actual copy is not older than the 13th century. It consists of twelve folio sheets of parchment, which originally formed one long strip. It has been published by Scheyb (1753) and Mannert (1834), and in excellent facsimile by Desjardins (1869, &c.). That the original of this remarkable map was of a circular shape has been satisfactorily proved, the pattern followed being that of the map of the world in the portico of the Campus Agrippæ, which for centuries retained the rank of a model. Probably, however, such an *orbis pictus* was not exactly round, but rather oval. In its construction effect was also given to the opinion current from the time of Herodotus that the extent of the inhabited world was greater from east to west than from north to south. From this it is clear that the Romans had not advanced beyond the earlier Greek conception, and were ignorant of the astronomico-mathematical method inaugurated by Hipparchus.

4. *Map-making in the Middle Ages.*—The scholastic Middle Ages confined themselves to imitation of the Roman *orbes.* Fulness of detail, moreover, was gradually lost, meagreness and crudity appearing in its place. Cartography in fact fell back to a second childhood. Fanatical exponents of the orthodox faith, like Lactantius, looked with disdain on all scientific culture. Geographical questions were of no interest to him because he regarded them as mere matters of opinion. Astronomy was a piece of fantastic folly, the knowledge of distant lands mere learned lumber. "Quæ beatitudo," he exclaims, "erit mihi proposita si sciero unde Nilus oriatur vel quicquid de cœlo physici delirant?" As this narrow conception of things became on the whole the dominant one, geography and map-making practically ceased to exist. The doctrine of the sphericity of the earth was placed under the ban of the church, and people went back to the Homeric idea of a disk surrounded by the ocean. Isidore of Seville (*ob.* 636) taught: "Orbis a rotunditate circuli dictus quia sicut rota est. Undique enim Oceanus circumfluens ejus in circulo ambit fines. Divisus est autem trifarie; e quibus una pars Asia, altera Europa, tertia Africa, quæ et Libya nuncupatur." Isidore is a master of false etymological inferences. Deriving *rotunditas* from *rota*, a wheel, he declares that consequently the earth has the appearance of a wheel. Hence the name wheel-maps has been given to all those maps of the earlier Middle Ages. The three-fold division which he gives of the world-disk kept its ground for centuries, and the figure of the earth put on the miserable guise shown in fig. 2. It was only by the Greek fathers that the doctrine of the earth's sphericity continued to be taught; and, as the knowledge of Greek rapidly died out in western Europe, the fountain was dried up from which a better science might have been derived. Many minor modifications were introduced into the map of the world, but the fundamental type remained as given in fig. 2. Jerusalem lay in the centre, Paradise in the extreme east. Clever artists gave life to the disk of the world by turreted pictures of towns—Jerusalem, Troy, Babylon, Rome, &c., and drew Adam and Eve in the midst of a Paradise which

was defended by a fence of thorns or of flames, and, being considered the highest place in the world, was always introduced at the top of the map! The positions of Jerusalem and Paradise served to fix the other points. How long this conception remained in vogue appears from

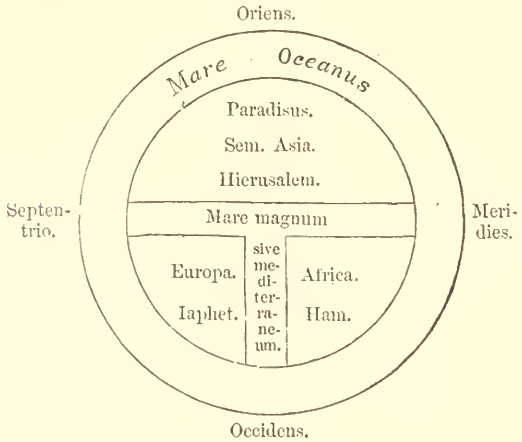

Fig. 2.

the fact that in 1422 Leonardo Dati, in a poem on the sphere (*Della Spera*), wrote, "A T within an O shows the design" (*Un T dentre a uno O mostra il disegno*), thus ⊖. In this way the whole science of cartography sank back below the level attained by the Ionian Greeks.

5. *Map-making among the Arabians.*—The first development of geographical science among the Arabs took place at Baghdad about 772 A.D., in the reign of the caliph Mansúr, and under the influence of an Indian astronomer and mathematician; and, not long after the works of Euclid, Archimedes, Aristotle, and Ptolemy were translated into Arabic, by orders of the caliph Mamún (813–833), a degree was measured in Mesopotamia in the plain of Sinjar, and a system of the world (Rasm el-ard) was constructed by his librarian Mohammed ben Musa of Khiva (Alcharesmius), in which every place was to be determined by longitude and latitude in the style of Ptolemy. But the science split up only too soon into a practical and a theoretical (astronomical) section—the one treating geography (ja'rafíyá) as the doctrine of routes and provinces, the other as the doctrine of latitudes and longitudes. Astronomy contented itself with the astronomical determination of the position of places without drawing maps or exerting any influence on their projection; travellers and topographers on the other hand did not trouble themselves about astronomy, but like Istakhri (*c.* 750) or Ibn Haukal (*c.* 750) added maps to their descriptions which were destitute of any system of degrees, and betrayed by the roughness of their outlines the clumsiness of the draughtsman. Ultimately, like Dimishkí (1327), they left mathematical geography completely out of their works, Ibn Haukal having already declared that mathematical division only brought confusion into geography. Only Edrísí's map, engraved for King Roger II. of Sicily upon a silver plate (1164), forms an exception; but, as it was not drawn according to the Ptolemaic projection, but simply indicated the seven climates, it was after all but an unsuccessful copy of Ptolemy.

6. *Nautical Maps.*—The nautical (loxodromic or compass) maps, which make their first appearance in Italy in the 13th century, indicate a gratifying improvement in cartography after a long period of stagnation. These maps were constructed with the aid of the compass, and took the name of compass-maps because they are covered with the figure of a compass from which numerous straight lines radiate out in all directions over the sheet. The fact that the magnet turns towards the north is first mentioned in 1187. Flavio Gioja of Amalfi was perhaps the first to make a mariner's compass and to teach seamen the use of that important instrument. The Italians divided the compass into eight parts (venti), assigning 45° to each—Tramontane (N.), Greco (N.E.), Levante (E.), Sirocco (S.E.), Ostro (S.), Libeccio or Garbino (S.W.), Ponente (W.), Maestro (N.W.). Every division had four quarters (quarte di vento), each of $11\frac{1}{4}$ degrees. The maps were produced as follows. The courses of individual ships were first of all inserted as straight lines, calculated according to the distances traversed, from particular ports, as Genoa or Venice, to other ports, and when a good supply of such material had been collected and a series of diagonals drawn in accordance therewith, the most important points on the coast and in the islands were fixed. The lines by which the meridians were cut at the same angle were called loxodromes; they gave a correct indication when they cut the true astronomical meridian, a false one when they cut the magnetic meridian. On the Italian charts the loxodromes were drawn as straight lines. The numerous radii of the compass shown on the maps enabled the seaman to find the direction which he had to take to reach his goal. Hence the title loxodromic maps.

Charts on which the degrees were marked became necessary only when navigation extended to the ocean; they were introduced by the Portuguese, probably at the suggestion of Prince Henry the Navigator. They are "plane charts" with lines of longitude and latitude.

The oldest loxodromic charts which have been preserved come from Pisa, Genoa, and Venice. The earliest, the so-called Pisan chart, belongs probably to the middle of the 13th century, and already comprises the whole Mediterranean. As this representation of the whole must of necessity have been preceded by surveys of the several portions, the beginning of the chart may be placed at least as far back as the first part of the 13th century. Next in point of age comes (2) the Luxoro Atlas in Genoa about the year 1300, in the possession of the Cavaliere Tomas Luxoro. Then follow (3) Petrus Vesconte, 1311, in the national archives at Florence, including the eastern Mediterranean (*Petrus Vesconte de Janua fecit ista carta ann dñi M°CCCXI°*), see fig. 3; (4) Marino Sanudo, a map of the world representing the Mediterranean and the Atlantic coasts as far as Flanders, probably drawn between 1312 and 1321—several copies in Rome (the Vatican), Venice, and Brussels; (5) an atlas of Petrus Vesconte's about 1318 (in Venice, in eight sheets; in Milan, ten sheets); (6) Perrinus Vesconte, 1327, in the Laurentian Library at Florence; (7) Joannes da Carignano, between 1306 and 1333, in the archives of Florence (*Presbiter Joannes rector sancti Marci de portu Januæ me fecit*); (8) a map of 1346 in the Castilian tongue, in the National Library at Paris; (9) the Medicean atlas of 1351 in the Laurentian Library at Florence, eight sheets, which represents also the Caspian Sea, and, remarkable enough, the whole of Africa; (10) Pizigani, 1367, in the National Library at Parma, a map of the world which extends as far as Persia, with numerous entries not only on the coasts but also in the interior; (11) an atlas of Pizigani, of date 1363, nine sheets in folio, in the Ambrosian Library in Milan, comprising the Mediterranean and the Ocean as far as Jutland (*M.CCCLXXIII a die VIII di zugno franzescho piziganij veniziano in veniexia me fecit*); (12) the famous Catalonian map of the world of 1375, in four sheets, in the National Library at Paris; (13) a map by Guill. Solerio of Majorca, 1385, in the public archives in Florence; and (14) atlas by some unknown hand, four sheets folio, in the Biblioteca Marciana at Venice.

Several of these Italian maps give indubitable evidence that as early as the 14th century the Azores and Canaries had been discovered, as well as the coast of Africa as far as beyond Cape Bojador. With the middle of the century the coast maps developed into maps of countries with trade routes, pictorial figures, and numerous inscriptions. Maps preserved from the 15th century are still more numerous:—(15) a map by the Venetian Nicolao, of date 1408, in Vienna; (16) Mecia de Villa destes, 1413, in the National Gallery at Paris; (17) a map of the world of 1417, in the National Library at Florence; (18) Francesco de Cesanis, 1421, in the Museo Correr at Venice; (19) a map of 1424 at Weimar; (20) atlases by Giacomo de Giraldi, 1426–43, in Venice and Milan; (21) Gabriel de Valsecqua, 1434, from Majorca; (22) Francesco Beccario, three maps, in the British Museum; (23) two maps by Battista Beccario in Munich (1426) and Parma (1435); (24) Andrea Bianco, 1436, an atlas of ten sheets, where for the first time the mediæval circular maps are accompanied by the Ptolemaic maps, in the Biblioteca

Marciana at Venice; also a map of 1448, drawn at London, now in the Ambrosian Library at Milan (*Andrea Bianco veneccian comito di galia me fexe a londra*, 1448); (25) an elliptical map of the world in the Pitti Palace at Florence, of Genoese origin, and of date 1447; (26) Hannibal de Madiis, 1449, in the Ambrosian Library; (27) a Catalonian map of the world, of 1450 (?), in the National Library at Florence; (28) Giovanni Leardo, two maps of the world, of date 1448 (in the museum at Vicenza) and 1452 (the property of Consul-general von Pilat at Venice); (29) Fra Mauro, a famous map of the world from 1457–59 in the Biblioteca Marciana at Venice; (30) Gratioso Benincasa of Ancona, a diligent cartographer, twenty-five very carefully executed works dating from between 1460 and 1482; most of them are in Italy, chiefly at Venice, two in Paris, one at Munich, and one without date in the British Museum; (31) Andrea Benincasa, son of the preceding, three maps of 1476 (Geneva) and 1490 (Ancona and Rome); (32) Bartolomeo Pareto, a map of the world, of 1455, at Rome; (33) Giorgio Giovanni, 1484 (Parma); (34) Count Hortomanus Fredutius of Ancona, 1497 (Wolfenbüttel).

In the beginning of the 16th century, (35) Alberto Cantino, about 1501–3, was the first in Italy to draw a map representing portions of America, *Carta da navigare per le Isole nuovamente trovate in la parte delle Indie*, in the library at Modena. (36) The Maggiolo family, famous for its cartography, flourished in Genoa between 1511 and 1648. Visconte Maggiolo, the founder of the family, is known to have produced nineteen atlases between 1511 and 1587. A map by Giacomo Maggiolo, of date 1562, is in the British Museum. (37) Battista Agnese laboured between 1527 and 1554 in Venice, and the thirteen atlases he has left behind him are pieces of fine artistic work adorned with charming miniatures. Two of these atlases, of date 1527 and 1536, are in the British Museum.

In the 15th century and the beginning of the 16th Spanish, Portuguese, Greek, and French cartographers appear as competitors with the Italian, Catalonian, and Balearic artists. We name only the most important. Juan de la Casa, a Basque, and a companion of Columbus, drew in 1500 a map of the world in which for the first time the hitherto discovered coasts and islands of

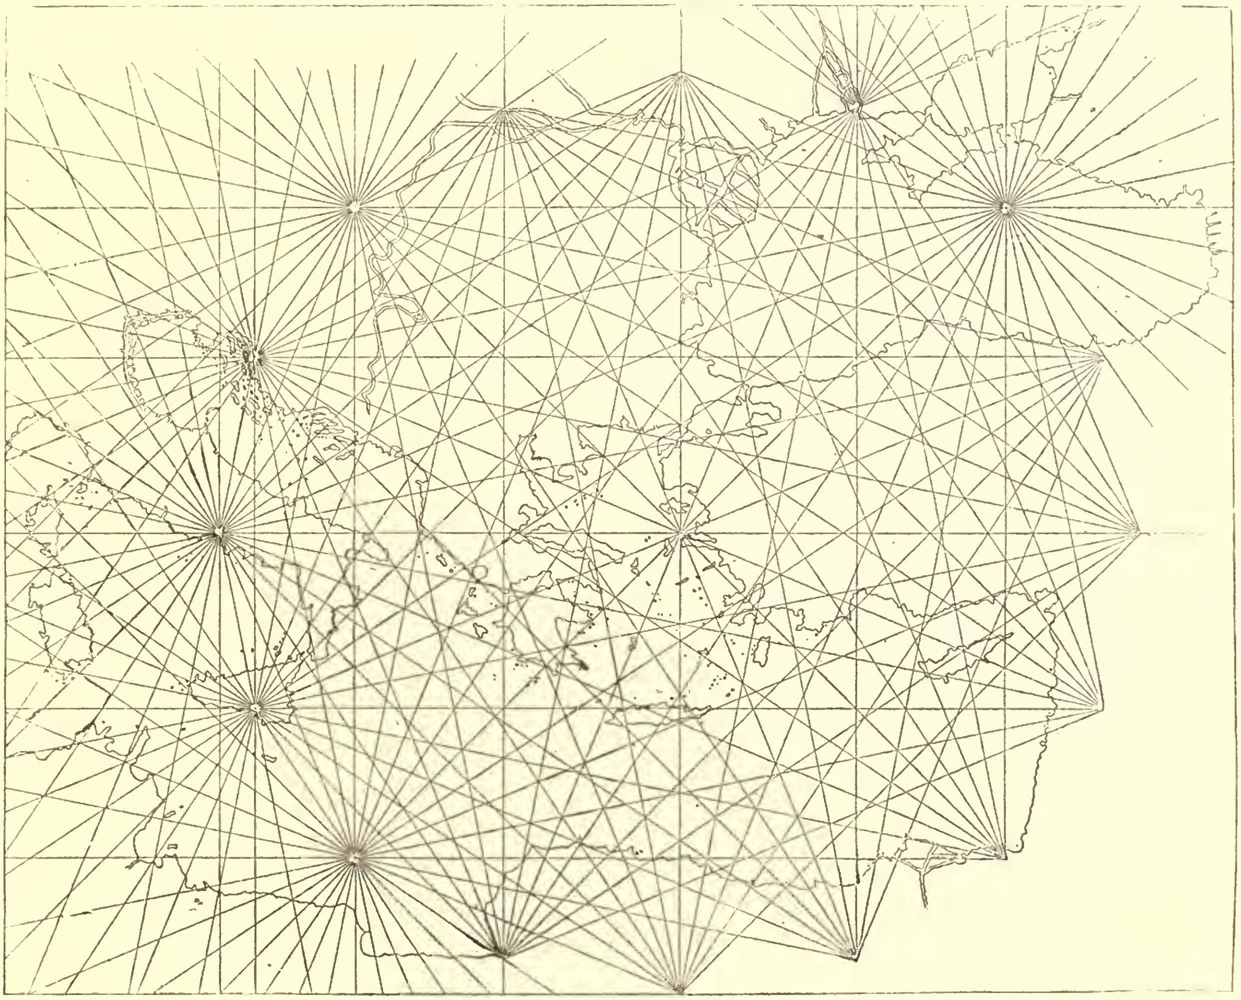

FIG. 3.—Chart of the Mediterranean (P. Vesconte, 1311).

America were introduced. A map of the world by Garcia de Torero, 1522, is preserved at Turin; and two general maps, the one dating 1527 (probably by Fernando Colon, son of Columbus) and the other 1529 (by Diego Ribero), exist at Weimar. Between 1558 and 1569 Diego Homem produced several beautiful atlases; of these four are in Italy, and one, of date 1568, at Dresden. Among the French world-maps a special place is due to that drawn up by order of King Henry II. It is published by Jomard in his *Monumens de la géographie.*

As far as Italian navigation extended, and especially within the limits of the Mediterranean, a very correct representation of the coasts and of the contours of the several countries was secured at an early date. The interior of the countries, on the other hand, remained confused and inexact. These defects were first supplied in the 15th century, when recourse was again had to the contributions of the Greeks, and especially of Ptolemy.

Before proceeding to discuss this new development, it may be as well to mention the various names by which the representations of the earth's surface have been designated. The Greeks employed the expression πίναξ (picture), the Romans in like manner said *tabula.* The word map came into use in the Middle Ages, the name *mappamundi*, *mappemonde* ("world-napkin"), proving that maps were originally painted on cloth. In English map is applied only to a land-map, the sea-map being known as a chart. The Romance languages had the expressions *disegno*, *figura*, *pintura*, *padron.* When the loxodromic maps came into existence, hand-books with sailing directions were written to accompany them, hence the titles "sailing directions," "sea-books," portulani (by which word actual maps were afterwards meant), or cartas da marear. The Latin word *charta* signifies originally a letter, a written document; and in like manner the Portuguese and Spanish form *carta.* But as early as the 14th century this expression was (as appears from the inscription quoted under No. 3 above) used to distinguish a sea-map. In the same sense Paolo Toscanelli speaks of his *carta*, which he sent to the king of Portugal. But the expression did not become general till the 16th century; in 1513 we find it in Germany in a Strasburg edition of Ptolemy (Carta Marina Portugalensium), in 1524 in Spain (in the Junta of Badajoz), in 1582 in England (Michael Lock).

7. *The Revival of Ptolemy.*—This produced in the 15th century a revolution in the construction of maps, and laid the foundations of modern cartography. Ptolemy's great work again became generally well known in western Europe only after it was translated into Latin by Jacobus Angelus de Scarparia in 1409; and this version was first printed in 1475 at Vicenza without maps. The first edition with maps (to wit, a map of the world, ten maps of Europe, four of Africa, and twelve of Asia) appeared at Rome in 1478. Afterwards there were editions at Bologna (1482), Ulm (1482, by Nicolaus Donis with five modern maps), Ulm (1486), Rome (1490, 1507, and 1508, the last with seven modern maps, among which the famous map of the world by Joh. Ruysch), Strasburg (1513, with forty-seven maps); and in the course of the same century twenty-five other editions might be mentioned at Strasburg, Basel, Lyons, Cologne, Venice, and Paris. From this long series, which if prolonged to the beginning of the Thirty Years' War would be further increased by five, it is evident that Ptolemy was the great master of the modern time. At first maps were drawn according to Ptolemy's determinations of geographical position; but, in proportion as the study of mathematics, astronomy, and cosmography excited the interest of men of culture, opportunities were afforded of correcting Ptolemy's astronomical positions, especially in the case of central and northern Europe, where the range of the great cosmographer's knowledge had hardly enabled him to collect original material. The new arts of wood and copper engraving supplied the means for a rapid diffusion of *printed* maps. The oldest map printed from a wooden block (in the National Library at Paris), dating from 1460, and thus belonging to the earliest period of wood engraving, was produced in Germany, and represents Germany and western Europe. It is considered to be a copy from an old Roman map.

After the foundations of trigonometry had been laid by Purbach, Regiomontanus, and others, attempts of a rather rude kind were made in the beginning of the 16th century to execute geographical triangulations and delineations. The towns formed the central points of the system, their direction and position from the post of observation being fixed as precisely as possible, and their distance estimated in miles according to the best available data without being accurately measured. It was considered sufficient to assign in this way the relative positions of inhabited places, and the representation of the physical relations was very superficial; the course of rivers, for instance, was not measured, but carried past the towns on their banks in conventional lines.

In the Ptolemy of 1513 we already find three topographical maps, viz., one of Switzerland, one of the district of the upper Rhine from Basel to Mainz and Lorraine, and a large one of Crete, which it has been conjectured was taken from a Venetian original. The number of maps of smaller districts rapidly increased. In 1528 Aventinus drew the duchy of Bavaria, in 1533 Sebastian of Rotenhamm produced a map of East Franconia. Map drawing became a favourite occupation with the Germans. The best geographical survey of this period was the *Chorographia Bavariæ*, by the famous Philip Apianus (twenty-four sheets, at Ingolstadt, 1568). The number of cartographers increased so rapidly that Abraham Ortelius, in the first edition of his collection of maps (*Theatrum Mundi*, 1570), was able to give the names of ninety-three. The first attempts to improve and to increase the methods of projection known to the Greeks were made by Germans,—namely, Johann Stöffler (1452–1536), Johann Werner of Nuremberg (1468–1528), Peter Apianus (1495–1552). The last-mentioned introduced the favourite method of representing both hemispheres together in an elliptical form with lines of latitude. Maps of the world were compiled by Peter Apianus, Oronce Finé (1494–1555), Sebastian Cabot (1544), Giacomo Gastaldo (1546–48), Giov. Batt. Guicciardini (1549), Giov. Domin. Methoni at Venice, Heinrich Pontanus of Arnhem (1556, a map of the world in the shape of an imperial eagle), Guill. Postel at Paris (1581), &c.

8. *Mercator and his Successors.*—Gerhard Kramer, usually called Mercator (born of German parents at Rupelmonde in Flanders in 1512), has the honourable place of a reformer of cartography. We possess his map of Palestine (1537), a map of Flanders (Louvain, 1540) in nine sheets, phototyped in 1882, a globe (1541), and the first critical map of Europe (1554), by which he laid the foundation of his fame as the first cartographer of his age. The exclusive use of Latin letters for maps in Germany was due to his example. Especially famous is his map of the world (fig. 4) dating from 1569: "Nova et aucta orbis terræ descriptio ad usum navigantium emendate accommodata" (one copy in the National Library at Paris). This map is drawn in the projection of increasing latitudes with lines of latitude and parallel meridians, the basis of which was furnished by Edward Wright in 1599 in *Certain Errors in Navigation.* It is the first chart on which true rhumb lines could be drawn as straight lines. By 1601 Mercator's projection was in use for all sea charts. In 1578 Mercator drew up maps for Ptolemy exactly in accordance with his determinations; and these were followed by maps of Germany, the Low Countries, and France (1585), and of Italy (1590). It was his purpose to produce a complete collection of new maps, to which he gave the name *Atlas*; but he died in 1594, and the publication of this first atlas (1595) was left to his son. The title took the place of the designations previously in fashion—*Theatrum Orbis*, *Speculum Mundi*, &c. The second edition of the *Atlas* appeared in 1602. The later editions were issued by Jodocus Hondius in Amsterdam.

Before Mercator collections of maps, including various countries, and independent of Ptolemy, had begun to be published. Thus Christoffel Froschover in Zurich issued various "Landtaflen" in 1562—a map of the world (Universalis Cosmographia, in the shape of a heart, dated MD.XL.VI.), Europe, Germania, Gallia, "die gantze Eydgnoschafft," and eight topographical maps of Swiss districts. Of much greater importance and influence was the collection published by Abraham Ortelius of Antwerp (1527–98), *Theatrum Orbis Terrarum* (1570), in which the best maps from all countries were re-engraved. The first edition with a Latin text contained fifty-three sheets; the seventh (1573) had sixty-nine maps, the twelfth (1579) ninety-two. Editions appeared with the text in German, French, Dutch, and after 1600 in English and Italian, and obtained the widest diffusion. Through this work the centre of cartographic activity was transferred to Holland. There too laboured the successors of Mercator, Jodocus Hondius (1563–1611) and his son Henricus Hondius (1580–1644). Their maps, in several folio volumes, were numbered by hundreds. To the school of Mercator belonged also Petrus Plancius and Lucas Janszoon Waghenaer of Enkhuyzen (Aurigarius), who by his *Spieghel der Zeevaerdt* (Leyden, 1583) became the founder of nautical map-collections. In 1588 a reproduction of this atlas appeared in London as the first "Waggoner." In the beginning of the 17th century the town of Dieppe also produced excellent charts,—Guill. Levasseur (1601), Jean Dupont (1625), and Jean Guerard (1631) being at work there. About the same time another famous cartographic family arose in Holland. William Jansz. Blaeu (1571–1638) and his sons Jan and Cornelis turned out about four hundred maps previous to 1655. William Blaeu was in 1633 appointed by public decree cartographer to the States-General; and it was his duty to examine the ships' logs and so amend the maps. He had a rival in the person of Jan Janszoon (Jansonius), who, working with the material inherited by him from his father-in-law Jodocus Hondius, produced a Dutch atlas in six volumes, a French in six folios, a German in nine folios, and a Latin in two. Cartography became a lucrative business, but the scientific value of the work grew less and less in the hands of Nicolaus Visscher (Piscator) from 1621 to 1670 and his son of the same name (*ob.* 1709), of Friedrich de Witt and his sons, and of Peter Schenck. The influence of the Dutch school, which had previously been so great, disappeared with the close of the 17th century.

In the 16th century the Italians were still active competitors with the Germans and Dutch. In engraved maps Venice held a specially high rank up to 1570, the Piedmontese Giacomo Gastaldo and Paolo Forlani of Verona being settled there. Their publications comprised well-nigh all parts of the earth. The progress of discovery can be followed on their general (*universale*) and topographical maps. Gastaldo's period of activity lay between 1546 and 1569, Forlani's between 1560 and 1570. They had a successor in Antonio

Magini (1555-1617) of Padua, who in his *Novæ geogr. tabulæ*, published in 1596, gave greater precision to the determinations of position. Giovanni Battista Nicolosi (1610-70) of Sicily issued at Rome a series of huge maps of the hemispheres and continents. Among the French map-makers of this period must be mentioned Oronce Finé (Finæus) from Dauphiné (1494-1555), who published in 1531 his *Planisphærium geographicum* in the shape of a heart according to the projection of Apianus; Jolivet (about 1560); Guillaume Postel (1505-81), who in 1570 drew a new map of France; the Franciscan André Thevet (1502-90), who in 1575 edited a *Cosmographie universelle* (2 vols. in folio), and finally Melchior Tavernier, a pupil of Ortelius (*ob.* 1641), who published many maps of European countries. In England there appeared in 1544 the great map of the world by Sebastian Cabot. The first modern map of England was produced by Humphrey Lhuyd in 1569 (*Angliæ regni tabula* and *Corographia Cambriæ*). He was succeeded by Christopher Saxton, who travelled through different parts of the country with several engineers, and in 1575 gave to the world his British atlas of thirty-six sheets, which Philip Lea afterwards reduced to twelve sheets. John Speed's atlas (*Theatrum*) of Great Britain was published at Amsterdam in 1610 by Jodocus Hondius. The first map of Scandinavia (*Regnorum Aquiloniorum Descriptio*) was produced in 1539 by Olaus Magnus, archbishop of Upsala. Much more accurate was the map drawn by Adrian Veno in 1613, and engraved by Jodocus Hondius, but the real reformer of northern cartography was Anders Buré (Buræus, 1571-1646), who surveyed the several parts of the country. His maps were afterwards published in the atlas of the brothers Blaeu between 1650 and 1660.

The first new map of Spain and the first of Portugal both appeared in the same year, 1560, the former being due to Pedro de Medina, the latter to Fernando Alvarez Secco.

During all this period there prevailed a remarkable variety in the determination of the first meridian. Whilst the Spaniards and Portuguese reckoned from the line of demarcation (370 leagues west of the Cape Verds) sanctioned by the pope, the Protestant Dutch, Germans, and English at first went back to Ptolemy, who began at the Canaries. Mercator, on his globe of the year 1541, chose the island Forteventura in the Canaries as his starting-point, but he afterwards adopted Corvo in the Azores, because he there approached the true indication of the magnetic needle. For the same reason Ortelius, the younger Mercator, Jansonius, and at first also William Blaeu fixed on the Isla del Fuego in the Cape Verd group. Blaeu afterwards proposed the Peak of Teneriffe, and in this he was followed by all Dutchmen. In the year 1634 Richelieu consulted the astronomers Gassendi (1592-1655) and Morin (1583-1656), and in accordance with their decision Louis XIII. commanded, under penalty, that all French ships should calculate their longitudes from the meridian of Ferro, though it was not till the close of the 17th century that a French expedition determined with accuracy the relation of the position of Ferro to that of the observatory of Paris. It was in this way that the Ferro meridian obtained almost universal currency down to the 19th century. As in this period it was still practically impossible to secure precise determinations of longitude, all cartographic representations were naturally subject to considerable distortions, especially in countries outside of Europe.

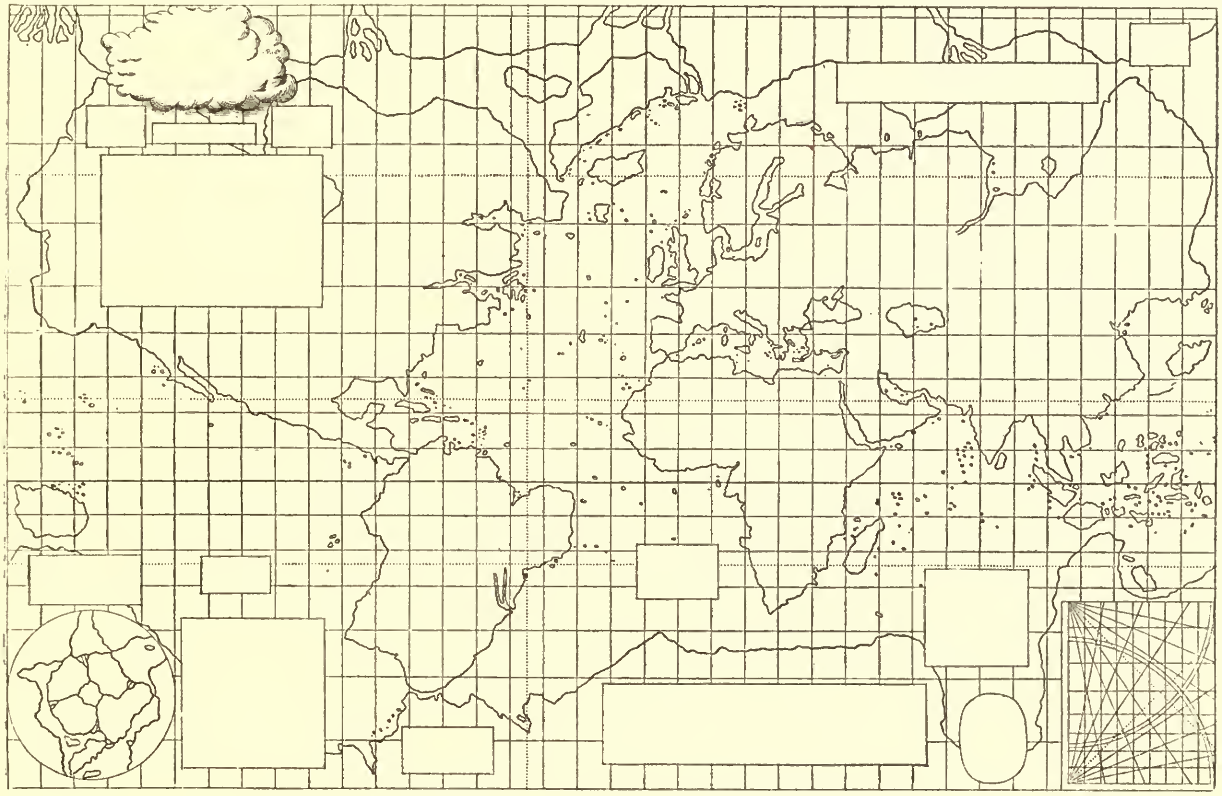

FIG. 4.—Outline of Mercator's *Nova et Aucta Orbis Descriptio*, 1569.

9. *Period of Transition.*—A series of important discoveries and inventions in mathematics, physics, and astronomy having provided the means of making much more accurate observations and calculations, there followed as a matter of course a substantial improvement in cartography. Of chief moment were the invention of the telescope (1606), Galileo's discovery of Jupiter's moons (1610) and Cassini's calculation of their periods of rotation, so important for determinations of longitude (1666), the first application of trigonometry to geodesy by Snellius (1615), Picard's measurement of a degree between Paris and Amiens (1669 and 1670), the French measurement of a degree between Dunkirk and Perpignan by Cassini and Lahire (1683-1718), Hadley's mirror-sextant (1731; according to Newton's idea, 1699), the improvements made on the lunar tables by Tobias Mayer (1753), and John Harrison's chronometer (1761). In this way there set in a period of transition in cartography which lasted till somewhere about 1750; the results of new investigations and measurements were gradually turned to account, but, while here and there traditional blunders were corrected and expunged, nothing essentially new was as yet created.

To this epoch in Germany belong Johann Baptist Homann, (1664-1724), whose elegantly engraved maps, published in Nuremberg, continued to have a wide sale after his death, Johann Matthias Hase in Nuremberg (*ob.* 1743), and the famous Tobias Mayer (1723-86), who published in Nuremberg a critical map of Germany. In France eminence was obtained by Nicolas Sanson (1600-67) of Abbeville, who from 1627 worked at Paris as royal geographer, and issued more than three hundred maps; and the reputation of the house was maintained by his sons Nicolas, Adrien, and

Guill. Sanson, who worked along with Hubert Jaillot (1681–1717), Pierre du Val (1619–83), and Jean Baptiste Nolin (1692) at the French book of charts, *Neptune françois*, 1693, in which for the first time the new astronomical determinations were turned to account. Greater critical acumen was shown by the royal geographer Guill. de l'Isle (1675–1726), and especially by the talented Jean Baptiste Bourgignon d'Anville (1697–1782) and his younger contemporary Philippe Buache (1700–1773). In this period France was *facile princeps* in cartographic achievements, and led the way to the next and latest epoch. In England Dowet's *Atlas* was published at the cost of the duke of Argyll, and in the same year Aaron Arrowsmith was born (*ob.* 1828). A beginning of geodetic labour was at this time made in Sweden under Charles XI.,—the proceedings being carried on first under the Baron Karl Griepenhielm (*ob.* 1684) and afterwards under Count Dahlberg. For political reasons, however, the king did not allow the publication of the map of Sweden; but, the French ambassador D'Avaux having in 1704 got possession of copies, it was engraved at Paris by De l'Isle. In Italy P. Vincent Coronelli (*ob.* 1718) deserves to be mentioned.

10. *The Period of Triangulations and Geodetic Surveys.*—Up to this point the whole art of map-making had been treated as a matter of private speculation. It was France that gave the first example of carrying out the cartographic survey of the country at the cost of the state. Such surveys had a double object, one military, to provide the army with satisfactory maps, and the other administrative, to furnish a cadastre for the land tax. The military interest predominated; consequently the surveys have in almost all countries been carried out by officers of the general staff, and the maps are briefly designated as general staff or ordnance maps. For such a survey the whole country is covered with a network of triangles, and, in order to secure the most trustworthy basis for the representation, numerous points are astronomically fixed. In comparison with those of earlier date the maps thus produced are distinguished by correctness of detail. In the century between 1750 and 1850 attention was mainly directed to the accurate rendering of the horizontal development of the face of the country; but during the last thirty years the vertical configuration has also been faithfully represented on topographical maps of large scale by the introduction of contour lines. The first example of this also was given by France, when at Laplace's suggestion (1816) it was determined to publish a new map of France with curves of altitude. But owing to the great extent of the country, and the consequent difficulty and slowness of the undertaking, only four sheets of this kind were published by 1833. Hanover, however, followed suit in 1829, Baden in 1833, Hesse in 1840, and so on. Since the middle of last century nearly all the states of Europe have been active in map-making; and prolonged effort has produced rich results. Surveying and mapping have been followed by the publication of topographic maps. The states of the Balkan peninsula alone lag behind; there no comprehensive survey has been undertaken at public expense. As a summary of these great achievements in the larger part of Europe, we append a chronological[1] table of the most important surveys, with the date of the publication of the first sheet, the name of the country, the title of the map, the scale, and the number of sheets. Outside of Europe there are but few countries in which a survey based on exact triangulation has been carried out. The largest areas thus measured are the United States of North America and British India, where great activity has been shown; and to these may be added Asiatic Russia, portions of Australia, portions of the Dutch possessions in the East Indies, and Algeria. In the whole of South America there is only one country, Chili, of which we possess a map based upon a careful survey. In the second portion of the table consequently some maps are included which are merely the work of private cartographers, and the list must be regarded as tentative.

List of Topographic Maps.

Year.	Country.	Title of Map.	Scale.	No. of Sheets.
1750	France.	Carte géometrique de la France.	1:86,400	134

(S. R.)

MAP, MAPES, or MAPUS, WALTER, an ecclesiastical statesman and renowned wit of the 12th century, must be ranked among the greatest of English writers, though French was the language that he used, and his personal fame has long been lost in the splendour of his creations. He was the cosmogonist and one of the principal creators of the Round Table legends, which supplied the ideal of chivalrous life to so many succeeding centuries. Most of the facts that are known about his position in the world have been gathered from a gossipy anecdotical work of his in Latin, *De Nugis Curialium.* He was probably a native of Herefordshire or Gloucestershire. He tells us that his parents rendered services to Henry II. both before and after his accession. He was acquainted with the household of Thomas Becket before this famous ecclesiastic became archbishop of Canterbury, which was in 1162. He studied in the university of Paris, attending the lectures of Girard la Pucelle, who began lecturing in 1160. Map seems to have risen rapidly in favour at the court of Henry II., combining ecclesiastical with civil and political functions. In 1173 he was an itinerant justice at the assize of Gloucester, and in the same year was with the court at Limoges, where the duty fell to him of entertaining the archbishop of Tarentaise, about whom he tells some marvellous stories. He was sent on a diplomatic mission to Louis le Jeune, king of France, and sat as a delegate in a council called by Pope Alexander III. (probably 1179), enjoying such repute that he was deputed to argue with the Waldenses. He accompanied Henry II. on all his progresses, and in return for his services received several ecclesiastical preferments. Apparently he maintained his position at court under Richard and John. In 1196 he was appointed archdeacon of Oxford, and in 1207–8 the custodes of the abbey of Eynsham were ordered to pay him his accustomed rent of five marks per annum. In the 12th century the abuses of the church were assailed with great freedom and abundance of humorous wit in rhymed Latin verse, and a century or two later rubrics appear in the MSS. of these satirical poems ascribing them to Walter Map. "Golias Episcopus" is the nominal author and hero of a great many of these effusions; that is to say, they represent the sayings and doings of Golias, the revelation made to him, the confession made by him, his creed, his reasons for not marrying, and so forth. The fact that Map's friend Giraldus Cambrensis denounces Golias as a foul-mouthed scoffer is rather against Map's alleged authorship, and they have probably been attributed to him in consequence of his great reputation as a wit, and a tradition that he had such a hatred of the White Monks that he exempted them from his oath as king's deputy to render even justice to all men. If these coarse and witty poems were really Map's, they are a proof of astonishing versatility, for they offer as great a contrast as possible to the high imaginative qualities, gracious tenderness, pure and lofty idealism, of his contributions to the Round Table legends. This is not the place for an exposition of the origin of these legends, but the *Quest du Saint Graal* was undoubtedly written by Map, being assigned to him in the earliest MSS. M. Paulin Paris ascribes to him also, upon grounds which commend themselves as being at least highly probable, the *Saint Graal*, and the noble prologue and the concluding parts of *Lancelot du Lac.* The effect of these contributions to the cycle was to completely transform its character, making out of it a lofty spiritual allegory, and forcing the paganism of the earlier legends into the service of the morality of the church. With such consummate skill did Map insinuate his story of the Graal into the cycle that the separate legends of Lancelot, Gawain, Percival, and Tristan seem to grow out of it; the whole luxuriant and irregular growth acquires a unity from its connexion with this root and stem. This reorganizing achievement alone, apart from the high romantic value of Map's independent additions, entitles him to a high place in literature.

The *De Nugis Curialium* and the Latin poems commonly attributed to Walter Mapes were edited by Mr Thomas Wright for the Camden Society; and the *Quest du Saint Graal*, by Mr Furnivall, for the Roxburghe Club.

MAPLE. Maples and the sycamore are species of *Acer*, suborder *Acerineæ*, order *Sapindaceæ*. The genus includes about fifty species, natives of Europe, North America, North Asia, especially the Himalayas and Japan (Benth. and Hook., *Gen. Pl.*, i. 409). Maples are for the most part trees with palmately-lobed leaves. The flowers are in corymbs or racemes,—the lowermost mostly male, the terminal bisexual. The fruit is a two-winged "samara."

The earliest known maples occur in the Miocene strata of Oeningen, where nineteen species have been discovered, —a greater number than occurs in any one district at the present day (Lyell's *El. of Geol.*, 6th ed. p. 250). A typical species appears to have been *Acer trilobatum*, Heer (*Flora Tert. Helv.*, pl. 114). This had many marked varieties, of which leaves, flowers, and fruit have all been discovered. The foliage was even attacked by a fungus, *Rhytisma induratum*, Heer, just as the sycamore is now by *R. acerinum*, which forms black spots on the leaves.

The common maple, *A. campestre*, L., is the only species indigenous to Great Britain. This and the sycamore were described by Gerard in 1597 (*Herball*, p. 1299), the latter being "a stranger to England." Many species have been introduced, especially from Japan, for ornamental purposes. The following are more especially worthy of notice.

European Species.—*Acer campestre*, L., the common maple, is common in hedgerows, but not often seen as a tree (see, however, Loudon, *Arboretum*, vol. i. p. 430). Loudon gives four varieties,—the downy-fruited, the variegated, the hill-inhabiting, and the

Austrian. It occurs in northern Europe, the Caucasus, and northern Asia. The wood is excellent fuel, and makes the best charcoal. It is compact, of a fine grain, sometimes beautifully veined, and takes a high polish. Hence it has been celebrated from antiquity for tables, &c. The wood of the roots is frequently knotted, and valuable for small objects of cabinet work. The young shoots, being flexible and tough, are employed in France as whips. *A. pseudo-Platanus*, L., the sycamore, or great maple, is a handsome tree of quick growth, with a smooth bark. The leaves are large, with finely acute and serrated lobes, affording abundant shade. Its longevity is from one hundred and forty to two hundred years. It is found in various parts of Europe in wooded mountainous situations. The wood when young is white, but old heart-wood is yellow or brownish. Like the common maple it is hard and takes a high polish. It is much prized by wheelwrights, cabinetmakers, sculptors, &c., on the Continent, while knotted roots are used for inlaying. Sugar has been obtained from the sap of this as from other species, the most being one ounce from a quart of sap. The latter has also been made into wine in the Highlands of Scotland. There are many varieties, the variegated and cut-leaved being the most noticeable (see *Gard. Chron.*, 1881, p. 229). For remarkable variations in the number of cotyledons arising from fusion, see a paper by the late Prof. J. S. Henslow in *Mag. Nat. Hist.*, vol. v. p. 346. *A. Platanoides*, L., the Norway maple (Loudon, *l.c.*, p. 408; *Gard. Chron.*, 1881, p. 564), is met with from Norway to Italy, Greece, central and south Russia. It was introduced into Britain in 1683. It is a lofty tree (from 40 to 70 feet), resembling the sycamore, but with yellow flowers, and more spreading wings to the fruit. There are several varieties. The wood is used for the same purposes as that of the sycamore. Sugar has been made from the sap in Norway and Sweden. The leaves of this species, in common with those of the sycamore especially, and perhaps all others, are liable to produce honeydew, which appears to be extravasated cell-sap. The present writer suggests that the starch formed in the leaves may be rapidly converted into sugar, which is then condensed on the surface of the leaf under excessive transpiration.

Asiatic Species.—Thirteen species are described by Hiern, chiefly in the temperate Himalayas (*Flor. of Brit. India*, p. 692; see also Brandis, *For. Fl.*, 110). The wood of some species is used, as that of *A. lævigatum*, Wall., for building; that of *A. cæsium*, Wall., being soft, inferior drinking cups are made of it; while that of *A. pictum*, Thunb., is white, light, and fine-grained.

Japanese Species.—Species, and many varieties, especially of *A. palmatum*, Thunb., generally known as *polymorphum*, with variously laciniated and more or less coloured foliage, have lately been introduced as ornamental shrubs. The original species was introduced in 1832. The branches and corolla are purple, the fruit woolly. The foliage of the typical form is bright green with very pointed lobes. It occurs in the central mountains of Nippon and near Nagasaki. Beautiful varieties have been introduced under the names *A. P. ampelopsifolium*, *atropurpureum*, *dissectum*, &c. They are remarkable for the coppery purple tint that pervades the leaves and young growths of some of the varieties (for figs., see *Catalogue of Hardy Trees*, &c., by Messrs Veitch). Of other Japanese species, *A. rufinerve*, Sieb. and Zucc., with the habit of the sycamore, from Nippon; *A. distylum*, Sieb. and Zucc., bearing leaves without lobes; *A. diabolicum*, Bl., with large plane-like leaves, from Nippon; and *A. carpinifolium*, Sieb. and Zucc., with foliage resembling that of the hornbeams, are especially worthy of note.

North American Species.—*A. saccharinum*, L., the sugar, rock, or bird's-eye maple, was introduced in 1735. It sometimes attains to 70 or even over 100 feet, more commonly 50 to 60 feet. It is remarkable for the whiteness of the bark. The wood is white, but acquires a rosy tinge after exposure to light. The grain is fine and close, and when polished has a silky lustre. The timber is used instead of oak where the latter is scarce, and is employed for axle-trees and spokes, as well as for Windsor chairs, &c. It exhibits two accidental forms in the arrangement of the fibres, an undulated one like those of the curled maple (*A. rubrum*), and one of spots which gives the name bird's-eye to the wood of this species. Like the curled maple, it is used for inlaying mahogany. It is much prized for bedsteads, writing desks, shoe lasts, &c. The wood forms excellent fuel and charcoal, while the ashes are rich in alkaline principles, furnishing a large proportion of the potash exported from Boston and New York. Sugar is principally extracted from this species, the sap being boiled and the syrup when reduced to a proper consistence run into moulds to form cakes. Trees growing in low and moist situations afford the most sap but least sugar. A cold north-west wind, with frosty nights and sunny days in alternation, tends to incite the flow, which is more abundant during the day than the night. A thawing night is said to promote the flow, and it ceases during a south-west wind and at the approach of a storm; and so sensitive are the trees to aspect and climatic variations that the flow of sap on the south and east side has been noticed to be earlier than on the north and west side of the same tree. The average quantity of sap per tree is from 12 to 24 gallons in a season. For full details of the preparation, &c., see Loudon, *l.c.*, p. 413; and *Gard. Chron.* 1878, p. 137.

A. rubrum, L., the red-flowering or scarlet maple, is a middle-sized tree, and was introduced in 1656. It is the first tree to blossom in spring in North America. The wood, like that of other species, is applicable to many purposes, as for the seats of Windsor chairs, turnery, &c. The grain in very old trees is sometimes undulated, which suggested the name of curled maple, and gives beautiful effects of light and shade on polished surfaces. The most constant use of curled maple is for the stocks of fowling pieces and rifles, as it affords toughness and strength combined with lightness and elegance. The inner bark is dusky red. On boiling, it yields a purple colour which with sulphate of iron affords a black dye. The wood is inferior to that of the preceding species in strength and as fuel. Sugar was made from the sap by the French Canadians, but the production is only half as great as that from the sugar maple (Michaux). In Britain it is cultivated as an ornamental tree, as being conspicuous for its flowers in spring, and for its red fruit and foliage in autumn. *A. macrophyllum*, Pursch., furnishes material for hats, baskets, mats, &c., from its inner bark, and the sap gives sugar. *A. circinatum*, Pursch., of California, has a fine, white, tough wood, which takes a good polish.

For description of other species of North America, see *Gard. Chron.*, 1881, index. *s.v.* "Acer"; Sargent's *Cat. of For. Trees of N. Amer.*; Loudon, *l.c.*, p. 405 *sq.*; Gray's *Manual of Bot.*, p. 84. (G. H.)

MAR, Earldom of. Mar, one of the ancient divisions or provinces of Scotland, comprised the larger portion of Aberdeenshire, extending from north of the Don southwards to the Mounth. It is remarkable for its association with the oldest historical dignity of Scotland, or perhaps of any country, which has been perpetuated to our own time. Donald MacEnun MacCainech, mormaer (hereditary ruler or steward) of Mar, fought, according to nearly contemporary testimony, at the battle of Clontarf in Ireland in 1014. Under Anglo-Saxon influences mormaers or great stewards became earls; and Ruadri, mormaer of Mar, whose name appears in the Book of Deer, is designed "Rothri comes" in a charter of Alexander I. of 1114 or 1115. His representative in the latter part of the 12th century was Gratney, earl of Mar, who married Christian Bruce, sister of King Robert, a lady famed for her defence of the chief stronghold of the earldom, Kildrummy Castle, against David of Strathbogie, earl of Athole, then (1335) in alliance with the English. Their son, Earl Donald, in his youth a captive in England, was restored to his country after Bannockburn. On the landing of Edward Balliol in 1332, and death of Thomas Randolph, earl of Moray, he was invested with the regency, and the troops hastily assembled by him to meet the invader suffered a disastrous defeat at Dupplin, the earl of Mar being himself among the slain. Earl Thomas, the regent's son, dying without issue in 1377, his successor was his sister Margaret, countess of Douglas by marriage. From her the earldom of Mar passed to her daughter, Isabel Douglas, countess of Mar, whose second marriage forms a notable episode in Scottish history. Alexander Stewart, natural son of Alexander, earl of Buchan, and, according to common belief, the instigator of a murderous attack on that lady's first husband, stormed the widowed countess of Mar in Kildrummy Castle in 1404, compelled her to marry him, and extorted from her a charter which, had the king been prevailed on to confirm it, would have made over the earldom to him and his heirs, in exclusion of the heirs of his wife. But, weak as was the law north of the Mounth in the reign of Robert III., this outrage was too flagrant to be condoned. The indispensable confirmation was refused by the king; but a compromise was effected, by which Isabel voluntarily accepted Stewart as her husband, and, by a charter which Robert duly confirmed, gave him a right to the earldom for life, with remainder, however, to her own heirs. *Qua* earl of Mar, the quondam leader of freebooters became a supporter of law and order; and in 1411, when Donald, lord of the Isles, was leading his marauding host southwards, it was under Alexander, earl of Mar, that the lowland gentry and the burghers of Aberdeen mustered to oppose his advances. The sanguinary battle of Harlaw arrested the progress of the highlanders, and left Mar master of the field.

Earl Alexander died in 1435, when the right to the earldom passed to Isabel's nearest heir, Robert Lord Erskine (descended from a daughter of Earl Gratney), who established his right by retour in 1438, and became earl of Mar. The crown, however, had seized on the valuable territories of the earldom, of which he could only obtain partial possession; and James II. and his advisers, after temporizing for a length of time, in 1457 reduced Earl Robert's retour by a collusive "service negative," based on the plea that, either by the bastardy of Alexander or in virtue of a resignation by him to James I., the earldom had lapsed to the crown, two *ex facie* worthless pretexts, inasmuch as Alexander had only been a liferenter. The wrongful possession of the crown lasted more than a century, in the course of which time the earldom was twice temporarily in possession of younger members of the royal house, and portions of it were given away to favourites; while its lawful owners, the Erskines, continued loyally to serve the sovereigns who had usurped their inheritance.

At length, on 23d May 1565, Queen Mary, made aware of the wrongs inflicted by her predecessors, and "moved by conscience" to make the fullest reparation, granted to John Lord Erskine a charter restoring the earldom of which he and his ancestors had been unjustly deprived. The earl of Mar, thus replaced in his rights, was regent of Scotland during the last two years of his life; and his son, who succeeded him in 1572, and was treasurer to James VI., recovered by process of law those portions of his inheritance which had been alienated by the crown during the period of illegal possession. In the next two generations the attachment of the family to the Stewarts brought with it fines and impaired fortunes. John, earl of Mar, fourth in descent from the treasurer, headed the rebellion of 1715, and suffered attainder, but escaped abroad and survived till 1732. His daughter Lady Frances (who married an Erskine, the younger son of her uncle, Lord Grange) would, but for the attainder, have inherited his title; and what remained of the lands was preserved to her by arrangement with the commissioners of forfeited estates. In 1824 her son, John Francis Erskine of Mar, was, as "grandson and lineal heir" of the attainted earl, restored by Act of Parliament from the effects of the forfeiture.

At the death in 1866 of John Francis Miller Erskine, earl of Mar, grandson of the restored earl, there seemed no room for doubt that the earldom devolved, in accordance with the rule of succession which it had always followed, on his sister's son John Francis Erskine Goodeve, in preference to his cousin and heir male, the earl of Kellie. The latter, however, claimed, not indeed the ancient dignity, but a separate titular earldom, supposed to have been bestowed by Queen Mary, not by her charter above alluded to, but by a lost and till then unheard-of patent a few weeks later in date, and with a different remainder, namely, to heirs male of the body. The resolution of the committee of privileges of the House of Lords in 1875, finding Lord Kellie entitled to the earldom thus claimed by him, has caused great surprise; and Scotch lawyers generally, while disbelieving as a question of fact in this creation of 1565, seem also to hold in point of law that the resolution alluded to leaves untouched the right of the heir general to the ancient historical honour. The same view has been expressed by way of protest by a large number of the Scottish peers, and enforced by the late earl of Crawford in his ably written posthumous work *The Earldom of Mar in Sunshine and Shade.*

MARABOUT is a corruption of the Arabic *Morábit*, a Moslem name for a hermit or a devotee. Primarily the word is derived from *ribát*, a fortified frontier station. To such stations pious men betook them to win religious merit in war against the infidel; their leisure was spent in devotion, and the habits of the convent superseded those of the camp (see De Slane in *Jour. As.*, 1842, i. 168; Dozy, *Suppl.*, i. 502). Thus *ribát* came to mean a religious house or hospice (*záwiya*). The great sphere of the marabouts is North Africa. There it was that the community formed by King Yaḥya and the doctor Abdalla developed into the conquering empire of the Morábiṭs, or, as Christian writers call them, the ALMORAVIDES (*q.v.*), and there still, among the Berbers, the marabouts enjoy extraordinary influence, being esteemed as living saints and mediators. They are liberally supported by alms, direct all popular assemblies, and have a decisive voice in intertribal quarrels and all matters of consequence. On their death their sanctity is transferred to their tombs, where chapels are erected and gifts and prayers offered. The prominent part which the marabouts took in the resistance offered to the French by the Algerian Moslems is well known; and they have been similarly active in recent politico-religious movements in Tunis and Tripoli.

MARACAIBO, a city and seaport of Venezuela, the capital of the state of Zulia (formerly Maracaibo), lies about 25 miles from the sea on the west bank of Lake Maracaibo, the suburbs presenting, with their cocoa-nut groves, a fine contrast to the background of barren-looking hills sloping up from the shore to a height of about 200 feet. The streets are laid out at right angles; the houses are poor structures of a crude concrete or rubble, strengthened by wooden beams; and even the public buildings—such as the churches, the government house, the court-house, and the theatre—owe their pretentious appearance to plaster and paint. The water of the lake being brackish, and the sinking of Artesian wells as yet in the experimental stage, Maracaibo is dependent on the rains for its drinking water. The markets are well supplied with provisions (especially game), and the lower classes, with whom the plantain forms the staff of life, are able to subsist in a state of comparative idleness. The prosperity of the place is due to the fact that it forms the outlet for the produce of a wide region; and if the bar at the mouth of the lake, preventing the entrance of vessels drawing more than 10 or 11 feet, were removed Maracaibo would bid fair to become the chief mercantile centre of the north coast of South America. Coffee, not of prime quality, cocoa, and hides are the principal exports at present, $4,029,852 out of the $4,188,617 at which the whole exports were valued in 1880 being drawn from those items. Steamers ascend the Catatumbo as far as San Buenaventura and Villarnizar and the Escalente to Santa Cruz, thus tapping the border provinces of both Venezuela and Colombia. Bricks and tiles, leather and admirable saddlery, cocoa-nut oil, sugar, rum, and chocolate are manufactured in the town. Though the Jesuit College, which formerly made Maracaibo one of the few real seats of learning in this part of the world, no longer exists, means of education are fairly abundant (a national college, a nautical school, &c.); and, although they devote themselves mainly to political agitation, the upper classes are not without culture. Maracaibo was founded by Alonso Pacheco in 1571. The population, returned in 1873 as 21,954, is estimated at 30,000 in 1881.

See Engel, "Maracaibo," in *Zeit. d. Ges. Erdk.*, Berlin, 1870; and *U. S. Consular Reports*, 1882.

MARÁGHA, a town of Persia, province Azerbijan, 37° 20′ N., 46° 25′ E., 68 miles from Tabríz, 232 north-west of Tehrán, pleasantly situated in a long narrow valley opening towards Lake Urmiah, which lies 10 miles to the north-west. The town consists mostly of mud houses enclosed by a high dilapidated wall, and containing no conspicuous buildings except a large bazaar and fine public bath. Náṣir-ed-dín's observatory formerly stood on a hill to the west, where there are some old tombs covered with Cufic inscriptions. The surrounding gardens and plantations are watered by canals from a small river crossed here by two good bridges built in 1809. At the village of Dash-Kesen, 6 miles from Deh Kurgán in this district, are the famous Marágha marble pits, occupying a space half a mile in circumference, and sunk to a depth of about 12 feet. Here a multitude of springs charged with carbonic acid gas bubble up in all directions, precipitating large quantities of carbonate of lime. The marble in the semi-crystallized formation of this deposit forms horizontal layers, which when cut in thin slabs are nearly transparent, and serve as windows in the Tabríz baths and elsewhere. Larger blocks are also used as pavements in bazaars and palaces, and the famous throne in the Díwán Khána at Tehrán is made of the same material. Marágha was formerly the capital of Húlakú, grandson of Jenghis Khán, and its fifteen thousand inhabitants still belong mostly to the Mukadam Turki tribe.

MARANHÃO, or Maranham (Latinized as *Maragnanum*), in full form Sao Luiz de Maranhão, the chief town of the province of Maranhão in Brazil, is situated in 2° 30′ S. lat. and 44° 17′ W. long., on the west side of an island of the same name 28 miles long and 15 broad. Though built on so hilly a surface that carriages cannot be used, it is laid out with regularity, and has straight, wide, and clean-looking streets. The public institutions comprise a naval arsenal, a high court of appeal, a tribunal of commerce, a military hospital, several general hospitals, a theatre, a museum, a public library, and a botanic garden, as well as a cathedral and an episcopal palace, both built by the Jesuits. Maranhão has some commercial importance, exporting cotton, sugar, hides, &c., from a wide region of the interior, and receiving manufactured goods from Europe, and especially from England. Though somewhat difficult of access to large sailing vessels, the port affords good anchorage to all drawing less than 20 feet. Steamers ply to Rio de Janeiro and Pará, as well as up the rivers Itapicuru, Guajahu, and Pindare; and direct steam communication is maintained with Lisbon and Liverpool. The population of the island Maranhão was 34,023 in 1872, about 30,000 belonging to the city.

French colonists settled at St Luiz in 1612, but they were expelled by Jeronimo d'Albuquerque in 1614. The Dutch were in possession from 1641 to 1653. The bishopric was created in 1676. The city was captured in 1823 by Lord Cochrane, who was afterwards created marquis of Maranham.

MARAT, Jean Paul (1743–1793), a famous revolutionary leader, was the eldest child of Jean Paul Mara of Cagliari and Louise Cabrol of Geneva, and was born at Boudry, in the principality of Neuchâtel, on May 24, 1743. His father was a doctor of some learning, who had abandoned his country and his religion, and had married a Swiss Protestant. It was he that laid the basis of the young Jean Paul's scientific learning, and the son at the same time imbibed the doctrines of Rousseau. On his mother's death in 1759 he set out on his travels, and spent two years at Bordeaux in the study of medicine, whence he moved to Paris, where he made use of his knowledge of his two favourite sciences, optics and electricity, to subdue an obstinate disease of the eyes. After some years in Paris he went to Holland, the retreat of philosophers, where all the works of the Encyclopédists were printed for the French market, and then on to London, where he settled in Church Street, Soho, a fashionable district, and practised his profession. In 1773, at the age of thirty, he made his first appearance as an author with a *Philosophical Essay on Man, being an Attempt to Investigate the Principles and Laws of the Reciprocal Influence of the Soul on the Body*, of which only two volumes are extant, though at the end of the second volume he speaks of a third. The book shows a wonderful knowledge of English, French, German, Italian, and Spanish philosophers, and directly attacks Helvetius, who had in his *L'Esprit* declared a knowledge of science unnecessary for a philosopher. Marat, as he now began to call himself, declares that physiology alone can solve the problems of the connexion between soul and body, and proposes the existence of a nervous fluid as the true solution. In 1774 he published a political work, *The Chains of Slavery*, which appeared without his name, and was intended to influence constituencies to return popular members, and reject the king's friends, with innumerable examples from classical and modern history of the ways in which kings enslaved their peoples. The book was too late to have any influence on the general election, and was got up in a style too costly for a wide circulation, but its author declared later that it procured him an honorary membership of the patriotic societies of Carlisle, Berwick, and Newcastle. He remained devoted to his profession, and in 1775 published in London a little *Essay on Gleets*, price 1s. 6d., of which no copy is to be found, and in Amsterdam a French translation of the first two volumes of his *Essay on Man*. In this year, 1775, he visited Edinburgh, and on the recommendation of certain Edinburgh physicians, was, on June 30, made an M.D. of St Andrews University. On his return to London he published an *Enquiry into the Nature, Cause, and Cure of a Singular Disease of the Eyes*, with a dedication to the Royal Society. In the same year there appeared the third volume of the French edition of the *Essay on Man*, which reached Ferney, and exasperated Voltaire, by its onslaught on Helvetius, into a sharp attack, that only made the young author more conspicuous. His fame as a clever doctor was now great, and on June 24, 1777, the Comte d'Artois, afterwards Charles X. of France, "owing to the report he had heard of the good and moral life, and of the knowledge and experience in the art of medicine, of J. P. Marat," made him by brevet physician to his guards, with 2000 livres a year and allowances.

Marat was soon in great request as a court doctor among the aristocracy; and even Brissot, in his *Mémoires*, admits his influence in the scientific world of Paris. The next years were much occupied with scientific work, especially the study of heat, light, and electricity, on which he presented memoirs to the Académie des Sciences, but the Academicians were horrified at his temerity in differing from Newton, and, though acknowledging his industry, would not receive him among them. His experiments greatly interested Benjamin Franklin, who used to visit him; and Goethe always regarded his rejection by the Academy as a glaring instance of scientific despotism. In 1780 he had published at Neuchâtel without his name a *Plan de Législation Criminelle*, founded on the humane principles established by Beccaria. In April 1786 he resigned his court appointment. The results of his leisure were in 1787 a new translation of Newton's *Optics*, and in 1788 his *Mémoires Académiques, ou Nouvelles Découvertes sur la Lumière*.

His scientific life was now over, his political life was to begin; in the notoriety of that political life his great scientific and philosophical knowledge was to be forgotten, the high position he had given up denied, and he himself to be scoffed at as an ignorant charlatan, who had sold quack medicines about the streets of Paris, and been glad to earn a few sous in the stables of the Comte d'Artois. In 1788 the notables had met, and advised the assembling of the states-general. The elections were the cause of a flood of pamphlets, of which one, *Offrande à la Patrie*, was by Marat, and, though now forgotten, dwelt on much the same points as the famous brochure of the Abbé Siéyès. When the states-general met, Marat's interest was as great as ever, and in June 1789 he published a supplement to his *Offrande*, followed in July by *La Constitution*, in which he embodies his idea of a constitution for France, and in September by his *Tableau des Vices de la Constitution d'Angleterre*, which he presented to the assembly. The latter alone deserves remark. The assembly was at this time full of Anglomaniacs, who desired to establish in France a constitution exactly similar to that of England. Marat, who had lived in England, had seen that England was at this time being ruled by an oligarchy using the forms of liberty, which, while pretending to represent the country, was really being gradually mastered by the royal power. His heart was now all in politics; and, feeling that his energies needed a larger scope than occasional tracts afforded, he decided to start a paper. At first appeared a single number of the *Moniteur patriote*, followed on September 12 by the first number of the *Publiciste parisien*, which on September 16 took the title of *L'Ami du Peuple*, and was to absorb his future life.

The life of Marat now becomes part of the history of the French Revolution. From the beginning to the end he stood alone. He was never attached to any party; the tone of his mind was to suspect whoever was in power; and therefore no historian has tried to defend him, and all state the facts about him with a strong colouring. About his paper, the incarnation of himself, the first thing to be said is that the man always meant what he said; no poverty, no misery or persecution, could keep him quiet; he was perpetually crying—"nous sommes trahis."

Further, the suspicious tone of his mind extended to his paper, and he made it play the part of the lion's mouth at Venice: whoever suspected any one had only to denounce him to the *Ami du Peuple*, and the denounced was never let alone till he was proved innocent or guilty. He began by attacking the most powerful bodies in Paris,—the corps municipal, with Bailly at their head, and the court of the Châtelet,—and after a struggle found them too strong for him, and fled to London (January 1790). There he wrote his *Denonciation contre Necker*, and in May dared to return to Paris and continue the *Ami du Peuple*. He was embittered by persecution, and continued his vehement attacks against all in power—against Bailly, against La Fayette, and at last, after the day of the Champs du Mars, against the king himself. All this time he was hiding in cellars and sewers, where he was attacked by a horrible skin disease, tended only by the woman Simonne Evrard, who remained true to him. The end of the constituent assembly he heard of with joy, and with bright hopes (soon dashed by the behaviour of the legislative) for the future, when almost despairing in December 1791 he fled once more to London, where he wrote his *École du Citoyen*. In April 1792, summoned again by the Cordeliers, he returned to Paris, and published No. 627 of the *Ami*. The war was now the question, and Marat saw clearly enough that it was not sought for the sake of France, that it was to serve the purposes of the royalists and the Girondins, who thought of themselves alone. The early days of the war being unsuccessful, the proclamation of the duke of Brunswick excited all hearts; who could go to save France on the frontiers and leave Paris in the hands of his enemies? Marat, like Danton, foresaw the massacres of September. After the events of August 10th he took his seat at the commune, and demanded a tribunal to try the royalists in prison. No tribunal was formed, and the massacres in the prisons were the inevitable result. In the elections to the convention, Marat was elected seventh out of the twenty-four deputies for Paris, and for the first time took his seat in an assembly of the nation. At the declaration of the republic, he closed his *Ami du Peuple*, and commenced a new paper, the *Journal de la République Française*, which was to contain his sentiments as its predecessor had done, and to be always on the watch. In the assembly Marat had no party; he would always suspect and oppose the powerful, refuse power for himself. After the battle of Valmy, Dumouriez was the greatest man in France; he could almost have restored the monarchy, yet Marat did not fear to go uninvited to the tragedian Talma's, and there accuse Dumouriez in the presence of his friends of want of patriotism. His unpopularity in the assembly was extreme, yet he insisted on speaking on the question of the king's trial, declared it unfair to accuse Louis for anything anterior to his acceptance of the constitution, and, though implacable towards the king, as *the* one man who must die for the people's good, he would not allow Malesherbes, the king's counsel, to be attacked in his paper, and speaks of him as a "sage et respectable vieillard." The king dead, the months from January to May were spent in an unrelenting struggle between Marat and the Girondins. Marat despised the ruling party because they had suffered nothing for the republic, because they talked too much of their feelings and their antique virtue, because they had for their own purposes plunged the country into war; while the Girondins hated Marat as representative of that rough red republicanism which would not yield itself to a Roman republic, with themselves for tribunes, orators, and generals. The Girondins conquered at first in the convention, and ordered that Marat should be tried before the Tribunal Revolutionnaire. But their victory ruined them, for Marat was acquitted on April 24, and returned to the convention with the people at his back. Their fall was a veritable victory for Marat. But it was his last. The skin disease he had contracted in the subterranean haunts was rapidly closing his life; he could only ease his pain by sitting in a warm bath, where he wrote his journal, and accused the Girondins, who were trying to raise France against Paris. Sitting thus on the 13th July he heard in the evening a young woman begging to be admitted to see him, saying that she brought news from Caen, where the escaped Girondins were trying to rouse Normandy. He ordered her to be admitted, asked her the names of the deputies then at Caen, and, after writing their names, said, "They shall be soon guillotined," when the young girl, whose name was Charlotte Corday, stabbed him to the heart. Grand was the funeral given to the man who had suffered so much for the republic. Whatever his political ideas, two things shine clearly out of the mass of prejudice which has shrouded the name of Marat—that he was a man of great attainments and acknowledged position, who sacrificed fortune, health, life itself, to his convictions, and that he was no *bête feroce*, no factious demagogue, but a man, and a humane man too, who could not keep his head cool in stirring times, who was rendered suspicious by constant persecution, and who has been regarded as a personification of murder, because he published every thought in his mind, while others only vented their anger and displayed their suspicions in spoken words.

The only works of Marat not mentioned in the text are *Les aventures du Comte Potowski*, a poor novel, which must have been written in his early days, and which was discovered in MS. and published by Bibliophile Jacob; two brochures on a balloon accident, 1785; *Les Charlatans Modernes, ou Lettres sur le Charlatanisme académique*, 1791; *Le Junius Français, journal politique*, June 2 to June 24, 1790; translation of *Chains of Slavery*, with fifty pages on French history prefixed, year 1.

On Marat's life should be read *L'ami du peuple, Skizzen aus Marat's journalistichen Leben*, Hamburg, 1846; A. Bougeart, *Marat, l'ami du peuple*, 2 vols., 1864; G. Piazzoli, *Marat, l'amico del Popolo e la Rivoluzione*, Milan, 1874; A. Vermorel, *Œuvres de J. P. Marat, l'ami du peuple, recueillies et annotées*, 1869; F. Chevremont, *Marat, Index du Bibliophile*, &c., 1876; Id., *Placards de Marat*, 1877; and particularly his *Jean Paul Marat, esprit politique, accompagné de sa vie scientifique, politique, et privée*, 2 vols., 1881.

(H. M. S.)

MARATHON was a plain on the north-east coast of Attica, containing four villages—Marathon, Probalinthos, Tricorythos, and Oinoe, which formed a tetrapolis. It was divided from the plain of Athens by Mount Pentelicus and the hilly district of Diacria, and was in the early period an autonomous state. After it became incorporated in the Attic state, it retained something of its original distinctive character. The worship of Apollo had its first home in Attica here, and it was carried hence to Athens when the tetrapolis was made part of the Athenian commonwealth. The district was one of the chief seats of the worship of Hercules, and boasted that it was the first place where he had been worshipped as a god. Hence legend localized here several events in the story of the Heraclidæ, and especially the self-sacrifice of Macaria, daughter of Hercules. The legend of Theseus was also known in the district; here the hero slew the Marathonian bull. The plain derived its fame chiefly from the battle in which the Athenians and Platæans under Miltiades defeated the Persians, 490 B.C. The one hundred and ninety-two Athenians that were slain were buried on the field of battle, contrary to the usual Attic custom, and a mound, which is still called Soro, was erected over them. Another tumulus covered the bodies of the slain Platæans and slaves, and a special monument was raised to Miltiades.

MARBLE is a term applied to any limestone which is sufficiently close in texture to admit of being polished. Many other ornamental stones—such as serpentine, alabaster, and even granite—are sometimes loosely designated as marbles, but by accurate writers the term is invariably restricted to those crystalline and compact varieties of carbonate of lime which, when polished, are applicable to purposes of decoration. The crystalline structure is typically shown in statuary marble. A fractured surface of this stone displays a multitude of sparkling facets, which are the rhombohedral cleavage-planes of the component grains. On placing a thin section of Carrara marble under the microscope, it is seen that each grain is an imperfect crystal, or crystalloid, of calc-spar, having an irregular boundary, and being itself made up of a number of crystalline plates twinned together (see fig. 5, article GEOLOGY, vol. x. p. 231). It is said that a somewhat similar polysynthetic structure may be artificially induced in calc-spar by means of pressure. As marble appears to be, in many cases, a metamorphic rock, it is probable that pressure and heat have been the principal natural agents concerned in the alteration of compact into crystalline limestones. It was shown many years ago by Sir James Hall that even an earthy limestone, like chalk, when strongly heated in a closed vessel, might assume a saccharoidal texture; and it is a fact familiar to the field-geologist that a crystalline structure is often locally developed in limestone where it happens to have been invaded by an eruptive rock. Prof. Geikie proposes to distinguish this kind of metamorphism by the term *marmarosis* (*Text-Book of Geology*, 1882).

Among statuary marbles the first place may be assigned to the famous Pentelic marble, the material in which Phidias, Praxiteles, and other Greek sculptors executed their principal works. The characteristics of this stone are well seen in the Elgin marbles, which were removed from the Parthenon at Athens, and are now in the British Museum. The marble was derived from the quarries of Mount Pentelicus in Attica. The neighbouring mountain of Hymettus likewise yielded marbles, but these were neither so pure in colour nor so fine in texture as those of Pentelicus. Parian marble, another stone much used by Greek sculptors and architects, was quarried in the isle of Paros, chiefly at Mount Marpessa. It is called by ancient writers *lychnites*, in allusion to the fact that the quarries were worked by the light of lamps. The Venus de' Medici is a notable example of work in this material. Carrara marble is better known than any of the Greek marbles, inasmuch as it constitutes the stone invariably employed by the best sculptors of the present day. This marble occurs abundantly in the Apuan Alps, an offshoot of the Apennines, and is largely worked in the neighbourhood of Carrara, Massa, and Serravezza. Stone from this district was employed in Rome for architectural purposes in the time of Augustus, but the finer varieties, adapted to the needs of the sculptor, were not discovered until some time later. It is in Carrara marble that the finest works of Michelangelo and of Canova are executed. The purest varieties of this stone are of snow-white colour and of fine saccharoidal texture. Silica is disseminated through some of the marble, becoming a source of annoyance to the workman; while occasionally it separates as beautifully pellucid crystals of quartz known as Carrara diamonds. The geological age of the marbles of the Apuan Alps has been a subject of much dispute, some geologists regarding them as metamorphosed Triassic or even Liassic rocks, while others are disposed to refer them to the Carboniferous system. Much of the common marble is of a bluish colour, and therefore unfit for statuary purposes; when streaked with blue and grey veins, the stone is known as *bardiglio*. Curiously enough, the common white marble of Tuscany comes to England as Sicilian marble—a name probably due to its having been formerly re-shipped from some port in Sicily.

Although crystalline marbles fit for statuary work are not found to any extent in Great Britain, the limestones of the Palæozoic formations yet yield a great variety of marbles well suited for architectural purposes. The Devonian rocks of South Devon are rich in handsome marbles, presenting great diversity of tint and pattern. Plymouth, Torquay, Ipplepen, Babbacombe, and Chudleigh may be named as the principal localities. Many of these limestones owe their beauty to the fossil corals which they contain, and are hence known as madrepore marbles.

Of far greater importance than the marbles of the Devonian system are those of Carboniferous age. It is from the Carboniferous or Mountain Limestone that British marbles are mainly derived. Marbles of this age are worked in Derbyshire and Yorkshire, in the neighbourhood of Bristol, in North Wales, in the Isle of Man, and in various parts of Ireland. One of the most beautiful of these stones is the encrinital marble, a material which owes its peculiarities to the presence of numerous encrinites, or stone-lilies. These fossils, when cut in various directions, give a characteristic pattern to the stone. The joints of the stems and arms are known from their shape as "wheel-stones," and the rock itself is sometimes called entrochal marble. The most beautiful varieties are those in which the calcareous fossils appear as white markings on a ground of grey limestone. On the Continent a black marble with small sections of crinoid stems is known as *petit granit*, while in Derbyshire a similar rock, crowded with fragments of minute encrinites, is termed bird's-eye marble.

Perhaps the most generally useful marbles yielded by the Carboniferous system are the black varieties, which are largely employed for chimney-pieces, vases, and other ornamental objects. The colour of most black limestone is due to the presence of bituminous matter, whence the mineralogical name anthraconite. Such limestone commonly emits a fetid odour when struck; and the colour, being of organic origin, is discharged on calcination. Black marbles, more or less dense in colour, are quarried in various parts of Ireland, especially at Kilkenny and near Galway; but the finest kind is obtained from near Ashford in Derbyshire. From Ashford is also derived a very beautiful stone known as rosewood marble. This is a dense brown laminated limestone, displaying when polished a handsome pattern somewhat resembling the grain of rosewood; it occurs in very limited quantity, and is used chiefly for inlaid work.

With the rosewood marble may be compared the well-known landscape marble or Cotham stone, an argillaceous limestone with peculiar dendritic markings, due probably to the infiltration of water containing oxide of manganese. This limestone occurs in irregular masses near the base of the White Lias, or uppermost division of the Rhætic series. It is found principally in the neighbourhood of Bristol. The arborescent forms depicted in bluish-grey upon this landscape marble form a marked contrast to the angular markings of warm brown colour which are seen on slabs of ruin marble from Florence—a stone occasionally known also as landscape stone, or *pietra paesina*.

British limestones of Secondary and Tertiary age are not generally compact enough to be used as marbles, but some of the shelly beds are employed to a limited extent for decorative purposes. Ammonite marble is a dark brown limestone from the Lower Lias of Somersetshire, crowded with ammonites, principally *A. planicostata*. Under the name of Forest marble, geologists recognize a local division of the Lower Oolitic series, so named by W. Smith from Wychwood Forest in Oxfordshire, where shelly limestones occur; and these, though of little economic value, are capable of being used as rough marbles. But the most important marbles of the Secondary series are the shelly limestones of the Purbeck formation. Purbeck marble was a favourite material with mediæval architects, who used it freely for slender clustered columns and for sepulchral monuments. It consists of a mass of the shells of a fresh-water snail, *Paludina carinifera*, embedded in a blue or grey limestone, and is found in the Upper Purbeck beds of Swanage in Dorsetshire. Excellent examples of its use may be seen in Westminster Abbey and in the Temple Church, as well as in the cathedrals of Salisbury, Winchester, Worcester, and Lincoln. Sussex marble is a very similar stone, occurring in thin beds in the Weald clay, and consisting largely of the shells of *Paludina*, principally *P. sussexiensis* and *P. fluviorum*. The altar stones and the episcopal chair in Canterbury cathedral are of this material.

Mixtures of limestone and serpentine frequently form rocks which are sufficiently beautiful to be used as ornamental stones, and are generally classed as marbles. Such serpentinous limestones are included by petrologists under the term ophicalcite. The famous *verde antico* is a rock of this character. Mona marble is an ophicalcite from the metamorphic series of the Isle of Anglesey, while the "Irish green" of architects is a similar rock from Connemara in western Galway. It is notable that some of the "white marble" of Connemara has been found by Messrs King and Rowney to consist almost wholly of malacolite, a silicate of calcium and magnesium.

A beautiful marble has been worked to a limited extent in the island of Tiree, one of the Hebrides, but the quarry appears to be now exhausted. This Tiree marble is a limestone having a delicate carnelian colour diffused through it in irregular patches, and containing rounded crystalloids of sahlite, a green augitic mineral resembling malacolite in composition. When dissolved in acid the marble leaves a brick-red powder, which has been studied by Dr Heddle, who has also analysed the sahlite.

Many marbles which are prized for the variegated patterns they display owe these patterns to their formation in concentric zones,—such marbles being in fact stalagmitic deposits of carbonate of lime, and probably consisting in many cases of aragonite. One of the most beautiful stalagmitic rocks is the so-called onyx marble of Algeria. This stone was largely used in the buildings of Carthage and Rome, but the quarries which yielded it were not known to modern sculptors until 1849, when M. Delamonte rediscovered the marble near Oued-Abdallah. The stone is a beautifully translucent material, delicately clouded with yellow and brown, and is greatly prized by French workmen. Large deposits of a very fine onyx-like marble, similar to the Algerian stone, have been worked of late years at Técali, about 35 miles from the city of Mexico. Among other stalagmitic marbles, mention may be made of the well-known Gibraltar stone, which is often worked into models of cannon and other ornamental objects. This stalagmite is much deeper in colour and less translucent than the onyx marbles of Algeria and Mexico. A richly tinted stalagmitic stone worked in California is known as Californian marble. It is worth noting that the "alabaster" of the ancients was stalagmitic carbonate of lime, and that this stone is therefore called by mineralogists "Oriental alabaster" in order to distinguish it from our modern "alabaster," which is a sulphate, and not a carbonate, of lime.

The brown and yellow colours which stalagmitic marbles usually present are due to the presence of oxide of iron. This colouring matter gives special characters to certain stones, such as the *giallo antico*, or antique yellow marble of the Italian antiquaries. Siena marble is a reddish mottled stone obtained from the neighbourhood of Siena in Tuscany; and a somewhat similar stone is found in King's County, Ireland. True red marble is by no means common, but it does occur, of bright and uniform colour, though in very small quantity, in the Carboniferous limestone of Derbyshire and north-east Staffordshire. It may be noted that the red marble called *rosso antico* is often confounded with the *porfido rosso antico*, which is really a red porphyritic felstone.

Fire marble is the name given to a brown shelly limestone containing ammonites and other fossil shells, which present a brilliant display of iridescent colours, like those of precious opal. It occurs in rocks of Liassic age at the lead-mines of Bleiberg in Carinthia, and is worked into snuff-boxes and other small objects. By mineralogists it is often termed *lumachella*, an Italian name which may, however, be appropriately applied to any marble which contains small shells.

It would unnecessarily extend this article to enumerate the local names by which marble-workers in different countries distinguish the various stones which pass under their hands. The quarries of France, Belgium, and Italy, not to mention less important localities, yield a great diversity of marbles, and almost each stone bears a distinctive name, often of trivial meaning.

America possesses some valuable deposits of marble, which in the eastern States have been extensively worked. The crystalline limestones of western New England furnish an abundance of white and grey marble, while a beautiful material fit for statuary work has been quarried near Rutland in Vermont. A grey bird's-eye marble is obtained from central New York, and the greyish clouded limestones of Thomaston in Maine have been extensively quarried. Of the variegated and coloured marbles, perhaps the most beautiful are those from the northern part of Vermont, in the neighbourhood of Lake Champlain. A fine brecciated marble is found on the Maryland side of the Potomac, below Point of Rocks. Among the principal localities for black marble may be mentioned Shoreham in Vermont and Glen Falls in New York. In Canada the crystalline limestones of the Laurentian series yield beautiful marbles.

Turning to India, we find important quarries at Makrana in Rajputana—a locality which is said to have yielded the marble for the famous Taj Mahal at Agra. In the valley of the Nerbudda, near Jabalpur, there is a large development of marble. The white marble which is used for the delicately-pierced screens called *jalee* work is obtained from near Raialo, in Ulwar. See Ball's *Economic Geology of India*, 1882.

For descriptions of ancient marbles see F. Corsi's treatise *Delle Pietre antiche*; and for marbles in general consult Professor Hull's *Building and Ornamental Stones*, 1872. (F. W. R.*)

MARBLEHEAD, a town and port of entry of the United States, in Essex county, Massachusetts, situated on the coast, 17 miles by rail north-east of Boston, and 4 miles south-east of Salem, and communicates by two branch lines with the main line of the Eastern Railway. It is built on a rocky peninsula of about 3700 acres in extent, which juts out into Massachusetts Bay, and has a deep, roomy, and nearly land-locked harbour. The fisheries in which Marblehead was once largely engaged have declined; but shoemaking has become an important industry, and the town is rising into favour as a summer resort. Many of the houses date from the "colonial" period, and one of the churches was built in 1714, but in the summer of 1877 nearly the whole business part of the town was burnt to the ground. The population was 7703 in 1870, and 7467 in 1880.

Marblehead was incorporated in 1649. Of the original settlers, a considerable number were from the Channel Islands, and their peculiarities of speech continued for a long time to affect the local dialect. As at that period the second town of Massachusetts in wealth and size, Marblehead sent one thousand men to the War of Independence, and its privateers rendered excellent service; but its trading prosperity never recovered from the effects of the contest. Elbridge Gerry, vice-president of the United States in 1812, was born at Marblehead; and the town is the scene of the grim revenge celebrated, with considerable poetical licence, in Whittier's *Skipper Ireson's Ride*.

MARBURG, an ancient university town of Prussia, in the province of Hesse-Nassau and district of Cassel, is very picturesquely situated on the slope of a hill on the right bank of the Lahn, 50 miles to the north of Frankfort-on-the-Main, and about the same distance to the south-west of Cassel. On the opposite bank of the river, which is here spanned by two bridges, lie the suburb of Weidenhausen and the station of the Main-Weser Railway. The streets of the town proper are steep and narrow, and the general character of the architecture is quaint and mediæval. The hill on which the town lies is crowned by the extensive old schloss, a fine Gothic building, the most noteworthy parts of which are the rittersaal (see below), dating from 1277–1320, and the beautiful little chapel. This chateau was formerly the residence of the landgraves of Hesse, afterwards served as a prison, and is now the repository of the historically interesting and valuable archives of Hesse. The chief architectural ornament of Marburg is, however, the Elisabethenkirche, a veritable gem of the purest Early Gothic style, erected by the grand master of the Teutonic Order in 1235–83, to contain the tomb of St Elizabeth of Hungary. The remains of the saint were deposited in a rich silver-gilt sarcophagus, which is still extant, and were afterwards visited by myriads of pilgrims, until the Protestant zeal of Landgrave Philip the Generous caused him to remove the body to some unknown spot in the church. The church also contains the tombs of numerous Hessian landgraves and knights of the Teutonic Order. The Lutheran church is another good Gothic edifice, dating mainly from the 15th century. The town-house, built in 1512, and several fine houses in the Renaissance style, also deserve mention. The university of Marburg, founded by Philip the Generous in 1527, was the first university established without papal privileges, and speedily acquired a great reputation throughout Protestant Europe. It has a library of 140,000 volumes, and is admirably equipped with medical and other institutes, which form some of the finest modern buildings in the town. The number of students is now about seven hundred. Marburg also possesses a gymnasium, a "realschule," an agricultural school, a society of naturalists, a hospital, a poorhouse, and an extensive lunatic asylum. It is the seat of a district court, and of superintendents of the Lutheran and Reformed churches. Marburg pottery is renowned; and leather, iron wares, and surgical instruments are also manufactured there. The population in 1880 amounted to 11,225. The environs are very picturesque.

Marburg is first historically mentioned in a document of the beginning of the 13th century, and received its municipal charter from Landgrave Louis of Thuringia in 1227. On his death it became the residence of his wife, Elizabeth of Hungary, who built a hospital there and died in 1231, at the age of twenty-four, worn out with works of religion and charity. She was canonized soon after her death. By 1247 Marburg had already become the second town of Hesse, and in the 15th and 16th centuries it alternated with Cassel as the seat of the landgraves. In 1529 the famous conference between Luther and Zwingli on the subject of transubstantiation took place there in the rittersaal of the schloss. During the Thirty Years' and Seven Years' Wars Marburg suffered considerably from sieges and famine. In 1806, and again in 1810, it was the centre of an abortive rising against the French, in consequence of which the fortifications of the castle were destroyed.

Several monographs have been published on the conference and university of Marburg. A general account of the town, with references to the most important of these, is given in Bücking's *Wegweiser durch Marburg*, 1875.

MARBURG, the second town of the Austrian duchy of Styria, is very picturesquely situated on both banks of the river Drave, in a plain called the Pettauer-Feld, at the base of the well-wooded Bachergebirge. It is the seat of the bishop of Lavant, and of the judicial and administrative authorities of the district, and contains a gymnasium, a "realschule," an episcopal seminary, a normal school, a pomological school, a theatre, and three hospitals. The principal buildings are the cathedral, the tower of which commands a beautiful view, and the old castle. Its situation in the midst of a fertile vine-growing district, connected by the navigable Drave with Hungary, and by railway with Vienna, Trieste, the Tyrol, and Carinthia, makes it the centre of a considerable traffic in wine and grain. Its industrial products are leather, iron and tin wares, liqueurs, and sparkling wine, and it also contains several large cooperages. The extensive workshops of the South Austrian Railway are situated in the suburb of Magdalena, on the right bank of the Drave, and give employment to nearly three thousand hands. With the exception of a successful resistance to Matthias Corvinus in 1480–81, the history of the town presents no notable event. In 1880 Marburg contained 17,628 inhabitants, including a garrison of 1600 men. The environs abound in interesting and picturesque points.

See Puff's *Handbook to Marburg*, Gratz, 1847.

MARCANTONIO, or, to give him his full name, MARCANTONIO RAIMONDI, is celebrated as the chief Italian master of the art of engraving in the age of the Renaissance. The date of his birth is uncertain, nor is there any good authority for assigning it, as is commonly done, approximately to the year 1488. He was probably born some years at least earlier than this, inasmuch as he is mentioned by a contemporary writer, Achillini, as being an artist of repute in 1504. His earliest dated plate, illustrating the story of Pyramus and Thisbe, belongs to the following year, 1505. Marcantonio received his training in the workshop of the famous goldsmith and painter of Bologna, Francesco Raibolini, usually called Francia. "Having more aptitude in design," says Vasari, "than his master, and managing the graver with facility and grace, he made waist-buckles and many other things in niello, such being then greatly in fashion, and made them most beautifully, as being in truth most excellent in that craft." The real fame, however, of Marcantonio was destined to be founded on his attainments, not in the goldsmith's art generally, but in that particular development of it which consists of engraving designs on metal plates for the purpose of reproduction by the printing press. This art was not new in Italy in the days of Marcantonio's apprenticeship. It had been practised, in a more or less elementary form, for not less than forty or fifty years in the workshops of both Tuscany and Lombardy. A school of engravers had formed itself at Florence under the inspiration, as it appears, chiefly of Sandro Botticelli; in Lombardy the prevailing influence upon the nascent art had been that of Andrea Mantegna. But hitherto neither the engravers of Florence nor those of the Lombard cities had produced anything comparable for richness of effect and technical accomplishment to the work done during the same period on the other side of the Alps. The aim of the Italian engravers had not hitherto been directed, like that of Schongauer or Dürer, towards securing such freedom and precision in the use of the burin as should impart to the impressions taken from their engraved plates both a striking decorative effect and a power of suggesting to the eye a complex variety of natural objects and surfaces in light and shade. The Italian masters had been satisfied with a much more primitive order of effects. They had been content to omit all accessories and details except the simplest. They had merely drawn with the needle, or dry-point, upon the copper, in just the same way as they were accustomed to draw on paper with the pen or silver point,—taking great pains to get the outlines true and pure, and indicating shadows only by means of straight lines rapidly drawn in, or very simple hatchings.

By the beginning of the 16th century, however, when Marcantonio began to work at engraving along with the other pupils of Francia, a desire for a more complicated kind of effects was already arising among the followers of the art in Italy. Both backgrounds and passages of foreground detail were often imitated, inartificially enough, from the works of the northern masters. Marcantonio himself was among the foremost in carrying out this movement. There exist about eighty engravings which can be referred to the first five or six years of his career (1505–11). Their subjects are very various, including many of pagan mythology, and some of obscure allegory, along with those of Christian devotion. The types of figures and drapery, and the general character of the compositions, bespeak for the most part the inspiration, and sometimes the direct authorship, of that artist as graceful as he was grave, Francia. But the influence of German example is very perceptible also in the work of the young Marcantonio, particularly in the landscape backgrounds, and in the endeavour shown by him to express form by means of light and shadow with greater freedom than had been hitherto the practice of the southern schools. In a few subjects also the figures themselves correspond to a coarse Teutonic, instead of to the refined Italian, ideal. But so far we find Marcantonio only indirectly leaning on the north for the sake of self-improvement. It must have been for the sake of commercial profit that he by and by produced a series of direct counterfeits of northern work. We allude to the celebrated facsimiles engraved by Marcantonio on copper from Albert Dürer's woodcuts. These facsimiles are sixty-nine in number, including seventeen of Dürer's *Life of the Virgin,* thirty-seven of his *Little Passion* on wood, and a number of single pieces. According to Vasari, Dürer's indignation over those counterfeits was the cause of his journey to Venice, where he is said to have lodged a complaint against Marcantonio, and induced the signoria to prohibit the counterfeiting of his monogram, at any rate, upon any future imitations of the kind. Vasari's account must certainly be mistaken, inasmuch as Dürer's journey to Venice took place in 1506, and neither of the two series of woodcuts imitated by Marcantonio was published until 1511. The greater part of the designs for the *Life of the Virgin* had, it is true, been made and engraved seven years earlier than the date of their publication; and it is to be remarked that, whereas Marcantonio's copies of the *Little Passion* leave out the monogram of Dürer, it is inserted in his copies of the *Life of the Virgin*; whence it would after all seem possible that he had seen and counterfeited a set of impressions of this series at the time when they were originally executed, and before their publication. But the real nature of the transaction, if transaction there was, which took place between Dürer and Marcantonio, we cannot now hope to recover. Enough that the Bolognese engraver evidently profited, both in money and in education of the hand, by his work in imitating in a finer material the energetic characters of these northern woodcuts. He was soon to come under a totally different influence, and to turn the experience he had gained to account in interpreting the work of a master of a quite other stamp. Up till the year 1510 Marcantonio had lived entirely at Bologna, with the exception, it would appear, of a visit or visits to Venice. Very soon afterwards he was attracted for good and all into the circle which surrounded Raphael at Rome. Where or when he had first made Raphael's acquaintance is uncertain. His passage to Rome by way of Florence has been supposed to be marked by an engraving, dated 1510, and known as the Climbers, *Les Grimpeurs* (Bartsch 487), in which he has reproduced a portion of the design of Michelangelo's cartoon of the Battle of Anghiari, and has added behind the figures a landscape imitated from the then young Dutch engraver Lucas of Leyden. The piece in which he is recorded to have first tried his hand after Raphael himself is the Lucretia (Bartsch 192). From that time until he disappears in the catastrophe of 1527, Marcantonio was almost exclusively engaged in reproducing, by means of engraving, the designs of Raphael or of his immediate pupils. Raphael, the story goes, was so delighted with the print of the Lucretia that he personally trained and helped Marcantonio afterwards, adding, as some think, a touch of his own here and there to the engraver's work. A printing establishment was set up under the charge of Raphael's colour grinder, Il Baviera, and the profits, in the early stage of the business, were shared between the engraver and the printer. The sale soon became very great; pupils gathered round about Marcantonio, of whom the two most distinguished were Marco Dente, known as Marco da Ravenna, and Agostino de' Musi, known as Agostino Veneziano; and he and they, during the last ten years of Raphael's life, and for several years following his death, gave forth a great profusion of engravings after the master's work,—not copying, in most instances, his finished paintings, but working up, with the addition of simple backgrounds and accessories, his first sketches and trials, which often give the composition in a different form from the finished work, and are all the more interesting on that account.

The best of these engravings produced in the workshop of Marcantonio—those, namely, done by his own hand, and especially those done during the first few years after he had attached himself to Raphael—justly count among the most prized and coveted examples of the art. In them he enters into the genius of his master, the genius of choice, of balance, of rhythmical purity and charm; he loses little of the chastened science and subtle grace of

Raphael's contours, or of the inspired and winning sentiment of his faces; while in the parts where he is left to himself—the rounding and shading, the background and landscape—he manages his burin with all the skill and freedom which he had gained by the imitation of northern models, but puts away the northern emphasis and redundance of detail. His work, however, does not long remain at the height marked by pieces like the Lucretia, the Dido, the Judgment of Paris, the Poetry, the Philosophy, or the first Massacre of the Innocents. Marcantonio's engravings after the works of Raphael's later years are cold, ostentatious, and soulless by comparison. Still more so, as is natural, were those which he and his pupils produced after the designs of the degenerate scholars of Raphael and Michelangelo, of a Giulio Romano, a Polidoro, or a Bandinelli. Marcantonio's association with Giulio Romano was the cause of his first great disaster in life. He engraved a series of obscene designs by that painter in illustration of the *Sonnetti lussuriosi* of Pietro Aretino, and thereby incurred the anger of Pope Clement VII., at whose order he was thrown into prison. Marcantonio's ruin was completed by the calamities attendant on the sack of Rome in 1527. He had to pay a heavy ransom in order to escape from the hands of the Spaniards, and fled from Rome, in the words of Vasari, "all but a beggar." It is said that he took refuge in his native city, Bologna; but he never again emerges from obscurity, and all we know with certainty is that in 1534 he was dead. (S. C.)

MARCASITE. Modern mineralogists, following Haidinger, have restricted this name to those forms of native bisulphide of iron which crystallize in the orthorhombic system, and are sometimes known as "prismatic iron-pyrites." By the older mineralogists the word was used with less definite meaning, being applied to all crystallized and radiated pyrites, whether rhombic or cubic. In the last century both minerals were extensively used as ornamental stones. The marcasites were generally of small size, faceted like rose diamonds, and brilliantly polished, in which form they were mounted in pins, brooches, shoe-buckles, watch-cases, and other ornamental objects. The lustre of the polished surface was so brilliant that the stone, although opaque, formed a rough substitute for diamond; and this lustre was not readily impaired by atmospheric influences. Much of the old marcasite jewellery is of so pale a colour as almost to resemble burnished steel; such kinds generally belong to the true modern marcasite, sometimes called "white pyrites"; while the specimens which possess a brassy yellow colour are mostly referable to the cubic species, which is distinctively termed pyrite. Some of the finest pyrites suitable for the jeweller is found in Elba and in Brazil; but the mineral enjoys a very wide geographical distribution, and is common in England, especially in Cornwall, where it is known to the miners as "mundic." By the ancient Peruvians the mineral was extensively used for amulets, while the larger pieces were polished as mirrors; hence marcasite is sometimes called *pierre des Incas.* The word marcasite, variously written *marchasite, marchesite, marquesite,* &c., appears to have been introduced from Spain, and is supposed to be of Arabic origin. It is notable that the word was applied by early writers on chemistry to the metal now called bismuth.

MARCELLINUS, St, according to the Liberian catalogue, became bishop of Rome on June 30, 296; his predecessor was Caius or Gaius. Of his pontificate virtually nothing is known. In the *Concilia* of Mansi and Hardouin there is an account of a synod alleged to have been held in 303 at Sinuessa (between Rome and Capua), at which Marcellinus was accused by three of his priests and two of his deacons of having accompanied Diocletian into the temple of Vesta and Isis, and there burnt incense. The narrative goes on to say that ultimately he confessed his guilt in the presence of the three hundred assembled bishops, but that his condemnation was left to himself, for "prima sedes non judicatur a quoquam." It is further stated in the same account that he and many of the other bishops were put to death by Diocletian on August 23, 303. The story of the synod of Sinuessa was current at an early date, but was condemned by Augustine and Theodoret as a mere invention of the Donatists. Its fabulous character is maintained by Döllinger (*Papstfabeln*) and by Hefele (*Conciliengeschichte*), even against the weighty authority of the *Breviary*, where it constitutes a lesson in one of the nocturns for April 26, the commemoration day of Marcellinus. Marcellinus died, according to the Liberian catalogue, in 304, after a pontificate of eight years three months and twenty-five days; after a considerable interval he was succeeded by Marcellus, who has sometimes been identified with him.

MARCELLUS, Marcus Claudius, Roman warrior, was born about 268 B.C., and served first in Sicily against Hamilcar. In his first consulship (222) he was engaged in the war against the Insubres, and won the *spolia opima* by slaying their chief Viridomarus. In 216 he was to have gone as prætor to Sicily with a fleet, but was detained on the news of the defeat at Cannæ. He went to Canusium and took command of the fragments of the army. He tried without success to prevent Capua going over to Hannibal, but saved Nola. In 214 he was in Sicily as consul at the time of the revolt of Syracuse; he stormed Leontini and besieged Syracuse, but the engineering skill of Archimedes repelled his attacks and compelled him to content himself with a blockade. Himilco landed with a Carthaginian army, and Marcellus failed to prevent their occupying Agrigentum. Taking the opportunity of a feast of Artemis, Marcellus stormed Epipolæ; but the old town and the island remained untaken, as also the fort of Euryalus, which was, however, cut off and soon fell. Meanwhile pestilence raged among the Carthaginian army encamped outside. After several months, during which disorder reigned in the town, he gained a lodgment by the aid of a Spanish officer, and Syracuse was surrendered (212). Marcellus spared the lives of the Syracusans, but carried off their art treasures to Rome. Consul again in 210, he took Salapia by help of the Roman party there, and put to death the Numidian garrison. Proconsul in 209, he attacked Hannibal near Venusia, and after a desperate battle retired to that town; he was accused of bad generalship, and had to leave the army to defend himself in Rome. In his last consulship (208), while both consuls were reconnoitring near Venusia, they were unexpectedly attacked, and Marcellus was killed. His successes have probably been exaggerated, but he was a brave soldier, and the name often given to him, the "sword of Rome," was well deserved. Though plebeians, the Marcelli henceforth took a high position; they were hereditary patrons of Sicily.

MARCELLUS, M. Claudius, was curule ædile in 56 B.C. with P. Clodius. In 52 he spoke on behalf of Milo at his trial. In 51 he was consul with Ser. Sulpicius. During his consulship he proposed to remove Cæsar from his army from March 49. The decision was, however, delayed by Pompeius's irresolution till February 50, and then the tribune C. Curio insisted that Pompeius also should vacate his command; and the senate voted this by a large majority. But at last C. Marcellus, cousin of Marcus, and then consul, went to Pompeius with the two consuls elect, and offered him the command of the army against Cæsar. In January 49 M. Marcellus tried to put off declaring war till an army could be got ready; but when Pompeius left Italy Marcus and his brother Caius followed, while his cousin withdrew to Liternum. After Pharsalus M. Marcellus retired to Mytilene. He long made no attempt to return, till in 46 the senate appealed to Cæsar. Marcellus accepted this favour reluctantly. Pressed by Cicero, he left Mytilene for Italy, but was murdered in May by Magius Cilo in the Piræus. Marcellus was a thorough aristocrat, but free from the violence which disgraced many of his party.

MARCELLUS, M. CLAUDIUS, son of C. Marcellus and Octavia, sister to Octavianus, was born about 43 B.C. Octavianus adopted him and made him pontifex and senator with prætorian rank. In 25 he married Julia, daughter of Octavianus, and was looked on as his future successor. Yet in a dangerous illness Augustus gave his signet to Agrippa. Differences arising, Agrippa was made proconsul of Syria to separate the rivals. In 23 Marcellus, while curule ædile, fell ill and died at Baiæ. Livia was suspected of having poisoned him to get the empire for her son Tiberius. Great hopes had been built on the youth, and he was celebrated by many writers, especially by Virgil, in a famous passage in *Æn.* vi.

MARCELLUS I., pope, succeeded Marcellinus, after a considerable interval, most probably in May 307; under Maxentius he was banished from Rome in 309 on account of the tumult caused by the severity of the penances he had imposed on Christians who had lapsed under the recent persecution. He died the same year, being succeeded by Eusebius.

MARCELLUS II., Marcellus Cervini, cardinal of Santa Croce, a native of the Mark of Ancona, was elected pope in the room of Julius III. on April 9, 1555, but his feeble constitution succumbed to the fatigues of the conclave, the exhausting ceremonies connected with his accession, and the anxieties arising from his high office, on the twenty-first day after his election. He had a high reputation for integrity, tact, and ability. His successor was Paul IV.

MARCH, the third month of our modern year, contains thirty-one days. As in the Roman year so in the English ecclesiastical calendar used till 1752 this was the first month, and the legal year commenced on the 25th of March. The Romans called this month *Martius*, from the god Mars; and it received the name *Illyd Monath, i.e.*, loud or stormy month, from the Anglo-Saxons. In France March was also generally reckoned the first month of the year until 1564, when, by an edict of Charles IX., January was decreed to be thenceforth the first month. Scotland followed the example of France in 1599; but in England the change did not take place before 1752. There is an old saying, common to both England and Scotland, which represents March as borrowing three days from April; thus the last three days of March are called the "borrowing" or the "borrowed days." In the *Complaynt of Scotland* we find "the borial blastis of the thre borouing dais of Marche hed chaisset the fragrant flureise of evyrie fruit-tree far athourt the feildis." An ancient popular rhyme says:—

> "March borrowit from Averill
> Three days, and they were ill;"

and then there is another rhyme which graphically characterizes those three "ill" days in detail:—

> "The first, it sall be wind and weet,
> The next, it sall be snaw and sleet;
> The third, it sall be sic a freeze,
> Sall gar the birds stick to the trees."

There is an old proverb, "A bushel of March dust is worth a king's ransom." Dry weather in March is generally favourable to the production of grain on clay lands; and hence a "dusty March" portended a plenteous season; while, on the contrary, a "wet March" frequently proved destructive of both wheat and rye.

The principal fixed days now observed and noted in the course of this month are the following:—March 1st, St David; March 12th, St Gregory; March 17th, St Patrick; and March 25th, Lady Day, one of the established quarter-days in England.

MARCHE, a former province of central France, was bounded on the N. by Berri, on the N. E. by Bourbonnais, on the E. by Auvergne, on the S. by Limousin, and on the W. by Angoumois and Poitou, embracing the greater part of the modern department of Creuse, a considerable portion of Haute-Vienne, and fragments of Charente and Indre. It derived its name from the circumstance of its being the "mark" or boundary between Poitou and Berri; it is sometimes referred to as Marche Limousine. It is first mentioned in history as a separate fief about the middle of the 10th century, when the countship of Marche was committed by Duke William III. of Aquitania to Boso I., count of Limoges and Charroux.

MARCHENA, a town of Spain, in the province of Seville, lies in a sandy valley, not far from the Corbones, a tributary of the Guadalquivir, about 30 miles east-south-east from Seville. It is a station on the line by which Seville and Utrera are connected with Osuna and the Cordova-Malaga line. Formerly it was surrounded with walls and towers, of which some traces still remain. Among the principal buildings is the palace of the dukes of Arcos (descendants of Ponce de Leon), within the enclosure of which is an ancient Moorish building, now the church of Santa Maria de la Mota, with a tower of considerable architectural merit. The ancient parish church of San Juan, rebuilt in 1490, has five naves. At the eastern end of the town is a sulphur spring which is a place of considerable resort for the cure of cutaneous diseases. The manufactures of the place are unimportant; there is some trade in the wheat, barley, olives, oil, and wine produced in the neighbourhood. The population in 1877 was 13,768. Marchena (the *Castra Gemina* of Pliny?) was taken from the Moors by St Ferdinand in 1240, and was presented to Ponce de Leon by Ferdinand IV. in 1309.

MARCIAN (MARCIANUS), emperor of the East from 450 to 457, was born in a private station of life in Illyria or Thrace, about the year 391, and at an early age entered the army, where after a considerable term of obscurity he attracted the attention of Ardaburius and subsequently of Aspar, being made military secretary and a captain in the guards. He accompanied Aspar in the ill-fated expedition against Genseric, by whom he was taken prisoner, but soon released. In 450, having in the meantime become tribune and senator, he went through the form of marriage with Pulcheria, the sister and successor of Theodosius II., and was crowned on August 25. In 451 he assembled the œcumenical council of Chalcedon, at which the proceedings of the "robber-synod" of Ephesus were annulled, and the Eutychian heresy condemned, a service to orthodoxy which has greatly endeared his memory to the minds of Catholic historians. In 452 his generals Ardaburius and Maximin respectively gained victories of some importance over the Arabs near Damascus and over the Blemmyes who had invaded the Thebaid; and after the death of Attila (453) he set about the task of repopulating the extensive tracts which had been devastated by the Huns. He maintained the peace of his dominions during the troubles which convulsed the Western empire in 455; and in 456 his arms were free to repress disturbances in Lazica which had been fomented by the Armenians and Persians. He died in 457, and was succeeded by Leo I.

MARCION AND THE MARCIONITE CHURCHES. In the period between 130 and 180 A.D. the varied and complicated Christian fellowships in the Roman empire crystallized into close and mutually exclusive societies[1]—churches with fixed constitutions and creeds, schools with distinctive esoteric doctrines, associations for worship with peculiar mysteries, and ascetic sects with special rules of conduct. Of churchly organizations the most important, next to catholicism, was the Marcionite community. Like the catholic church, this body professed to comprehend everything belonging to Christianity. It admitted all believers without distinction of age, sex, rank, or culture. It was no mere school for the learned, disclosed no mysteries for the privileged, but sought to lay the foundation of the Christian community on the pure gospel, the authentic institutes of Christ. The pure gospel, however, Marcion found to be everywhere more or less corrupted and mutilated in the Christian circles of his time. His undertaking thus resolved itself into a reformation of Christendom. This reformation was to deliver Christendom from false Jewish doctrines by restoring the Pauline conception of the gospel,—Paul being, according to Marcion, the only apostle who had rightly understood the new message of salvation as delivered by Christ. In Marcion's own view, therefore, the founding of his church—to which he was first driven by opposition—amounts to a reformation of Christendom through a return to the gospel of Christ and to Paul; nothing was to be accepted beyond that. This of itself shows that it is a mistake to reckon Marcion among the Gnostics. A dualist, we shall see, he certainly was, but he was not a Gnostic. For he ascribed salvation, not to "knowledge" but to "faith"; he appealed openly to the whole Christian world; and he nowhere consciously added foreign elements to the revelation given through Christ. It is true that in many features his Christian system—if we may use the expression—resembles the so-called Gnostic systems; but the first duty of the historian is to point out what Marcion plainly aimed at; only in the second place have we to inquire how far the result corresponded with those purposes.

The doctrines of Marcion and the history of his churches from the 2d to the 7th century are known to us from the controversial works of the catholic fathers. From Justin downwards, almost every eminent church teacher takes some notice of Marcion, while very many write extensive treatises against him. The most important of those which have come down to us are the controversial pieces of Irenæus (in his great work against heretics), Tertullian (*Adv. Marc.*, i.–v.), Hippolytus, Pseudo-Origen Adamantius, Epiphanius, and the Armenian Esnik. From these works the contents of the Marcionite Gospel, and also the text of Paul's epistles in Marcion's recension, can be settled with tolerable accuracy. His opponents, moreover, have preserved some expressions of his, with extracts from his principal work; so that our knowledge of Marcion's views is in part derived from the best sources.

Marcion was a wealthy shipowner, belonging to Sinope in Pontus. He appears to have been a convert from paganism to Christianity, although it was asserted in later times that his father had been a bishop. That report is probably as untrustworthy as another, that he was excommunicated from the church for seducing a virgin. What we know for certain is that after the death of Hyginus (or *c.* 139 A.D.) he arrived, in the course of his travels, at Rome, and made a handsome donation of money to the local church. Even then, however, the leading features of his peculiar system must have been already thought out. At Rome he tried to gain acceptance for them in the college of presbyters and in the church; indeed he had previously made similar attempts in Asia Minor. But he now encountered such determined opposition from the majority of the congregation that he found it necessary to withdraw from the great church and establish in Rome a community of his own. This was about the year 144. The new society increased in the two following decades; and very soon numerous sister-churches were flourishing in the east and west of the empire. Marcion took up his residence permanently in Rome, but still undertook journeys for the propagation of his opinions. In Rome he became acquainted with the Syrian Gnostic Cerdo, whose speculations influenced the development of the Marcionite theology. Still Marcion seems never to have abandoned his design of gaining over the whole church to his gospel. The proof of this is found, partly in the fact that he tried to establish relations with Polycarp of Smyrna,—from whom, to be sure, he got a sharp rebuff,—partly in a legend to the effect that towards the end of his life he sought re-admission to the church. Such, presumably, was the construction put in after times on his earnest endeavour to unite Christians on the footing of the "pure gospel." When he died is not known; but his death can scarcely have been much later than the year 165.

The distinctive teaching of Marcion originated in a comparison of the Old Testament with the gospel of Christ and the theology of the apostle Paul. Its motive was not cosmological or metaphysical, but religious and historical. In the gospel he found a God revealed who is goodness and love, and who desires faith and love from men. This God he could not discover in the Old Testament; on the contrary, he saw there the revelations of a just, stern, jealous, wrathful, and variable god, who requires from his servants blind obedience, fear and outward righteousness. Overpowered by the majesty and novelty of the Christian message of salvation, too conscientious to rest satisfied with the ordinary attempts at the solution of difficulties, while yet he was in no position to reach an historical insight into the relation of Christianity to the Old Testament and to Judaism—who indeed was so in those days?—he believed that he expressed Paul's view by the hypothesis of two Gods: the just God of the law (the God of the Jews, who is also the Creator of the world), and the good God, the Father of Jesus Christ. Paradoxes in the history of religion and revelation which Paul draws out, and which Marcion's contemporaries passed by as utterly incomprehensible, are here made the foundation of an ethico-dualistic conception of history and of religion. It may be said that in the 2d century only one Christian—Marcion—took the trouble to understand Paul; but it must be added that he misunderstood him. The profound reflexions of the apostle on the radical antithesis of law and gospel, works and faith, were not appreciated in the 2d century. Marcion alone perceived their decisive religious importance, and with them confronted the legalizing, and in this sense Judaizing, tendencies of his Christian contemporaries. But the Pauline ideas lost their truth under his treatment; for, when it is denied that the God of redemption is at the same time the almighty Lord of heaven and earth, the gospel is turned upside down.

The assumption of two gods necessarily led to cosmological speculations. Under the influence of Cerdo, Marcion carried out his ethical dualism in the sphere of cosmology; but the fact that his system is not free from contradictions is the best proof that all along religious knowledge, and not philosophical, had the chief value in his eyes. The main outlines of his teaching are as follows. Man is, in spirit, soul, and body, a creature of the just and wrathful god. This god created man from Hyle (matter),[1] and imposed on him a strict law. Since no one could keep this law, the whole human race fell under the curse, temporal and eternal, of the Demiurge. Then a higher God, hitherto unknown, and concealed even from the

[1] On the relation of matter to the Creator Marcion himself seems not to have speculated, though his followers may have done so.

Demiurge, took pity on the wretched, condemned race of men. He sent His Son (whom Marcion probably regarded as a manifestation of the supreme God Himself) down to this earth in order to redeem men. Clothed in a visionary body, in the likeness of a man of thirty years old, the Son made His appearance in the fifteenth year of Tiberius, and preached in the synagogue at Capernaum. But none of the Jewish people understood Him. Even the disciples whom He chose did not recognize His true nature, but mistook Him for the Messiah promised by the Demiurge through the prophets, who as warrior and king was to come and set up the Jewish empire. The Demiurge himself did not suspect who the stranger was; nevertheless he became angry with Him, and, although Jesus had punctually fulfilled his law, caused Him to be nailed to the cross. By that act, however, he pronounced his own doom. For the risen Christ appeared before him in His glory, and charged him with having acted contrary to his own law. To make amends for this crime, the Demiurge had now to deliver up to the good God the souls of those who were to be redeemed; they are, as it were, purchased from him by the death of Christ. Christ then proceeded to the underworld to deliver the spirits of the departed. It was not the Old Testament saints, however, but only sinners and malefactors who obeyed His summons. Then, to gain the living, Christ raised up Paul as His apostle. He alone understood the gospel, and recognized the difference between the just God and the good. Accordingly, he opposed the original apostles with their Judaistic doctrines, and founded small congregations of true Christians. But the preaching of the false Jewish Christians gained the upper hand; nay, they even falsified the evangelical oracles and the letters of Paul. Marcion himself was the next raised up by the good God, to proclaim once more the true gospel. This he did by setting aside the spurious gospels, purging the real Gospel (the Gospel of Luke) from supposed Judaizing interpolations, and restoring the true text of the Pauline epistles. He likewise composed a book, called the *Antitheses*, in which he proved the disparity of the two gods, from a comparison of the Old Testament with the evangelical writings.

On the basis of these writings Marcion proclaimed the true Christianity, and founded churches. He taught that all who put their trust in the good God, and His crucified Son, renounce their allegiance to the Demiurge, and approve themselves by good works of love, shall be saved. But he taught further—and here we trace the influence of the current Gnosticism on Marcion—that only the spirit of man is saved by the good God; the body, because material, perishes. Accordingly his ethics also were thoroughly dualistic. By the "works of the Demiurge," which the Christian is to flee, he meant the whole "service of the perishable." The Christian must shun everything sensual, and especially marriage, and free himself from the body by strict asceticism. The original ethical contrast of "good" and "just" is thus transformed into the cosmological contrast of "spirit" and "matter." The good God appears as the god of spirit, the Old Testament god as the god of matter. That is Gnosticism; but it is at the same time illogical. For, since, according to Marcion, the spirit of man is derived, not from the good, but from the just God, it is impossible to see why the spiritual should yet be more closely related to the good God, than the material. There is yet another direction in which the system ends with a contradiction. According to Marcion, the good God never judges, but everywhere manifests His goodness,—is, therefore, not to be feared, but simply to be loved, as a father. But here the question occurs, What becomes of the men who do not believe the gospel? Marcion answers, The good God does not judge them, but merely removes them from His presence. Then they fall under the power of the Demiurge, who—rewards them for their fidelity? No, says Marcion, but on the contrary—punishes them in his hell! The contradiction here is palpable; and at the same time the antithesis of "just" and "good" ultimately vanishes. For the Demiurge now appears as an inferior being, who in reality executes the purposes of the good God. It is plain that dualism here terminates in the idea of the sole supremacy of the good God.

It is not surprising, therefore, that even in the 2d century the disciples of Marcion diverged in several directions. Rigorous asceticism, the rejection of the Old Testament, and the recognition of the "new God" remained common to all Marcionites, who, moreover, like the catholics, lived together in close communities ruled by bishops and presbyters (although their constitution was originally very loose, and sought to avoid every appearance of "legality"). Some, however, accepted three first principles (the evil, the just, the good); others held by two, but regarded the Demiurge as the god of evil, *i.e.*, the devil; while a third party, like Apelles, the most distinguished of Marcion's pupils, saw in the Demiurge only an apostate angel of the good God,—thus returning to monotheism. The golden age of the Marcionite churches falls between the years 150 and 250. During that time they were really dangerous to the great church; for in fact they maintained certain genuine Christian ideas, which the catholic church had forgotten. From the beginning of the 4th century they began to die out in the West; or rather they fell a prey to Manichæism. In the East also many Marcionites went over to the Manichæans; but there they survived much longer. They can be traced down to the 7th century, and then they seem to vanish. But it was unquestionably from Marcionite impulses that the new sects of the Paulicians and Bogomiles arose; and in so far as the western Katharoi, and the antinomian and anticlerical sects of the 13th century are connected with these, they also may be included in the history of Marcionitism.

Literature.—Baur, *Die Gnosis*, 1835; Möller, *Geschichte der Kosmologie in der griechischen Kirche*, 1860; Lipsius, *Gnosticismus*, 1860; Harnack, *Zur Quellenkritik der Geschichte des Gnosticismus*, 1873, and in the *Zeitschrift f. hist. Theol.*, 1874; Harnack, *De Apellis gnosi monarchica*, 1874; Lipsius, *Quellen der ältesten Ketzergeschichte*, 1875; Mansel, *The Gnostic Heresies*, 1875; Harnack, *Zur Geschichte der Marcionitischen Kirchen* (Hilgenfeld's *Zeitschrift*, 1876). Of the numerous works on Marcion's Gospel and Apostolos lists will be found in any introduction to the New Testament or history of the canon. The following are the ascertained results of criticism:—(1) Marcion was the first to make a canonical collection of New Testament writings; (2) his Gospel is to be regarded as a reconstruction, and not as the basis, of our canonical Gospel of Luke. (A. HA.)

MARCO POLO. See Polo.

MARCUS, the successor of Pope Sylvester I., according to the Liberian catalogue, had a pontificate of eight months and twenty days, from January 18 to October 7, 336. Of his character or history nothing is recorded. He was succeeded by Julius I.

MÁRDÍN, a town of Turkish Kurdistan, the seat of a governor dependent on the pasha of Diarbekir, is situated in 37° 20′ N. lat. and 41° E. long., about 60 miles south-east of Diarbekir, at a height of 3900 feet above the sea. Climbing the southern side of a steep conical hill (of soft limestone) in such a way that the roofs of the lower tier of houses serve as a street for those immediately above, Márdín presents a very picturesque appearance; and on the summit of the hill, which affords an unusually wide view over the Mesopotamian plain, stand the ruins of the famous castle Kal'ah Shubbá (Maride and Marde in Latin, and similarly in Syriac), which, at least from the time of the Romans, played an important part in the history of this region. The Arabian geographers characterize it as impregnable; and, the approaches being extraordinarily steep, narrow, and well arranged for purposes of defence, it was able to offer a protracted resistance to the Mongolian conqueror Hulagu, and to the armies of Timur. The castle was for hundreds of years the residence of princes more or less independent. The town has not much commerce or industry, but the surrounding country is distinguished for its excellent water and general fertility, and more especially for its fruit trees and, melons. As regards their capacity and the honesty of their dealings, the people of Márdín do not enjoy the best reputation. They are estimated to number from 15,000 to 18,000; in 1870 Professor Socin was informed in the town that there were 600 Jacobite, 300 Catholic Armenian, 200 Catholic Syrian, 30 Chaldæan, and 57 Protestant families. Among the Jacobites are included a few remnants of the old sect called Shemsiye. See Ritter, *Erdkunde von Asien*, 2d ed., vol. vii.

MARGARET of Anjou, who became the queen of Henry VI. of England, was born at Pont à Mousson in Lorraine on the 24th[1] March 1429. Her father, "the good King René," as he was called in later years, did not at the time of her birth possess any of the pompous titles to which he afterwards laid claim, but was simply count of Guise, and younger brother of the existing duke of Anjou. He had, however, married Isabella, daughter of Charles II., duke of Lorraine, and during Margaret's infant years he succeeded to two dukedoms, first Lorraine and then Anjou, and afterwards to the crowns of Naples, Sicily, and Jerusalem. Some of these acquisitions, however, were no more than empty titles. He had a competitor for the duchy of Lorraine against whom he was unsuccessful in war, and he was actually a prisoner in the hands of the duke of Burgundy when the death of Joan II. of Naples first made him nominally a king. He deputed his wife Isabella to go to Naples and take possession of his new kingdom for him, and she took with her while on this enterprise her second son Louis and her second daughter Margaret, then in her seventh year. René himself obtained his liberty after a time, and followed his wife to Naples, but, being defeated by a rival there also, he returned to France after more than four years' absence. Before revisiting Lorraine or Anjou, he spent some time in Provence, and there received a proposal for the marriage of Margaret, who had by this time nearly completed her fourteenth year, from Charles, count of Nevers. It was accepted, and the contract was actually signed; but the marriage was delayed on account of some disputes about the settlement, and next year it was set aside for the more splendid match offered by the king of England.

This was in 1444. The earl, afterwards duke, of Suffolk, had proposed the match to Henry VI. as a means of terminating the long war with France, and securing peace upon a solid basis. Henry fully entered into the scheme, and was content for so great an object, not only to accept a bride without a dowry, but to give up to King René the provinces of Anjou and Maine. A great embassy was sent over to France, with Suffolk himself at its head, to negotiate the matter, and some months later the marriage was celebrated by proxy at Tours, Suffolk acting as Henry's representative. In April of the following year, 1445, Margaret crossed the Channel, and was received by Henry on her landing at Porchester. A few days later, 22d April, they were married in Tichfield Abbey, or, as some other authorities say, at Southwick,[2] and on Sunday the 30th of May Margaret was crowned at Westminster. Suffolk was now high in favour at court, but the policy he had pursued of giving up territory for the sake of peace was not likely to be generally acceptable in itself, and the events of the next few years completed his unpopularity. War broke out again with France in 1449, and in the course of a single year the whole of Normandy was lost to the English. Suffolk was impeached by the Commons, and the king was persuaded that the best way to protect him was to order him to quit the country. But he was taken and murdered at sea, and for some time the country was in a state of fearful anarchy. Margaret's position was now one that required great tact and delicacy. The king's marriage was already unpopular, and the fact was soon manifest that his wife possessed far higher abilities and greater power of governing than himself. This, together with the king's occasional attacks of mental imbecility, was really the great source of her misfortunes. During Henry's intervals of sanity it was she who really governed, and unfortunately she gave her whole support to the duke of Somerset, whose mismanagement abroad had been the immediate cause of the loss of Normandy. The duke of York vainly endeavoured to procure Somerset's removal, but he was so protected by the court that the complaints of his accuser were utterly unheeded, except during the king's periods of total incapacity, when the lords made York protector. Civil war at last broke out, and Somerset fell at St Alban's in 1455. Party feeling was bitterly exasperated, and Margaret, as we learn from a contemporary French historian, actually instigated an attack on Sandwich by the French out of hatred to the duke of York. At length, in 1460, that nobleman openly challenged the crown as his right and obtained from parliament, with the consent of Henry himself, a settlement of the succession in his favour. But at this time Margaret was out of the way. The king had been taken prisoner the year before by the Yorkists at the battle of Northampton, and she had sought refuge in Wales and Scotland along with her only son Edward, prince of Wales, then seven years old, who was now disinherited. Margaret's friends took up her cause in the north of England, and the duke of York, going to meet them, fell at the battle of Wakefield, 30th December 1460. Margaret naturally endeavoured to improve her victory by marching on to London. But Edward, earl of March, the duke of York's son, defeated her adherents on the borders of Wales, while the earl of Warwick with the king in his custody left London to oppose her. The ill-disciplined troops that she brought with her from the north ravaged the country as they went, and made themselves generally detested. But they overthrew Warwick's forces at St Alban's (the second battle fought there in this war), and liberated the king. The earl of March, however, soon came up and entered London, where he was proclaimed king by the name of Edward IV., amid the shouts of the citizens, who had always been devoted to his father. Margaret then thought it advisable to withdraw into the north along with Henry and her son, and Edward and Warwick pursued them into Yorkshire, where the bloody battle of Towton (29th March 1461) utterly crushed for the time the hopes of the house of Lancaster. Henry and Margaret fled to Scotland, and surrendered Berwick to the Scots as the price of their assistance. Margaret and her son soon after entered England with a body of Scots, who besieged Carlisle, but they were driven back by Lord Montague. Then King Henry accompanied another invasion into the county of Durham which was equally unsuccessful. Next year (1462) Margaret sailed from Kirkcudbright to seek aid in France, and offered the surrender of Calais to Louis XI. if Louis enabled her husband to regain his kingdom. Louis gave her two

[1] Most authorities say the 23d, but according to the MS. *Heures* of René, cited in the *Nouvelle Biographie Générale*, the day was the 24th.

[2] Southwick, according to Fabyan, who is followed by Hall and later writers; but William Wyrcestre and the anonymous author of the *English Chronicle* edited by Davies for the Camden Society, who are both strictly contemporary, say Tichfield.

thousand men under the command of Pierre de Brézé, and with these she made a descent upon Northumberland and took Bamborough and some other castles, which, however, were soon after besieged by King Edward's forces, and after a while recovered. King Edward himself, on hearing of her landing, hastened into the north, on which Margaret took ship to sail for France, but meeting with a storm was driven to land at Berwick and lost all her treasure. On the total failure of this expedition the well-known story is told by a French writer of her wandering with her son in a forest where she was attacked by robbers, and appealing successfully to the loyalty of one of them to save the son of his king.

Soon after, in April 1463,[1] she sailed to Flanders and sought the aid of Philip of Burgundy, but he declined to do more than relieve her poverty, and she retired to a castle in Lorraine, which her father gave her to occupy. Here Sir John Fortescue, who accompanied her into exile, superintended the education of her son, and composed for his benefit his celebrated treatise on the laws of England. Here also she apparently remained while her husband made further efforts and met with further defeats,—while he lay concealed, for more than a year, in Lancashire, was taken prisoner, and committed to the Tower. But in 1470, when her old enemy the earl of Warwick, having rebelled against King Edward, sought a refuge in France, Louis XI. induced her, though with great difficulty, to pardon him and concert measures along with him for her husband's restoration to the throne. The negotiation was cemented by an agreement for the marriage of her son, the prince of Wales, to the earl's daughter after the kingdom should be recovered, and so successful was the project that Edward was actually driven into exile, and for a period of six months Henry was again acknowledged as king. But the return of King Edward and the battle of Barnet once more changed the aspect of affairs before Margaret was able to rejoin her husband, and when she at length landed again in England she was defeated and taken prisoner at Tewkesbury. To add to her misery her only son Prince Edward was butchered after the battle. Four years later, in 1475, on peace being made between England and France, she was ransomed by Louis XI., and returned to her native country. She died at Dampierre near Saumur in Anjou, on the 25th of August 1482.

Principal Authorities.—Bourdigné, *Chroniques d'Anjou et du Maine*; Villeneuve Bargemont, *Histoire de René d'Anjou*; William Wyrcestre, *Annals*, edited by Hearne (with *Liber Niger Scaccarii*); *Fragment relating to Edward IV.*, ed. Hearne (with *Sprott's Chronicle*); *English Chronicle*, ed. Dupont; Lord Clermont's edition of the *Works* of Sir John Fortescue. Mrs Hookham's *Life and Times of Margaret of Anjou* (London, 8vo, 1872) is an elaborate and useful work, but not always accurate and discriminating in the use of authorities.

MARGARET OF AUSTRIA (1480-1530), duchess of Savoy, and regent of the Netherlands from 1507 to 1530, was the daughter of the emperor Maximilian and Mary of Burgundy, and was born at Brussels on January 10, 1480. In 1482 she was betrothed to Charles, the son of Louis XI. (afterwards Charles VIII. of France); and in 1497 she was actually married to the infante John of Aragon, who left her a widow a few months afterwards. In 1501 she became the wife of Philibert II. of Savoy, who only survived until 1504; and in 1507 she was entrusted by Maximilian with the regency of the Netherlands and also with the charge of his grandson Charles. She died at Mechlin in 1530.

[1] This is clearly the date intended by William Wyrcestre (p. 496); and it agrees entirely with Monstrelet (iii. 96). Yet almost all modern historians (except Lingard) and even biographers of Margaret of Anjou date her departure to Flanders after the battle of Hexham, at which she certainly was not present, as they would have her.

MARGARET OF AUSTRIA (1522-1586), duchess of Parma, and regent of the Netherlands from 1559 to 1567, was a natural daughter of Charles V. by Margaret van Gheenst, a Flemish lady, and was born at Brussels in 1522. In 1533 she was married to Alexander, duke of Florence; and, having been left a widow in 1537, she became the wife of Ottavio Farnese, duke of Parma, in 1542. The union proved an unhappy one, and she for the first time found a sphere for her somewhat masculine abilities in the Netherlands, which were entrusted to her care by her brother Philip II. of Spain on his departure for the peninsula in 1559 (see HOLLAND, vol. xii. pp. 74, 75). It was with much reluctance that she resigned the reins of power into the hands of the duke of Alva in 1567 and retired to Italy. Before her death, which occurred at Ortona in 1586, she had the satisfaction of seeing her son Alexander Farnese appointed to the government which she had occupied some twenty years before.

MARGARET, ST, queen of Scotland, born in Hungary about 1040, was a daughter of Edward the Atheling, son of Edmund Ironside; her mother was Agatha, most probably a niece of Queen Gisela of Hungary and of the emperor Henry II. She accompanied her father to England in 1057, and after the Norman Conquest she was brought (1068) to Scotland, where she became the wife of Malcolm Canmore in the spring of 1069. She survived her husband, who died in November 1093, by only a few days (see SCOTLAND). The chroniclers all agree in depicting Queen Margaret as a strong, pure, noble character, who had very great influence over her husband, and through him over Scottish history, especially in its ecclesiastical aspects. Her religion, which was genuine and intense, was of the newest Roman style; and to her are attributed a number of reforms by which the Church of Scotland was considerably modified from the insular and primitive type which down to her time it had exhibited. Among those expressly mentioned are a change in the manner of observing Lent, which thenceforward began as elsewhere on Ash Wednesday and not as previously on the following Monday, and the abolition of the old practice of observing Saturday (Sabbath), not Sunday, as the day of rest from labour (see Skene's *Celtic Scotland*, book ii. chap. 8). Her sons Edgar, Alexander, and David successively occupied the throne of Scotland; her elder daughter, Matilda, became the wife of Henry I. of England in 1101. Margaret was canonized by Innocent IV. in 1251, and by Clement X. she was made patroness of Scotland. Her festival (semi-duplex) is observed by the Roman Church on June 10.

MARGARET (1283-1290), known in Scottish history as the "Maid of Norway," was, through her mother Margaret, who had been married to Eric of Norway, the only grandchild of Alexander III. of Scotland, and was born in Norway in 1283. At the death of her grandfather (1286), while she was still an infant, Edward I. of England arranged for her betrothal to his son, but this policy was defeated by her early death, which took place, it was alleged, in Orkney, as she was on her way to Scotland, in 1290. The circumstances of her death were so obscure that doubts were entertained in some quarters whether she had not rather been spirited away. About 1300 a woman presented herself in Leipsic as the long-lost queen of Scotland; ultimately, however, she was burnt at Bergen as an impostor.

MARGARET OF VALOIS. See MARGUERITE.

MARGARITA, an island in the Caribbean Sea, about 8 miles off the coast of Venezuela, constituting along with the lesser islands Blanquilla and Hermanos the new state of Nueva Esparta. It has an area of 400 square miles, consists of two portions united by a low and narrow isthmus, is generally mountainous, and attains its greatest elevation of 4630 feet in Mont Macanao. The pearls from which Margarita takes its name, and which proved a considerable source of wealth in the 16th and 17th centuries, are no longer sought after; but the ordinary fisheries are actively prosecuted, and since the War of Independence, agriculture, trade, and industry have all greatly improved. Pompatar is the only harbour, Pueblo del Norte and Pueblo de la Mar being rather open roadsteads. Asuncion, the chief town, contains about 3000 inhabitants. The population of the island was 16,200 in 1807 (about 8000 being whites), and that of the state 30,983 in 1873.

Discovered by Columbus in 1498, Margarita was in 1524 bestowed by Charles V. on Marceto Villalobos. In 1561 it was ravaged by Lopez de Aguirre, a notorious freebooter, and in 1662 the town of Pompatar was destroyed by the Dutch. Long included in the government of Cumana, Margarita attained administrative independence only in the 18th century. In the War of Independence the inhabitants made an effective stand against Murillo; and to this they owe the honour of having their island erected into the state of New Sparta.

MARGARITA, St, virgin and martyr, is celebrated by the Church of Rome on July 20, but her feast formerly fell on the 13th, and her story is almost identical, even in the proper names, with that of the Greek St Marina (July 17). She was of Antioch (in the Greek story Antioch of Pisidia), daughter of a priest Ædesius. She lived in the country with a foster mother, scorned by her father for her Christian faith, and keeping sheep. Olybrius the "præses Orientis" sees her and offers his hand as the price of renunciation of Christianity. Her refusal leads to her being cruelly tortured, and after various miraculous incidents, in which a heavenly dove plays a prominent part, she is put to death. Women prayed to St Margarita for easy deliverance. It has been shown by H. Usener (*Legenden der heiligen Pelagia*, Bonn, 1879) that this legend belongs to a group of curious narratives which all have their root in a transformation of the Semitic Aphrodite into a Christian penitent or saint. Of these legends that of St Pelagia (*q.v.*) is perhaps the most important. Marina is a translation of Pelagia, and both are epithets of Aphrodite as she was worshipped on the coasts of the Levant. Pelagia in the legend has Margarito as her second name. The association of the marine goddess with the pearl is obvious, and the images of Aphrodite were decked with these jewels.

MARGATE, a municipal borough, market-town, and watering-place of Kent, England, is situated in the Isle of Thanet, 4 miles west of North Foreland, and by rail 90 miles east of London, with which it has also in summer daily steam communication by water. The streets of the town are regular and spacious, and there are many good villas in the suburbs. There is a marine terrace 2500 feet in length, parallel to which there is an esplanade. The pier, 900 feet long, was constructed by Rennie in 1810. A landing-place permitting the approach of vessels at all tides was constructed in 1854, and enlarged in 1876. The church of St John the Baptist, founded in 1050, contains some portions of Norman architecture, the remainder being Decorated and Late Perpendicular. It possesses several fine brasses and monuments. Among the other public buildings are the new town-hall, the market, the assembly rooms, the deaf and dumb asylum, and the royal sea-bathing infirmary, which has lately been much enlarged through the munificence of Sir Erasmus Wilson. The old name of Margate was *Meregate*, the entrance to the sea. Previous to the last century it was only a fishing village with a small coasting trade, but since then, owing principally to its fine stretch of sand, it has been steadily rising into favour as a watering-place, and is now one of the most favourite resorts of the middle classes of London. It received municipal privileges in 1857. The population of the municipal borough (384 acres) in 1871 was 11,995, and in 1881 it was 15,889.

MARGHILAN, Baber's Marghinan, 40° 28′ N. lat., 71° 45′ E. long., now the administrative centre of the Russian province of Ferghana (*q.v.*), a very old town, with high earthen walls and twelve gates, commanded by the fort of Yar Mazar, lies in a beautiful and extraordinarily fertile district of the same name, irrigated by canals from the Shahimardán river. The heat in summer is excessive. Population about 40,000, chiefly Usbeg. The principal industry is the production and manufacture of silk; camels' hair and woollen fabrics are also made. The new Russian town, planned by General Skobeleff, is 15 versts distant.

MARGUERITE de Valois. The name Marguerite was common in the Valois dynasty, and during the 16th century there were three princesses, all of whom figure in the political as well as in the literary history of the time, and who have been not unfrequently confounded. The first and last are the most important, but all deserve some account.

I. Marguerite d'Angoulême (1492–1549). This, the most celebrated of the Marguerites, bore no less than four surnames. By family she was entitled to the name of Marguerite de Valois; as the daughter of the Count d'Angoulême she is more properly and by careful writers almost invariably called Marguerite d'Angoulême. From her first husband she took during no small part of her life the appellation Marguerite d'Alençon, and from her second, Henri d'Albret, king of Navarre, that of Marguerite de Navarre. She was born at Angoulême on the 12th April 1492, and was two years older than her brother Francis I. She was betrothed early to Charles, Duke d'Alençon, and married him in 1509. She was not very fortunate in this first marriage, but her brother's accession to the throne made her, with their mother Louise of Savoy, the most powerful woman of the kingdom. She became a widow in 1525, and was sought in marriage by many persons of distinction, including, it is said, Charles V. and Henry VIII. In 1527 she married Henri d'Albret, titular king of Navarre, who was considerably younger than herself, and whose character was not faultless, but who seems on the whole, despite slander, to have both loved and valued his wife. Navarre was not reconquered for the couple as Francis had promised, but ample apanages were assigned to Marguerite, and at Nérac and Pau miniature courts were kept up, which yielded to none in Europe in the intellectual brilliancy of their frequenters. Marguerite was at once one of the chief patronesses of letters that France possessed, and the chief refuge and defender of advocates of the Reformed doctrines. Round her gathered Marot, Bonaventure Desperiers, Denisot, Peletier, Brodeau, and many other men of letters, while she protected Rabelais, Dolet, &c. For a time her influence with her brother was effectual, but latterly political rather than religious considerations made him discourage Lutheranism, and a fierce persecution was begun against both Protestants and freethinkers, a persecution which drove Desperiers to suicide and brought Dolet to the stake. Marguerite herself, however, was protected by her brother, and her personal inclinations seem to have been rather towards a mystical pietism than towards dogmatic Protestant sentiments. Nevertheless bigotry and the desire to tarnish the reputation of women of letters have led to the bringing of odious accusations against her character, for which there is not the smallest foundation. Marguerite died in 1549. By her first husband she had no children, by her second a son who died in infancy, and a daughter, Jeanne d'Albret, who became the mother of Henry IV. Although the poets of the time are unwearied in celebrating her charms, she does not, from the portraits which exist, appear to have been regularly beautiful, but as to her sweetness of disposition and strength of mind there is universal consent.

Her literary work has not yet been given entirely to the world, but the printed portion of it makes her a considerable figure in French literature. It consists of the *Heptameron*, of poems entitled *Les Marguerites de la Marguerite des Princesses*, and of *Letters*. The *Heptameron*, constructed as its name indicates on the lines of the *Decameron* of Boccaccio, consists of seventy-two short stories told to each other by a company of ladies and gentlemen who are stopped in the journey homewards from Cauterets by the swelling of a river. It was not printed till 1558, ten years after the author's death. Internal evidence is strongly in favour of its having been a joint work, in which more than one of the men of letters who composed Marguerite's household took part. It is a delightful book, and strongly characteristic of the French Renaissance. The sensuality which characterized the period appears in it, but in a less coarse form than in the great work of Rabelais; and there is a poetical spirit which, except in rare instances, is absent from *Pantagruel*. The *Letters* are interesting and good. The *Marguerites* consist of a very miscellaneous collection of poems, mysteries, farces, devotional poems of considerable length, spiritual and miscellaneous songs, &c. Other poems, said to be of equal merit, are still unprinted, or have appeared only in part.

II. The second MARGUERITE (1523–1574), daughter of Francis I., married the duke of Savoy in 1559. She is noteworthy as having given the chief impulse at the court of her brother Henry II. to the first efforts of the Pléiade.

III. The third MARGUERITE (1553–1615), called more particularly Marguerite de Valois, was great-niece of the first and niece of the second, being daughter of Henry II. by Catherine de' Medici. She was born in 1553. When very young she became famous for her beauty, her learning, and the looseness of her conduct. She was married to Henry of Navarre, afterwards Henry IV., on the eve of St Bartholomew's Day. Both husband and wife were extreme examples of the licentious manners of the time, but they not unfrequently lived together for considerable periods, and nearly always on good terms. Later, however, Marguerite was established in the castle of Usson in Auvergne, and after the accession of Henry the marriage was dissolved by the pope. But Henry and Marguerite still continued friends; she still bore the title of queen; she visited Marie de' Medici on equal terms; and the king frequently consulted her on important affairs, though his somewhat parsimonious spirit was grieved by her extravagance. Marguerite exhibited during the rest of her life, which was not a short one, the strange Valois mixture of licentiousness, pious exercises, and the cultivation of art and letters, and died in 1615. She left letters and memoirs, the latter of which are admirably written, and rank among the best of the 16th century. She is the "Reine Margot" of anecdotic history and romance.

The best editions of the works of Marguerite d'Angoulême are—of the *Heptameron*, that of Leroux de Lincy, 3 vols., Paris, 1855; of the *Letters*, that of Genin, Paris, 2 vols., 1842–43; and of the *Marguerites*, that of Frank, Paris, 4 vols., 1873; the *Heptameron* is also obtainable in several cheap editions. The *Mémoires* of Marguerite de Valois are contained in the collection of Michaud and Poujoulat, and have been published separately by Guessard, Lalanne, Caboche, &c. (G. SA.)

MARIA THERESA (1717–1780), archduchess of Austria, queen of Hungary and Bohemia, and empress of Germany, was the daughter of the emperor Charles VI. of Austria, by his wife Elizabeth Christina of Brunswick-Wolfenbüttel, and was born in Vienna on May 13, 1717. By the Pragmatic Sanction of 1713, a settlement which was guaranteed by the principal states of Europe, her father had regulated the succession in the imperial family; and in 1724 accordingly, after the death of the archduke Leopold, her only brother, she was publicly declared sole heiress of the Austrian dominions. In 1736 she married Francis Stephen of Lorraine, who in the following year became grand-duke of Tuscany; and on October 20, 1740, she came to the throne, her husband (emperor in 1745) being declared co-regent. The events of her reign have been briefly summarized under AUSTRIA (vol. iii. p. 127–129) and HUNGARY (xii. 370). She died at Vienna on November 29, 1780. Of sixteen children whom she bore to Francis, ten reached maturity. Her sons were Joseph II., who succeeded his father as Holy Roman emperor in 1765; Leopold, grand-duke of Tuscany, afterwards the emperor Leopold II.; Ferdinand, duke of Modena; and Maximilian, elector of Cologne. Of her daughters the best-known is Marie Antoinette, the wife of Louis XVI. of France.

MARIANA, JUAN DE (1536–1624), a celebrated Spanish historian, was born of obscure parentage at Talavera de la Reina in 1536. He studied at the university of Alcalá, and was admitted at the age of seventeen into the Society of Jesus, where he soon attracted notice by his brilliant talents and extensive acquirements. Called to the Collegium Romanum in 1561, he there professed theology four years, and reckoned among his pupils Robert Bellarmine, afterwards the famous cardinal. He then passed into Sicily, where he remained for about two years, and in 1569 he was sent to Paris, where his expositions of the writings of Aquinas attracted large audiences. In 1574 the decline of his health compelled him to give up teaching, and he obtained permission to return to Spain; the rest of his life was passed at the Jesuits' house in Toledo, in a vigorous literary activity which was interrupted only by the molestations to which his too great independence, liberality, and candour exposed him. He died on February 17, 1624.

His great work, *Historiæ de Rebus Hispaniæ*, first appeared in twenty books at Toledo in 1592; ten books were subsequently added (1605), bringing the work down to the accession of Charles V., and in a still later abstract of events the author completed it to the accession of Philip IV. in 1621. It was so well received that Mariana was induced to translate it into Spanish. The first part of this in some respects new work (*Historia de España*) appeared in 1601; it was completed in 1609, and much enlarged and improved in three subsequent editions which appeared during the translator's lifetime. It has been frequently reprinted since 1624, both in Latin and in Spanish; and an English translation by J. Stevens appeared in 1699. Mariana's *History* is justly esteemed for the extent of the author's researches, for the general accuracy of his acquaintance with the materials at his command, for the sagacity of his reflexions and characterizations, and above all for the merit of his style, which, in its simplicity, vividness, and directness, has deservedly been compared to that of Livy. The modern student may regret but can hardly blame the credulity with which in too many cases he has without the least attempt at historical criticism adopted the "received traditions of his country." Of the other works of Mariana, the most interesting is his treatise *De Rege et Regis Institutione*, of which the first edition, dedicated to Philip III., appeared at Toledo in 1599. In its sixth chapter the question whether it is lawful to overthrow a tyrant is freely discussed and answered in the affirmative,—a circumstance which brought much popular odium upon the Jesuits, especially after the assassination of Henry IV. of France in 1610. See Bayle's *Dictionnaire* and Hallam's *Literary History*, part ii. chap. iv. A volume entitled *Tractatus VII. Theologici et Historici*, published by Mariana at Cologne in 1609, containing in particular a tract "On Mortality and Immortality," and another "De Mutatione Monetæ," was put upon the Index Expurgatorius, and led to the confinement and punishment of its author by the Inquisition. During his confinement there was found among his papers a criticism upon the Jesuits (*De las Enfermedades de la Compañia de Jesus y de sus Remedios*), which was believed to have been written by him. It was not printed until after his death (1625).

MARIAZELL, a village in the duchy of Styria, Austria, with about 1200 inhabitants, is very picturesquely situated in the valley of the Salza, amid the Styrian Alps. Its entire claim to notice lies in the fact that it is the most frequented sanctuary in Austria, being visited annually by about 100,000 pilgrims. The object of veneration is a miracle-working image of the Virgin, carved in lime-tree wood, and about 18 inches high. This was presented to the place in 1157, and is now reverently enshrined in a chapel lavishly adorned with objects of silver and other costly materials. The large church of which the chapel forms part was erected in 1644 as an expansion of a smaller church built in 1363 by Louis I., king of Hungary, after a victory over the Turks. It possesses four lofty towers. In the immediate vicinity of Mariazell there is a very large and important iron foundry, formerly worked by Government, but now leased to a company.

MARIE ANTOINETTE, Josephe Jeanne (1755-1793), queen of France, was the fourth daughter of Maria Theresa and the emperor Francis I., and was born on the 2d November 1755, on the day of the great earthquake at Lisbon, and in the year in which the hereditary policy of enmity between the houses of France and Austria was changed to an alliance between them. From her earliest years she was destined by her mother to sustain this alliance, and was educated, with a view to a marriage with a French prince, by the Abbé de Vermond, who was to have a great influence on her future life. In 1770 Choiseul negotiated her marriage to the young dauphin, which took place on May 16 with the greatest pomp, but which was soon overshadowed by a terrible accident in Paris at the fête given in honour of the marriage. The dauphine soon found her position very difficult; she was but fourteen, and was intended by her mother to support the Austrian alliance and Choiseul at the court of France. This use of her daughters for political purposes has been recently denied by Von Arneth, the able editor of Maria Theresa's letters; but a consideration of the letters themselves confirms the idea, which was at the bottom of Marie Antoinette's unpopularity in France, that she was only an Austrian spy in a high position. She had hardly arrived at Paris, when her friend and the friend of the Austrian alliance, Choiseul, was dismissed from the ministry, and she was left alone to steer a difficult course by the advice of the Austrian minister, the Count de Mercy-Argenteau, whose reports of her daily doings to Maria Theresa have been published. In May 1774 Louis XV. died, and Marie Antoinette became queen of France. Through the first years of her reign she played a very important political part, but, except, as in the cases of Poland and the Bavarian succession, when her mother pressed her to maintain the alliance, she chiefly exerted her influence with regard to individuals, not to measures or policies. Thus she effected the dismissal of Turgot, and, by the Abbé de Vermond's advice, the summons of Loménie de Brienne to the ministry, not from political but from personal motives, and obtained enormous presents for her intimate friends without thinking that they were interested in her for selfish motives of their own. This political rôle of hers, which was more than suspected, made her intensely unpopular to the French people, and this feeling was increased by her social mistakes. Her extravagance in dress and her passion for the card-table had greatly incensed and disgusted her mother; and, when her mother's death removed her only frank and bold adviser, she became more extravagant and more frivolous than ever. Her passion for play, her love of amusement, her intimacy with the Polignacs and their wild and dissipated society, her night visits to masked balls in Paris, and her favours to many officers of her guards and young foreigners at her court were the subject of ribald conversation in every coterie of Paris. The scandal of the diamond necklace, in which the queen was not to blame, spread her name with infamy all over France as if she had been guilty; and among the people her extravagance was regarded as a potent cause of their poverty and want. Such was her unpopularity when the states-general met in May 1789; she was believed to be debauched and dissipated, when her real faults were that she was frivolous and careless of public opinion, Austrian at heart, though queen of France, and opposed to Necker as she had been to Turgot, and to all the reforms and economies her husband, Bonhomme Louis, was willing to institute. From July 14 onward Marie Antoinette headed the party of reaction and armed opposition to the Revolution, and became unwittingly the means of her husband's unpopularity and downfall; for she always had influence enough to prevent his carrying out the frank, honest policy of reform which he desired, but not enough to make him adopt hers in its stead, and is to blame for his vacillations in decisive moments. Left to himself, Louis would, from the beginning of his reign, have been a reforming king like Charles III. of Spain, and the great outbreak might have passed over. To trace her policy minutely from 1789 to 1793 is made very difficult by the numerous pretended letters of hers which have been published, and till recently believed in. She inspired the collection of foreign troops round Paris, contrary to the king's opinion, and thus brought on the taking of the Bastille. She was present at the banquet at Versailles which caused the march of the women to Versailles and the transference of the royal family to Paris. When there, she still looked forward to undoing all that had been done, and would never frankly recognize her position. When brought into negotiation with Mirabeau, she refused to trust him or deal frankly with him. Had she done so, she would probably have established a strong constitutional government, but she would not have been the self-willed Marie Antoinette. He advised her to go with the king and royal family to some provincial capital, declare the royal adherence to all the early acts of the assembly, but declare also that its later acts were passed under constraint, and were null and void; but she must not do two things—she must not fly towards the frontier, else she would be suspected of seeking foreign aid, and she must not depend on the army but the people. She would not act while Mirabeau was alive,—she was too independent to act by any one's advice; but when he was dead she did what he had advised her not to do, fled towards the frontier, and to Bouillé's army. The royal family were stopped at Varennes, and brought back to Paris, but from that time were regarded as traitors to France. She had yet two more chances. She might have thrown herself into the hands of Barnave, Duport, and the constitutional party of the constituent assembly, who were ready to rally round their constitutional king, but she would not trust them or take their advice. When she was at the end of her power, when the Tuileries had been stormed, and she was in prison, and the republic proclaimed, Dumouriez was ready, after his victory of Valmy, to turn his army on Paris, dissolve the Jacobins, and re-establish the old constitution, but she would not trust him. It was her last chance. When once the republic was proclaimed, it was evident that Louis must die both to cement its foundations and to remove a dangerous centre of reaction; and in January 1793 Marie Antoinette became a widow, never to the last recognizing that she had sacrificed her husband to her obstinacy and self-will. Harrowing descriptions have been given of her treatment in prison during the few remaining months of her life, but, though she was separated from her children, she had every material comfort, no less a sum than 1110 livres being spent on her food alone between August and October, at the rate of 15 livres a day. At last her trial came on,—a mock trial indeed, as all those of the time, for her execution was determined before she came before the tribunal. Much has been said of the shameful charges made against her; but, shameful as they were, they were based on a confession made by her son, which, though probably forced from him and utterly false, was yet put in evidence. The trial was soon over, and on the same day, October 16, 1793, she was guillotined.

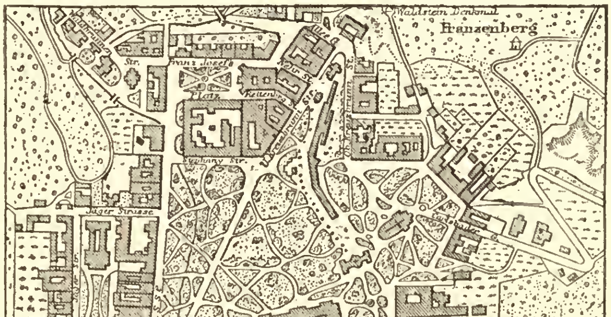
It is hard to speak of Marie Antoinette with justice; her faults were caused by her education and position rather than her nature, and she expiated them far more bitterly than was deserved. She was thoroughly imbued with the imperial and absolutist ideas of Maria Theresa, and had neither the heart nor the understanding to sympathize with the aspirations of the lower classes. Her love of pleasure and of display ruined both her character and her reputation in her prosperous years, and yet, after a careful examination of many of the libels against her, it may be asserted with confidence that she was personally a virtuous woman, though always appearing to be the very reverse. Innocence is not always its own protection, and circumspection is as necessary for a queen as for any other woman. Her conduct throughout the Revolution is heart-rending; we, who live after the troubled times, can see her errors and the results of her pride and her caprice, but at the time she was the only individual of the royal family who could inspire the devotion which is always paid to a strong character. In the Marie Antoinette who suffered on the guillotine we pity, not the pleasure-loving queen, not the widow, who had kept her husband against his will in the wrong course, not the woman, who throughout her married life did not scruple to show her contempt for her slow and heavy but good-natured and loving king, but the little princess, sacrificed to state policy, and cast uneducated and without a helper into the frivolous court of France, not to be loved, but to be suspected by all around her, and eventually to be hated by the whole people of France.

For lives and memoirs of Marie Antoinette before 1863, as well as engravings of her, the student is referred to a complete and careful bio-bibliography, contained in M. de Lescure's *La Vraie Marie Antoinette*, Paris, 1863. This work, however, contains many forged letters, purporting to be hers, and leads to the question of Marie Antoinette's published letters. There can be no doubt that very many fabrications by autograph makers for autograph collectors are published as authentic in D'Hunolstein, *Correspondance inédite de Marie Antoinette*, Paris, 1864; and in Feuillet des Conches, *Louis XVI., Marie Antoinette, et Madame Elisabeth, lettres et documents inédites*, Paris, 1865. The falsity of these letters was shown by Professor Von Sybel and by M. Geffroy in the *Revue des Deux Mondes*, and still more clearly in the latter's appendix to his *Gustave III. et la cour de France*, Paris, 1867. To study Marie Antoinette as she really lived, the student must consult Von Arneth's numerous publications on her and her mother and brothers, and particularly Arneth and Geffroy, *Marie Antoinette: Correspondance secrète entre Marie-Thérèse et le Comte de Mercy-Argenteau*, Paris, 3 vols., 1874, in which Marie Antoinette's daily life for ten years, from 1770–80, is described for her mother's own eyes. For the affair of the necklace read Carlyle's *Essay*. For her imprisonment, trial, and execution, see Campardon's *Tribunal Révolutionnaire*, vol. i., and the same author's *Marie Antoinette à la Conciergerie*, Paris, 1863. (H. M. S.)

MARIE DE FRANCE is one of the most interesting figures in the literary history of the Middle Ages. She is also one of the most mysterious. Nothing is known of her except from her own statements, which amount to little more than that her name was Marie and her country France, that she dedicated one of her works to an unnamed king, and another to a certain Count William. She is mentioned by Denis Pyramus, who was her contemporary, and who says that she was very popular, but gives no particulars. Attempts have been made to identify conjecturally the king and the count,—the most probable hypotheses being that the former was Henry III. of England, and the latter William Longsword of Salisbury; that is to say, Marie lived in the first half of the 13th century, and rather towards the beginning than the end of that half. Her work which remains to us is entirely poetical, and by no means inconsiderable in extent. It falls naturally into three divisions. The first consists of *lais* or narrative poems in octosyllabic couplets. There are fourteen of them, the titles being *Gugemer*, *Equitan*, *Le Frêne*, *Le Bisclavaret*, *Lanval*, *Les deux amants*, *Ywenec*, *Le Laustic* ("the Nightingale"), *Milon*, *Le Chaitivel* ("the Unhappy One"), *Le Chèvrefeuille*, *Eliduc*, *Graelent*, *L'Épine*. The longest of these contains nearly twelve hundred lines; the shortest only just exceeds a hundred. The term *lai* is of Breton origin, and is believed to have had reference originally to the kind of music to which it was performed. But in Marie it is simply a short romance, generally of an amatory character. The merits of these poems are very great. They have much tenderness and delicacy of expression, flowing and melodious verse, and not a little descriptive power. The dialect is decidedly Norman in character, and English words occasionally occur, but are invariably explained in French. Some of these poems were paraphrased by the late Mr O'Shaughnessy in his *Lays of France* (London, 1872), but the translator indulged to such an extent in amplification that the effect is very dissimilar to that of the original. The second division of Marie's work is of less poetical but of greater general interest. It consists of an *Ysopet* (a general term in the Middle Ages for a collection of fables) of one hundred and three fables, of which Marie tells us that Henry Beauclerk translated it from Latin into English, and that for the love of Count William, "the most valiant of this realm," she herself rhymed it from English into French. The fables are exceedingly well told, with a liveliness, elegance of verse, and ingenious aptness of moral which make Marie a worthy forerunner of La Fontaine. The question has been debated whether the great fabulist was acquainted with her work. All that can be said is that, though it is by no means impossible, and from internal evidence not even wholly improbable, it cannot be said to be very likely. The third of Marie's works is a poem of two thousand three hundred verses, describing the purgatory of Saint Patrick, written at the request of an unidentified "prudom," or man of worship. Marie has been longer and better known than most of the poets of mediæval France, and perhaps she has been relatively a little overvalued, but her positive excellence is very considerable. Her style is a good example of the pure and highly organized language of the 13th century; and despite its great age it can be read by any person acquainted with modern French with a very small expense of attention, and with but slight use of glossaries.

The standard edition of Marie's works is by B. de Roquefort, 2 vols., Paris, 1820.

MARIENBAD, one of the prettiest and most frequented watering-places on the Continent of Europe, with a station (about $1\frac{1}{4}$ miles S.E. of the town) on the Kaiser Franz Josephs Railway, lies in a pleasant valley in the district of Tepl, in the north-west of Bohemia, about 18 miles south of Carlsbad, and nearly 2000 feet above the level of the sea. The gently-sloping hills which enclose it on all sides except the south are picturesquely wooded with fragrant pine forests. The town has an attractive and clean appearance, and is amply provided with buildings for the lodging and amusement of its thirteen thousand annual visitors, including a theatre and a large kurhaus. The handsome Roman Catholic church and the tasteful little



Plan of Marienbad.

English church are among the chief ornaments of the place. The springs resemble those of Carlsbad, except that they are cold, and contain nearly twice the quantity of purgative salts. The water is used both internally and externally, and is deemed efficacious in disorders of the stomach and other organs, skin diseases, gout, and nervous complaints. About one million bottles are annually exported. The curative appliances of Marienbad also include the use of goats' milk whey, and peat, pine-cone, and gas baths. The climate is healthy and bracing, the mean annual temperature being about 45° Fahr. The springs of Marienbad, though previously used by the peasantry of the district, first came into general notice about the beginning of this century through the instrumentality of Dr Nehr, to whom a monument was erected here in 1857. They belong to the rich abbey of Tepl, which lies about 9 miles to the east. The permanent population of Marienbad was 2009 at the census of 1880.

MARIENBURG (in Polish, *Malborg*), the chief town of a circle in the district of Dantzic, Prussia, lies 30 miles to the south-east of Dantzic, in a fertile plain on the right bank of the Nogat, a channel of the Vistula, here spanned by a handsome railway bridge and by a bridge of boats. Marienburg contains a large chemical wool-cleaning work and several other factories, carries on a considerable trade in grain, wood, linen, feathers, and brushes, and is the seat of important cattle, horse, and wool markets. Its educational institutions include a gymnasium and a Protestant normal school. In the old market-place, many of the houses in which are built with arcades in the Italian style, stands a Gothic town-house, dating from the end of the 14th century. The town is also embellished with a good statue of Frederick the Great, who added this district to Prussia, and a monument commemorating the war of 1870–71. The population in 1880 was 9559. Marienburg is chiefly interesting from its having been for a century and a half the residence of the grand masters of the Teutonic order. The large castle of the order here was originally founded in 1274 as the seat of a simple commandery against the pagan Prussians, but in 1309 the headquarters of the grand master were transferred hither from Venice, and the "Marienburger Schloss" soon became one of the largest and most strongly fortified buildings in Germany. On the decline of the order in the middle of the 15th century, the castle passed into the hands of the Poles, by whom it was allowed to fall into neglect and decay. It came into the possession of Prussia in 1772, and was carefully restored at the beginning of the present century. This interesting and curious building consists of three parts, the Alte or Hohe Schloss, the Mittel Schloss, and the Vorburg. It is built of brick, in a style of architecture peculiar to the Baltic provinces, and is undoubtedly one of the most important secular buildings of the Middle Ages in Germany.

Of the numerous monographs published in Germany on the castle of Marienburg, it will suffice to mention here Büsching's *Schloss der Deutschen Ritter zu Marienburg*, Berlin, 1828; Voigt's *Geschichte von Marienburg*, Königsberg, 1824; and Bergau's *Ordenshaupthaus Marienburg*, Berlin, 1871.

MARIETTA, a city of the United States, the capital of Washington county, Ohio, lies on the right bank of the Ohio, at the mouth of the Muskingum, 85 miles south-east of Columbus, and is the eastern terminus of the Marietta and Cincinnati Railroad, and the southern terminus of the Cleveland and Marietta Railroad. The surrounding country being rich in petroleum, iron, and coal, the city has become the seat of no inconsiderable industry in the shape of oil-works, iron foundries, and machine-shops, a rolling mill, tanneries, and carriage, car, bucket, and chair factories. Marietta College, chartered in 1835, and maintained by voluntary endowment and subscription, is a flourishing institution, with eight instructors and a library of 25,000 volumes, occupying a fine group of buildings in the midst of extensive grounds. The population of the city has risen from 3175 in 1850 to 5444 in 1880. At the latter date the township, which includes the village of Harmar (1572), contained 8830 persons.

Marietta, founded in 1788 by General Putnam, and named in honour of Marie Antoinette, is the oldest town in Ohio. It is built on the site of a remarkable group of prehistoric monuments, the largest of which are two enclosures, respectively 40 and 20 acres in extent, formed by walls from 20 to 30 feet broad at the base, and still in some places 5 and 6 feet high. See Squier and Davis, *Ancient Monuments of the Mississippi Valley*.

MARIETTE, AUGUSTE FERDINAND FRANÇOIS, elder son of François P. Mariette, advocate and town-clerk of Boulogne-sur-Mer, was born in that town on the 11th of February 1821. Educated at the Boulogne municipal college, he distinguished himself in geometry, physics, chemistry, history, Latin, Greek, and English. He also evinced a remarkable talent for art. In 1839, when but eighteen years of age, he went to England in the capacity of professor of French and drawing at a boys' school at Stratford-on-Avon, which occupation he exchanged in 1840 for that of pattern-designer to a ribbon manufacturer at Coventry. Weary of ill-paid exile, he returned that same year to Boulogne, resumed his interrupted studies, and in March 1841 took his bachelor's degree (with honourable mention) at Douai. He now became a professor at the college where he had formerly been a student, and for some years supplemented his modest salary by giving private lessons, and writing on historical and archæological subjects for various local periodicals. In the meanwhile his cousin, Nestor L'Hôte, the friend and fellow-traveller of Champollion, died; and upon Auguste Mariette devolved the pious task of sorting the multitudinous papers of the deceased savant. The young man thenceforth became passionately interested in Egyptology, devoted himself to the study of hieroglyphs and Coptic, and in 1847 published a *Catalogue Analytique* of the Egyptian Gallery of the Boulogne Museum. He had now found his vocation, and in 1849, being appointed to a subordinate position in the Louvre, left Boulogne for Paris. Entrusted shortly after with a Government mission for the purpose of seeking and purchasing Coptic, Syriac, Arabic, and Ethiopic MSS. for the national collection, he started for Egypt in 1850. Soon after his arrival he made his celebrated discovery of the ruins of the Serapeum and the subterraneous catacombs of the Apis-bulls, buried for probably some two thousand years under the sands of the Libyan desert (see vol. vii. p. 773). His original mission being abandoned, funds were now advanced for the prosecution of his researches, and he remained in Egypt for four years, excavating, discovering, and despatching archæological treasures to the Louvre, of which museum he was, on his return, appointed an assistant conservator. In 1858, by permission of his own Government, he accepted the position of conservator of Egyptian monuments to the ex-khedive, Ismail-Pasha, and so removed with his family to Cairo. His history thenceforth becomes a chronicle of unwearied exploration and brilliant success. The pyramid-fields of Memphis and Sakkara, and the necropolises of Meydum, Abydos, and Thebes were ransacked for sepulchral treasures; the great temples of Denderah and Edfoo were disinterred, and, with their tens of thousands of inscriptions and bas-reliefs, restored to the light of day; important excavations were carried out at Karnak, Medinet-Habu, and Deir-el-Bahari; Tanis (the Zoan of the Bible) was partially explored in the Delta; and even Gebel Barkal in the far Soudan was made to yield monuments of the Ethiopic kings. The Sphinx was also bared to the rock-level, and the famous granite and alabaster monument miscalled the "Temple of the Sphinx" was discovered. In the meanwhile Mariette, raised successively to the rank of bey and then of pasha, had founded the "École Française d'Égyptologie" and the "Institut Égyptien," and created *ab ovo* the museum at Bulak, the richest and by far the most interesting Egyptian collection in the world. Honours and orders were showered upon him. Poor in purse but rich in fame, he received in 1852 the grand cross of the Legion of Honour and of the Medjidie, in 1855 the Red Eagle (first class) of Prussia, in 1857 the Italian order of SS. Maurice and Lazarus, and in 1858 the Austrian order of Francis-Joseph. In 1873 the Academy of Inscriptions decreed to him the great biennial prize of 20,000 francs, and in 1878 he was elected a member of the Institute. He was also an honorary member of most of the learned societies of Europe. Though of herculean strength and indomitable energy, he was not proof against over-work of all kinds, physical, mental, and official. Prostrated in 1877 by a first attack of the insidious malady from which only death released him, he lingered for a few years, working to the last, and died at Cairo January 19, 1881. His remains, enclosed in an ancient Egyptian sarcophagus chosen by himself for that purpose, are interred within the precincts of the museum-garden at Bulak, facing the entrance to that unrivalled collection which is his own noblest monument.

Of Mariette's numerous and important contributions to the literature of Egyptology, we may here especially note the following works, which are not only distinguished for their erudition and accuracy, but for the exquisite grace of style with which they are written:—*Le Sérapéum de Memphis*, folio, 1857 and following years; *Dendérah*, five folios and one 4to, 1873–75; *Abydos*, two folios and one 4to, 1870–80; *Karnak*, folio and 4to, 1875; *Deir-el-Bahari*, folio and 4to, 1877; *Listes géographiques des pylônes de Karnak*, folio, 1875; *Catalogue du Musée de Boulaq*, six editions, 1864–76; *Aperçu de l'histoire d'Égypte*, four editions, 1864–74, &c. His last, and one of his most important works, *Les Mastabas de l'Ancien Empire*, text and illustrations facsimiled from the original MSS., folio, is now in course of publication, edited by Professor G. Maspero.

MARIGNOLLI, GIOVANNI DE', a notable traveller to the far East of the 14th century, born probably prior to 1290, and sprung from a noble family in Florence. The family is long extinct, but a street near the cathedral (Via de' Cerretani) formerly bore the name of the Marignolli.

In vol. v. pp. 628–29 some account has been given of the extraordinary episode of intercourse between Europe and China in the first half of the 14th century. In 1338 there arrived at Avignon, where Benedict XII. held his court, an embassy from the great khan of Cathay, bearing letters to the pontiff from the khan himself, and from certain Christian nobles of the Alan race in his service. These latter represented that they had been eight years without a spiritual guide, and earnestly desired one. The pope replied to the letters, and appointed four ecclesiastics as his legates to the khan's court. The name of Marignolli, a Franciscan of some repute for learning, appears, as John of Florence, third on the letters of commission. We know not what became of his colleagues; he was the chief if not the sole envoy who actually went.

The mission left Avignon in December 1338, picked up the Tartar envoys at Naples, and sailed across the Black Sea to Caffa, whence they travelled to the court of Mohammed Uzbek, khan of the Golden Horde, at Sarai on the Volga. The khan entertained them hospitably during the winter of 1339–40, and then sent them across the steppes to Armalec or Almaligh, the northern seat of the house of Chaghatai, in what is now the province of Ili. "There," says Marignolli, "we built a church, bought a piece of ground . . . . sung masses, and baptized several persons, notwithstanding that only the year before the bishop and six other minor friars had there undergone glorious martyrdom for Christ's salvation." Quitting Almaligh in 1341, they seem to have reached Peking (by way of Kamil or Hami) in May or June 1342. They were well received by the reigning khan, the last of the Mongol dynasty in China.

"The grand kaam, when he beheld the great horses (*dextrarios*) and the pope's presents, with his letter, and that of King Robert (of Naples) too, with their golden seals, and when he saw us also, rejoiced greatly, being delighted, yea exceedingly delighted with everything. . . . And when I entered the kaam's presence, it was in full festival vestments, with a very fine cross carried before me, and candles and incense, whilst *Credo in unum Deum* was chaunted, in that glorious palace where he dwells. And when the chaunt was ended I bestowed a full benediction, which he received with all humility."

An entry in the Chinese annals fixes the year of Marignolli's presentation by its mention of the arrival of the great horses from the kingdom of Fulang (*Farang* or Europe), one of which was 11 feet 6 inches in length, and 6 feet 8 inches high, and black all over!

Marignolli stayed at Peking or Cambalec three or four years, after which he travelled through eastern China to Zayton or CHINCHEW (*q.v.*), quitting China apparently in December 1347, and reaching Columbum (Kaulam or Quilon in Malabar) in Easter week of 1348. At this place he found a church of the Latin communion, probably founded by Jordanus of Séverac, who had been consecrated bishop of Columbum by Pope John XXII. in 1328. Here Marignolli remained sixteen months, after which he proceeded on what seems a most devious voyage. First he visited the shrine of St Thomas near the modern Madras, and then proceeded to what he calls the kingdom of Saba, and identifies with the Sheba of Scripture, but which seems from various particulars to have been Java. Taking ship again for Malabar on his way to Europe, he encountered great storms, of which he gives an imaginative account:—

. . . . "The sea as if in flames, and fire-spitting dragons flying by, which, as they passed, slew persons on board the other junks, whilst ours remained untouched, by God's grace, and by virtue of the Body of Christ which I carried with me, and through the merits of the glorious Virgin and of St Clare."

They found shelter in the little port of *Pervilis* (Beruwala or Berberyn) in the south-west of Ceylon; but here the legate fell into the hands of "a certain tyrant Coya Jan (Khoja Jahán), an eunuch and an accursed Saracen," who professed to treat him with all deference, but detained him four months, and plundered all the gifts and Eastern rarities that he was carrying home. This detention in "Seyllan" enables Marignolli to give a variety of curious particulars regarding Adam's Peak and other marvels. After this we have only fragmentary notices, showing that his route to Europe lay by Ormuz, the ruins of Babel, Baghdad, Mosul, Aleppo ("where there were many Christians who dressed after the Latin fashion, and spoke a language very near the French; at any rate like the French of Cyprus"), and thence to Damascus and Jerusalem. In 1353 he arrived at Avignon, and delivered a letter from the great khan to Pope Innocent VI. In the following year the emperor Charles IV., on a visit to Italy, made Marignolli one of his chaplains. Soon after, the pope made him bishop of Bisignano; but he seems to have been in no hurry to reside there. He appears to have accompanied the emperor to Prague; in 1356 he is found acting as envoy to the pope from Florence; and in 1357 he is at Bologna. We know not when he died. The last trace of Marignolli is a letter addressed to him, which was found last century among the records in the Chapter Library at Prague. The writer is an unnamed bishop of Armagh, easily identified with Richard Fitz Ralph, a strenuous foe of the Franciscans, who had broken lances in controversy with Ockham and Burley. The letter implies that some intention had been intimated from Avignon of sending

Marignolli to Ireland in connexion with matters then in debate. The wrath of Fitz Ralph is sorely stirred at this, and he brandishes the shillelah in a style of energetic metaphor very like what we have been used to from like quarters in later days.

Fitz Ralph's contemptuous language had probably a good deal of foundation. The fragmentary notes of Marignolli's Eastern travels often contain most vivid remembrance and graphic description, but combined with an incontinent vanity, and an incoherent lapse from one thing to another, matched by nothing in literature but the conversation of Mrs Nickleby. They have no claim to be called a narrative, and it is with no small pains that anything like a narrative can be pieced out of them. Indeed the mode in which they were elicited curiously illustrates how little mediæval travellers thought of publication. The emperor Charles, instead of urging his chaplain to write a history of his vast journeys, set him to the repugnant task of recasting the annals of Bohemia; and he consoled himself by salting the insipid stuff by interpolations, *à propos de bottes*, of his recollections of Asiatic travel.

Nobody seems to have noticed the work till 1768, when the chronicle was published in vol. ii. of the *Monumenta Hist. Bohemiæ nusquam antehac edita* by Father Gelasius Dobner. But, though Marignolli was thus at last in type, no one seems to have read him till 1820, when an interesting paper on his travels was published by J. G. Meinert. The late Professor Kunstmann of Munich also devoted to the subject one of a series of very intelligent papers on the ecclesiastical travellers of the Middle Ages. And the whole of the passages bearing on the journey were excerpted, translated, and commented on by Col. H. Yule in a collection printed in 1866.

Monumenta Historica, &c., collegit, &c., P. Gelasius Dobner a S. Catherina, tom. ii., Prague, 1768; Meinert, in *Abhandl. der K. Böhm. Gesellsch. der Wissenschaften*, vii.; Kunstmann, in *Historische Politische Blättern von Phillips und Görres*, Bd. xxxviii. pp. 701, 793, Munich, 1859; Wadding, *Annales Minorum*, vii.; Sbaralea, *Supplem. et Castigatio ad Scriptores Trium Ordd. S. Francisci a Waddingo*, Rome, 1806; *Cathay and the Way Thither*, Hak. Soc., 1866. (H. Y.)

MARIGOLD. This name has been given to several plants, of which the following are the best known:—*Calendula officinalis*, L., the pot-marigold; *Tagetes erecta*, L., the African marigold; *T. patula*, L., the French marigold; and *Chrysanthemum segetum*, the corn marigold. All these belong to the order *Compositæ*; but *Caltha palustris*, L., the marsh marigold, is a ranunculaceous plant.

The first-mentioned is the familiar garden plant with large orange-coloured blossoms, and is a native of the meadows of southern Europe (DC., *Prod.*, vi. p. 451). It is unisexual, the "ray" florets being female, the "disk" florets male. This and the double variety have been in cultivation for at least three hundred years, as well as a proliferous form, *C. prolifera*, or the "fruitful marigolde" of Gerard (*Herball*, p. 602), in which small flower-heads proceed from beneath the circumference of the flower. The figure of "the greatest double marigold," *C. multiflora maxima*, given by Gerard (*l.c.*, p. 600) is larger than most specimens now seen, being 3 inches in diameter. He remarks of "the marigolde" that it is called *Calendula* "as it is to be seene to flower in the calends of almost euerie moneth." It was supposed to have several specific virtues, but they are now discredited. "The marigold, that goes to bed wi' the sun," is mentioned by Shakespeare, *Winter's Tale*, iv. 3.

Tagetes patula, L., and *T. erecta*, L. (DC., *Prod.*, v. p. 643), the French and African marigolds, are natives of Mexico, and are equally familiar garden plants, having been long in cultivation. Gerard figures four varieties of *Flos africanus*, of the single and double kinds (*l.c.*, p. 609); but they do not appear to be specifically distinct; indeed Parkinson (*Par.*, p. 303, 1629) regarded them as one. Besides the above species the following have been introduced later, *T. lucida*, Cav., *T. signata*, also from Mexico, and *T. tenuifolia*, Cav., from Peru (Hemsley's *Handbook of Hardy Trees*, &c., p. 247).

Chrysanthemum segetum, L., the yellow corn marigold, is indigenous to Great Britain, and is frequent in corn-fields in most parts of England. A decoction of the fresh plant gathered before flowering is acrid, and is said to be useful medicinally. When dried it has been employed as hay It is also used in Germany for dyeing yellow (Baxter, *Brit. Gen. of Pl.*, vol. iv. 306). Gerard observes that in his day "the stalke and leaues of Corne Marigolde, as Dioscorides saith, are eaten as other potherbes are."

Caltha palustris, L., the marsh marigold, the "winking Mary-buds" of Shakespeare (*Cymb.*, ii. 3), is a common British plant in marshy meadows and beside water. It bears cordate leaves, the flowers having a golden yellow calyx but no corolla, and blossoming in March and April. The flower-buds preserved in salted vinegar are a good substitute for capers. A double-flowered variety is often cultivated, and is occasionally found wild (Baxter, *l.c.*, vol. ii. 153).

MARINES. With all maritime nations, especially if they be insular and capable of taking the offensive in war, there must frequently be cases in which naval operations can be supplemented by the landing of a force. The armament, equipment, and discipline of the armies and navies of such nations were in early days practically alike. But with the introduction of more regular levies and better organization arose the necessity for having on board ships-of-war an armed body organized to meet the altered condition of things. Sailors were but engaged for periods during which ships were commissioned; and their previous history and training did not tend to furnish the material required. Regular armies on shore called for disciplined forces afloat,—that is to say, for marines, or sea soldiers, who should have the steadiness of the troops of the line, be accustomed to the peculiar duties of ship life, and be subordinate to the naval authorities.

Previous to 1664 the British navy had been manned chiefly by "impress"; but in that year an order in council appeared, authorizing the formation of a force of 1200 soldiers, in six companies, to be raised for sea service during the Dutch War. Probably it was recruited from the London Trained Bands, as the Royal Marines, with the 3d battalion of the Grenadier Guards, the East Kent Regiment, and the Royal London Militia, alone possess the privilege of marching through the city with colours flying and bayonets fixed. Recruits were also obtained from the foot guards; and in 1672 companies of the guards were employed on shipboard. The Army List of 1684 shows for the first time the organized battalion of marines, in H.R.H. the duke of York and Albany's maritime regiment of foot or "Admiral's Regiment," which, in that year, mustered on Putney Heath twelve companies, with a full proportion of officers. This stood third in seniority in the line, and eventually became the Coldstream Guards; the 4th, or "Holland Regiment," which also sent companies to sea, and had like the above regiment been raised by the City of London, taking its place as 3d or "Old Buffs." Several other maritime regiments were successively formed and disbanded, until, in 1702, Queen Anne directed the addition to the army of six regiments as a marine corps, while six existing regiments were also appointed "for sea service." These were done away with in 1714, three only being retained, as the 30th, 31st, and 32d of the line. Independent companies, for service in the West Indies, were also formed, becoming in 1742 the 49th foot. In 1739 six fresh regiments were levied, and augmented in 1742 to ten, of 1000 men in ten companies each; while three others were collected in America for colonial duty. Though commanded by generals and colonels of the army, they were to be quartered in the neighbourhood of the dockyards at Portsmouth, Sheerness, Chatham, Deptford, Woolwich, and Plymouth; and the proportion of officers, viz., 100 men with a captain to twenty with a subaltern, was fixed for the different classes of vessels. No field officer was embarked unless a full battalion were sent. In

1745 two other battalions were specially raised for service at Cape Breton, becoming finally the 50th and 51st foot; and in 1746 the ten regiments were restored to the army, taking rank from the 44th to the 53d. Previous to their disbandment as marines they had been partially under the orders of the lord high admiral.

By an order in council of 1755 a force of 5000 men in 50 companies was raised and definitely placed under the naval authorities. They were to be stationed at Chatham, Portsmouth, and Plymouth, the 4th or Woolwich division not being added until 1805; and this body was gradually increased to 19,000 men in 1762, but reduced in 1763 to about 4000. Commissions ceased to be purchasable, but exchange with the army was, for a time, sanctioned. Naval admirals and captains were appointed generals and colonels of marines in 1760, in consequence of a representation from the commandants of divisions that there was an insufficient number of field officers "for the discipline of the service." This absurd anomaly existed until 1833, when these useless sinecures were abolished.

The revolt of the American colonies in 1775 led, again, to an increase in the establishment, which by 1783 had reached 25,291 men,—followed by a reduction to 4495 the ensuing year. So urgent was the demand for marines during the struggle that men were frequently embarked untrained; yet, so popular was the service, they still "recruited better in every part of the island" than the army. Owing to this unwise policy of reduction, the force, on the outbreak of the French War in 1793, had to be supplemented, as formerly, by companies from the line; and at its conclusion the marine corps again reached a total strength of more than 30,000 men. But there had been differences between the military and naval authorities as to the employment of soldiers from the army; so that from 1815, when the numbers again fell to about 6000, there has been a steady increase, until an establishment suitable to the wants of the navy has been fixed. During the long war, moreover, the necessity for the formation of a body of marine artillery had become increasingly apparent. The services of marines in this capacity had been previously demanded during the American War, when they were employed in the half-moon battery and citadel at Halifax, and elsewhere in batteries on shore, as some of them had been "trained in the service of great guns" by Lieutenant Gillespie of the Royal Artillery. By an order in council of the 18th August 1804, therefore, "in consequence of the inconvenience of embarking the Royal Artillery," it was directed that one company of marine artillery, composed of the most intelligent and experienced officers and men, should be formed at each division to be employed for the training of the infantry, so as to embark efficient artillerymen in other vessels besides "bombs." This force suffered a reduction to two companies in 1822, since which date it also has been steadily increased; and in 1862 the artillery companies were separated from the light infantry and formed into a separate division at Fort Cumberland, Portsmouth, whence the headquarters were transferred to Eastney in 1869. In 1869 the Woolwich division was abolished, a depôt for the training of recruits being formed at Walmer. At present the Royal Marine force numbers 48 companies of infantry and 16 of artillery, showing a total force of 2532 artillery and 9862 infantry, at an expenditure of £913,456.

Each division of Royal Marines has a total force of 16 companies, with a colonel commandant, second commandant, 4 lieutenant-colonels, 14 majors, 20 captains, and 42 subalterns, inclusive of the divisional staff of instructors of gunnery, musketry, &c. The headquarter staff, in London, consists of a deputy and an assistant adjutant-general, &c.; and there are, in addition, three generals, three lieutenant-generals, and six major-generals on the active list. The men are recruited by special parties; they are enlisted for twelve years, with permission to re-engage for nine more. All recruits undergo their preliminary training at Walmer, and are then drafted to the several divisions,—those who reach a higher standard being allowed to volunteer for the artillery. The standard for infantry and artillery, and the system of pay, equipment, pension, and divisional administration, are similar to those of the line and Royal Artillery respectively. Officers are obtained by open competition from the pass-lists for entrance to the Military Academy, Woolwich, and the Royal Military College, Sandhurst. The successful infantry candidates are drafted to their several divisions, and undergo a course of instruction under the military instructor to the corps,—those for the artillery receiving a special training for two years at the Royal Naval College, Greenwich.

The Royal Marines, reckoning as part of the naval forces, are accounted for in the navy estimates; though the names of the officers appear both in the Army and Navy Lists. They are particularized in the Army Act as subject to military law at stated times, serving on shore under the Act and the regulations in force in the garrisons, where they perform the same duties as the land forces. Afloat they are subject to the Naval Discipline Act; and a Marine Mutiny Act was formerly passed annually for the "regulation of Her Majesty's Royal Marine forces while on shore," stating that they were under the direction of the lord high admiral, &c. On board ship their duties are of a purely military character, being confined to guard mounting, assisting to man boats for shore operations, and helping to form the crews for the heavy guns. Though under the supreme command of the naval authorities, they are only obliged to aid in work on deck, and when landed are entirely commanded by their own officers.

The war services of the corps are so numerous that they can be but briefly referred to. First employed at Cork in 1690, they have been present in nearly all the actions in which the navy has since then been engaged; and between that date and 1800 they took part in 227 sea fights and 70 important operations on shore. At Gibraltar and Manila, at Belleisle and Bunker's Hill, at Negapatam, the Cape, and Acre, they earned the special commendation of the leaders, as well as for Lord Howe's victory, and the great sea fights of Camperdown, Cape St Vincent, and the Nile. Nor were their enemies backward in recognizing their worth. At Belleisle the French, in describing the troops whose valour had been most conspicuous, designated the battalions of marines "les petits grenadiers"; and at Acre General Berthier bore testimony to the conspicuous gallantry of Major Oldfield, who fell in the attack on the fortress. From 1800 to 1815 they saw constant service in 99 coast operations and 142 naval actions. After the landing at Aboukir Bay in 1801 the "Bull Dogs" received high praise for the way in which they had done their work. At the siege of Gaeta, at Rosas, and at Santa Maura, the marines again distinguished themselves; and they took part in the decisive battles at Copenhagen, Trafalgar, San Domingo, and the Dardanelles. Three battalions were also specially brigaded with the line for active service in America and Holland in 1813-15. Since that period the marines have shared in the naval actions at Algiers, Navarino, Acre, the Baltic, and Black Sea, and have fought by the side of the land forces at the Cape, in India, China, New Zealand, Abyssinia, Ashantee, and Zululand, as also in those numerous petty skirmishes in which the navy has been so repeatedly engaged. In the bombardment of Alexandria (1882), and in the operations that followed it, the corps has again seen service by sea and land. Nor have their services been less important in other cases. Though forming part of the ships' companies, and therefore at times suffering from the same grievances, they have always been faithful to their trust. In 1797, a period of much sedition throughout the country, all efforts to shake their allegiance were fruitless, and the duke of York especially commended their loyalty and zeal. Between that year and 1802, after the mutinies of the Nore, Spithead, and Bantry Bay, of the "Temeraire," "Castor," "Impétueux," "Hermione," "Gibraltar," and "Excellent," the marines were publicly thanked for their devotion.

As part of a ship's company in naval actions, as a force landed to assist in coast operations, and as troops acting in concert with the army, the marines have won distinction and the commendation of both naval and military authorities for two hundred years. The motto of the corps, "Per mare per terram," needs no explanation; the title "Royal" was added in 1802 "for its many and varied services during the war," and its former facings were altered from white to royal blue; it was also in 1820, by an order in council, placed next in seniority to the 49th Regiment. In 1827 the globe, surrounded by the laurel wreath, for the siege of Belleisle, together with "Gibraltar," in commemoration of the services performed there, was added by George IV. In 1855 the infantry branch of the corps became "light infantry."

Although in the "armed strengths" of the great European powers marines and marine artillery are mentioned, these troops have little in common with those in the British navy. In France their duties are to garrison the five military ports and colonies, and to take part in marine and other wars. In Germany the marine battalions and artillery divisions at Kiel and Wilhelmshafen are intended for coast defence only. In Holland, Austria, and Italy also they have a military organization, but do not form a recognized part of the complements of sea-going ships. America alone employs marines in the same manner as England; and they have won, as their British comrades have, the approbation of the naval authorities and, on nineteen occasions, the thanks of Congress. Admiral Farragut's opinion that "the marine guard is one of the great essentials of a man-of-war" is corroborated by that of Admiral Wilkes, who considered that "marines constituted the great difference between a man-of-war and a privateer." Formed in 1775 for the "publick defense," they rank as the oldest force in the American service; and since that time they have shared in land and sea operations in all parts of the world. In the famous battles between the "Bonhomme Richard" and "Serapis" in 1777, and in that between the "Chesapeake" and "Shannon," they displayed brilliant gallantry; and while on the one hand they at Derne in 1803 first planted the American flag on a fortress of the Old World, for which exploit "Tripoli" is inscribed on their colours, they on the other shared in the hard fighting of the Mexican war as well as all the important coast actions of the civil war of 1861-65. A proposal to incorporate them with the army after the struggle met with universal condemnation from the authorities best qualified to judge of their value. At present they number seventy-eight officers and two thousand men under the command of a commandant, who ranks as brigadier-general, with headquarters at Washington. Their administration, organization, and equipment are, as in England, identical with those of the soldiers of the line. They are enlisted for five years, must be 5 feet 6 inches in height, between eighteen and thirty-five years of age, and able to read and write. The complement on board ship varies from thirteen to fifty-one officers and men, depending on the rating of the vessel. Their device is a globe resting on an anchor and surmounted by an eagle. "Ever faithful" is the title which Captain Luce, the historian of the force, appropriately applies to them. (C. C. K.)

MARINI, or Marino, Giambattista (1569-1625), Italian poet, was born at Naples on October 18, 1569. At an early age he secured the powerful patronage of Cardinal Aldobrandini, whom he accompanied from Rome to Ravenna and Turin. His ungoverned pen and disordered life compelled him to take refuge from 1615 to 1622 in Paris, where he was favourably recognized by Mary de' Medici. He died at Naples on March 25, 1625. See Italy, vol. xiii. p. 511.

MARINUS I. (Martinus II.) succeeded John VIII. in the pontificate about the end of December 882. On three separate occasions he had been employed by the three popes who preceded him as legate to Constantinople, his mission in each case having reference to the controversy excited by Photius. Among his first acts as pope were the restitution of Formosus, cardinal bishop of Porto, and the anathematizing of Photius. He died in May or June 884, his successor being Adrian III.

MARINUS II. (Martinus III.), pope from 942 to 946, was preceded by Stephen IX., and followed by Agapetus II.

MARION, Francis (1732-1795), American general, was born in 1732 at Winyah, near Georgetown, South Carolina. In 1759-61 he served as lieutenant in expeditions against the Cherokees, and in 1775 he was elected a member of the provincial congress of South Carolina. This voted two regiments of infantry, and Marion was elected captain in the second. He was made lieutenant-colonel after the defence of Fort Moultrie at the entrance of Charleston harbour (June 28, 1776), and was present at the unsuccessful attack on Savannah, September 1779. In August he joined Gates, but was detached a few days before Gates's defeat at Camden on August 16; at Nelson's Ferry, on the 20th, he rescued one hundred and fifty of the prisoners from a strong guard. He soon received a general's commission. Pursued by Tarleton and Wemyss, he was driven to North Carolina, but soon returned. After successful skirmishes against superior forces, he formed a camp at Snow's Island in the midst of the swamps of the Pedee and the Santee. In March 1781 he defeated Watson at Black River; but meanwhile Doyle had destroyed Marion's camp. In April Lee and Marion took Fort Watson, and in May Fort Motte. In June Greene detached Sumter with Marion and others to make an incursion into the low country. At Quinby Marion's men fought well against Coates; and in August he made a forced march to Parker's Ferry and rescued Colonel Harden, pressed by a superior force. At Eutaw Springs he commanded the right under Greene. After the British retreat to Charleston, Marion went to an important session of the colonial assembly; on the very day that he returned to his brigade, February 24, 1782, it was surprised and dispersed, Marion arriving too late to recover the day. After the war he occupied himself with farming. He died February 27, 1795.

MARIONETTES (probably from *morio*, a fool or buffoon), Fantoccini (from *fantino*, a child), or Puppets (*poupée*, a baby or doll), are figures, generally below life-size, suspended by threads or wires and imitating with their limbs and heads the movements of living persons.

The high antiquity of puppets appears from the fact that figures with movable limbs have been discovered in the tombs of Egypt and among the remains of Etruria; they were also common among the Greeks, from whom they were imported to Rome. Plays in which the characters are represented by puppets or by the shadows of moving figures, worked by concealed performers who deliver the dialogue, are not only popular in India and China at the present day, but during several centuries past maintained an important position among the amusements of the people in most European countries. Goethe and Lessing deemed them worthy of attention; and as late as 1721 Le Sage wrote plays for puppets to perform. Every one remembers in Don Quixote "the curious puppet show, which represents the play of Melisandra and Don Gayferos, one of the best shows that has been acted time out of mind in this kingdom." Reference to puppet shows is frequent in English literature from Chaucer onward. Thus Davenant says:—

> "And man in chimney hid to dress
> Puppet that acts our old Queen Bess,
> And man that, while the puppets play,
> Through nose expoundeth what they say."

The earliest performances in English were drawn or founded upon Bible narratives and the lives of the saints, in the same vein as the "morality" plays which they succeeded. Popular subjects in the 16th century were *The Prodigal Son* and *Nineveh, with Jonah and the Whale*. And in a pamphlet of 1641, describing Bartholomew Fair, we read, "Here a knave in a fool's coat, with a trumpet sounding or a drum beating, invites you to see his puppets. Here a rogue like a wild woodman, or in an antic shape like an incubus, desires your company to view his motion." In 1667 Pepys recorded how, at Bartholomew Fair, he found "my Lady Castlemaine at a puppet play, Patient Grizill." Besides *The Sorrows of Griselda*, other puppet plays of the period were *Dick Whittington*, *The Vagaries of Merry Andrew*, and *The Humours of Bartholomew Fair*. Powell's noted marionette show was the subject of an article in *The Tatler*, 1709, and again in *The Spectator*, 1711. The latter refers also to Pinkethman, a "motion-maker," in whose scenes the divinities of Olympus ascended and descended to the strains of music. An idea of the class of representation may be gathered from an advertisement of Crawley, a rival of Pinkethman, which sets forth—"The Old Creation of the World, with the addition of Noah's Flood," also several fountains playing water during the time of the play. The best scene represented "Noah and his family coming out of the ark, with all the animals two by two, and all the fowls of the air seen in a prospect sitting upon trees; likewise over the ark is the sun rising in a gorgeous manner; moreover a multitude of angels in a double rank," the angels ringing bells. "Likewise machines descending from above, double, with Dives rising out of hell and Lazarus seen in Abraham's bosom; besides several figures dancing jiggs, sarabands, and country dances, with the merry conceits of Squire Punch and Sir John Spendall." Yates showed a moving picture of a city, with an artificial cascade, and a temple,—with mechanical birds in which attention was called to the exact imitation of living birds, the quick motion of the bills, just swelling of the throat, and fluttering of the wings. The puppets were wax figures 5 feet in stature. Toward the end of the 18th century, Flockton's show presented five hundred figures at work at various trades. Brown's Theatre of Arts showed at country fairs, from 1830 to 1840, the battle of Trafalgar, Napoleon's army crossing the Alps, and the marble palace of St Petersburg; and at a still later date Clapton's similar exhibition presented Grace Darling rescuing the crew of the "Forfarshire" steamer wrecked on the Fern Islands, with many ingenious moving figures of quadrupeds, and, in particular, a swan which dipped its head into imitation water, opened its wings, and with flexible neck preened and trimmed its plumage. In these mechanical scenes the figures, painted upon a flat surface and cut out, commonly of pasteboard, are slid along grooves arranged transversely in front of the set scenery, the actions of legs and arms being worked by wires from the hands of persons below the stage, though sometimes use is made of clockwork.

Marionettes proper, and the dolls exhibited in puppet shows (not including Punch and his companion actors), are constructed of wood or of pasteboard, with faces of composition, sometimes of wax; and each figure is suspended by a number of threads to a short bar of wood which is commonly held in one hand of the hidden performer while the finger of his other hand poses the figure or gives action to it by means of the threads. In the mode of constructing the joints, and the greater elaboration with which the several parts of the limbs are supported and moved, and especially in the fine degrees of movement given to the heads, marionettes have been so improved as to present very exact imitations of the gestures of actors and actresses, and the postures and evolutions of acrobats; and, in addition, ingenious exhibitors such as Theodon, who introduced many novelties from twenty to thirty years ago, have employed mechanical arrangements for accomplishing the tricks of pantomime harlequinade. Among the puppet personages presented in the small street shows are generally included a sailor who dances a hornpipe, a hoop-dancer, a dancer of the Highland fling, a wooden-legged pensioner, a vaulter on a pole also balancing two chairs, a clown playing with a butterfly, a dancing figure without head until the head rises out of the body, gradually displaying an enormously long neck, a juggler tossing gilt balls which, sliding up and down upon tight invisible threads, fall into his hands again, a milk-woman carrying buckets out of which fly white dolls, and a skeleton, seen at first in scattered parts lying about the stage, but piece successively flying to piece, the body first sitting up, then standing, and finally capped by the skull, when the completed figure begins to dance.

Ombres Chinois are the shadows of figures projected upon a stretched sheet of thin calico or a gauze scene painted as a transparency. The cardboard flat figures are held behind this screen, illuminated from behind,—the performer supporting each figure by a long wire held in one hand while wires from all the movable parts terminate in rings in which are inserted the fingers of his other hand.

MARIOTTE, EDME (died 1684), a celebrated French physicist, was a native of Burgundy. He lived chiefly near Dijon as prior of St Martin sous Beaune, and was one of the first members of the Academy of Sciences, which was founded at Paris in 1666. He died at Paris May 12, 1684. The first volume of the *Histoire et Mémoires de l'Académie* (1733) contains many original papers by him upon a great variety of physical subjects, such as the motion of fluids, the nature of colour, the notes of the trumpet, the barometer, the fall of bodies, the recoil of guns, the freezing of water, &c. His *Essais de Physique*, four in number, of which the first three were published at Paris between 1676 and 1679, are his most important works, and form, together with an elaborate treatise on the percussion of bodies, the first volume of the *Œuvres de Mariotte* (2 vols., Leyden, 1717). The second of these essays ("De la Nature de l'Air") contains the statement of the law connecting the pressure and volume of a gas which, though very generally called by the name of Mariotte, was discovered seven years before by Boyle. The fourth essay is a systematic treatment of the nature of colour, with a description of many curious experiments and a discussion of the rainbow, halos, parhelia, diffraction, and the more purely physiological phenomena of colour. The discovery of the blind spot is noted in a short paper in the second volume of his collected works.

MARITIME LAW. See SEA LAWS.

MARITIME PROVINCE (Russian, *Primorskaya Oblast*), a province of the Russian empire, and part of the general-governorship of Eastern Siberia, is a strip of territory which extends along the Siberian coast of the Pacific from Corea to the Arctic Ocean, and also includes the peninsula of KAMCHATKA (*q.v.*), the island of Saghalien or Sakhalin, and several small islands scattered along the coast. Its western boundary stretches northwards from the Corean town of King-hing (41° 45′ N. lat.) by Lake Khangka and along the Usuri, keeping to the eastward of the hilly tracts and prairies of northern Manchuria; it then follows an imaginary line which runs due north from the mouth of the Usuri to the bay of Udskoy, separating the province from the lowlands and mountain wildernesses of the Amur province; it next runs along the Stanovoy watershed between the Pacific and the Arctic Ocean, leaving to the west the elevated tracts of the Siberian plateau, and finally it crosses the spurs of this plateau through barren *tundras* belonging to Yakutsk, reaching the Arctic Ocean at the Chaunskaya Bay (70° N. lat.). The province has a length of 2300 miles and a width varying from 40 to 420 miles; it covers an area of 730,000 square miles, and exhibits very great varieties of climate, scenery, and population. The northern part, known as the land of the Chukchees, occupies the north-eastern peninsula of Asia between the Arctic Ocean on the one side and the Seas of Behring and Okhotsk on the other, and has the character of a barren plateau from 1000 to 2000 feet high, deeply indented by the rivers of the Anadyr basin, and by long fiords, such as the Koluchin Bay (the wintering-place of Nordenskjöld's "Vega"), the Gulf of Anadyr, and the Bays of Penzhina and Ghizhiga. To the north this plateau is bordered by a chain of mountains, the highest known within the Arctic circle, several summits of which reach a height of 8200 feet (Makachinga peak and others), while the promontories by which the Asiatic continent terminates towards Behring Strait—Serdtze-kamen, Cape Vostochnyi (the most easterly point of Asia), and Cape Chukotskiy—have heights ranging from 1000 to 2000 feet. Only lichens and mosses, with a few dwarf species of Siberian trees, cover this district, in marked contrast to the rich forests of the corresponding part of Arctic America. The fauna, however, is far richer than might have been expected, owing to the migrations of animals along the plateaus of Eastern Siberia, which extend in a north-eastern direction from the very heart of Asia to Behring Strait. The fauna is further enlarged by a few American birds and mammals, which cross the strait when it is frozen. This country, and still more the seas by which it is surrounded, have been for the last two centuries the paradise of hunters, and have supplied Siberian trade with its best furs. Entire species of animals have been exterminated within this short period; the renowned blue fox and black sable have nearly disappeared, and the whale, which was hunted a few decades ago by hundreds of American vessels, has become very rare. The sea-otter, of which the party of Steller killed seven hundred during its eight months' stay on Behring's Island, is rapidly becoming extinct, as well as the sea-lion (*Otaria stelleri*); whilst the sea-cow (*Rhytina stelleri*) was completely extirpated in the course of forty years. Thanks to the care taken by an American company which has the monopoly of hunting on Behring and Copper Islands, the sea-bear (*Otaria ursina*), which was likely to meet with the same fate, is nearly domesticated at present, and multiplies rapidly, yielding no less than twelve thousand skins per annum. The inhabitants of this region, the Chukchees (Tuski, or Chaouktoos), who number no more than 12,000 souls (according to some authorities only 5000), seem to have immigrated from the south; their racial characters make them an ethnological link between the Mongols of Central Asia and the Indians of America; they are also very nearly akin in their features and customs to the Eskimo. They are subdivided, however, into two distinct branches, with different customs and languages. Those of the interior support themselves by reindeer breeding (herds of ten thousand being not uncommon) and by hunting; whilst those of the coast live by fishing, and are very poor. All travellers who have had dealings with Chukchees speak in the highest terms of the character of the former branch, and of the fraternal feelings shown by them in their mutual relations. The Koryaks (about 5000), who occupy the southern part of this region, are nearly akin to Chukchees. They extend their migrations also to the northern part of Kamchatka. Those of the interior are reindeer proprietors and hunters, and like the Chukchees are quite independent, own no superiors, and live in federations of families. They have firmly resisted Russian conquest; and there are tribes among them which still refuse to pay the *yasak* (tribute in furs) to the Russian authorities. Their national character is described by travellers as very different from that of the settled Koryaks of the coast, who live in the utmost poverty, and have acquired vicious habits from their intercourse with European and American sailors.

The middle part of the Maritime Province is a narrow strip of land (40 to 60 miles wide) along the shores of the Sea of Okhotsk, including the basin of the Ud in the south. This area is occupied by wild mountains, 4000 to 7000 feet high, forming the eastern border of the high plateau of Eastern Siberia. Thick forests of larch clothe the mountains to nearly one-half of their height, as well as the deep valleys, where short streams discharge into the Pacific the water produced by the melting of accumulations of snow and ice (*nakipi*, *naledi*). The undulating hills of the basin of the Ud, which is a continuation to the south-west, between the Stanovoy and Bureya mountains, of the deep indentation of the Sea of Okhotsk, are covered with forests and marshes. Only Tunguses visit these inhospitable mountain wildernesses and the bays of the coast, living by hunting or fishing.

The southern part of the province includes two distinct regions. From the north-eastern extremity of the Bureya, or Little Khingan range, of which the group of the Shantar Islands is a continuation, a wide and deep depression runs south-westwards to the junction of the Amur and Usuri, and thence to the lowlands of the lower Sungari. It is for the most part less than 500 feet above sea-level.

The Amur, which takes a north-eastern course after reaching these lowlands, runs close to their eastern boundary, at the foot of the mountains of the sea-coast; whilst on its left or western bank it spreads into numberless lakes and marshes, large and small, and extensively inundates the swamps at time of flood. The area on the right banks of the Amur and Usuri, between these rivers and the sea-coast, is occupied by a very little known hilly tract consisting of several intricate systems of mountains, usually represented on maps as a single range, and known under the general name of Sikhota-alin. The summits reach the height of 5150 feet (Golaya Gora peak) and the average elevation of the few passes is about 2500 feet. There is, however, one depression in these mountains, occupied by Lake Kizi, which may have been at one time an outflow of the Amur to the sea. The Sikhota-alin mountains are covered with thick impracticable forests, through which a passage can be forced only by means of the hatchet. The lowlands and the countless islands of the Amur are covered with a grass vegetation as luxuriant as that of the forests, and present the same difficulties to the pioneer. Herbaceous plants, 7 to 10 feet high, intertwined with numberless climbing plants, cover the soil with an impenetrable thicket, and, when destroyed by fire, rapidly grow again to their former height. The flora and fauna of this region (especially in the Usuri district) exhibit a striking combination of species of warm climates with those of subarctic regions; the wild vine clings to the larch and cedar-pine, and the tiger meets the bear and the sable. The quantity of fish in the rivers is immense, and in August the wide channels of the Amur and Usuri literally swarm with the ascending salmon. The mountain-wildernesses are visited by nomadic Tunguses, while the banks of the great rivers are inhabited, besides Russians, by Golds and Orochons, both of Tungusian origin, and the lower Amur by Ghilyaks, closely allied to the Ainos of Saghalien. Manchus and Chinese are scattered here and there among the Russian population on the right bank of the Usuri.

The best part of the Maritime Province is at its southern extremity, in the valley of the Suifun river, which enters the Pacific in the Gulf of Peter the Great, and on the shores of the bays of the southern coast, where new settlements have appeared since this territory was annexed to Russia in 1860. But even here the climate is very harsh. The warm sea-current of the Kuro-sivo does not reach the coasts of Siberia, while a cold current, originating in the Sea of Okhotsk, brings its icy water and chilling fogs to the coasts of Saghalien, and flows along the Siberian shores to the eastern coast of Corea. The high mountains of the sea-coast and the monsoons of the Chinese Sea contribute to produce in the southern parts of the Maritime Province cold winters and wet summers. Accordingly, at Vladivostok (in the Gulf of Peter the Great), which has the same latitude as Marseilles, the average yearly temperature is only 39°·5 Fahr., and the harbour is frozen for nearly three months; the Amur and Usuri are frozen in November. Towards the end of summer the moist monsoons cause heavy rainfalls, which destroy the harvests and bring about such inundations that even in the two miles wide channel of the Amur the water within a few days rises more than 15 feet, and covers the lowlands to a breadth of 15 to 20 miles; the navigation also becomes dangerous for small river steamers and barges, on account of storms from the Chinese Sea. The sea-coast farther north has a continental and arctic climate. At Nikolayevsk, temperatures as low as − 41°·5 Fahr. are observed in winter, and as high as 94°·6 in summer, the average yearly temperature being below zero (− 0·9). At Ayan (56° 27′ N. lat.) the average temperature of the year is 25°·5 (− 0°·4 in winter, and 50°·5 in summer), and at Okhotsk (59° 21′ N. lat.) it is 23° (− 6° in winter, and 52°·5 in summer).

Russian settlements occur at intervals throughout the whole of the province, but, with exception of those on the banks of the Amur and Usuri, and the southern ports of the sea-coast, they are mere centres of administration. Anadyrsk on the Anadyr river, Penzhinsk and Ghizhiga at the heads of bays of the same name, Ayan on the coast of the Sea of Okhotsk, and Udskoy Ostrog on the river Ud, all have played an important part in the conquest of Siberia by Cossacks and merchants; but at present they are only small blockhouses with a few buildings around them, and the seat of local authorities; the population of none exceeds two hundred. Okhotsk, which has given its name to the sea between Kamchatka and the Siberian coast, is one of the oldest towns of Eastern Siberia, having been founded in 1649. Until the acquisition by Russia of the Manchurian sea-coast, this port, 700 miles distant from Yakutsk, poor though it is, was an object of special solicitude to the Russian Government for the maintenance of its possessions on the Pacific. It is connected by a bridle path with Yakutsk, and even in 1851–56, during the conquest of the Amur, all communication with the mouth of the Amur was by this route. It has now but 210 inhabitants. Nikolayevsk, on the left bank of the Amur, 23 miles from its mouth, was until lately the capital of the Maritime Province. Great expectations were formed regarding it when it was founded in 1851. It was provided with machine-works, foundries, and dockyards, and was proclaimed a free port. But the difficulties of navigation and of communication with the interior, and the complete failure of the governmental colonization of the Amur, made the prosperity of the new Russian port on the Pacific impossible, and the seat of government was transferred to the more central Khabarovka. At present Nikolayevsk has only 3500 inhabitants, nearly all military or officials, and a few foreign merchants trading chiefly in groceries and spirits. The port is visited every year by from twenty to twenty-five ships, importing manufactured and grocery wares to the value of about £100,000, and of wines and spirits estimated at £20,000. On the banks of the Amur, from Nikolayevsk to the mouth of the Usuri, is a chain of Russian settlements at distances not exceeding 25 miles. Their inhabitants, free settlers from Russia, are very badly off on account of the difficulties of agriculture in this region, and from the bad selection of sites. Many have migrated to the sea-coast, whilst those who still remain are for the most part very poor, and almost every year require to be provided by Government with corn brought from Transbaikalia. Sofiysk (1000 inhabitants, of whom 700 are military) is a purely military post. Khabarovka, on a high promontory at the confluence of the Amur and Usuri, is the present capital of the Maritime Province. It has a settled population of about seven hundred, besides military and officials. A few Russian merchants carry on an active trade in furs with natives (about £20,000 a year), in silver money brought from Russia and sold to Chinese, and in spirits and groceries. The Russian settlements on the right bank of the Usuri are very like those of the lower Amur. The peasants, who have received the name of Cossacks, and have a military organization, with the exception of a few settlements on the upper Usuri, are mostly in a wretched condition, and since 1859 have been dependent for food almost every year on Government aid. A line of posts and settlements connects the villages of the Usuri with the settlements on the shores of the Gulf of Peter the Great. This wide gulf, divided into two long bays,—those of Amur and Usuri, which are connected by an inlet called the Eastern Bosphorus,—is regarded as the principal port of Russia on the Pacific, and the town on the inlet has received the name of Vladivostok ("ruler of the East"); its spacious harbour, very similar to that of Sebastopol, has been called the Golden Horn. At present Vladivostok has, however, merely the aspect of a middle-sized Russian village. One-half of its 8500 inhabitants are Chinese and Coreans, the other half being military and officials. All necessaries of life, including rye-bread biscuits, continue to be imported by sea, and every spring, before the opening of the navigation, provisions become scarce. The trade is in the hands of Chinese, who export stag-horns, sea-weed, and mushrooms to a value of about £10,000 a year, and of Germans, who import groceries and spirits (£218,500 in 1879). The entrance to the harbour is well-fortified, and the town possesses a machine-work, storehouses, and a station of the Northern Telegraph Company. Other settlements (at the Imperial, Vladimir, and Olga harbours, &c.) are developing very slowly. Altogether the Russian population of these settlements has still a provisional character, and has to overcome great difficulties before it can become independent of the interior for its means of subsistence. The total population of the Maritime Province is estimated at 20,000 Russians, (12,000 military and officials), and at about 37,000 natives; but this is certainly under the truth. The province is made up of one territory—that of the Usuri—and six circles (*okrughi*):—Nikolayevsk, Sofiysk, Petropavlovsk (Kamchatka), Okhotsk, Ghizhighinsk, and Udskoy; the territory of the Usuri is subdivided into five circles:—Usuri, Suifun, Khangka, Avvakumovo, and Suchan. (P. A. K.)

MARIUPOL, a seaport of Russia, on the northern shore of the Sea of Azoff, at the mouth of the Kalmius, in the government of Ekaterinoslav, 55 miles west of Taganrog. It is connected by a branch railway with the line between Kharkoff and Taganrog, and is situated on the highway between the latter town and the Crimea. The place is said to have been inhabited in remote times under the name of Adamakha; but the present town was built only in 1779 by Greek emigrants from the Crimea who settled on the shores of the Sea of Azoff and on the left bank of the lower Kalmius. Mariupol is the chief town of this district, the 40,000 inhabitants of which are engaged in agriculture, cattle-breeding, and fishing, and sell their produce in the town. In export trade Mariupol ranks next to Taganrog among the ports of the Sea of Azoff; but its harbour is open to the south-east and shallow, the line of 14 feet being $1\frac{1}{2}$ miles from the shore, with a narrow strip, 12 to 22 feet deep, which allows larger flat-bottomed ships to approach the town, especially during south-east winds. Like all ports on this sea it is becoming more and more shallow. Mariupol is visited every year by about 150 foreign ships (about 30,000 tons) and by 700 to 800 coasting vessels (65,000 tons), mainly carrying wheat and linseed, as also skins and tallow, from the Greek district, and from the provinces of Don and Ekaterinoslav. The importance of the port may increase when the mineral riches of the district (coal close to the sea-shore, kaolin, and quartz sand) are exploited. Population, with two suburbs, Marinsk and Karasou, 9800

MARIUS, CAIUS (155–86 B.C.), is one of the most striking figures in Roman history. Born the son of a small farmer at Arpinum (Arpino), the birthplace also of Cicero, in 155 B.C., he worked his way up from this humble origin, in spite of the most determined opposition from the senate and the aristocracy, to the highest position in the state, was seven times consul, and was spoken of as a third Romulus and a second Camillus. He began life as a soldier, and first saw war in Spain under the great Scipio Africanus, whose good opinion he won, and so rose from the ranks to be an officer. But this was not enough to help him forward, on his return to Rome, in rising to those political offices which were invariably a stepping-stone to the highest military rank. He had, however, when about forty years of age, the good luck to marry a great lady, of patrician rank, Julia, the aunt of Julius Cæsar; and, being at the same time a popular favourite, as a man of plain and simple tastes, and a brave energetic soldier, he was in 115 B.C. elected prætor, which gave him an opportunity of still further showing his military ability in the thorough subjugation of the troublesome province of Further Spain (Spain west of the Ebro), where a good officer was specially wanted to check the marauding raids of a number of wild tribes. But it was in the war with Jugurtha, from 109 to 106 B.C., that he distinctly came to the front as the lieutenant of the consul Quintus Metellus. It would seem that his conduct towards his superior officer was not perfectly straightforward and honourable, as he tried to make the Roman traders in Africa, and through them the people of Rome, believe that the war was intentionally prolonged from corrupt motives. Under the circumstances this was comparatively easy, as political feeling was just at this time particularly bitter, and the senate was reputed, not without some good reason, to be venal and corrupt. Already Marius had achieved some important successes over Jugurtha, and had shown that he was the man to settle a tiresome guerilla war, and now, when he was a little over fifty, in 107 B.C., he was, amid great popular enthusiasm, elected consul for the first time. In the following year, in conjunction with his future political rival, Sulla, he brought the war to a triumphant issue, and passed two years in his province of Numidia, which he thoroughly subdued and annexed to Rome's dominion.

By this time Marius was generally recognized as the ablest general of the day, and in face of the great peril now beginning to threaten Rome from the north of the Alps, where an immense multitude of Cimbri and Teutones were hanging on the borders of Italy, public opinion promptly summoned him to the chief command. Two armies had been utterly destroyed in the neighbourhood of the Lake of Geneva, and it seemed as if a repetition of the disaster of Allia in 390 B.C., and the capture of Rome itself, might be not impossible. Marius, out of unpromising materials and a demoralized soldiery, organized a well-disciplined army, with which he inflicted on the invading hordes two decisive defeats, the first in 102 B.C. at Aquæ Sextiæ (Aix in the department of Bouches du Rhône, some way north of Marseilles), and the second in the following year at Vercellæ (Vercelli, about midway between Turin and Milan), the result being that for a period of some centuries Rome had nothing to fear from the northern barbarians. Deservedly indeed was Marius elected consul a fifth time, hailed as the "saviour of his country," and honoured with a triumph of unprecedented splendour.

The really glorious part of his career was now over, and the remainder of his life is associated with the worst cruelties and horrors of civil war, revolution, and proscription. The hideous strifes of Marius and Sulla have passed into a proverb. It is indeed a dreadful and monotonous story of bloodshed, but it must be carefully studied if we are to understand the nature of the political changes which had their final development in imperialism. Marius was a plain, rough, though very able, soldier, without any of the intellectual culture which is indispensable to a statesman, and which the Gracchi, his political ancestors, possessed. As a politician he on the whole failed, though almost to the last he had the confidence of the popular party. But he unfortunately associated himself with low and vulgar demagogues, men probably more degraded than the worst of the senators and of the aristocracy, and thus, although perhaps he never quite sank to their level, he let himself be guilty of cruel and perfidious acts, which it is hard to reconcile with the character of a brave man and a hero. He was indeed appointed in 88 B.C., after a riot and partial revolution, to the command in the war in the East with Mithridates, but the triumph of Sulla and the aristocratical party almost immediately afterwards drove him as an outlaw from Rome, and he had to seek safety amid the marshes round Minturnæ (Garigliano) in Latium. The Gallic trooper sent by the local authorities to strike off the old man's head quailed, it is said, before the fire of his eye, and fled with the exclamation, "I cannot kill Caius Marius." Meantime, in the absence of Sulla, who had left Italy for the Mithridatic war, Cinna's sudden and violent revolution had put the senate at the mercy of the popular leaders, and Marius greedily caught at the opportunity of a bloody vengeance, which became in fact a reign of terror in which senators and nobles were slaughtered wholesale. He had himself elected consul, for the seventh time, in fulfilment of a prophecy given to him in early manhood. Thus, full of honours in one sense, but really hated and execrated, he closed his career, dying in the delirium of fever in 86 B.C., at seventy years of age.

Marius was not only a great and successful general, but also a great military reformer. A citizen militia was from his time exchanged for a professional soldiery, which had hitherto been as little liked by the Roman people as it was by our own ancestors. A standing army, their instincts told them, would be a ready tool of despotism; and indeed the changes of which Marius was the author paved the way for the subsequent military imperialism. The Roman soldier was henceforth a man who found his home in the camp, and who had no trade but war. A great general could hardly fail to become the first and foremost man in the state. Marius, however, himself did not attempt to overturn the oligarchy, as Cæsar afterwards did, by means of the army, but rather by such expedients as the constitution seemed to allow, though they had to be backed up by street riots and mob violence. He failed as a political reformer because the merchants and the moneyed classes, whom the more statesmanlike Gracchi tried to conciliate, feared that they would themselves be swept away by a revolution of which the mob and its leaders would be the ultimate controllers. The farmer's son, the rough blunt soldier, the saviour of his country in middle life, and its curse and pest in his old age, had a decided tinge of fanaticism and that vein of superstition which is often allied to such natures. In matters so important as canvassing for the consulship he would be guided by the counsels of an Etruscan soothsayer, and would be accompanied in his campaigns by a Syrian prophetess. The fashionable accomplishments of the day, and the new Greek culture, were wholly alien to his taste, and he was thus really disqualified for the political life of his time. When his military career was once ended, failure and disgrace became a certainty for him.

For the life of Marius our original sources are a multitude of passages in Cicero's works, Sallust's *Jugurthan War*, the epitomes of the lost books of Livy, Plutarch's *Lives*, &c. In Smith's *Biographical Dictionary* the life is given at great length, and the details stated generally with great accuracy. In Mommsen's *History of Rome*, bk. iv. chaps. 6, 7, 8, a clear picture of the whole period is presented to us; and Niebuhr's *Lectures on Roman History* (Lectures 81–86) may be consulted with great advantage.

MARIVAUX, PIERRE CARLET DE CHAMBLAIN DE (1688–1763), novelist and dramatist, was born at Paris on the 4th February 1688. His father was a financier of Norman extraction, whose real name was Carlet, but who after the loose fashion of the period assumed the surname of Chamblain, and then, finding that others of his class had chosen the same, superadded that of Marivaux. M. Carlet de Marivaux, however, was a man of good reputation, and he received the appointment of director of the mint at Riom in Auvergne, where and at Limoges the young Pierre was brought up. It is said that he developed literary tastes early, and wrote his first play, the *Père Prudent et Equitable*, when he was only eighteen; it was not, however, published till 1712, when he was twenty-four. His chief attention in those early days was paid to novel writing, not the drama. In the three years from 1713 to 1715 he produced three novels—*Les Effets Surprenantes de la Sympathie*, *La Voiture Embourbée*, and a book which had three titles *Pharsamon*, *Les Folies Romanesques*, and *Le Don Quichotte Moderne*. All these books were in a curious strain, not in the least resembling the pieces which long afterwards were to make his reputation, but following partly the Spanish romances and partly the heroic novels of the preceding century, with a certain intermixture of the marvellous. Then Marivaux's literary ardour took a new phase. He fell under the influence of La Motte, and thought to serve the cause of that ingenious paradoxer by travestying Homer, an ignoble task, which he followed up by performing the same office in regard to Fénelon. His friendship for La Motte, however, introduced him to the *Mercure*, the chief newspaper of France, where in 1717 he produced various articles of the "Spectator" kind, which were distinguished by much keenness of observation and not a little literary skill. It was at this time that the peculiar style called Marivaudage first made its appearance in him. The year 1720 and those immediately following were very important ones for Marivaux; not only did he produce a comedy, now lost except in small part, entitled *L'Amour et la Vérité*, and another and far better one entitled *Arlequin Poli par l'Amour*, but he wrote a tragedy, *Annibal*, which was and deserved to be unsuccessful. Meanwhile his worldly affairs underwent a sudden revolution. His father had left him a comfortable subsistence, but he was persuaded by friends to risk it in the Mississippi scheme, and after vastly increasing it for a time lost all that he had. His prosperity had enabled him to marry a certain Mademoiselle Martin, of whom much good is said, and to whom he was deeply attached, but who died very shortly. His pen now became almost his sole resource. He had a connexion with both the fashionable theatres, for his *Annibal* had been played at the Comédie Française and his *Arlequin Poli* at the Comédie Italienne, where at the time a company who were extremely popular, despite their imperfect command of French, were established. He endeavoured too to turn his newspaper practice in the *Mercure* to more account by starting a weekly *Spectateur Français*, to which he was the sole contributor. But his habits were the reverse of methodical; the paper appeared at the most irregular intervals; and, though it contained some excellent work, its irregularity killed it. For nearly twenty years the theatre, and especially the Italian theatre, was Marivaux's chief support, for his pieces, though they were not ill received by the actors at the Français, were rarely successful there. The best of a very large number of plays (Marivaux's theatre numbers between thirty and forty items) were the *Surprise de l'Amour* (1722), the *Triomphe de Plutus* (1728), the *Jeu de l'Amour et du Hasard* (1730), *Les Fausses Confidences* (1737), all produced at the Italian theatre, and *Le Legs*, produced at the French. Meanwhile he had at intervals returned to both his other lines of composition. A periodical publication called *L'Indigent Philosophe* appeared in 1727, and another called *Le Cabinet du Philosophe* in 1734, but the same causes which had proved fatal to the *Spectateur* prevented these later efforts from succeeding. In 1731 Marivaux published the first two parts of his best and greatest work, *Marianne*, a novel of a new and remarkable kind. As was usual, however, with him when he ventured on any considerable task, he was very slow with it. The eleven parts appeared in batches at intervals during a period of exactly the same number of years, and after all it was left unfinished. In 1735 another novel, the *Paysan Parvenu*, was begun, but this also was left unfinished. The year afterwards Marivaux, who was then nearly fifty years of age, was elected of the Academy. He survived for more than twenty years, and was not idle, again contributing occasionally to the *Mercure*, writing plays, "reflexions" (which were seldom of much worth), and so forth. He died on the 12th February 1763, aged seventy-five years.

The personal character of Marivaux was curious and somewhat contradictory, though not without analogies, one of the closest of which is to be found in Goldsmith. He was, however, unlike Goldsmith, at least as brilliant in conversation as with the pen. He was extremely good-natured, but fond of saying very severe things, unhesitating in his acceptance of favours (he drew a regular annuity from Helvetius), but exceedingly touchy if he thought himself in any way slighted. He was, though a great cultivator of *sensibilité*, on the whole decent and moral in his writings, and was unsparing in his criticism of the rising *Philosophes*. This last circumstance, and perhaps jealousy as well, made him a dangerous enemy in Voltaire, who lost but few opportunities of speaking disparagingly of him. Not very much is known of his life, though anecdotes of his sayings are not uncommon. He had good friends, not merely, as has been said, in the rich, generous, and amiable Helvetius, but in Madame de Tencin, in Fontenelle, and even in Madame de Pompadour, who gave him, it is said, a considerable pension, of the source of which he was ignorant. It is even asserted that annoyance at the discovery of the origin of a benefit which he thought came directly from the king hastened his death; and, though this is scarcely likely, his extreme sensitiveness is shown by many stories, one of which carries out in real life and almost to the letter Farquhar's famous *mot* as to "laughing consumedly." He had one daughter, who took the veil, the duke of Orleans, the regent's successor, furnishing her with her dowry.

We have no space here for a detailed criticism of Marivaux's extensive work. The so-called Marivaudage is the main point of importance about it, though the best of the comedies have great merits, and *Marianne* is an extremely important step in the legitimate development of the French novel,—legitimate, that is, in opposition to the brilliant but episodic productions of Le Sage. The subject-matter of Marivaux's peculiar style has been generally and with tolerable exactness described as the metaphysic of love-making. His characters, in a happy phrase of Crebillon's, not only tell each other and the reader everything they have thought, but everything that they would like to persuade themselves that they have thought. The style chosen for this is justly regarded as derived mainly from Fontenelle, and through him from the Précieuses, though there are traces of it even in La Bruyère. It abuses metaphor somewhat, and delights to turn off a metaphor itself in some unexpected and bizarre fashion. Now it is a familiar phrase which is used where dignified language would be expected; now the reverse. In the same criticism of Crebillon's which has been already quoted occurs another happy description of Marivaux's style as being "an introduction to each other of words which have never made acquaintance, and which think that they will not get on together," a phrase as happy in its imitation as in its satire of the style itself. Yet this fantastic embroidery of language has a certain charm, and suits perhaps better than any other style the somewhat unreal gallantry and *sensibilité* which it describes and exhibits. The author possessed, moreover, both thought and observation, besides considerable command of pathos. He is not, and is never any more likely to be, generally popular, but he is one of the authors in whom those who do like them are sure to take particular delight.

The best and most complete edition of Marivaux is that of 1781, 12 vols. 8vo. There is a good modern edition of the plays by E. Fournier, and another of *Marianne* and the *Paysan Parvenu* in two volumes. J. Fleury's *Marivaux et le Marivaudage* (Paris, 1881) is worth consulting by those who are interested in the subject. (G. SA.)

MARK, the traditional name of the author of the Second Gospel. The name Mark occurs in several books of the New Testament. In the Acts of the Apostles, chap. xii. mention is made of "John whose surname was Mark," to the house of whose mother, Mary, at Jerusalem, Peter went when miraculously released from prison.[1] This John Mark went with Barnabas and Paul on their missionary journey, as far as Perga in Pamphylia, and then, "departing from them, returned to Jerusalem" (Acts xii. 25; xiii. 13). His departure was afterwards the occasion of a "sharp contention" between Paul and Barnabas; the former "thought not good to take with them him who withdrew from them from Pamphylia, and went not with them to the work"; the latter "took Mark, and sailed away into Cyprus" (Acts xv. 38, 39). On the subsequent history of Mark the Acts of the Apostles are silent.

The same name Mark occurs in three Pauline epistles. (1) In Col. iv. 10 the writer enumerates Mark among his fellow-workers, mentioning also that he was a nephew (some translate "cousin") of Barnabas, and implying that he was a Jew ("of the circumcision"). He is evidently about to send him, in accordance with a previous intimation, on a special mission to the Colossians; but there is no evidence, except the statement of the Coptic subscription to the epistle, to show whether the contemplated journey took place. (2) In Philemon 24 the writer also mentions Mark as one of his fellow-workers, *i.e.*, probably in preaching the gospel during his imprisonment at Rome. (3) In 2 Tim. iv. 11 the writer gives the charge to Timothy, "Take Mark and bring him with thee, for he is useful to me for ministering." It is a plausible conjecture that this is a request that Mark might be brought back to Rome after his mission to Colossæ.

The same name also occurs in 1 Peter v. 13, "Mark, my son." This expression has sometimes been taken literally; but it is more usually understood in a metaphorical sense, as meaning that Peter had converted Mark. Those who take "Babylon" in the same passage to mean Rome necessarily infer that Mark was with Peter at Rome; a tradition to the same effect is mentioned in fragments of Clement of Alexandria, preserved in Eusebius, *H. E.*, ii. 15; vi. 14.

The preponderance of patristic and mediæval tradition is in favour of the hypothesis that the same person is designated in all these passages of the New Testament. But other hypotheses have found favour, especially among those writers of various schools who have felt a difficulty in understanding how the same person should be an intimate companion at once of St Paul and of St Peter. It has been supposed (1) that the John Mark of the Acts is the Mark of the Pauline epistles, but not the Mark of 1 Peter; (2) that the John Mark of the Acts, the Mark of the Pauline epistles, and the Mark of 1 Peter are all different; (3) that the John Mark of the Acts is the Mark of 1 Peter, but not the Mark of the Pauline epistles. Into the arguments for these several hypotheses it is unnecessary to enter here; they are of course complicated by the prior question of the authenticity and date of the books of the New Testament in which the name occurs. The most elaborate modern discussion of the question, which arrives at the conclusion that the first of the three hypotheses just mentioned is the true one, is contained in the work of Molini, whose title is given below. But, whether there was only one Mark or more than one, there is a general belief, which rests ultimately on the testimony of the presbyter (John) who is quoted by Papias (ap. Euseb., *H. E.*, iii. 39, 15), that the second canonical Gospel, or its original, is to be ascribed to the Mark who was the disciple of St Peter.[2] Of this Mark

[1] This double name, the one Jewish, the other Roman, may be compared with the double name "Saul, who is also called Paul," in succeeding chapters of the Acts; sometimes the double name, sometimes one or other of the single names, is used.

[2] Most of the arguments by which Kienlen (*Stud. u. Krit.*, 1843, pp. 423 *sq.*) endeavours to show that the Gospel is the work of the

the evangelist, as of other persons whose names are prominent in the New Testament, there is a large mass of traditional biography, in which possible fact and obvious fiction are so closely interwoven as not to be easily disentangled, and which would not be worth recording were it not for the later historical associations which have clustered round it.

Of Mark's birth and country nothing is positively known; the majority of mediæval writers state that he was a Levite; but this is probably no more than an inference from his supposed relationship to Barnabas. The Alexandrian tradition seems to have been that he was of Cyrenæan origin; and Severus, a writer of the 10th century, adds to this the statement that his father's name was Aristobulus, who, with his wife Mary, was driven from the Pentapolis to Jerusalem by an invasion of barbarians (Severus Aschimon, ap. Renaudot, *Hist. Patriarch. Alex.*, p. 2). In the apocryphal Acts of Barnabas, which profess to be written by him, he speaks of himself as having been formerly a servant of Cyrillus, the high priest of Zeus, and as having been baptized at Iconium. The presbyter John, whom Papias quotes, says distinctly that "he neither heard the Lord nor accompanied Him" (ap. Eusebius, *l.c.*); and this positive statement is fatal to the tradition, which does not appear until about two hundred and fifty years afterwards, that he was one of the seventy disciples (Epiphanius, pseudo-Origen *De recta in Deum fide*, and the author of the *Paschal Chronicle*). Various other results of the tendency to fill up blank names in the gospel history must be set aside on the same ground; it was, for example, believed that Mark was one of the disciples who "went back" because of the "hard saying" (pseudo-Hippolyt., *De LXX. Apostolis* in Cod. Barocc. ap. Migne, *Patrol. Græc.*, vol. x. 955); there was an Alexandrian tradition that he was one of the servants at the miracle of Cana of Galilee, that he was the "man bearing a pitcher of water" in whose house the last supper was prepared, and that he was also the owner of the house in which the disciples met on the evening of the resurrection (Renaudot, *l.c.*); and even in modern times there has been the conjecture that he was the "certain young man" who "fled naked" from Gethsemane, Mark xiv. 51, 52 (Olshausen).

A tradition which was widely diffused, and which is not in itself improbable, was that he afterwards preached the gospel and presided over the church at Alexandria (the earliest extant testimony is that of Eusebius, *H. E.*, ii. 16, 1; ii. 24; for the fully-developed legend of later times see Symeon Metaphrastes, *Vita S. Marci*, and Eutychius, *Origines Ecclesiæ Alexandrinæ*). There was another, though perhaps not incompatible, tradition that he preached the gospel and presided over the church at Aquileia in North Italy. The earliest testimony in favour of this tradition is the vague statement of Gregory of Nazianzus that Mark preached in Italy, but its existence in the 7th century is shown by the fact that in 629 A.D. Heraclius sent the patriarchal chair from Alexandria to Grado, to which city the patriarchate of Aquileia had been then transferred (*Chron. Patriarch. Gradens.*, ap. Ughelli, *Italia Sacra*, tom. v. p. 1086; for other references to the general tradition see De Rubeis, *Monum. Eccles. Aquileien.*, c. 1; *Acta Sanctorum*, ad April. xxv.). It was through this tradition that Mark became connected with Venice, whither the patriarchate was further transferred from Grado; an early Venetian legend, which is represented in the Cappella Zen in the basilica of St Mark, antedates this connexion by picturing the evangelist as having been stranded on the Rialto, while it was still an uninhabited island, and as having had the future greatness of the city revealed to him (Danduli, *Chron.*, iv. 1, ap. Muratori, *Rer. Ital. Script.*, vol. xii. 14).

The earliest traditions appear to imply that he died a natural death (Eusebius, Jerome, and even Isidore of Seville); but the Martyrologies claim him as a martyr, though they do not agree as to the manner of his martyrdom. According to the pseudo-Hippolytus he was burned; but Symeon Metaphrastes and the *Paschal Chronicle* represent him to have been dragged over rough stones until he died. But, however that may be, his tomb appears to have been venerated at Alexandria, and there was a firm belief at Venice in the Middle Ages that his remains had been translated thither in the 9th century (the fact of the translation is denied even by Tillemont; the weakness of the evidence in support of the tradition is apparent even in Molini's vigorous defence of it, lib. ii., c. 2; the minute account which the same writer gives, lib. ii. c. 11, of the discovery of the supposed actual bones of the evangelist in 1811 A.D., is interesting). There was another though less widely accepted tradition, that the remains soon after their translation to Venice were retranslated to the abbey of Reichenau on Lake Constance; a circumstantial account of this retranslation is given in the treatise *Ex Miraculis S. Marci*, ap. Pertz, *Mon. Hist. German. Script.*, tom. iv. p. 449. It may be added that the Venetians prided themselves on possessing, not only the body of St Mark, but also the autograph of his Gospel; this autograph, however, proved on examination to be only part of a 6th-century book of the Gospels, the remainder of which was published by Bianchini as the *Evangeliarium Forojuliense*; the Venetian part of this MS. was found some years ago to have been wholly destroyed by damp.

It has been at various times supposed that Mark wrote other works besides the Gospel. Several books of the New Testament have been attributed to him: viz., the Epistle to the Hebrews (Spanheim, *Op. Miscell.*, vol. ii. p. 240), the Epistle of Jude (*cf.* Holtzmann, *Die Synoptische Evangelien*, p. 373), the Apocalypse (Hitzig, *Ueber Johannes Marcus*, Zürich, 1843). The apocryphal *Acta Barnabæ* purport to have been written by him. There is a liturgy which bears his name, and which exists in two forms; the one form was found in a MS. of the 12th century in Calabria, and is, according to Renaudot, the foundation of the three liturgies of St Basil, St Gregory Nazianzen, and St Cyril; the other is that which is used by the Maronite and Jacobite Syrians. Both forms have been published by Renaudot, *Liturg. Oriental. Collect*, vol. i. p. 127, and vol. ii. p. 176, and in Neale's *History of the Holy Eastern Church*; but neither has any substantial claim to belong to the ante-Nicene period of Christian literature.

The symbol by which Mark is designated in Christian art is usually that of a lion. Each of the "four living creatures" of Ezekiel and the Apocalypse has been attributed to each of the four evangelists in turn; Augustine and Bede think that Mark is designated by the "man"; Theophylact and others think that he is designated by the eagle; Anastasius Sinaita makes his symbol the ox; but mediæval art acquiesced in the opinion of Jerome that he was indicated by the lion. Most of the martyrologies and calendars assign April 25 as the day on which he should be commemorated; but the *Martyr. Hieron.* gives September 23, and some Greek martyrologies give January 11. This unusual variation probably arises from early differences of opinion as to whether there was one Mark or more than one.

The work of Canon Molini of Venice, *De Vita et Lipsanis S. Marci Evangelistæ*, edited, after the author's death, by S. Pieralisi, the librarian of the Barberini library, in 1864, gives full information on all that relates to the subject of the present article. (E. HA.)

Pauline and not of the Petrine Mark are used by other writers in support of the hypothesis that in its present form it is not the work of which Papias speaks.

MARK, GOSPEL OF. See GOSPELS.

MARKIRCH (in French, *Ste-Marie-aux-Mines*), a flourishing industrial town of Germany, in Upper Alsace, circle of Rappoltsweiler, is prettily situated in the valley of the Leber or Liepvrette, an affluent of the Rhine, near the French frontier. The once productive silver, copper, and lead mines of the neighbourhood are now no longer worked; and the present chief industries of the place are weaving and dyeing. In and about Markirch there are nearly forty wool and cotton factories, besides numerous looms in the cottages of the weavers; and these produce cloth to the annual value of £625,000. It is estimated that there are about 40,000 workpeople in the industrial district of which Markirch is the centre. The small river Leber, which intersects the town, was at one time the boundary between the German and French languages, and traces of this separation still exist. The German-speaking inhabitants on the right bank were Protestants, and subject to the counts of Rappoltstein, while the French inhabitants were Roman Catholics, and under the rule of the dukes of Lorraine. The population in 1880 was 11,824.

MARLBOROUGH, a municipal and parliamentary borough of Wiltshire, England, situated on the great high-road between London and Bath, and distant 75 miles from the former, 32 from the latter, and 13 from Devizes. It stands on the left bank of the Kennet, a tributary of the Thames, in 51° 25′ N. lat. and 1° 43′ W. long. It is an agricultural centre, and has a weekly market. In the days of its prosperity forty-two public coaches halted daily at its doors, and it had a fair trade in corn and malt; but its traffic was to a great extent diverted by the opening of the Great Western Railway, and it now carries on a very small trade in tanning, rope-making, and malting. It consists mainly of a long and broad street, terminated at one end by St Mary's church and the town-hall, and at the other by St Peter's church and the college. The municipal council consists of a mayor, four aldermen, and twelve councillors, and the borough returns one member to parliament. In 1881 the population of the municipal borough (area 186 acres) was 3343, and of the parliamentary borough (area 4665 acres) 5180.

The name has been a frequent matter for discussion, some declaring it to be the hill (*berg*) or fortress (*bury*) of Merlin the Briton, others the *Marl* borough, in allusion to the surrounding soil, which, however, is chalk. A great British mound exists at the south-west extremity of the town, and a castle was erected around it by William the Conqueror. This became a somewhat notable place. Henry I. kept Easter here in 1110, and Henry II. granted it to John Lackland. Henry III. held his last parliament here in 1267, and passed the "Statutes of Marleberge." Later the castle served as an occasional royal residence; it was probably dismantled during the Wars of the Roses. The town was besieged and taken during the civil wars, and a few years later (1653) was almost entirely consumed by fire. A large mansion was erected by Lord Seymour in the reign of Charles II. near the site of the castle, and this, after various vicissitudes, was in 1843 converted into "Marlborough College,"—a public school designed mainly for the education of the sons of the clergy. A large group of buildings—chapel, schools, dining hall, racket courts, &c.—soon sprung up around the original building, and the school numbered five hundred and eighty in 1882.

MARLBOROUGH, a town of the United States, in Middlesex county, Massachusetts, about 25 miles west from Boston, with stations on the Old Colony and the Fitchburg Railways. It lies in a fertile hilly district, and contains a beautiful sheet of water 160 acres in extent, known as Williams Lake. Shoemaking is the staple industry, some of the factories in the department rivalling the largest in the world. There is a good public library; and three weekly newspapers are published in the town. The population increased from 8474 in 1870 to 10,126 in 1880. Marlborough, colonized by settlers from Sudbury in 1655, and incorporated in 1661, occupies the site of the Christian Indian village of Okommakamesitt.

MARLBOROUGH, JOHN CHURCHILL, DUKE OF (1650–1722). In the small manor house of Ashe, situated in the parish of Musbury in Devonshire, but hardly a stone's throw beyond the parish of Axminster, John Churchill the first duke of Marlborough was born 24th of June 1650. Arabella Churchill, his eldest sister, and the mother of the duke of Berwick, was born in the same house on the 28th of February 1648. They were the children of Winston Churchill of Glanville Wotton in Dorset and Elizabeth the fourth daughter of Sir John Drake, who after the close of the civil war received his son-in-law into his own house. For a year or two after the Restoration John Churchill went to St Paul's school, and there is a tradition that during this period he showed the bent of his taste by reading and re-reading Vegetius *De Re Militari*. When fifteen years old he obtained a place in the household of the duke of York, and about the same time his sister Arabella became maid of honour to the duchess, two events which contributed greatly to the advancement of the Churchills. Next year, in 1666, he received, through the influence of his master, a commission in the guards, and left England for service at Tangiers. Such fighting as was waged with the Moors did not accord with his feelings, and he soon returned to his own country. For a few years afterwards Churchill remained in attendance at the court, and it was during this period that the natural carefulness of his disposition was shown by his investing in an annuity a present of £5000 given him by a court beauty. In 1672, when England to her shame sent six thousand troops to aid Louis XIV. in his attempt to subdue the Dutch, Churchill formed one of the company, and soon attracted the attention of Turenne, by whose profound military genius the whole army was directed. At the siege of Nimeguen Churchill acquitted himself with such success that the French commander predicted his ultimate rise to distinction. When Maestricht was besieged he saved the life of the duke of Monmouth, and received the thanks of Louis XIV. for his services. Early in 1678 he was married to Sarah Jennings, the favourite attendant on the Princess Anne, the younger daughter of the duke of York. Her father Richard Jennings, a Hertfordshire squire, had twenty-two brothers and sisters; one of the latter married a London tradesman called Hill, and their daughter Abigail Hill afterwards succeeded her cousin the duchess of Marlborough as favourite to Queen Anne. Sarah Jennings had as little money as her husband, but this deficiency was more than compensated for by an abundance of energy and ambition.

On the accession of James II. the Churchills received a great increase in fortune. Colonel Churchill had been created a Scotch peer in 1682, and as a reward for his services in going on a special mission from the new monarch to Louis XIV. he was advanced to the English peerage under the title of Baron Churchill of Sandridge in Hertfordshire, the village in which the Jennings's property was situated. A step in the army was at the same time conferred upon him, and when the duke of Monmouth attempted his ill-fated enterprise in the western counties the second position in command was bestowed on Lord Churchill. Through his vigilance and energy victory declared itself on the king's side. After the death of Monmouth he withdrew as far as possible from the administration of public business. Whilst on his embassy to the French court he had declared with emphasis that if the king of England should change the religion of the state he should at once leave his service, and it was not long before the design of James became apparent to the world. Churchill was one of the first to send overtures of obedience to the prince of Orange. Although he continued in a high position under James, and drew the emoluments of his places, he promised William of Orange to use every exertion to bring over the troops to his side. James had been warned against putting any trust in the loyalty of the man on whom he had showered so many favours, but the warnings were in vain, and on the landing of the Dutch prince at Brixham Churchill was sent against him with five thousand men. When the royal army had advanced to the downs of Wiltshire and a battle seemed imminent, James was disconcerted by learning that in the dead of night his general had stolen away like a thief into the opposite camp. For this timely act of treachery Churchill received another advancement in the peerage. He had now become the earl of Marlborough and a member of the privy council, a mark of royal favour which during this and the next reign was more than an unmeaning honour. William felt, however, that he could not place implicit reliance in his friend's integrity; and, with a clear sense of the manner in which Marlborough's talents might be employed without any detriment to the stability of his throne, he sent him with the army into the Netherlands and into Ireland. For some time there was no open avowal of any distrust in Marlborough's loyalty, but in May 1692 the world was astonished at the news that he had been thrown into the Tower on an accusation of treason. Though the evidence which could be brought against him was slight, and he was soon set at liberty, there is no doubt that Marlborough was in close relations with the exiled king at St Germains, and that he even went so far as to disclose to his late master the intention of the English to attack the town of Brest. The talents of the statesmen of this reign were chiefly displayed in their attempts to convince both the exiled and the reigning king of England of their attachment to his fortunes. The sin of Marlborough lay in the fact that he had been favoured above his fellows by each in turn, and that he betrayed both alike apparently without scruple or without shame. Once again during the Fenwick plot he was charged with treason, but William, knowing that if he pushed Marlborough and his friends to extremities there were no other statesmen on whom he could rely, contented himself with ignoring the confessions of Sir John Fenwick, and with executing that conspirator himself. Not long afterwards the forgiven traitor was made governor to the young duke of Gloucester, the only one of Anne's numerous children who gave promise of attaining to manhood. During the last years of William's reign Marlborough once more was placed in positions of responsibility. His daughters were married into the most prominent families of the land: the eldest became the wife of the eldest son of Lord Godolphin; the second, the loveliest woman at the court, with her father's tact and temper and her mother's beauty, married the only son of Lord Sunderland. Higher honours were in store for his family, and they came on the accession of Queen Anne in March 1702. She had not been more than three days upon the throne before the knighthood of the Garter was conferred upon Marlborough. He was made captain-general of the English troops both at home and abroad, and master-general of the ordnance. The new queen did not forget the life-long service of his wife; three positions at the court by which she was enabled to continue by the side of the sovereign as closely as she had lived with the princess were united in her person. The queen showed her devotion to her friend by another signal mark of favour. The rangership of Windsor Park was granted her for life, with the especial object of enabling Lady Marlborough to live in the Great Lodge. These were the opening days of many years of fame and power. A week or two after the death of William it was agreed by the three great powers, England, Holland, and Austria, which formed the grand alliance, that war should be declared against France on the same day, and on May 4, 1702, the declaration was made by the three countries. Marlborough was made commander-in-chief of the united armies of England and Holland, but throughout the war his plans were impeded by the jealousy of the commanders who were nominally his inferiors, and by the opposite aims of the various countries that were striving to break the power of France. He himself wished to penetrate into the French lines; the anxiety of the Dutch was for the maintenance of their frontier and for an augmentation of their territory; the desire of the Austrian emperor was to ensure his son's rule over Spain. To secure concerted action by these different powers taxed all the diplomacy of Marlborough, but he succeeded for the most part in his desires. In the first year of the campaign it was shown that the armies of the French were not invincible. Several fortresses which Louis XIV. had seized upon surrendered themselves to the allies. Kaiserswerth on the Rhine and Venloo on the Meuse soon passed from the hands of the French to the English. The prosperous commercial town of Liége with its commanding citadel quickly capitulated. The successes of Marlborough caused much rejoicing in his own country, and for these brilliant exploits he was raised to the highest rank in the peerage, and rewarded with a handsome annuity. In the spring of the following year a crushing blow fell upon the duke and duchess. Their eldest and only surviving son, the marquis of Blandford, was seized whilst at King's College, Cambridge (under the care of Hare, afterwards bishop of Chichester), with the small-pox, and died on the 20th February 1703, in his seventeenth year. If the character of the youth which is given by Cole, the Cambridge antiquary, can be accepted as true, and Cole was not likely to be prejudiced in favour of the family of Churchill, his talents had already justified the prediction that he would rise to the highest position in the state.

The result of the campaign of 1703 inspired the French king with fresh hopes of ultimate victory. The dashing plans of Marlborough were frustrated by the opposition of his Dutch colleagues. When he wished to invade the French territory they urged him to besiege Bonn, and he was compelled to accede to their wishes. After this digression from his first purpose he returned to his original plan of attacking Antwerp; but, in consequence of the incapacity of the Dutch leaders, the generals (Villeroi and Boufflers) of the French army surprised the Dutch division and inflicted on it a loss of many thousands of men. Marlborough was forced to abandon his enterprise, and all the compensation which he received was the capture of the insignificant forts of Huy and Limburg. After a year of comparative failure for the allies, Louis XIV. was emboldened to enter upon an offensive movement against Austria; and Marlborough, smarting under the misadventures of 1703, and conscious that the war could only be brought to an end by more decisive measures, was eager to meet him. A magnificent army was sent by the French king under the command of Marshal Tallard, with instructions to strike a blow at Vienna itself. Marlborough divined the intention of the expedition, and, without communicating his intentions to his colleagues, led his troops into Bavaria. The two armies (that under Marlborough and Prince Eugène numbering more than fifty thousand men, whilst Tallard's forces were nearly ten thousand stronger) met in battle array near the village of Blenheim. The French commander made the mistake of supposing that the enemy's attack would be directed against his position in the village, and he concentrated an excessive number of his troops at that point. The early part of the fight was in favour of the French. Three times were the troops led by Prince Eugène driven back in confusion; Marlborough's cavalry failed on their first attack in breaking the line of the enemy. But in the end the victory of the allies was conclusive. Nearly thirty thousand of the French and Bavarians were killed and wounded, and in Blenheim alone ten thousand were made prisoners. Never was a victory more eagerly welcomed than this, and never was a conquering leader more rewarded than Marlborough. On his return to his own country he was received with enthusiasm on all sides. Poets and prose writers were employed to do him honour, and the lines of Addison comparing the English commander to the angel who passed over "pale Britannia" in the storm of 1703 have been famous for nearly two centuries. The manor of Woodstock, which was transferred by Act of Parliament from the crown to the duke, was a reward more after his own heart. The gift even in that form was a noble one, but the queen heightened it by instructing Sir John Vanbrugh to build a palace in the park at the royal expense, and, although the works subsequently caused much anxiety to the duke and duchess, £240,000 of public money was spent on the buildings.

The following year was not marked by any stirring incident. Marlborough was hampered by tedious formalities at the Hague and by jealousies at the German courts. The armies of the French were again brought up to their full standard, but the generals of Louis were instructed to entrench themselves behind earthworks and to act on the defensive. In the darkness of a July night these lines were broken through, and the French were forced to take shelter under the walls of Louvain. Marlborough urged an attack upon them in their new position, but his passionate arguments were spent in vain, and when 1705 had passed away the forces of the French king had suffered no diminution. This immunity from disaster tempted Villeroi in the next spring into meeting the allied forces in an open fight, but his assurance proved his ruin. The battle of Ramillies (23d May 1706) ended in the total rout of the French, and caused the transference of nearly the whole of Brabant and Flanders to the allies. Five days afterwards the victor entered Brussels in state, and the inhabitants acknowledged the rule of the archduke. Antwerp and Ostend surrendered themselves with slight loss. Menin held out until three thousand of the soldiers of the allies were laid low around its walls, but Dendermonde, which Louis had forty years previously besieged in vain, quickly gave itself up to the resistless Marlborough. Again a year of activity and triumph was succeeded by a period of languor and depression. During the whole of 1707 fortune inclined to the other side, with the result that early in the next year Ghent and Bruges returned to the allegiance of the French, and Marlborough, fearing that their example might be followed by the other cities, advanced with his whole army towards Oudenarde. Had the counsels of Vendome, one of the ablest of the French generals, prevailed, the fight might have had a different issue, but his suggestions were disregarded by the duke of Burgundy, the grandson of Louis, and the battle, like its predecessor, ended in their defeat. After this victory Marlborough, ever anxious for decisive measures, wished to advance on Paris, but he was overruled. The allied army invested the town of Lille, on the fortifications of which Vauban had expended an immensity of thought; and after a struggle of nearly four months, and the loss of thirty thousand men, the citadel surrendered. By the end of the year Brabant was again subject to the rule of the allies. The suffering in France at this time weighed so heavily upon the people that its proud king humbled himself to sue for peace. Each of the allies in turn did he supplicate, and his minister endeavoured by promises of large sums of money to obtain the support of Marlborough to his proposals. These attempts were in vain, and when the winter passed away a French army of one hundred and ten thousand, under the command of Villars, took the field. On the 3d of August 1709 Tournay capitulated, and the two leaders, Marlborough and Eugène, led their forces to Mons, in spite of the attempt of Villars to prevent them. For the last time during the protracted war the two armies met in fair fight at Malplaquet, 11th September 1709, where the French leader had strengthened his position by extensive earthworks. The fight was long and doubtful, and, although the French ultimately retreated under the direction of Boufflers, for Villars had been wounded on the knee, it was in good order, and their losses were less than those of their opponents. The campaign lasted for a year or two after this indecisive contest, but it was not signalized by any such "glorious victory" as Blenheim. All that the English could plume themselves on was the acquisition of a few such fortresses as Douai and Bethune, and all that the French had to fear was the gradual tightening of the enemy's chain until it reached the walls of Paris. The energies of the French were concentrated in the construction of fresh lines of defence, until their commander boasted that his position was impregnable. In this way the war dragged on until the conclusion of the peace of Utrecht.

All that Marlborough had effected on the battlefield during these years of war had not prevented his position from being undermined by party intrigues at home. In the early part of Queen Anne's reign his political friends were to be found among the Tories, and the ministry was chiefly composed of members of that party. After a year or two, however, the more ardent Tories withdrew, and two younger adherents of the same cause, Harley and St John (both of whom were at present content to conceal their animosity to Marlborough), were introduced into the ministry. The duchess, partly through the influence of her son-in-law, the earl of Sunderland, and partly through the opposition of the Tories to the French war, had gone over to the Whig cause, and she pressed her views on the sovereign with more vehemence than discretion. She had obtained for her indigent cousin, Abigail Hill, a small position at court, and the poor relation very soon began to injure the benefactor who had befriended her. With Hill's assistance Harley and St John widened the breach with the queen which was commenced by the imperious manner of the duchess. The love of the two friends changed into hate, and no opportunity for humiliating the family of Marlborough was allowed to pass away neglected. Sunderland and Godolphin were the first to fall (July–August 1710); a few months later the duchess was dismissed from her offices; and, although Marlborough himself was permitted to continue in his position a short time longer, his fall was only delayed until the last day of 1711. Life in England had become so unpleasant that he went to the Continent, and he remained abroad until the death of Anne (1st August 1714). Then he once more returned to the shores of England and resumed his old military posts, but he took little part in public affairs. Even if he had wished to regain his commanding position in the country, ill health would have prevented him from obtaining his desires. Johnson, indeed, says, in the *Vanity of Human Wishes*, that "the streams of dotage" flowed from his eyes; but it is not desirable to examine too critically the assertions of a poem which relied for its success upon the strength of its comparisons. It is certain that at the time of his death he was able to understand the remarks of others and to express his own wishes. At four o'clock on the morning of the 16th June 1722, he died at Cranbourn Lodge near Windsor. His remains were at first deposited in Westminster Abbey, in the vault at the east end of King Henry VII.'s chapel, but they now rest at Blenheim.

His widow, to whom must be assigned a considerable share both in his rise and in his fall, survived till October 1744. Those years were spent in bitter animosity with many within and without her own family. Left by her husband with the command of boundless wealth, she used it for the vindication of his memory and for the justification of her own resentment. Two of the leading opponents of the ministry, Chesterfield and Pitt, were especially honoured by her attentions. To Pitt she left ten thousand pounds, to the other statesman twice that sum and a reversionary interest in her landed property at Wimbledon. Whilst a widow, she received numerous offers of marriage from many titled suitors. She refused them all: from her marriage to her death her heart had no other inmate than the man as whose wife she had become almost a rival to royalty.

Marlborough obtained his first start in life through a handsome pension, and his rapid rise to the highest position in the state was due to his singular tact and to his skill in the management of men. In an age remarkable for grace of manner and for adroitness of compliment, his courteous demeanour and the art with which he refused or granted a favour extorted the admiration of every one with whom he came in contact. Through his consideration for the welfare of his soldiers he held together for years an army drawn from every nation in Christendom. His talents may not have been profound (he possessed "an excellent plain understanding and sound judgment" is the opinion of Lord Chesterfield); but they were such as Englishmen love. Alike in planning and in executing, he took infinite pains in all points of detail. Nothing escaped his observation, and in the hottest moment of the fight the coolness of his intellect shone conspicuous. His enemies indeed affected to attribute his uniform success in the field to fortune, and they magnified his love of money by drawing up balance sheets which included every penny which he had received, but omitted the pounds which he had spent in the cause he had sincerely at heart. All that can be-alleged in excuse of his attempt to serve two masters, the king whom he had deserted and the king who had received him into favour, is that not one of his associates was without sin in this respect.

The books on Marlborough are very numerous. Under his name in the catalogue of the British Museum there are 121 entries, and 32 under that of his wife. The chief works are Lediard's, Coxe's, and Alison's *Lives*; a French memoir in 3 volumes, 1808; Marlborough's *Letters and Despatches*, edited by Sir George Murray (5 volumes); and Mrs Creighton's interesting summary. The descriptions in Mr John Hill Burton's *Reign of Queen Anne* of the battle scenes of Marlborough are from personal observation. A good account of his birthplace and country will be found in Pulman's *Book of the Axe District*; and for the home of the duchess the reader can refer to Mr Cussan's *History of Hertfordshire*. Long after the death of the duke there were many pamphlets written on the conduct of his wife from her appearance at court; but they relate to matters of little interest at the present time. (W. P. C.)

MARLOW, Great, a parliamentary borough of Buckinghamshire, England, is finely situated on the Thames, and on a branch of the Great Western Railway, 37 miles west of London and 25 south-east of Oxford. It consists principally of two streets which cross each other at right angles. The church of All Saints, in the Later English style, erected in 1835, and lately extensively restored, possesses a number of brasses. The former bluecoat school has been reorganized under the endowed schools commission as a grammar school. The town has paper-mills, a brewery, and manufactures of lace and embroidery. It is also a favourite resort for boating and fishing. Marlow, anciently *Merlaw*, is a very ancient manor, and for some time after William the Conqueror it was in the possession of the crown. It returned members to parliament from the 28th of Edward I. till the 2d of Edward II., and the privilege was again restored in the 21st of James I.; since 1868 it has returned but one member. The borough includes Great and Little Marlow, Medmenham, and Bisham in Berkshire, which is united with Great Marlow by a suspension bridge, erected in 1835, at a cost of £20,000. The population of the borough, which has an area of 14,514 acres, 2424 being in the county of Berks, was 6627 in 1871 and 6779 in 1881.

MARLOWE, Christopher (1564–1593), the father of English tragedy and the creator of English blank verse, was born at Canterbury in February 1564, and christened on the 26th of that month. John Marlowe, his father, is said, on authority which satisfied the best editor of the poet, to have been a shoemaker by trade; it is supposed also that he was clerk of his parish, and survived his illustrious son for upwards of eleven years. The boy was educated at the King's School, Canterbury; matriculated as pensioner of Benet College, Cambridge, March 17, 1581; took the degree of bachelor of arts in 1583, and that of master of arts four years later. Before this date he had produced the first tragedy worthy of that name in our language, and called into existence that highest and most difficult of all its other than lyrical forms of verse, which alone has proved worthy of acceptance among his countrymen as the fit and adequate instrument of tragic drama. At some uncertain date of his early life he is supposed to have been an actor, and said to have broken his leg in the practice of his profession. But for this and many other traditions of his career and conversation there is no better evidence than that of a religious libeller. His first tragedy of *Tamburlaine the Great*, in two parts, was successively followed by *Doctor Faustus*, *The Jew of Malta*, *Edward the Second*, and *The Massacre at Paris*. The tragedy of *Dido*, *Queen of Carthage*, was probably completed for the stage after his death by Thomas Nash, the worthiest English precursor of Swift in vivid, pure, and passionate prose, embodying the most terrible and splendid qualities of a social and personal satirist; a man gifted also with some fair faculty of elegiac and even lyric verse, but in no wise qualified to put on the buskin left behind him by the "famous gracer of tragedians," as Marlowe had already been designated by their common friend Greene from among the worthiest of his fellows.

The only authentic record concerning the death of Marlowe is an entry "in the burial-register of the parish church of St Nicholas," Deptford: "Christopher Marlowe, slain by Francis Archer, June 1, 1593." Two Puritan scribblers have left two inconsistent reports as to the circumstances of this manslaughter. On the more respectable authority of Francis Meres the critic (1598) we are told that Marlowe was "stabbed to death" by a "servingman" of bad character, "a rival of his in his lewd love." The one thing unhappily certain is that one of the greatest among English poets died of a wound received in a brawl (stabbed in the head, according to one account, with his own dagger) at the untimely age of twenty-nine years and three months. Like Sir Walter Raleigh and a few less memorable men of the same generation, he was attacked in his own time not merely as a freethinker, but as a propagandist or apostle of atheism; nor was the irregularity of his life thought worthier of animadversion than the uncertainty of his livelihood. The informer whose name has survived as that of his most venomous assailant was duly hanged the year after Marlowe's death; and the list of his charges, first published by Ritson, is hardly a document which can commend itself to any man's confidence as plausibly or even possibly accurate in all its detailed report of the violent and offensive nonsense attributed to the freethinking poet in common conversation "concerning his damnable opinions."

The majestic and exquisite excellence of various lines and passages in Marlowe's first play must be admitted to relieve, if it cannot be allowed to redeem, the stormy monotony of Titanic truculence which blusters like a simoom through the noisy course of its ten fierce acts. With many and heavy faults, there is something of genuine greatness in *Tamburlaine the Great*; and for two grave reasons it must always be remembered with distinction and mentioned with honour. It is the first poem ever written in English blank verse, as distinguished from mere rhymeless decasyllabics; and it contains one of the noblest passages, perhaps indeed the noblest in the literature of the world, ever written by one of the greatest masters of poetry in loving praise of the glorious delights and sublime submission to the everlasting limits of his art. In its highest and most distinctive qualities, in unfaltering and infallible command of the right note of music and the proper tone of colour for the finest touches of poetic execution, no poet of the most elaborate modern school, working at ease upon every consummate resource of luxurious learning and leisurely refinement, has ever excelled the best and most representative work of a man who had literally no models before him, and probably or evidently was often if not always compelled to write against time for his living.

The just and generous judgment passed by Goethe on the *Faustus* of his English predecessor in tragic treatment of the same subject is somewhat more than sufficient to counterbalance the slighting or the sneering references to that magnificent poem which might have been expected from the ignorance of Byron or the incompetence of Hallam. And the particular note of merit observed, the special point of the praise conferred, by the great German poet should be no less sufficient to dispose of the vulgar misconception yet lingering among sciolists and pretenders to criticism, which regards a writer than whom no man was ever born with a finer or a stronger instinct for perfection of excellence in execution as a mere noble savage of letters, a rough self-taught sketcher or scribbler of crude and rude genius, whose unhewn blocks of verse had in them some veins of rare enough metal to be quarried and polished by Shakespeare. What most impressed the author of *Faust* in the work of Marlowe was a quality the want of which in the author of *Manfred* is proof enough to consign his best work to the second or third class at most. "How greatly it is all planned!" the first requisite of all great work, and one of which the highest genius possible to a greatly gifted barbarian could by no possibility understand the nature or conceive the existence. That Goethe "had thought of translating it" is perhaps hardly less precious a tribute to its greatness than the fact that it has been actually and admirably translated by the matchless translator of Shakespeare—the son of Victor Hugo; whose labour of love may thus be said to have made another point in common, and forged as it were another link of union, between Shakespeare and the young master of Shakespeare's youth. Of all great poems in dramatic form it is perhaps the most remarkable for absolute singleness of aim and simplicity of construction; yet is it wholly free from all possible imputation of monotony or aridity. *Tamburlaine* is monotonous in the general roll and flow of its stately and sonorous verse through a noisy wilderness of perpetual bluster and slaughter; but the unity of tone and purpose in *Doctor Faustus* is not unrelieved by change of manner and variety of incident. The comic scenes, written evidently with as little of labour as of relish, are for the most part scarcely more than transcripts, thrown into the form of dialogue, from a popular prose *History of Dr Faustus*, and therefore should be set down as little to the discredit as to the credit of the poet. Few masterpieces of any age in any language can stand beside this tragic poem—it has hardly the structure of a play—for the qualities of terror and splendour, for intensity of purpose and sublimity of note. In the vision of Helen, for example, the intense perception of loveliness gives actual sublimity to the sweetness and radiance of mere beauty in the passionate and spontaneous selection of words the most choice and perfect; and in like manner the sublimity of simplicity in Marlowe's conception and expression of the agonies endured by Faustus under the immediate imminence of his doom gives the highest note of beauty, the quality of absolute fitness and propriety, to the sheer straightforwardness of speech in which his agonizing horror finds vent ever more and more terrible from the first to the last equally beautiful and fearful verse of that tremendous monologue which has no parallel in all the range of tragedy.

It is now a commonplace of criticism to observe and regret the decline of power and interest after the opening acts of *The Jew of Malta*. This decline is undeniable, though even the latter part of the play is not wanting in rough energy and a coarse kind of interest; but the first two acts would be sufficient foundation for the durable fame of a dramatic poet. In the blank verse of Milton alone, who perhaps was hardly less indebted than Shakespeare was before him to Marlowe as the first English master of word-music in its grander forms, has the glory or the melody of passages in the opening soliloquy of Barabas been possibly surpassed. The figure of the hero before it degenerates into caricature is as finely touched as the poetic execution is excellent; and the rude and rapid sketches of the minor characters show at least some vigour and vivacity of touch.

In *Edward the Second* the interest rises and the execution improves as visibly and as greatly with the course of the advancing story as they decline in *The Jew of Malta*. The scene of the king's deposition at Kenilworth is almost as much finer in tragic effect and poetic quality as it is shorter and less elaborate than the corresponding scene in Shakespeare's *King Richard II*. The terror of the death-scene undoubtedly rises into horror; but this horror is with skilful simplicity of treatment preserved from passing into disgust. In pure poetry, in sublime and splendid imagination, this tragedy is excelled by *Doctor Faustus*; in dramatic power and positive impression of natural effect it is as certainly the masterpiece of Marlowe. It was almost inevitable, in the hands of any poet but Shakespeare, that none of the characters represented should be capable of securing or even exciting any finer sympathy or more serious interest than attends on the mere evolution of successive events or the mere display of emotions (except always in the great scene of the deposition) rather animal than spiritual in their expression of rage or tenderness or suffering. The exact balance of mutual effect, the final note of scenic harmony, between ideal conception and realistic execution is not yet struck with perfect accuracy of touch and security of hand; but on this point also Marlowe has here come nearer by many degrees to Shakespeare than any of his other predecessors have ever come near to Marlowe.

Of *The Massacre at Paris* it is impossible to judge fairly from the garbled fragment of its genuine text which is all that has come down to us. To Mr Collier, among numberless other obligations, we owe the discovery of a noble passage excised in the piratical edition which gives us the only version extant of this unlucky play, and which, it must be allowed, contains nothing of quite equal value. This is obviously an occasional and polemical work, and being as it is overcharged with the anti-Catholic passion of the time has a typical quality which gives it some empirical significance and interest. That antipapal ardour is indeed the only note of unity in a rough and ragged chronicle which shambles and stumbles onward from the death of Queen Jeanne of Navarre to the murder of the last Valois. It is possible to conjecture, what it would be fruitless to affirm, that it gave a hint in the next century to Nathaniel Lee for his far superior and really admirable tragedy on the same subject, issued ninety-seven years after the death of Marlowe.

In the tragedy of *Dido, Queen of Carthage*, a servile fidelity to the text of Virgil's narrative has naturally resulted in the failure which might have been expected from an attempt at once to transcribe what is essentially inimitable and to reproduce it under the hopelessly alien conditions of dramatic adaptation. The one really noble passage in a generally feeble and incomposite piece of work is, however, uninspired by the unattainable model to which the dramatists have been only too obsequious in their subservience. It is as nearly certain as anything can be which depends chiefly upon cumulative and collateral evidence that the better part of what is best in the serious scenes of *King Henry VI.* is mainly the work of Marlowe. That he is at any rate the principal author of the second and third plays passing under that name among the works of Shakespeare, but first and imperfectly printed as *The Contention between the two Famous Houses of York and Lancaster*, can hardly be now a matter of debate among competent judges. The crucial difficulty of criticism in this matter is to determine, if indeed we should not rather say to conjecture, the authorship of the humorous scenes in prose, showing as they generally do a power of comparatively high and pure comic realism to which nothing in the acknowledged works of any pre-Shakespearean dramatist is even remotely comparable. Yet, especially in the original text of these scenes as they stand unpurified by the ultimate revision of Shakespeare or his editors, there are tones and touches which recall rather the clownish horseplay and homely ribaldry of his predecessors than anything in the lighter interludes of his very earliest plays. We find the same sort of thing which we find in their writings, only better done than they usually do it, rather than such work as Shakespeare's a little worse done than usual. And even in the final text of the tragic or metrical scenes the highest note struck is always, with one magnificent and unquestionable exception, rather in the key of Marlowe at his best than of Shakespeare while yet in great measure his disciple.

Had every copy of Marlowe's boyish version or perversion of Ovid's *Elegies* deservedly perished in the flames to which it was judicially condemned by the sentence of a brace of prelates, it is possible that an occasional bookworm, it is certain that no poetical student, would have deplored its destruction, if its demerits could in that case have been imagined. His translation of the first book of Lucan alternately rises above the original and falls short of it,—often inferior to the Latin in point and weight of expressive rhetoric, now and then brightened by a clearer note of poetry and lifted into a higher mood of verse. Its terseness, vigour, and purity of style would in any case have been praiseworthy, but are nothing less than admirable, if not wonderful, when we consider how close the translator has on the whole (in spite of occasional slips into inaccuracy) kept himself to the most rigid limit of literal representation, phrase by phrase and often line by line. The really startling force and felicity of occasional verses are worthier of remark than the inevitable stiffness and heaviness of others, when the technical difficulty of such a task is duly taken into account.

One of the most faultless lyrics and one of the loveliest fragments in the whole range of descriptive and fanciful poetry would have secured a place for Marlowe among the memorable men of his epoch, even if his plays had perished with himself. His *Passionate Shepherd* remains ever since unrivalled in its way—a way of pure fancy and radiant melody without break or lapse. The untitled fragment, on the other hand, has been very closely rivalled, perhaps very happily imitated, but only by the greatest lyric poet of England—by Shelley alone. Marlowe's poem of *Hero and Leander*, closing with the sunrise which closes the night of the lovers' union, stands alone in its age, and far ahead of the work of any possible competitor between the death of Spenser and the dawn of Milton. In clear mastery of narrative and presentation, in melodious ease and simplicity of strength, it is not less pre-eminent than in the adorable beauty and impeccable perfection of separate lines or passages.

The place and the value of Christopher Marlowe as a leader among English poets it would be almost impossible for historical criticism to overestimate. To none of them all, perhaps, have so many of the greatest among them been so deeply and so directly indebted. Nor was ever any great writer's influence upon his fellows more utterly and unmixedly an influence for good. He first, and he alone, guided Shakespeare into the right way of work; his music, in which there is no echo of any man's before him, found its own echo in the more prolonged but hardly more exalted harmony of Milton's. He is the greatest discoverer, the most daring and inspired pioneer, in all our poetic literature. Before him there was neither genuine blank verse nor a genuine tragedy in our language. After his arrival the way was prepared, the paths were made straight, for Shakespeare. (A. C. S.)

MARLY-LE-ROI, chief place of a canton in the department of Seine-et-Oise, France, 5 miles to the north of Versailles and 3 miles to the south of St Germain-en-Laye, is, notwithstanding some fine country houses, a dull and unattractive village of 1250 inhabitants, which owes all its celebrity to the sumptuous chateau of Louis XIV. It was originally designed as a simple hermitage to which the king could occasionally retire with a few of his more intimate friends from the pomp of Versailles, but gradually it grew until it became one of the most ruinous extravagances of the Grand Monarque. The central pavilion (inhabited by the king himself) and its twelve subsidiary pavilions were intended to suggest the sun surrounded by the signs of the zodiac. Seldom visited by Louis XV., and wholly abandoned by Louis XVI., it was demolished after the Revolution, its art treasures having previously been dispersed, and all that now remains consists of a few mouldering ivy-grown walls, some traces of parterres with magnificent trees, the park, which is well stocked with game, and the forest of 8½ square miles, one of the most pleasant promenades of the neighbourhood of Paris.

Close to the Seine, half-way between Marly-le-Roi and St Germain, is the village of Port-Marly (500 inhabitants), and 1 mile farther up is the hamlet of Marly-la-Machine. Here, under Louis XIV., an immense hydraulic engine, driven by the current of the river, was erected; it raised the water to a high tower of 155 metres (508 English feet), where the aqueduct of Marly commenced (2100 English feet in length, 75 in height, with 36 arches, still well-preserved), carrying the waters of the Seine to Versailles. The first engine of Marly began to work in 1682, but it was necessary to modify it in 1803. In 1826 a steam-engine was substituted, and since 1858 an atmospheric engine has been employed.

MARMONT, Auguste Frédéric Louis Viesse de (1774–1852), duke of Ragusa, and marshal of France, one of Napoleon's earliest friends and most trusted generals, was born at Châtillon-sur-Seine, on July 20, 1774. He was the son of an ex-officer in the army, who belonged to the *petite noblesse*, and had adopted the principles of the Revolution. His love of soldiering soon showing itself, his father took him to Dijon to learn mathematics prior to entering the artillery, and there he made the acquaintance of Bonaparte, which he renewed after obtaining his commission when he served in Toulon. The acquaintance ripened into intimacy; Marmont became General Bonaparte's aide-de-camp, and accompanied him to Italy and Egypt, winning distinction and promotion as general of brigade. In 1799 he left Egypt with Bonaparte to the mercy of the English; he was present at the revolution of the 18th Brumaire, and organized the artillery for the expedition to Italy, which he commanded with great effect at Marengo. For this he was at once made general of division. In 1801 he became inspector-general of artillery, and in 1804 grand officer of the Legion of Honour. In 1805 he received the command of a corps, with which he did good service at Ulm. He was then directed to occupy Dalmatia with his army; he defeated the Russians on October 30 at Castel Nuovo, and occupied Ragusa. The next five years were the most creditable in his life; he was both military and civil governor of Dalmatia, and has still left traces there both in great public works and in the memories of the people. In 1807 he was made duke of Ragusa, and in 1809, being summoned up to the help of Napoleon, who was closely beset in the island of Lobau, earned the marshal's baton by his conduct at Wagram. In July 1810 he was hastily summoned from his palace, where he lived in Eastern luxury, to succeed Masséna in the command of the French army in the north of Spain, called the army of Portugal. The skill with which he manœuvred his army during the year he commanded it has been always acknowledged. His relief of Ciudad Rodrigo in the autumn of 1811 in spite of the presence of the English army was a great feat, and in the tactics which preceded the battle of Salamanca he had the best of it. The extension of his left on the 22d July 1812 was, however, fatal, and its result was the great defeat of Salamanca, in which Marmont was severely wounded in the right arm and side. He retired to France to recover, and was still hardly cured when in April 1813 Napoleon gave him the command of the 6th corps. With it he served at the battles of Lützen, Bautzen, and Dresden, and throughout the great defensive campaign of 1814, until the last desperate battle before the walls of Paris, from which he drew back his forces to the commanding position of Essonne. Here he had 20,000 men in splendid condition, and was the pivot of all thoughts. Napoleon said of Essonne, "C'est là que viendront s'addresser toutes les intrigues, toutes les trahisons; aussi y ai-je placé Marmont, mon enfant élevé sous ma tente." Marmont betrayed this trust and suffered for it. On the restoration of the Bourbons he was made a peer of France, and a major-general of the royal guard, and in 1820 a knight of St Esprit and a grand officer of the order of St Louis, but he was never trusted, never popular. He was the major-general of the guard on duty in July 1830, and was ordered to put down with a strong hand any opposition to the ordinances (see FRANCE). After persevering some time he gave way, and allowed the republicans to succeed in their revolution. This defection brought more obloquy upon him, and the Duc d'Angoulême even ordered him under arrest, saying, "Will you betray us, as you betrayed him?" After this Marmont left France and wandered about the Continent for twenty years, publishing many volumes of travels, an edition of Cæsar and of Xenophon, and his *Esprit des Institutions Militaires.* Much of his time was spent upon his *Mémoires*, which are of real value for the military history of his time, though they must be read as a personal defence of himself in various junctures rather than as an unbiassed account of his times. They show Marmont, as he really was, an embittered man, who never thought his services sufficiently requited, a great artillery general indeed, but without the fire of genius which is so striking in several of his contemporaries, and above all, a man too much in love with himself and his own glory to be a true friend or a faithful servant.

For Marmont's military ability consult Napier, Jomini, and the historians of the time, particularly General Pelet. His own works are *Voyage en Hongrie*, &c., 4 vols., 1837; *Voyage en Sicile*, 1838; *Esprit des Institutions Militaires*, 1845; *César*; *Xenophon*; and *Mémoires*, 8 vols., published after his death in 1856. See also a long and careful notice by Sainte-Beuve, *Causeries du Lundi*, vol. vi.

MARMONTEL, JEAN FRANÇOIS (1723-1799), one of the most distinguished men of letters in Paris during the latter half of the 18th century, was born of poor parents in Limousin, on the 11th July 1723. After studying with the Jesuits at Mauriac, he taught in their colleges at Clermont and Toulouse; and in 1745, acting on the advice of Voltaire, he set out for Paris to try for literary honours. From 1748 to 1753 he wrote a succession of tragedies which,[1] though for the most part considered prolix and artificial by modern readers, had great success on the stage, and secured to Voltaire's new disciple a good position in literary and fashionable circles. Being now associated with Diderot and D'Alembert, he wrote for the great *Encyclopédie* a series of articles evincing considerable critical power and insight, which in their collected form, under the title *Éléments de Littérature*, still rank among the higher French classics. He also wrote several comic operas, the two best of which probably are *Sylvain* and *Zémire et Azore.* In 1758 he gained the patronage of Madame Pompadour, and was soon after appointed manager of the official journal *Le Mercure*, in which he had already commenced a series of elegant and attractive tales. These were the *Contes Moraux*, on which, according to some critics, Marmontel's literary reputation mainly rests. Their merit lies partly in the literary style, which in delicate finish frequently rivals that of his master Voltaire, but mainly in their graphic and charming pictures of French society under Louis XV. After being elected to the French Academy, in 1763, he appears to have been ambitious to create a new literary style, exemplified notably in his dull prose-epic romance *Bélisaire*, now remarkable only on account of a chapter on religious toleration which incurred the censure of the Sorbonne and the archbishop of Paris. Marmontel retorted in *Les Incas*, by tracing the cruelties in Spanish America to the religious fanaticism of the Roman Catholic invaders.

After being appointed historiographer of France, secretary to the Academy (1783), and professor of history in the Lycée (1786), Marmontel in 1788 wrote a history of the regency, which is of little value. To compensate for this, however, he in 1795 began his *Mémoires*, the most interesting and valuable if not the greatest of his works, being a picturesque review of his whole life, a literary history of two important reigns, a great gallery of portraits extending from the venerable Massillon, whom more than half a century previously he had seen at Clermont, to the fiery Mirabeau amidst the tempestuous first years of the French Revolution. Reduced to poverty by the Revolution, Marmontel in 1792 retired from the Reign of Terror to Evreux, and soon after to a cottage near Gaillon, in the department of Eure. To that retreat we owe the *Mémoires*, and there, after a short stay in Paris when elected in 1797 to the Conseil des Anciens, he died on the 31st December 1799.

See Villenave, *Notices sur Marmontel*; Sainte-Beuve, *Causeries*, vol. iv.; Morellet, *Éloge*, 1805; *Edinburgh Review*, January 1806.

MARMORA, SEA OF. See BLACK SEA.

MARMOT. The word marmot may be considered to include animals belonging to the three following genera:—the true marmots, forming the genus *Arctomys* ("bear-mouse"), so called from the thickset, bear-like form of its members; the prairie marmots of North America, better known as the "prairie dogs" (*Cynomys*, "dog-mouse"); and the pouched marmots, or sousliks, comprising the genus *Spermophilus*, or seed-lovers, so named from the character of their food. These three genera are all closely allied to each other, and together form the subfamily *Arctomyinæ* of the great squirrel family, the *Sciuridæ*, of which the only other subfamily, the *Sciurinæ*, consists of the true squirrels (*Sciurus*) and the flying-squirrels (*Pteromys*). The members of the marmot subfamily are confined to the northern hemisphere, and in fact are almost entirely limited to the north temperate zone, in marked contrast to the genera of the subfamily *Sciurinæ*, which attain their greatest development in tropical or semi-tropical countries.

The *Arctomyinæ* agree in the possession of somewhat short, stumpy bodies, comparatively short tails (except in certain sousliks), and long and powerful claws suitable for burrowing. They all have broad, strong, and ungrooved incisors or cutting teeth, two pairs of premolars above and one below, and three pairs of true molars in each jaw. The grinding teeth are all on the whole very similar, the first upper premolar much smaller than the others, and nearly round, the next three teeth triangular in outline, and each with either two or three transverse grooves upon the crown; the last molar is rather broader and more complicated than the others, as is shown in fig. 2. The general form of the skeleton is very similar to that of the true squirrels, but the bones as a rule are stouter and heavier.

1. The following are the generic characters of *Arctomys*. External form stout and heavy, ears short, tail short and hairy, cheek-pouches rudimentary or absent. Fore feet with four well-developed toes, and a rudimentary thumb provided with a flat nail; skull (see MAMMALIA, p. 417, fig. 92) similar in general form to that of the other genera, but very much larger and heavier, the post-orbital processes

[1] *Denys le Tyran*, 1748; *Aristomène*, 1749; *Cléopâtre*, 1750; *Héraclides*, 1752; *Egyptus*, 1753.

stouter, and at right angles to the axis of the skull. Incisors broad and powerful. First upper premolar nearly as large as the second. Molar series nearly parallel, scarcely converging behind at all.

The various species of marmot, about ten in number, are all much alike in general appearance, ranging in size from about 15 to 25 inches in length, with tails from 3 to 6 inches long. The following are the species now generally recognized, though the Central-Asiatic forms are still very imperfectly known :—

Arctomys marmotta, Linn., southern Europe, the Alps, Pyrenees, and Carpathians; *A. bobac*, Schreb., eastern Europe and Siberia; *A. himalayanus*, Hodgs., south-west Tibet; *A. hemachalanus*, Hodgs., Nepal; *A. caudatus*, Jacquemont, Cashmere; *A. dichrous*, Anderson, Afghanistan; *A. aureus*, Blanford, Turkestan; *A. monax*, Linn., eastern North America; *A. flaviventer*, Aud. and Bach, western United States; *A. pruinosus*, Gmel., north-western North America.

It will thus be seen that one species only is peculiar to Europe, and three to North America, while at least six, and perhaps more, are found in various parts of Central Asia,—one of these, *A. bobac*, occurring also as far west as Russia and eastern Germany.

Fig. 1.—Alpine Marmot (*Arctomys marmotta*). After Brehm.

The following account of the habits of the Alpine marmot, *A. marmotta*, extracted from Professor Blasius's well-known work on the mammals of Germany, applies, with but little variation, to all the members of the genus.

Marmots live high up in the snowy regions of the mountains, generally preferring exposed cliffs, whence they may have a clear view of any approaching danger, for which, while quietly basking in the sun or actively running about in search of food, a constant watch is kept. When one of them raises the cry of warning, the loud piercing whistle so well known to travellers in the Alps, they all instantly take to flight and hide themselves in holes and crannies among the rocks, often not reappearing at the entrance of their hiding-places until several hours have elapsed, and then frequently standing motionless on the look-out for a still longer period. Their food consists of the roots and leaves of various Alpine plants, which, like squirrels, they lift to their mouths with their fore paws.

For their winter quarters they make a large round burrow, with but one entrance, and ending in a sleeping-place thickly padded with hay. Here often from ten to fifteen marmots pass the winter, all lying closely packed together fast asleep until the spring. On awaking, hungry with their long fast, they remove the hay with which they stuff up the doors of their burrows, and resume their life of activity and watchfulness. The breeding season is in the early summer, when they bring forth from four to six young ones. Their flesh, although coarse and rank, is eaten by the peasants, and their fur, though of but little value, is also made use of.

2. Our second genus is *Cynomys*, containing only the well-known "prairie dogs," or more correctly "prairie marmots," of the United States. The genus may be characterized as follows. Size and form intermediate between *Arctomys* and *Spermophilus*. Ears and tail short. Cheek-pouches shallow. Fore feet with five claws, that on the thumb as large as that on the fifth toe. Skull heavily built, the post-orbital processes directed outwards. Dentition, as shown in fig. 2, remarkably heavy, the molar teeth differing from those of *Arctomys* and *Spermophilus* by having three instead of two transverse grooves on their crowns. First premolar nearly as large as the second. Molar series strongly convergent behind.

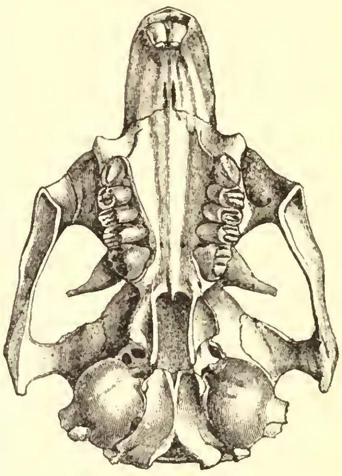


Fig. 2.—Under Side of Skull of *Cynomys ludovicianus*.

Of this genus two species have been described, very closely allied to each other, but separable by their slightly different size and coloration. The larger and better-known of the two is the eastern prairie marmot, *C. ludovicianus*, Ord., inhabiting the open prairies of the central United States, while the smaller species, *C. columbianus*, Ord., is found to the westward as far as the Rocky Mountains.

The habits of the prairie marmots have been so often described that every one is familiar with their custom of forming their burrows in groups or "towns," of sitting outside to watch intruders, and of making the peculiar barking sound from which they have derived their erroneous popular name of prairie dogs. In the burrows made by them there are commonly found three strange and, notwithstanding the earlier travellers' tales, certainly unwelcome visitors, namely, rattlesnakes, owls, and weasels, all of which at times probably prey upon the young marmots. Prairie marmots do not truly hibernate, although in the more northern and colder parts of their range they retire to their burrows during the very severest weather. They feed on grasses and roots, for whose mastication, however, their grinding teeth appear to be unnecessarily powerful.

3. The last genus to which the name marmot may be applied is that of the sousliks or pouched marmots (*Spermophilus*), of which the following are the characters. Size much smaller than that of *Arctomys* or *Cynomys*, and form more slender and squirrel-like. Tail very variable, from 1 to 8 or 9 inches in length. Cheek-pouches always present. Fore feet with four well-developed toes and a rudimentary thumb, of which the claw may be either present or absent. Skull much more lightly built than that of either of the preceding genera, and the post-orbital processes slender and directed backwards. Molar series nearly parallel, as in *Arctomys*, but all much smaller and lighter; the first premolar simply rounded, never more than about one-third of the size of the second.

The members of this large genus present a far greater range of variation than is found among the true marmots, some of them, such as the European souslik, being scarcely as large as a common squirrel, almost entirely without external ears, and with the tail reduced to a mere stump, barely an inch long, while others again are more than three times this size, with long and often tufted ears and long bushy squirrel-like tails. These differences, and other corresponding cranial ones, have caused the genus to be divided into the three following subgenera:—*Spermophilus* proper, containing thirteen or fourteen species, of small size, with rudimentary ear-conches, short stumpy tails, and comparatively large teeth; *Otospermophilus*, two species, of squirrel-like build, with large and tufted ears, and long bushy tails; and *Ictidomys*, with four species, of very slender, weasel-like form, with short ears, long but slender tails, and comparatively small teeth. The last two subgenera are confined to North America, while the range of the first is extremely similar to that of *Arctomys*, although certain species penetrate somewhat farther south in the New World, and none are found so far west in Europe. Professor Blasius gives the following details of the habits of the common European souslik (*S. citillus*, L.).

It lives in dry treeless plains, especially on a sandy or clayey soil, and is never found either in forests or on swampy ground. It forms burrows, often 6 or 8 feet deep, in which food is stored up and the winter sleep takes place. Each burrow has but one entrance, which is closed up when winter approaches,—a second hole, however, being previously formed from the sleeping-place to just below the surface of the ground. This second hole is opened the next year, and used as the ordinary entrance, so that the number of closed up holes round a burrow gives an indication of the length of time that it has been occupied. Sousliks ordinarily feed on roots, seeds, berries, &c., but occasionally also on animal food, preying readily on eggs, small birds, and mice, the remains of these latter being often found in their burrows. They bring forth in the spring from four to eight young ones, which, if taken early, may be easily tamed. They are often eaten by the peasants, the inhabitants of the Russian steppes considering their flesh an especial delicacy. (O. T.)

MARNE, a department of the north-east of France, made up from Champagne-Pouilleuse, Rémois, Perthois, Vallage, and La Brie-Champenoise, districts formerly belonging to Champagne. Its chief town, Châlons-sur-Marne, is 92 miles in a direct line east of Paris. Bounded on the W. by Seine-et-Marne and Aisne, on the N. by Ardennes, on the E. by Meuse, on the S. by Haute-Marne and Aube, it is situated between 48° 31′ and 49° 26′ N. lat., and 3° 25′ and 5° E. long. Its greatest length from north-east to south-west is 73 miles, and the area 3159 square miles. About one half of this consists of Champagne-Pouilleuse, a monotonous and barren plain covering a bed of chalk 1300 feet in thickness. On the west and on the east it is commanded by two ranges of hills. The highest point in the department (920 feet) is in the hill district of Rheims, which rises to the south-west of the town of the same name, between the Vesle and the Marne. The lowest level (164 feet), where the Aisne leaves the department, is not far distant. To the south of the Marne the hills of Rheims are continued by the heights of La Brie (700 to 800 feet). All these belong geologically to the basin of Paris. They slope gently towards the west, but command the plain of Champagne-Pouilleuse by a steep descent on the east. On the further side of the plain are the heights of Argonne (860 feet), formed of beds of the Lower Chalk, and covered by forests; they unite the calcareous formations of Langres to the schists of Ardennes, and a continuation of them stretches southward into Perthois and the marshy Bocage. The department belongs entirely to the Seine basin, but of that river there are only 13 miles, in the south-west; it there receives the Aube, which has 10 miles within the department. The principal river is the Marne, which runs through the department for 105 miles in a great sweep concave to the south-west, passing Vitry-le-François, Châlons, Épernay, and Dormans. In its course through the department it falls from 410 to 213 feet. The principal tributaries are the Saulx (which receives the Ornain) on the right, and on the left the Blaise, which waters Vassy, the Somme Soude, and the Surmelin (with its tributary the Dhuis), whence Paris is supplied; besides the Petit Morin and the Grand Morin. Of the last three only the upper courses lie within the department. The Aisne enters the department at a point 12 miles from its source, and traverses it for 35 miles, watering Ste Menehould. Two of its affluents on the left, the Suippe and the Vesle, on which stands Rheims, have a longer course from south-east to north-west across the department.

Marne has the climate of the region of the Seine; the annual mean temperature is 50° Fahr., the rainfall about 24 inches. Of the total area about three-fourths consists of arable land, and a sixth is under forest, whilst a twenty-fifth is meadow land. Vineyards cover 63·7 square miles. The department is largely stocked with sheep (536,000, of which 133,000 are a mixed merino breed, whose wool is used in the manufacture of merinoes, flannels, and cashmeres). Cattle are estimated to number 95,260; horses, 53,000; pigs, 62,000; goats, 6000; and asses, 6000; these last are used in the narrow pathways which intersect the vineyards. About 600,000 ℔ of honey and 240,000 ℔ of wax are produced. The vineyards, though not of great extent, are of high value from the quality of their products. The manufacture of the sparkling wines of Champagne is an important industry, of which Épernay, Rheims, and Châlons are the chief centres. The yearly exportation is about 20,000,000 bottles, at the average value of half a crown a bottle. Cereals are grown in excess of the local consumption. Corn, hay, rye, barley, potatoes, and beetroot are the chief crops. Several communes supply the more valuable vegetables. In 1881 the produce of wine was more than 14½ million gallons. The principal orchard fruits are the apple, plum, and cherry. Pine woods are largely planted in Champagne-Pouilleuse. The department produces iron ore, phosphate of lime, quantities of turf, and excellent millstones and stone for building.

The chief industry is that in wool, which has brought together, in the neighbourhood of Rheims, establishments for spinning, carding, dyeing, and weaving. The materials wrought are flannels, merinoes, tartans, shawls, rugs, and fancy articles. In 1879 the aggregate length of the various stuffs measured at Rheims was 12,198 miles. This business alone occupies 30,000 operatives in the department, and produces annually nearly 800,000 pieces, valued at £18,000,000. Hosiery in woollen employs 420 looms, and in cotton 1800. Marne contains blast-furnaces, iron, copper, and bell foundries, and manufactories of agricultural implements. Besides these there are tanyards, currying and leather-dressing establishments, and glassworks, which, with sugar-works and breweries, complete the list of the most important industries. Biscuits and gingerbread are a specialty of Rheims. The chief imports are wool, coal, and colonial wares; the exports are wine, grain, live stock, stone, whiting, pit-props, and woollen stuffs. Transport is supplied by the river Marne and the canal connecting it with the Rhine and with the Aisne, and by 300 miles of railway. The population in 1881 was 421,027, an increase of 116,371 since 1801. There are five arrondissements—those of Châlons (the chef-lieu), Épernay, Rheims, Ste Menehould, and Vitry-le-François. The department belongs partly to the archbishopric of Rheims and partly to the see of Châlons. Châlons is the headquarters of the 6th army corps; to the north of the town is the great camp devoted to military exercises.

MARNE, HAUTE-, a department of eastern France, made up for the most part of districts belonging to the former province of Champagne (Bassigny, Perthois, Vallage), with smaller portions of Lorraine and Burgundy, and some fragments of Franche-Comté. It lies between 47° 35′ and 48° 40′ N. lat., and between 4° 40′ and 5° 55″ E. long., the capital, Chaumont, being 133 miles east-south-east from Paris in a direct line, and it is bounded on the N.E. by Meuse, on the E. by Vosges, on the S.E. by Haute-Saône, on the S. and S.W. by Côte d'Or, on the W. by Aube, and on the N.W. by Marne. The extreme length from north-north-west to south-south-east is 81 miles, and the area 2402 square miles. Its greatest elevation (1693 feet) is in the plateau of Langres, between the sources of the Marne and those of the Aube; the watershed between the basin of the Rhone on the south and those of the Seine and Meuse on the north, which is formed by the plateau of Langres and the Monts Faucilles, has an average height of 1500 or 1600 feet. The country descends rapidly towards the south, but in very gentle slopes northwards. To the north is Bassigny ("pays bas," as distinguished from the highlands), a district of country characterized by monotonous flats of small fertility, and generally under wood. The lowest level of the department is 360 feet. Hydrographically Haute-Marne belongs for the most part to the basin of the Seine, the remainder to those of the Rhone and the Meuse. The principal stream is the Marne, which rises here, and has a course of 75 miles within the department. Among the more important affluents of the Marne are on the right the Rognon, and on the left the Blaise, one of the rivers of France most fully utilized for the supply of water-power. The Saulx, another tributary of the Marne on the right, also rises in Haute-Marne. Westward the department is watered by the Aube and its tributary the Aujon, both of which have their sources on the plateau of Langres. The Meuse also rises in the Monts Faucilles, and has a course of 31 miles within Haute-Marne. On the Mediterranean side the department sends to the Saône the Apance, the Amance, the Salon, and the Vingeanne. The climate is partly that of the Seine region, partly that of the Vosges, and partly that of the Rhone; the mean temperature is 51° F., nearly that of Paris; the rainfall is slightly below the average for France.

Of the total area rather more than one half is arable, about a third is under wood, a twentieth under meadow, and a fortieth is occupied by vineyards. There are 39,000 horses (extensively bred in Bassigny), 86,000 head of cattle, 170,000 sheep, 58,000 pigs, 6000 goats, 25,000 beehives, and a large quantity of all kinds of poultry. Though not very fertile, the soil is well cultivated, and in 1878 yielded 1,271,363 hectolitres of wheat, 144,348 of barley, 1,446,421 of oats, 1,177,187 of potatoes, besides meslin, rye, buckwheat, dried legumes, colza, beetroot, and hemp. Upwards of 8 million gallons of wine of ordinary quality were produced in 1881. The timber consists chiefly of oak, beech, elm, ash, maple, birch, and aspen; the orchards produce cherries, apples, pears, and prunes. The department is very rich in iron; the annual output of 300,000 tons is exceeded only by that of Meurthe-et-Moselle. Building and paving stones are quarried. The warm springs of Bourbonne-les-Bains are among the longest-known and most frequented in France. The leading industry is the metallurgical; in 1881 76,000 tons of pig iron and 85,000 of wrought iron were produced. The establishments include blast furnaces, foundries, forges, plate-rolling works, and shops for nailmaking and smith work of various descriptions. St Dizier, the place of largest population, is the chief centre of manufacture and distribution. The cutlery trade alone occupies 6000 persons in the neighbourhood of Langres. The department employs 1800 spindles in the woollen manufacture; glove-making, basket-making, brewing, tanning, and other industries are also carried on. The principal import is coal, while iron, stone, wood, and cereals are exported. The population in 1876 was 253,943, making an increase of 27,288 since 1801. There are three arrondissements (Chaumont, Langres, and Vassy), the capital being Chaumont.

MAROCCO. See MOROCCO.

MARONITES (Syriac, *Mârûnôyê*; Arabic, *Mawârina*), an ecclesiastical community, and therefore also, according to the usage of the Christian East, a distinct political or social body, found mainly in or near the Lebanon, acknowledging the headship of the pope and the Latin standard of orthodoxy, but still retaining some peculiar privileges, including the use of a Syriac service—which few even of the priests now understand—and permission for the inferior clergy to marry. Maronite writers, trained either at Rome (in the Maronite college, founded by Gregory XIII. in 1584) or under Roman influences, have not unnaturally striven to prove that their church was always in essential accord with the Church of Rome except in ritual, but there is clear evidence that this is incorrect. The earliest references to the Maronites (beginning in the 8th century) leave no doubt that they were Monothelites, and there is contemporary evidence (William of Tyre) that they only abjured their heresies in 1182, when with their patriarch and some bishops they joined the Latin Church. Even in later times it has cost Rome much pains and money to attach them closely to herself and produce real conformity to Latin or ultimately to Tridentine orthodoxy. The origin of the Maronites and their earlier history are obscure. The name is no doubt connected with the monastery of St Maron, near the source of the Orontes, one of the chief monasteries of Syria in the 6th century;[1] the Maronites themselves (Assemani, *Bib. Or.*, i. 496 *sq.*) have much to tell of their great patriarch John Maron, or rather John of Maron, who studied at the convent of St Maron, converted the Lebanon to orthodoxy, and died 707 A.D. Much of the history of this personage is certainly fabulous.[2]

Though the Maronite college at Rome sent forth some distinguished scholars—the grammarian Amíra, Gabriel Sionita, Abraham Ecchellensis, and the three Assemanis—the Maronite community never took on much Western culture. A simple warlike race, they long maintained a great measure of internal freedom under their native nobility, only paying tribute to the pasha of Tripoli; and for a time, when the princely house of Shiháb left Islam and became Maronites, they greatly outweighed the Druses in their influence in the Lebanon.[3] Since the fall, in 1840, of the Maronite emír Beshír, who was only by outward profession a Moslem, their power has sunk. For their subsequent history see vol. vii. p. 486, and for statistics, &c., at the present time, see LEBANON.

The seat of the Maronite patriarch is at Ḳannóbín (Cœnobium); the bishoprics are Aleppo, Baalbek, Jebeil, Tripoli, Ehden, Damascus, Beirút, Tyre, and Cyprus.

See in general Le Quien, *Oriens Christianus*, iii. 1-100; Nairon, *De origine, etc.*, *Maronitarum*, Rome, 1679; Dandini's account of the mission of 1596 in the French translation with R. Simon's notes (*Voyage du Mont Lebanon*, Paris, 1685); Schnurrer, *De Ecclesia Maronitica*, 1810-1811; and Rödiger's article "Maroniten" in Herzog's *Real-Encycl.*

MAROONS. A *nègre marron* is defined by Littré as a fugitive slave who betakes himself to the woods; a similar definition of *cimarron* (apparently from *cima*, a mountain top) is given in the *Dictionary* of the Spanish Academy. The old English form of the word is *symaron* (see Hawkins's *Voyage*, sec. 68). The designation in modern English is applied almost as a proper name to the descendants of those negroes in Jamaica who at the first English occupation in the 17th century fled to the mountains. See vol. xiii. p. 550.

MAROS-VÁSÁRHELY, a royal free town of Hungary, and capital of the Transylvanian county of Maros-Torda, is situated on the Maros and on the Hungarian Eastern Railway, 50 miles north-east of Hermannstadt, in 46° 30′ N. lat., 24° 31′ E. long. It is the seat of the "royal table" court of appeal for the Transylvanian circle, of royal and circuit courts of law, of a board of works, and of offices of assay and of the Government tobacco monopoly; as also the headquarters both of the militia and regular infantry for the district. The town is well built, partly upon rising ground, and has a citadel with barracks, three churches (one large and handsome), and a college belonging to the Calvinists; Roman Catholic and Greek Orthodox churches, religious houses, and schools; a public library of 80,000 volumes, with a picture gallery and fine collection of minerals; a theatre, a hospital, and several philanthropic and industrial institutes. The trade is chiefly in timber, planks, materials for house-roofing, grain, wine, tobacco, and other products of the neighbourhood. Both weekly and special markets are held. At the end of 1880 the population amounted to 12,843 (6265 males, 6578 females), Magyars and Roumanians by nationality.

[1] The ruins of this place are described by Robinson, *Bib. Researches*, iii. 539; Renan, *Phénicie*, p. 119.

[2] The John of Maron known to Bar-Hebræus (*Chron. Eccles.*, i. 463), and placed in the 10th century, was apparently a Monophysite. That Monophysite as well as Monothelite doctrine was once current among the Maronites appears from various things in their ecclesiastical books, which they now try to explain away or reject as interpolations.

[3] See Niebuhr, *Reisebeschr.*, vol. ii.; Volney, *Voyage*; Robinson, *Researches*, ii. 506.

MAROT, CLÉMENT (1496–1544), one of the most agreeable if not one of the greatest poets of France, and a figure of all but the first importance in her literary history, was born at Cahors, the capital of the province of Quercy, some time during the winter of the year 1496–97. He was, however, not a southern by blood, at least by his father's side. That father, Jean Marot, whose more correct name appears to have been Mares, Marais, or Marets, was a Norman of the neighbourhood of Caen. He was himself a poet of considerable merit, and held the post of *escripvain* (apparently uniting the duties of poet laureate and historiographer) to Anne of Britanny. He had however, on what business or in what capacity is not known, resided in Cahors for a considerable time, and was twice married there, his second wife, whose name is not known, being the mother of Clément. The boy was "brought into France"—it is his own expression, and is not unnoteworthy as showing the strict sense in which that term was still used at the beginning of the 16th century—in 1506, and he appears to have been educated at the university of Paris, and to have then begun the study of the law. But, whereas most other poets have had to cultivate poetry against their father's will, Jean Marot took great pains to instruct his son in the fashionable forms of versemaking, which indeed required not a little instruction. It was the palmy time of the *rhétoriqueurs*, poets who combined stilted and pedantic language with an obstinate adherence to the allegorical manner of the 15th century and to the most complicated and artificial forms of the *Ballade* and the *Rondeau*. Clément himself practised with diligence this poetry (which he was to do more than any other man to overthrow), and he has left panegyrics of its coryphæus Guillaume Crétin, the unfortunate suggester of the Raminagrobis of Rabelais. Nor did he long continue even a nominal devotion to law. He became page to a certain Messire de Neuville, and this opened to him the road of court life. Besides this, his father's interest must have been not inconsiderable, and the house of Valois, which was about to hold the throne of France for the greater part of a century, was devoted to letters. As early as 1514, before the accession of Francis I., Clément presented to him his *Judgment of Minos*, and shortly afterwards he was either styled or styled himself *facteur* (poet) *de la reine* to Queen Claude. In 1519 he was attached to the suite of Marguerite d'Angoulême, the king's sister, who was for many years to be the mainstay not only of him but of almost all French men of letters. In 1524 he drew 95 livres annually from her as a pension, and he had a post in the household of her husband the Duc d'Alençon. It is certain that Marot, like most of Marguerite's literary court, and perhaps more than most of them, was greatly attracted by her gracious ways, her unfailing kindness, and her admirable intellectual accomplishments, but there is not the slightest ground for thinking that his attachment was other than platonic. Indeed the most famous passage of his poems which relates to the future queen, in which he describes her "sweet refusal with a sweeter smile," is tolerably decisive on the point. It is, however, evident that at this time either sentiment or matured critical judgment effected a great change in his style, a change which was wholly for the better. At the same time he celebrates a certain Diane, whom it has been sought to identify with Diane de Poitiers. There is nothing to support this idea and much against it, for it was an almost invariable habit of the poets of the 16th century, when the mistresses whom they celebrated were flesh and blood at all (which was not always the case), to celebrate them under pseudonyms. In the same year 1524, Marot accompanied Francis on his disastrous Italian campaign. He was wounded and taken at Pavia, but soon released, and he was back again at Paris by the beginning of 1525. His luck had, however, turned. Marguerite for intellectual reasons, and her brother for political, had hitherto favoured the double movement of *Aufklärung*, partly humanist, partly Reforming, which distinguished the beginning of the century. Formidable opposition to both forms of innovation, however, now began to be manifested, and Marot, who was at no time particularly prudent, was arrested on a charge of heresy and lodged in the Chatelet, February 1526. But this was only a foretaste of the coming trouble, and a friendly prelate, acting for Marguerite, extricated him from his durance before Easter. The imprisonment gave him occasion to write a vigorous poem on it entitled *Enfer*, which was afterwards imitated by his luckless friend Dolet. His father died about this time, and Marot seems to have been appointed to the place which Jean had latterly enjoyed, that of valet de chambre to the king. He was certainly a member of the royal household in 1528, with a stipend of 250 livres, besides which he had inherited property in Quercy. In 1530, probably, he married. Next year he was again in trouble for heresy, and was again rescued; this time the king and queen of Navarre seem to have bailed him themselves. In 1532 he published, under the title of *Adolescence Clémentine*, a title the characteristic grace of which excuses its slight savour of affectation, the first printed collection of his works, which was very popular, and was frequently reprinted with additions. Dolet's edition of 1538 is believed to be the most authoritative. Unfortunately, however, the poet's enemies were by no means discouraged by their previous ill success, and the political situation was very unfavourable to the Reforming party. In 1535 Marot was again summoned to appear on the charge of heresy, and this time he was advised or thought it best to fly. He passed through Béarn, and then made his way to Renée of Ferrara, a supporter of the French Reformers as steadfast as her aunt Marguerite, and even more efficacious, because her dominions were out of France. At Ferrara he wrote a good deal, his work there including his celebrated *Blasons* (a descriptive poem, improved upon mediæval models), which set all the verse writers of France imitating them. But the duchess Renée was not able to persuade her husband, Ercole d'Este, to share her views, and Marot had to quit the city. He then went to Venice, but before very long obtained permission to return to France. Francis himself, though a fickle and unsafe patron, was attached to him, and in 1539 gave him a house and grounds in the suburbs. It was at this time that his famous translations of the Psalms appeared. The merit of these has been sometimes denied, owing apparently to the absurd partiality which seems in the case of some critics to make it impossible for the reader to appreciate the manner of a work to the matter of which he is opposed on political or religious grounds. It is, however, considerable, and the powerful influence which the book exercised on contemporaries is not denied by any one. The great persons of the court chose different pieces, each as his or her favourite. They were sung in court and city, and they are said, with exaggeration doubtless, but still with a basis of truth, to have done more than anything else to advance the cause of the Reformation in France. Indeed the vernacular prose translations of the Scriptures were in that country of little merit or power, and the form of poetry was still preferred to prose, even for the most incongruous subjects. At the same time Marot engaged in a curious literary quarrel characteristic of the time, with a bad poet named Sagon. Half the verse writers of France ranged themselves among the Marotiques or the Sagontiques, and a great deal of versified abuse was exchanged. The victory, as far as wit was concerned, naturally rested with Marot, but his biographers are probably not fanciful in supposing that a certain amount of odium was created against him by the squabble, and that, as in Dolet's case, his subsequent misfortunes were not altogether unconnected with a too little governed tongue and pen. Although on his last return into France he had formally abjured his errors, the publication of the Psalms gave the Sorbonne a handle, and the book was condemned by that body. In 1543 it was evident that he could not rely on the protection of Francis, who was probably too selfish in any case to have given him inconvenient help, and who, like many of his family, was disposed to compound with the church for a libertine life by ceremonial devotion and by sacrificing heretics liberally. Marot accordingly fled to Geneva; but the stars were now decidedly against him. He had, like most of his friends, been at least as much of a freethinker as of a Protestant, and, notwithstanding the immense service he had done to the cause by the publication of his Psalms, this was fatal to his reputation in the austere city of Calvin. He had again to fly, and made his way into Piedmont, where he seems to have enjoyed a sort of left-handed protection from Francis, who then held it. But the harassing effect of these constant persecutions, assisted very likely by the careless living which was but too common at the time, proved too much for him, and he died at Turin in the autumn of 1544, aged barely forty-eight.

In character Marot seems to have been a typical Frenchman of the old stamp, cheerful, good humoured, and amiable enough, but probably not very much disposed to elaborately moral life and conversation or to serious reflexion. He has sometimes been charged, though on no very definite grounds, with a want of independence of character, and his attitude towards his patrons was certainly not that of almost haughty equality which Ronsard brought in; but it is fair to remember that Marot belonged almost as much to the Middle Ages as to the Renaissance, and that in the Middle Ages men of letters naturally attached themselves as dependants to the great. Such scanty knowledge as we have of his relations with his equals is favourable to him. He certainly at one time quarrelled with Dolet, or at least wrote a violent epigram against him, for which there is no known cause. But, as Dolet quarrelled with almost every friend he ever had, and in two or three cases played them the shabbiest of tricks, the presumption is not against Marot in this matter. Whatever may have been Marot's personal weaknesses, his importance in the history of French literature is very great, and it is wont nowadays to be rather under- than over-valued. Coming immediately before a great literary reform—that of the Pléiade—Marot suffered the drawbacks of his position; he was both eclipsed and decried by the partakers in that reform. In the reaction against the Pléiade he recovered honour; but its restoration to virtual favour, a perfectly just restoration, has again unjustly depressed him. Yet Marot is in no sense one of those writers of transition who are rightly obscured by those who come after them. He himself was a reformer, and a reformer on perfectly independent lines, besides which it may be said that he carried his own reform as far as it would go. It has been said that his early work was couched in the *rhétoriqueur* style, the distinguishing characteristics of which are elaborate metre and rhyme, allegoric matter, and pedantic language. In his second stage he entirely emancipated himself from this, and became one of the easiest, least affected, and most vernacular poets of France. In these points indeed he has, with the exception of La Fontaine, no rival, and the lighter verse writers ever since have taken one or the other or both as model. In his third period he lost a little of this flowing grace and ease, but acquired something in stateliness, while he certainly lost nothing in wit. It is beyond question that Marot is the first poet who strikes readers of French as being distinctively modern. He is not so great a poet as Villon nor as some of his successors of the Pléiade, but he is much less antiquated than the first (whose works, as well as the *Roman de la Rose*, it may be well to mention that he edited) and not so elaborately artificial as the second. Indeed, if there be a fault to find with Marot, it is undoubtedly that in his gallant and successful effort to break up, supple, and liquefy the stiff forms and stiffer language of the 15th century, he made his poetry almost too vernacular and pedestrian. In his hands, and while the *style Marotique* was supreme, French poetry ran some risk of finding itself unequal to anything but graceful *vers de société*. But it is only fair to remember that for a century and more its best achievements, with rare exceptions, had been *vers de société* which were not graceful.

There is a very cheap, handsome, and useful edition of Marot by Jannet and Héricault, 4 vols., Paris, 1873; but M. Georges Guiffrey is slowly producing a costly and splendid work, containing a vast quantity of unpublished matter, which will undoubtedly be the standard. This work contains much biographical detail, which, however, as being still incomplete, is not available to modify former accounts. (G. SA.)

MARQUESAS ISLANDS, or MENDAÑA ISLANDS (French, *Les Marquises*), an archipelago of twelve islands lying between 7° 50′ and 10° 35′ S. lat., and 138° 30′ and 140° 50′ W. long. They extend over 200 miles from S.E. to N.W., and have a total area of 489 square miles. The lower or true Marquesas group consists of the islands Fatouhiva or Magdalena, Motane or San Pedro, Tahouata or Sta Christina, and Hivaoa or Dominica, the last with a coast-line of more than 60 miles. With these is often included the rocky islet of Fetohougo or Hood's, lying in mid-channel to the north of Hivaoa. The north-western or Washington group is formed of seven islands, the four largest being Roa-Poua or Adams, Houahouna or Washington, Noukahiva or Marchand (70 miles in circumference), and Hiaou. Along the centre of each island is a ridge of mountains, sometimes attaining an altitude of 3500 feet, whence rugged spurs forming deep valleys stretch towards the sea. The volcanic origin of the whole archipelago is proved by the principal rocks being of basalt, trachyte, and lava. Except on a few barren peaks the islands are clothed with verdure, and in the valleys, which are well watered with streams and brooks, the vegetation is luxuriant. The flora includes over four hundred known species, many of them identical with those belonging to the Society Islands. The vegetable products comprise bananas, bread-fruit, yams, plantains, wild cotton, bamboos, sugar-cane, cocoa-nut and dwarf palms, and several kinds of timber trees. The land fauna is, however, very poor: there are few mammals with the exception of dogs, rats, and pigs; and amphibia and insects are also generally scarce. Of twenty species of birds more than half belong to the sea, where animal life is as abundant as at other subtropical Polynesian groups.

The climate of the Marquesas, although hot and humid, is not unhealthy. During the greater part of the year moderate easterly trade winds prevail, and at the larger islands there are often both land and sea breezes; the rainy season, accompanied by variable winds, sets in at the end of November, and lasts for about six months. During this period the thermometer varies from 84° to 91° F.; in the dry season its average range is from 77° to 86°.

The inhabitants, a native Polynesian race, have in many respects a great affinity to the Tahitians, but excel them in symmetry of form. They live chiefly on bread-fruit, vegetables, and fish, almost entirely neglect agriculture, but rear hogs and fowls in great numbers. They exchange live stock, timber, vegetables, fruit, and fresh water with traders for iron utensils, firearms, gunpowder, cloth, tobacco, and brandy. They are polite in their intercourse with strangers, susceptible and courageous, but at the same time excitable, revengeful, addicted to stealing, lazy, and immoral. The efforts of missionaries, whether Protestant or Roman Catholic, have hitherto proved of little avail either in converting them to Christianity or in improving their moral and social condition. At the commencement of the present century the population exceeded 20,000, but since then petty warfare, infectious maladies, and various other causes have greatly reduced its number; and on the 31st December 1876 it reached only 5754.

In 1842 the Marquesas archipelago was formally taken possession of for France by Captain Du Petit-Thouars; and the French still maintain a nominal protectorate over the islands, with a resident and a small garrison at Noukahiva. Since 1861, however, French colonization has been virtually abandoned.

The Marquesas Islands were first discovered 21st July 1595, by Alvaro Mendaña, who, however, only knew of the south-east group, to which he gave the name of Marquesas de Mendoza, in honour of the viceroy of Peru. Cook, pursuing the same track, rediscovered this group, with the addition of Fetohougo, in 1774. The north-west islands were first sighted by Ingraham the American in 1791, and were subsequently visited by Marchand (1791) and Hergest (1792). A more extensive investigation of the archipelago was made by Krusenstern in 1804. Of later navigators to the Marquesas the most noteworthy are Stewart (1829), Bennett (1835), and D'Urville (1838), and, since the date of the French occupation, Dumoulin, Jouan, and above all Jardin.

See C. E. Meinicke, *Die Inseln des stillen Oceans*, Leipsic, 1875-76; *Tableaux de pop., &c., des col. franç.* for 1877.

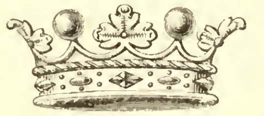
MARQUETRY. See FURNITURE.

MARQUETTE, a city and port of entry of the United States, and the county seat of Marquette county, Michigan, lies on a bluff about 25 feet above a bay of Lake Superior, and is a terminus of the Marquette, Houghton, and Ontonagon, and the Detroit, Mackinac, and Marquette Railroads. Though the population of the city was only 4690 in 1880, Marquette is a place of importance as the chief shipping port for the great iron-ore region of western Michigan (787,150 tons shipped in 1881), and contains a number of blast furnaces, foundries, machine-shops, and powder-mills, while at the same time it has a reputation as a resort for invalids and tourists. A Roman Catholic cathedral, convent, and orphan asylum are among the public buildings.

MARQUETTE, JACQUES, a Jesuit missionary and explorer, was born in 1637 at Laon in France, and died May 18, 1675, on the banks of a small stream, now known as the Marquette, which has its mouth on the eastern shore of Lake Michigan. Having joined the Society of Jesus, he sailed for Canada in 1666, spent eighteen months in the vicinity of Three Rivers, founded the mission of Sault Sainte Marie on Lake Superior in 1668, and followed the Hurons to Mackinaw in 1671. It is mainly, however, as Joliet's companion in his voyage down the Mississippi in 1673 that Marquette holds a permanent position in the history of discovery in America.

His narrative, first published in Thevenot's *Recueil de Voyages* (Paris, 1681), is printed along with other documents relating to him in Shea's *Discovery and Exploration of the Mississippi Valley* (New York, 1852).

MARQUIS, or MARQUESS, a title and rank of nobility, the second in the order of the British peerage, and therefore next to duke. The first marquis in England was Robert de Vere, the ninth earl of Oxford, who by Richard II., 1st December 1385, was created marquis of Dublin. On the 13th of October following the patent of this marquisate was recalled, Robert de Vere then having been raised to a dukedom. John de Beaufort, the second legitimate son of John of Gaunt, was created to the second marquisate as marquis of Dorset, 29th September 1397. From that period this dignity appears to have been dormant till the reign of Henry VI., when it was revived, and thenceforward it maintained its place in the British peerage. A marquis is "most honourable," and is styled "my lord marquis."



Marquis's Coronet.

His wife, who also is "most honourable," is a marchioness, and is styled "my lady marchioness." The coronet is a circlet of gold on which rest four leaves and as many large pearls, all of them of equal height and connected. The cap and lining, if worn, are the same as in the other coronets. The coronet, which in representations displays one central leaf with two pearls and two half-leaves, when without cap or lining, is shown in the annexed woodcut. The mantle of parliament is scarlet, and has three and a half doublings of ermine.

MARRIAGE, LAW OF.[1] Marriage may be defined here as the act, ceremony, or process by which the legal relationship of husband and wife is constituted. In most if not all legal systems it takes the form of a contract—the mutual assent of the parties being the prominent and indispensable feature of the ceremony. Whether it is really a contract or not, and if so to what class of contracts it belongs, are questions which have been much discussed, but into which it is not necessary to enter. While the consent of parties is universally deemed one of the conditions of a legal marriage, all the incidents of the relationship constituted by the act are absolutely fixed by law. In the United States it has been expressly decided that marriage is not a contract within the meaning of the constitutional law, which prohibits state enactments "impairing the obligation of contracts." Mr Bishop, however, in his very valuable book on *Marriage and Divorce*, suggests that a State law permitting the status of marriage to be created without the consent of both parties would not be constitutional; but that is a difficulty arising out of the peculiar relation of the States to the Union. The question whether marriage is merely a contract or more than a contract, whether a purely civil or also a religious act, belongs to a similar order of inquiries. The jurist has only to deal with marriage in so far as it creates the legal status of husband and wife. It should be added that, while marriage is generally spoken of by lawyers as a contract, its complete isolation from all other contracts is invariably recognized. Its peculiar position may be seen at once by comparing it with other contracts giving rise to continuous relationships with more or less indefinite obligations, like those of landlord and tenant, master and servant, &c. In these the parties may in general make their rights and duties what they please, the law only intervening when they are silent. In marriage every resulting right and duty is fixed by the law.[2]

Roman Law.—The three primitive modes of marriage were *confarreatio*, *coemptio in manum*, and *usus*, all of which had the effect of placing the woman in the "power" (*manus*) of her husband, and on the same footing as the children. The first was a religious ceremony before ten witnesses, in which an ox was sacrificed and a wheaten cake broken and divided between the spouses by the priest. *Coemptio* was a conveyance of the woman by *mancipatio*, and might be described as a fictitious sale *per æs et libram*, like that employed in emancipation and testamentary disposition and other processes. *Usus* was the acquisition of the wife by prescription, through her cohabiting with the husband for one year without having been absent from his house three continuous nights. But a true marriage might be concluded without adopting any of these modes, and they all fell into desuetude and with them the subjection of the wife to the manus. Marriage without manus was contracted by the interchange of consent, without writing or formality of any kind. By some jurists it is regarded as incomplete until consummated by delivery of the woman, and is accordingly referred to the class of *real* contracts. The restrictions as to age, relationship by consanguinity and affinity, previous marriage, &c., were in the main those which have continued to prevail in modern Europe with one important exception. The consent of the *paterfamilias* to the marriage of the children under his power was essential.

In the *Canon Law*, which is related on the one hand to the civil law, on the other to the modern matrimonial law of Europe, although marriage was not merely a contract but a sacrament, the validity of marriages by consent was nevertheless admitted. "When the natural and civil contract was formed," says Lord Stowell, "it had the full

[1] See also HUSBAND AND WIFE and DIVORCE.

[2] A full collection of juridical opinion as to the legal character of marriage is to be found in Lord Fraser's *Husband and Wife*, vol. i. chap. ii.

essence of matrimony without the intervention of a priest. It had even in that state the character of a sacrament, for it is a misapprehension to suppose that this intervention was required as a matter of necessity even for that purpose before the council of Trent."[1]

England.—Marriage may be the subject of an ordinary contract on which an action may be brought by either party. It is not necessary that the promise should be in writing, or that any particular time should be named. The parties were formerly inadmissible as witnesses in this action; but they are now competent to give evidence, subject to the condition that the plaintiff shall not recover "unless his or her testimony shall be corroborated by some other material evidence" (32 & 33 Vict. c. 68). The ordinary defences, *e.g.*, fraud, discharge, minority, are available in these actions, and there are also special defences arising from the nature of the contract, such as the bad character of the plaintiff, the relationship of the parties within the prohibited degrees, &c. Promises to marry are not within the meaning of "agreement made in consideration of marriage" in the statute of frauds, which requires such agreements to be in writing. Contracts in restraint of marriage, *i.e.*, whose object is to prevent a person from marrying anybody whatever, are void, as are also contracts undertaking for reward to procure a marriage between two persons. These latter are termed marriage brocage contracts.

Any man and woman are capable of marrying, subject to certain disabilities, some of which are said to be canonical as having been formerly under the cognizance of the ecclesiastical courts, others civil. The effect of a canonical disability as such was to make the marriage not void but voidable. The marriage must be set aside by regular process, and sentence pronounced during the lifetime of the parties. Natural inability at the time of the marriage to procreate children is a canonical disability. So was proximity of relationship within the prohibited degrees, which has been made an absolute avoidance of marriage by 5 & 6 Will. IV. c. 54. A pre-engagement to another person was at one time recognized as a canonical disability. Civil disabilities are (1) the fact that either party is already married and has a spouse still living;[2] (2) the fact that either party is a person of unsound mind; (3) want of full age, which for this purpose is fixed at the age of puberty as defined in the Roman law, viz., fourteen for males and twelve for females;[3] (4) proximity of relationship within the prohibited degrees, already alluded to. The statute which lawyers regard as establishing the rule on this last point is the 32 Henry VIII. c. 38 (repealed in part by 2 & 3 Edw. VI. c. 23, in whole by 1 & 2 P. and M. c. 8, but revived by 1 Eliz. c. 1, and so left as under the Act of Edward), which enacts that "no prohibition, God's law except, shall trouble or impeach any marriage without the Levitical degrees." The forbidden marriages, as more particularly specified in previous statutes, are those between persons in the ascending and descending line *in infinitum*, and those between collaterals to the third degree inclusive, according to the computation of the civil law, which reckons from one of the persons related to the common stock and so down to the other person. The prohibitions extend not only to *consanguinei* (related by blood) but to *affines* (related by marriage). A man may neither marry his sister nor his deceased wife's sister, for both are related to him in the second degree; nor his sister's daughter, nor his deceased wife's sister's daughter, for both are in the third degree; but he may marry his first cousin, for she is in the fourth degree. *Consanguinei* of either spouse are related by affinity to the other; but the *consanguinei* of the one are not necessarily related to the *consanguinei* of the other. Hence two brothers may marry two sisters, or a father and son a mother and daughter. A husband is not related to the *affines* of his wife, and so a man may marry the widow of his deceased wife's brother. The rule as to collaterals includes those related by the half blood and bastards (see Stephen's *Commentaries*, book iii. c. 2). Other disabilities previously admitted were abolished by the statute of Henry. The Act of 5 & 6 Will. IV. c. 54 enacted that "all marriages which shall hereafter be celebrated between persons within the prohibited degrees of consanguinity or affinity shall be absolutely null and void to all intents and purposes whatsoever." They had previously, as already stated, been only voidable. The Act at the same time legalized marriages within the prohibited degrees of affinity (but not consanguinity) actually celebrated before the 31st August 1835.

The celebration of marriages is now regulated wholly by statutory legislation. The most important Acts now in force are the 4 Geo. IV. c. 76 and the 6 & 7 William IV. c. 85.[4] The former regulates marriages within the Church of England, but was intended to be of universal application, Jews and Quakers only being excepted by section 31. It requires either the previous publication of banns, or a licence from the proper ecclesiastical authority. As to banns, the rule of the rubric, so far as not altered by the statute, is required to be observed. They must be published on three successive Sundays at morning service after the second lesson, in the church of the parish in which the parties dwell; the bishop may, however, authorize the publication of banns in a public chapel. Seven days' notice must be given to the clergyman of the names of the parties, their place of abode, and the time during which they have lived there. If either party is under age, the dissent of the parents or guardians expressed at the time of publication of banns renders such publication null and void. Licence in lieu of banns may only be granted by the archbishop, bishop, or other authority, for the solemnization of a marriage within the church of the parish in which one of the parties shall have resided for fifteen days before. Before a licence can be granted an oath must be taken as to the fact of residence and that the necessary consent has been obtained in the case of persons under age. The father, or lawful guardian, or mother if unmarried, or guardian appointed by the court, is each in order of substitution the proper person to consent to the marriage of a minor, and the place of any such person incapacitated mentally is taken by the lord chancellor. The absence of such consent does not, however, avoid a marriage once solemnized. But if persons wilfully intermarry (unless by special licence) in a place not being a church or public chapel, or without due publication of banns or proper licence, or before a person not in holy orders, the marriage is null and void to all purposes. Marriage must be celebrated within three months after banns or licence, and between the hours of eight and twelve in the morning.

For the relief of the great body of dissenters the Act 6 & 7 Will. IV. c. 85 was passed. It permits marriage to be solemnized in two additional ways,—viz. (1) by certificate of the superintendent registrar of a district without licence, and (2) by such certificate with licence. In the first case, notice must be given to the registrar of the district or districts within which the parties have resided for seven days previous, which notice is inscribed in a marriage notice book, open to public inspection at all reasonable times, and thereafter suspended for twenty-one days in some conspicuous place in the registrar's office. The notice must be accompanied by a declaration as to the absence of impediments, necessary consent, &c. Any person whose consent is necessary to an ecclesiastical licence may forbid the issue of a certificate, but in default of such prohibition the certificate will issue at the end of the twenty-one days. The marriage may then take place on any day within three months of the entry of notice, and in one of the following ways:—(1) in a certified place of religious worship, registered for the solemnization of marriage; in that case a registrar of the district with two witnesses must be present, and the ceremony must include a mutual declaration of assent by the parties and a disavowal of any impediment; (2) at the superintendent registrar's office, with the same

[1] Some restrictions on marriage peculiar to the canon law are noticed at the end of this article.

[2] A divorce *nisi* does not enable the parties to marry until it is made absolute.

[3] A marriage in which either of the parties is below the age of consent is, however, said to be not absolutely void; if the parties agree to continue together at the age of consent no new marriage is necessary, but either of them may disagree and avoid the marriage.

[4] A complete list of the acts regulating the solemnization of marriage or confirming marriages which through some defect might be void will be found in Phillimore's *Ecclesiastical Law*, vol. i.

declaration, but with no religious service; (3) in a church according to the usual form, the consent of the minister thereof having been previously obtained; (4) according to the usages of Jews and Quakers. The place of marriage in all cases must have been specified in the notice and certificate.

In the second case, when it is desired to proceed by licence, notice must be given to the registrar of the district in which one of the persons resides, together with a declaration that he or she has resided for fifteen days therein, that there is no impediment, and that the necessary consents if any have been obtained. The notice is not exhibited in the registrar's office, and the certificate may be obtained at the expiration of one whole day after entry, together with the licence. No registrar's licence can be granted for a marriage in church or according to the forms of the Church of England,—the ecclesiastical authorities retaining their monopoly in that respect. It is also provided that in the case of persons wilfully intermarrying in a place other than that mentioned in the notice and certificate, or without notice or certificate, &c., the marriage shall be null and void. And, as under the former Marriage Act of Geo. IV., a valid marriage between persons one of whom is under age, brought about by fraud or false oath, subjects the offending party to a forfeiture of all property that otherwise might accrue to him from the marriage, a like penalty is provided in like cases under the later Act.

It will be observed that the various rules as to consent of parents, &c., to the marriages of minors are regulations of procedure only. The absence of the necessary consent is not a disability invalidating a marriage actually solemnized.

The Act 26 Geo. II. c. 33, commonly known as Lord Hardwicke's Act, which forbids the solemnization of marriage without banns or licence, also enacts that "in no case whatsoever shall any suit or proceeding be had in any ecclesiastical court in order to compel a celebration *in facie ecclesiæ*, by reason of any contract of matrimony whatsoever whether *per verba de presenti* or *per verba de futuro*." Blackstone observes that previous to this Act "any contract made *per verba de presenti*, or in words of the present tense, and in case of cohabitation *per verba de futuro* also, was deemed valid marriage to many purposes; and the parties might be compelled in the spiritual courts to celebrate it *in facie ecclesiæ*." In his celebrated judgment in the case of Dalrymple *v.* Dalrymple, which turned on the effect of promises exchanged between the parties in Scotland, Lord Stowell laid it down "as the basis of the canon law, the known basis of the matrimonial law of Europe," that "in the irregular marriage, *i.e.*, *sponsalia per verba de presenti*, everything was presumed to be complete and consummated in substance but not in ceremony; and the ceremony was enjoined to be undergone as a matter of order. In the *sponsalia de futuro* nothing was presumed to be complete or consummated either in substance or in ceremony, but if the parties who had exchanged the promise had carnal intercourse with each other the effect was to convert the engagement into an irregular marriage." On the other hand, in the case of the Queen *v.* Millis in the House of Lords on appeal from the Irish Queen's Bench, the position of Lord Stowell was strongly criticized. Lord Lyndhurst's conclusion was that, "although a marriage contracted *per verba de presenti* was indissoluble, though it could not be released even by the mutual consent of the parties, though either of them might enforce it and compel solemnization, though it had the effect of rendering voidable a subsequent marriage solemnized *in facie ecclesiæ*, even after the cohabitation and birth of children, though it was considered to be of the essence and substance of matrimony—yet by the law of England it did not confer those rights of property or the more important right of legitimacy consequent on a marriage duly solemnized according to the rites of the church." The lords were equally divided in their decision, and the question has since been agitated not so much with reference to England, where after the Act of Geo. II. it had a merely historical interest, as to the colonies and the United States (see below), where the common law of England prevails unless changed by legislation. Dr Lushington in the case of a marriage in New South Wales declared that, when there has been a "fact of consent between two parties to become man and wife," such is "sufficient marriage to enable me to pronounce when necessary a decree of separation." In the cases noticed the promises had been exchanged before ministers of religion not technically "in holy orders," and the question has accordingly sometimes been put in the form whether, according to the common law, the intervention of a clergyman was necessary to a valid marriage.

Royal Marriages in England have been subject to special laws. The Royal Marriage Act of 1772 (12 Geo. III. c. 11), passed in consequence of the marriages of the dukes of Cumberland and Gloucester, enacted that "no descendant of his late majesty George II. (other than the issue of princesses married or who may marry into foreign families) shall be capable of contracting matrimony without the previous consent of his majesty, his heirs and successors, signified under the great seal. But in case any descendant of George II., being above twenty-five years old, shall persist to contract a marriage disapproved of by his majesty, such descendant, after giving twelve months' notice to the privy council, may contract such marriage, and the same may be duly solemnized without the consent of his majesty, &c., and shall be good except both Houses of Parliament shall declare their disapprobation thereto."

Scotland.—The chief point of distinction, as compared with English law, is the recognition of irregular marriages above noticed. (1) "A public or regular marriage," says Fraser, "is one celebrated, after due proclamation of banns, by a minister of religion; and it may be celebrated either in a church or in a private house, and on any day of the week at any hour of the day." The ministers of the national church at first alone could perform the ceremony; but the privilege was extended to Episcopalians by 10 Anne c. 7, and to other ministers by 4 & 5 Will. IV. c. 28. (2) A marriage may also "be constituted by declarations made by the man and the woman that they *presently* do take each other for husband and wife." These declarations "may be emitted on any day at any time and without the presence of witnesses," and either by writing or orally or by signs, and in any form which is clearly expressive of intention. Such a marriage is as effectual to all intents and purposes as a public marriage. The children of it would be legitimate; and the parties to it would have all the rights in the property of each other, given by the law of Scotland to husband and wife. (3) A promise followed by *copula* does not, according to Fraser, constitute marriage, unless followed either by solemnization *in facie ecclesiæ* or declarator. On the other hand, in Lorimer's *Handbook* it is urged that the promise and copula are mere tokens of consent recognized by the law, and that "the date of the marriage is the date of the copula." However this may be, Lord Moncreiff's opinion in the case of Brown *v.* Burns is admitted on both sides to be good law, viz., that declarator is essential to the constitution of a marriage of this kind, so that, if no such declarator be brought in the lifetime of both parties, the marriage can never be established afterwards. The *copula* is presumed to have reference to the promise, but evidence may be adduced to show that such was not the case.

By 19 & 20 Vict. c. 96, it is enacted that no *irregular* marriage shall be valid in Scotland, unless one of the parties has lived in Scotland for the twenty-one days next preceding the marriage, or has his or her usual residence there at the time.

"Habit and repute" has sometimes been spoken of as constituting marriage in the law of Scotland, but it is more correctly described as evidence from which marriage may be inferred. The repute must be the general, constant, and unvarying belief of friends and neighbours, not merely the controverted opinion of a section of them. The cohabitation must be in Scotland, but in one case proof of cohabitation in another country was allowed, as tending to throw light on the nature of the cohabitation in Scotland.

The consent of parents is not necessary to the validity of the marriage, even of minors, but marriage under the age of puberty with or without such consent is void.

United States.—The absence of ecclesiastical courts has suggested difficulties as to the extent to which the law of England on this subject continued to prevail after the revolution. Bishop holds it to be the universal fact running through all the cases that everywhere in the country the English decisions on marriage and divorce are referred to with the same apparent deference which is shown on other subjects to the decisions of the English common law and equity tribunals. The same author observes that "all our marriage and divorce laws, and of course all our statutes on the subject, in so far as they pertain to localities embraced within the limits of particular States, are State laws and State statutes, the national power with us not having legislative or judicial cognizance of the matter within those localities." Some of the States have extended the ages below which marriage cannot take place. The common law of the States is assumed to be that "a contract *per verba de presenti*, or *per verba de futuro cum copula*, constitutes a complete marriage." Conditions, however, may be imposed by the various State legislatures, and as to these the rule has established itself in American jurisprudence that "a marriage good at common law is good notwithstanding the existence of any statute on the subject, unless the statute contains express words of nullity." Thus in Pennsylvania, where a statute provided that all marriages "should be solemnized before twelve witnesses," marriages not so celebrated were nevertheless held to be good. In New Hampshire justices and ministers of the gospel are authorized to solemnize marriage, and all other persons are forbidden to do so under penalties; yet a marriage by consent, as at common law, without justice or minister, has been held valid. On the other hand, under a very similar statute in Massachusetts, it was held that "parties could not solemnize their own marriage," and that a marriage by mutual agreement, not in accordance with the statute, was void. Bishop regards this as an isolated exception to the general course of the decisions. So when State legislation requires any particular form to be used the want thereof only invalidates the act if the statute expressly so enacts. Many of the State codes inflict penalties on ministers or justices for celebrating the marriage of minors without the consent of the parents or guardians. The original law as to prohibited degrees has been considerably modified in the States. The prohibition of marriage with a deceased wife's sister is said by Bishop to be all but unknown in the United States, Virginia apparently being the only one where it is still retained. Some writers apply the term legislative marriages to cases in which the State by enactment confirms a marriage which was void for some defect. Questions sometimes arise as to whether such enactments are within the constitution of the State.

France.—Articles 144–226 of the Code Napoléon prescribe the qualifications and conditions of marriage. The man must be eighteen and the woman fifteen years of age. A son under twenty-five, and a daughter under twenty-one, cannot marry without consent of the father and mother, or of the father only if they disagree, or of the survivor if one be dead. If both are dead grandfather and grandmother take their place. A man after twenty-five and a woman after twenty-one are still bound formally to ask the consent of their parents; until the age of thirty and twenty-five respectively this request must be repeated twice, and after the third application parties are at liberty to marry without such consent. Even after the age of thirty, formal notice must be served on the parents or grandparents one month before marriage. If neither parents nor grandparents be alive, parties under twenty-one require the consent of the family council. These rules apply to natural children when affiliated; those not affiliated require the consent of a specially appointed guardian. Marriage is prohibited between all ascendants and descendants in the direct line, and between persons related by marriage in the same line, between brother and sister, between uncle and niece, and brother-in-law and sister-in-law.

Before the solemnization of marriage banns are required to be published on two distinct Sundays, containing the names, occupations, and domiciles of the parties and their parents. The marriage cannot take place until three days after the second publication, and if a year is allowed to elapse fresh banns must be put up. On the day appointed by the parties, and in the parish to which one of them belongs, the marriage is celebrated by the civil officer or registrar reading over to them the various necessary documents, with the chapter of the code relating to husband and wife, receiving from each a declaration that they take each other for husband and wife, and drawing up the act of marriage. All this has to be done in the presence of four witnesses.

Marriages contracted abroad between French subjects or between French subjects and foreigners are valid in France if celebrated according to the forms of the foreign law, provided the French conditions as to banns and consent of parents have been observed.

International Law.—In the "conflict of laws" on the subject of marriage, it has been well settled that the *lex loci* governs. If the marriage is valid by the law of the country where it is celebrated it is recognized as valid everywhere; if invalid there it is invalid everywhere. "This rule," says Story, "has received the most deliberate sanction of the English and American courts and of foreign jurists." The most prominent, if not the only known exceptions, Story considers to be marriages (1) involving incest or polygamy, or (2) forbidden by the public law of a country from motives of policy, and (3) marriages celebrated in a foreign country under circumstances which impose on the parties the law of their own country. Westlake (*Private International Law,* chap. iv.) lays it down as indispensable to the validity of a marriage that the *lex loci* should be satisfied in respect of forms, consent of parents and guardians, and capacity of the parties. The law of the parties' domicile should also be satisfied as to capacity unless when it imposes incapacity of a penal nature unknown to the *lex loci.* Story, in reference to the first of the three exceptions alluded to above, attempted to set up a clear and just moral difference between marriages that are incestuous by the law of nature and those that are so by the municipal law of particular States only, with more particular reference to consanguinity and affinity. "It would be a strong point to put that a marriage perfectly valid between a man and the sister of his former deceased wife in New England would be held invalid in Virginia or England, even though the parties formerly belonged to or were born in the latter country or State. But, as to persons not so belonging, it would be of the most dangerous consequence to suppose that the courts of either of them would assume the liberty to hold such marriages a nullity merely because their own jurisprudence would not in a local celebration of marriage therein uphold it." This position has been expressly disavowed by the English courts. In Brook *v.* Brook it was held that an Englishman's marriage with his deceased wife's sister during a residence in Denmark where the union is lawful is invalid in England. In Hyde *v.* Hyde in the English divorce court it was held that a marriage contracted in a country where polygamy is lawful between a man and a woman who profess a faith which allows polygamy is not a marriage as understood in Christendom; and, although it was a valid marriage by the *lex loci*, and at the time when it was contracted both the man and the woman were single and competent to contract marriage, the court will not recognize it as a valid marriage in a matrimonial suit. The difference in the law of divorce in different countries produces many complications of this kind. It appears that a divorce of an English marriage abroad for cause not recognized in England as ground for a divorce will be upheld in England if the parties were domiciled at the time of the divorce in the foreign state; otherwise not. Compare also the French rule as to marriages of French subjects in foreign countries. The too frequent consequence of these variances is that the same persons are held married in one country and unmarried in another, while their children are legitimate in one country and illegitimate in another. There is no subject in relation to which the establishment of a common code for all civilized nations is more urgently required.

Besides true marriage, with which we have been exclusively dealing hitherto, inferior forms of union have from time to time been recognized, and may be briefly noticed here. These have all but disappeared from modern society, depending as they do on matrimonial restrictions now obsolete.

The institution of slavery is a fruitful source of this kind of debased matrimony. In Roman law no slave could contract marriage whether with another slave or a free person. The union of male and female slaves (*contubernium*) was recognized for various purposes; a free woman entering into a union with a slave incurred under the S.C. Claudianum the forfeiture of her own liberty; but the bondwoman might be the concubine of a freeman. In the United States, where slavery was said to be regulated by the principle of the civil law, the marriage of slaves was so far recognized that on emancipation complete matrimony took effect and the children became legitimate without any new ceremony. Such at least is the purport of the more recent decisions.

In Roman law no legal marriage could be contracted unless there was *connubium* between the parties. Originally there was no connubium between plebs and patricians, and the privilege was conceded after a long struggle by the Lex Canuleia. In later times Latini and Peregrini were excluded from connubium except where the right had been expressly conferred. The great matrimonial law of the early empire (Lex Julia et Papia Poppæa) introduced restrictions depending on the condition of the parties which later legislation extended and perpetuated. Senators under that law were forbidden to marry freedwomen or women of inferior rank, and the husband of a freedwoman becoming a senator was set free from his marriage. In the canon law [1] new restrictions were developed. Persons who

[1] The restrictions are enumerated in the following lines:—
Error, Conditio, Votum, Cognatio, Crimen,
Cultus Disparitas, Vis, Ordo, Ligamen, Honestas,
Ætas, Affinis, si Clandestinus et Impos,
Raptave sit mulier nec parti reddita tutæ.

bound themselves not to marry were deemed incapable of marrying. The order of the clergy were forbidden to marry. And disparity of faith was recognized by the early church as a bar to matrimony, *e.g.*, between Christians and pagans, and between orthodox and heretics (see *Dictionary of Christian Antiquities*, art. "Marriage").

CONCUBINAGE, which such restrictions tended to develop, is noticed under a separate heading (*q.v.*). It might be described as marriage which has no consequences, or only slight and peculiar consequences, in legal *status*. In the left-handed or "morganatic"[1] marriages of the German royal families we have the nearest approach ever made by concubinage to true marriage, the children being legitimate, but neither they nor the wife acquiring any right to the rank or fortune of the husband. Under the Royal Marriage Act in England a union of this kind has no matrimonial effect whatever.

Differences of religion are no longer regarded in Christian countries as hindrances to marriage, except possibly in some branches of the Greek Church. But the marriage of persons of different religions frequently requires the intervention of the law as to the faith of the children, more particularly in Europe as between Catholics and Protestants. In some countries the clergy make it a condition of such marriages that the children shall be educated in the Catholic faith. English law gives the father an indefeasible right to dictate the faith of his children, no matter what engagements he may have entered into (see INFANT). The practice on this point varies in Europe—the question being ignored in French law, Germany following in some parts the same rule as England, in others giving effect to ante-nuptial stipulations. In Ireland mixed marriages (*i.e.*, between Catholic and Protestant) were by 19 Geo. II. c. 13 null and void if celebrated by a Catholic priest. This Act is repealed by 33 & 34 Vict. c. 110, which permits mixed marriages to be validly celebrated by an Episcopalian or Roman Catholic clergyman, subject to conditions set forth in section 38. (E. R.)

MARRYAT, FREDERICK (1792–1848), has never been surpassed as a writer of tales of nautical adventure. His own life supplied him with abundant raw materials for his art. The son of a wealthy London gentleman (who sat in parliament for several years for the boroughs of Horsham and Sandwich, and was a writer of verses and political pamphlets), he distinguished himself as a boy by frequently running away towards sea; and at last, at the age of fourteen, he was allowed to enter the navy. His first service was under Lord Cochrane in the famous "Impérieuse," and no midshipman ever had a livelier apprenticeship to the sea. "The cruises of the 'Impérieuse' were," he says, "periods of continual excitement, from the hour in which she hove up her anchor till she dropped it again in port; the day that passed without a shot being fired in anger was with us a blank day." During his two and a half years of service under the daring and active Cochrane, the young midshipman witnessed more than fifty engagements, many of them extremely brilliant, and had experience of every description of service, fighting duels with fairly matched ships of war, engaging gunboats, engaging batteries, storming forts, capturing and cutting out merchantmen. Before the general peace of 1815 he had added considerably to this experience of active service, and gained a wide knowledge of conditions of life on board ship under various commanders. He frequently received honourable mention for his behaviour in action, and in 1818 he received the medal of the Humane Society for "at least a dozen" gallant rescues. He commanded with distinction in the Burmese war of 1824-25. And Marryat's honours were not confined to gallant exploits; he was the inventor of a code of signals, obtained some celebrity as a caricaturist, and was elected an F.R.S.

Marryat brought ripe experience and unimpaired vivacity to his work when he commenced novelist. His first production was *Frank Mildmay, or the Naval Officer*, published in 1829, and his second, published nine months later, *The King's Own*. "I think," Washington Irving wrote to him soon after, "the chivalry of the ocean quite a new region of fiction and romance, and to my taste one of the most captivating that could be explored." This was the general feeling. The freshness of the new field opened up to the imagination, so full of vivid lights and shadows, light-hearted fun, grinding hardship, stirring adventure, heroic action, warm friendships, bitter hatreds, was felt all the more keenly from its contrast with the world of the historical romancer and the fashionable novelist, to which the mind of the general reader was at that date given over. The novels of the sea captain at once won public favour. His first attempt was somewhat severely criticized from an artistic point of view. It was without form, though the reverse of void; he had packed into it matter enough for half a dozen novels. Marryat was accused also of gratifying private grudges by introducing real personages too thinly disguised. He admitted the justice of these criticisms, and rapidly learnt the mechanical part of his new business without losing any of the vivacious charm of his style. *The King's Own* was a vast improvement, in point of construction, upon *Frank Mildmay*; and he went on, through a quick succession of tales, *Newton Forster*, *Peter Simple*, *Jacob Faithful*, *The Pacha of Many Tales*, *Japhet in Search of a Father*, *Mr Midshipman Easy*, *The Pirate and the Three Cutters*, till he reached his high-water mark of constructive skill in *Snarley-yow, or the Dog Fiend* (1837). If he never surpassed this in story-telling art, humorous portraiture, and richness of incident, the records of circulating libraries and the pencilled comments of their subscribers show that his subsequent works —he produced twenty-four in all during his twenty years of authorship—were no less capable of riveting the attention, especially of youthful readers. The following is the list, with the dates of publication:—*The Phantom Ship* (1839), *A Diary in America* (1839), *Olla Podrida* (1840), *Poor Jack* (1840), *Masterman Ready* (1841), *Joseph Rushbrook* (1841), *Percival Keene* (1842), *Monsieur Violet* (1842), *The Settlers in Canada* (1843), *The Privateer's Man* (1844), *The Mission, or Scenes in Africa* (1845), *The Children of the New Forest* (1847), *The Little Savage* (1847), and *Valerie*, not completed by Marryat (1849). Captain Marryat retired from the naval service in 1830, and thereafter worked as hard at literature as any professional man of letters, making special historical and geographical studies for several of the works in the above list. He edited the *Metropolitan Magazine* for four years (1832–36). Marryat's novels were in the first flush of their success when Dickens was a youth, and they have an interest in the history of literature as forming an important link between Smollett and Fielding and the author of *Sketches by Boz*. He died in 1848. There is a biography by his daughter, Florence Marryat.

MARS was a Roman deity whose name has passed into later literature as that of the war god. There grew in Rome a tendency, fostered by Greek influence, to consider Jupiter as the one great god, and the other deities as representing special sides of his character. Mars then was identified with the Greek ARES (*q.v.*), and was regarded as almost the same in nature with the warlike element in Jupiter as Feretrius and Triumphator. In the actual worship of the Romans Mars bears a very different character, which, however, had almost disappeared from the mind of the people before Augustus built in the Forum his temple to Mars Ultor, the avenger of the murder of Julius Cæsar.

Father Mars, Marspiter, Maspiter, Mavors, or Maurs, was the great god of one of the races that composed the Roman state. He is the god of heaven, the giver of light, the opener of the new year; he hurls the thunder and sends

[1] Said to be so called because the wife's rights were limited to the *Morgengabe* (donum matutinale). The common law in Germany permits them to the royal houses and the higher nobility, and the law of Prussia to the lower nobility also. Inequality of condition (Unebenbürtigkeit) is not necessary to a marriage of this kind, which may be made between persons of equal rank, *e.g.*, with the object of not prejudicing the children of a first marriage by allowing full rights to the offspring of a second. A woman of high rank may make a morganatic alliance with a man of inferior position.

the rain. In cases of drought the *lapis manalis*, which was kept in his temple on the Appian Way, was carried through the city by the *pontifices*. The first month of the old Roman year was the month of Mars, still called March. On the first day the god had been born; and on the same day various annual ceremonies both political and religious took place; and the holy fire was renewed in the temple of Vesta. When Mamurius Veturius, *i.e.*, Mars of the Year (*vetus*, Greek Ϝέτος), was beaten out of the city on March 14, the intention was originally to symbolize the driving away of the old year. The spear sacred to Mars was in its original sense doubtless the lightning, and his sacred shield was, like the ægis of Zeus and Athene, the storm shield, *i.e.*, the thundercloud. The Sabine words Marmar and Mamers (akin to μαρμαίρω) are evidently names of the heaven-god. The wolf which was sacred to Mars may be compared with the wolves of Zeus Lycaios, and the horse, the sacrifice of Mars, is the horse of the sun, which the Greeks also sacrificed to Helios.

As heaven-god and sender of rain, Mars is the giver of fertility and increase. Hence in some of the oldest cults he is the god of the land, of agriculture, and of the flocks. As he was powerful to send fertility, so he could cause also drought, sterility, and all evil; and propitiatory ceremonies, such as the Ambarvalia, were consecrated to him. The Arval brothers invoked Mars to assist them and to avert pestilence. In the Robigalia a sheep and a reddish dog were sacrificed by the flamen of Mars to avert mildew from the crops. The sacrifice of the "October horse" in the Campus Martius, whose head the people of the Subura and the Sacra Via struggled for in order to hang it up in their own precincts, had also a naturalistic and apotropaic character. In times of calamity there was an old Italian custom of dedicating to Mars a *ver sacrum*. Everything born in this spring was the property of the god; the animals were sacrificed, the young men when they grew up were sent out of the country. Mars seems also to have had some relation to the religious ceremony of marriage. Along with Juno, the goddess of women and of childbirth, he was worshipped by the Roman matrons on June 1 and at the Matronalia on March 1. As god of the land and giver of increase, Mars was also the god of death and the dead; he was one of the deities invoked by Decius when devoting himself to death. He was likewise the giver of oracles: like Zeus he revealed his will to men by certain signs. His ancient oracle at Tiora Matiene near Cære resembled in character the oracle of Zeus at Dodona, in so far as revelation took place by the medium of sacred birds and trees. Woodpeckers were the sacred birds of Mars, and the noise which they made tapping on the trees was one of the simplest methods of revelation. Picus, the woodpecker, was a name or form of Mars, and was ultimately individualized as a local hero, an early king of Latium, and son of the god. Faunus, the favouring deity, son of Picus, is pre-eminently the god of prophecy; he also is closely related to the original Italian character of Mars, which he retained far more truly than the great Roman god.

Although the worship of Mars was known both in Latium and in Etruria, it was probably of Sabine origin. Quirinus, an undoubtedly Sabine word, is merely a name of Mars, which never acquired complete individuality; the feeling always remained alive in Rome that Mars and Quirinus were one, although they had separate priests. It is in accordance with the Sabine character that the warlike element should have been very strong in their conception of deity; and thus the Sabine Mars became in the Roman pantheon the deity of war. Besides the ceremonies round the altar of Mars in the Campus Martius, the oldest cults of the god in Rome are the Sabine worship of Quirinus on the Quirinal and the Latin worship of the holy spear of Mars in the temple of Vesta. There likewise grew at an early time a cultus of the god on the Palatine, said to have been founded by Numa, and twelve Salii of the Palatine existed alongside of the twelve Quirinal Salii. The Palatine Salii performed one of the most remarkable ceremonies in the Roman worship of Mars. For many days, beginning from March 1, they danced in armour through certain parts of the city, clashing their lances on their shields, and repeated the prescribed song. The shields which they carried were the twelve sacred *ancilia* preserved on the Palatine. One of these, it was said, fell from heaven in the time of Numa, and the king, in order to preserve safely this pledge of victory for the state, had eleven others exactly like it made by Mamurius Veturius. The song of the Salii, besides mentioning all the gods of the city, referred to Mamurius, whose name is only a form of Mamers.

Next to Jupiter, Mars was the chief protecting god of the Roman state. Quirinus Mars was the father of the twin-founders of the city, and his sacred wolf was the emblem of the city and the foster-mother of the twins. The Campus Martius outside the city was dedicated to the god from a very early time; there the young men practised their warlike exercises; there the horse races, *equiria*, in honour of Mars (February 27) and the sacrifice of the "October horse" took place. There also was held the census every fifth year, followed by the purificatory ceremonial for the whole city, which was dedicated to Mars. When war broke out, the Roman general clashed the shield and spear in the temple of Mars and invoked the god; the spoils of victory belonged to him after Jupiter Feretrius.

There was an ancient temple of Mars outside the Porta Capena on the Appian Way; and on the ides of July, in commemoration of the battle of Lake Regillus, the knights had a procession

> "From Castor in the Forum,
> To Mars without the wall."

As the god of war, who marched with his people to battle, Mars was Gradivus; such at least was the later explanation of an old religious name. Inuus Lupercus, the averter, to whom the Lupercalia was dedicated, was probably a local form of Mars; his character as protector of the Palatine city, and the warlike element in him, resemble Mars (see LUPERCALIA). Silvanus is also closely related to the agricultural god Mars, who is sometimes called Mars Silvanus. A goddess named Nerio or Neriene is sometimes mentioned as wife of Mars. There was also a goddess Bellona, whose name marks her strictly as the goddess of war; she is called the sister or daughter or wife of Mars. Quirinus, on the Quirinal, had a festival called Quirinalia, on the 17th of February.

See Preller, *Röm. Mythol.*, and the other books on Roman religion; Marquardt on religious antiquities; Unger, "Lupercalia," *Rhein. Mus.*, 1881; Jordan, *Stadt Rom*; Roscher, *Apollo und Mars*; and on the Etruscan Mars, Müller, *Etrusker*, ed. Deecke, ii. 57 and 169.

MARSALA, a seaport on the west coast of Sicily, in the province of Trapani, 20 miles south of Trapani, to the north of the river Marsala, with a station on the railway between Trapani and Palermo. A flourishing and well-built town, with wide paved streets, it possesses a castle, a cathedral, a theatre, cavalry barracks (now occupied by Government offices), an academy of science and literature, and a public library. The Corinthian columns of the cathedral were originally intended for the cathedral at Canterbury, and owe their present destination to the wreck of the vessel which was conveying them to England. After the destruction of its harbour in the latter part of the 16th century as a precaution against its occupation by the Turkish pirates, the commercial importance of Marsala remained in abeyance till the construction of the new port to the south of the town. The sea-wall for this was begun in 1818; but it was not till 1835–36 that the pier was constructed. A great part of the surface of 44 acres constituting the port is now silted up; new works, however, on an extensive scale, are being undertaken. The wine trade, which forms the staple, was commenced in the end of the last century by Woodhouse & Co.; and the wines first got into favour by being supplied to the English fleet in 1802. They are for the most part white, and are usually "fortified." The number of seagoing vessels that entered at Marsala in 1863 was 149, with a burden of 9791 tons; in 1880 there were 249 vessels of 16,645 tons. From 31,350 in 1861 the population of the commune had increased by 1881 to 40,251; that of the town was 14,105 in 1871, or, with the suburbs of Porta Garibaldi, Porta Mazzara, and Porta Trapani, 17,666.

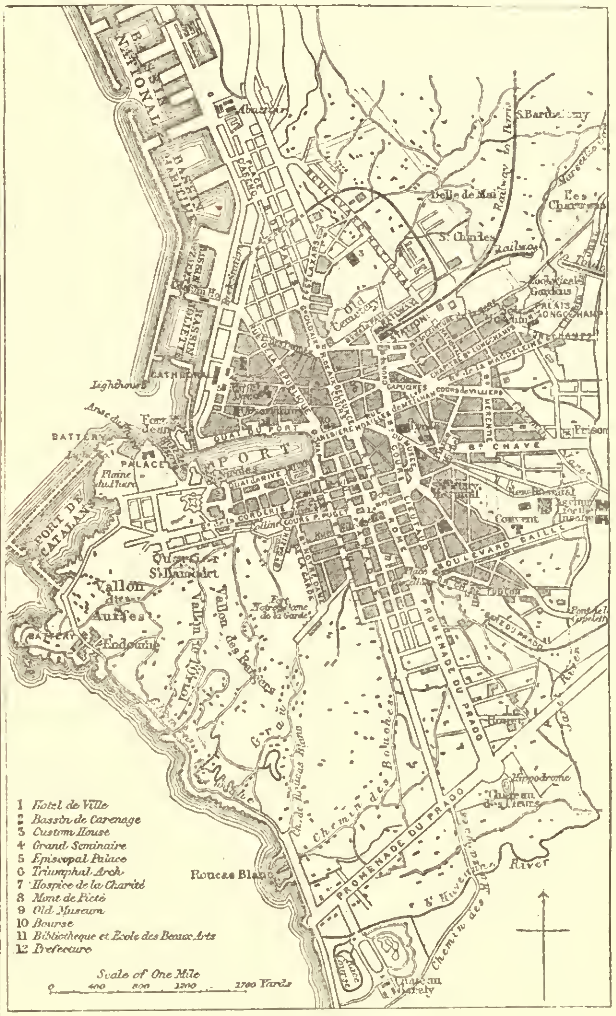
On the small island of San Pantaleone, about 6 miles north of Marsala, lay the Carthaginian stronghold of Motya (Ital., *Mozia*).[1] After the destruction of this settlement by Dionysius in 397 B.C. the defeated party established a new colony on the neighbouring promontory of Lilybæum. It was there that in 276 B.C. the Carthaginians held out successfully against Pyrrhus, who had already driven them from the rest of Sicily; and it was only after a siege of ten years that in the first Punic War they were obliged to surrender the fortress to the Romans. Under its new possessors Lilybæum continued to flourish and became the residence of one of the two quæstors of Sicily. It was still an important city under the later empire, and when occupied first by the Goths and then by the Vandals. The Arabs called it Mersá 'Aly, "port of 'Aly," and Edrisi (12th century) describes it as a considerable town, which, having been ruined, had been restored by Roger I. It was at Marsala that Garibaldi began his Sicilian campaign in 1860.

MARSDEN, WILLIAM (1754–1836), an eminent Oriental scholar, was the son of a Dublin merchant, and was born in 1754. After studying at Trinity College, he obtained an appointment in the civil service of the East India Company, and set sail for Bencoolen, Sumatra, in 1771. There he soon rose to the office of principal secretary to the Government, and was at the same time intent on acquiring that intimacy with the Malay language, and that knowledge of the country, which were afterwards the sources of his literary reputation. Returning to England in 1779 with a pension, he retired into literary seclusion, and in 1782 produced *The History of Sumatra*. Marsden was appointed in 1795 second secretary and afterwards first secretary to the admiralty. In 1807 he retired again into private life, and, devoting himself to study, published in 1812 his *Grammar and Dictionary of the Malay Language*, and in 1817 his translation of the *Travels of Marco Polo*. A pension of £1500, which he had received on his retirement from office, he voluntarily resigned in 1831 for the behoof of the public. In 1834 he presented his rich collection of Oriental coins to the British Museum, and his library of books and Oriental MSS. to King's College, London. He died of apoplexy in October 1836.

Marsden's other works are—*Numismata Orientalia*, London, 1823–25; *Catalogue of Dictionaries, Vocabularies, Grammars, and Alphabets*, 1796; and several papers on Eastern topics in the *Philosophical Transactions* and the *Archæologia*. His name will also be remembered in connexion with African philology, as he had—the first in England, and, it would appear, independently of Lichtenstein and Vater—drawn attention to the affinity of the Congo and Mozambique languages with those spoken by the Kaffre race. See Tuckey's *Narrative of an Expedition to explore the River Zaire*, London, 1818, p. 386 *sq.*

MARSEILLES (Fr. *Marseille*), the third largest city of France, and the chief commercial port of the Mediterranean, in 43° 17′ N. lat. and 5° 22′ E. long., is the chief town of the department of Bouches du Rhône, headquarters of the 15th army corps, the seat of a bishop, and of numerous commercial and scientific institutions. The population (1881) is 360,099.

The old harbour of Marseilles opens on the west to the Gulf of Lyons; and the famous Rue de la Cannebière, leading east-north-east from the inner end of the harbour, and continued by the Rue de Noailles, the Allées de Meilhan, and the Boulevard de Longchamps, to the Palais des Arts, forms the first main artery of the town. A second great artery, at right angles to the first, connects the Aix gate and its triumphal arch with the grand Promenade du Prado, by the Cours Belsunce and the Rue de Rome. North of the old harbour, between the Aix gate and the sea, lies the old town of Marseilles. The finest streets, the Rue St Ferréol, the Rue Paradis, and the Rue de Breteuil, are to the south of the Rue Cannebière,



Plan of Marseilles.

running parallel with the Rue de Rome, between it and the foot of the hill upon which is Notre Dame de la Garde. From La Cannebière to La Joliette, the centre of the new docks, runs the broad Rue de la République, lined with fine buildings, and opening a line through the oldest part of the town. The entrance to the old harbour is defended by Fort St Jean on the north and Fort St Nicolas on the south. Behind the latter is the Anse (Creek) de la Réserve. Beyond this again, situated in succession along the shore, come the old imperial palace, the Anse du Pharo, the military exercising ground, and the Anse des Catalans. The new parts of the town extend in this direction to the Vallon d'Endoume behind Fort St Nicolas. To the old harbour, which covered only 70 acres, the basin of La

[1] The ruins of Motya were excavated by Schliemann in 1876. See *Academy*, March 1876, p. 288.

Joliette (55 acres) was added in 1853. Communicating with the old harbour by a channel which passes behind Fort St Jean, this dock opens on the south into the outer harbour, opposite the palace and the Anse du Pharo; it is separated from the roadstead on the west by a simple jetty. A series of similar basins have since been added along the shore to the north, viz., the Lazaret or "Bassin des Docks" (37 acres), that of Arenc (59 acres), the "Bassin National," twice as large as the preceding, and the graving dock of 20 acres; a fine revolving bridge, worked by steam, separates the graving dock from the rest. Farther out, the Château d'If and the islets of Pomègue and Ratonneau, where vessels formerly did quarantine, have 45 acres of harbour accommodation. The port of Marseilles has in all an area of 422 acres, but there are only 4½ miles of quays, an amount of accommodation quite inadequate for the enormous traffic, now amounting to more than 3,400,000 tons. Protected on the east by Cape Croisette, and on the west by Cape Couronne, the roadstead of Marseilles and its approaches are lighted by six lighthouses, of which the most distant (130 feet high) is 8 miles south-west of the town, on the Planier rock. The docks along the Lazaret basin cover an area of 45 acres, and the company to which they belong also holds a large area of ground for their enlargement, and has exclusive rights over 1½ to 2 miles of quays. The warehouses occupy 27 acres of floor space on their several stories, and the 200,000 tons of goods for which they afford storage are easily manipulated by powerful hydraulic machinery wrought by steam. From the harbour station at the docks the railway is carried up to the principal station, "Gare St Charles," which commands the town. The Toulon line goes round the zoological gardens, and the whole upper part of Marseilles, and sends a branch to the Prado station. There is a fourth station to the south of the old harbour near the custom-house, and at the foot of the steps of St Victor; it is proposed to join it by a tunnel to the Marseille-Prado station. The large steam vessels for trading with Algiers, the Levant, and the further East lie in La Joliette, but the old harbour still displays the ancient characteristics of Marseilles. The old-fashioned Mediterranean traders with their lateen sails are crowded together in the Rive Neuve Canal to the south, while the sailing vessels of heavy tonnage are moored to the quay by their sterns. At the end of the old harbour opens out La Cannebière, so called from former rope-walks, of which it occupies the site; it is now the liveliest part of the town, where the principal cafés, shops, hotels, naval and commercial agencies, as well as the Bourse, are found.

Despite its antiquity, Marseilles has no ancient monuments. The old cathedral, which superseded a temple of Diana, itself preceded, it is said, by an altar of Baal, has given place to a modern structure, of which the exterior only is completely finished. It is a Byzantine basilica, in the form of a Latin cross, 460 feet long, built in grey Florentine stone blended with white stone from the neighbourhood of Arles. Near the cathedral stands the bishop's palace. The cathedral is situated at the entrance of the harbours, but a more distant church has superior attractions for the sailors,—the celebrated Notre Dame de la Garde, the steeple of which, surmounted by a gilded statue of the Virgin, 30 feet in height, rises 150 feet above the summit of the hill on which it stands, commanding a view of the whole port and town, as well as of the surrounding mountains and the neighbouring sea. The present chapel of Notre Dame de la Garde occupies the site of one built in 1214. Like the new cathedral it is in the Byzantine style, and constructed of the richest materials.

Descending from Notre Dame by steps, with shops on both sides containing objects of devotion, such as medals and chaplets, and passing the Promenade Pierre Puget, which affords another fine view of the sea, we reach the church of St Victor, close by Fort St Nicolas. Originally an abbey founded about 410 by St Cassian, it was afterwards destroyed by the Saracens, but rebuilt in the 11th century; destroyed a second time, it was finally restored by Pope Urban V., a former abbot, who surrounded it in 1350 with high square crenellated towers. Tradition relates that St Lazarus inhabited the catacombs under St Victor; and the black Virgin, still preserved there, is popularly attributed to St Luke. The spire of the ancient church des Accoules marks the centre of Old Marseilles. At its foot are a "Calvary" and a curious chapel of modern construction in rock work. Notre Dame du Mont Carmel, also in the old town, occupies the place of what was the citadel of the Massaliots when they were besieged by Julius Cæsar. The new Hôtel de la Préfecture, at the end of the Rue St Ferréol, the Palais de Justice, and the Bourse, are all buildings of the last twenty years. The first is a palatial edifice 300 feet long and 260 wide, adorned with statues and bas reliefs; it has a fine staircase and large reception rooms, decorated with paintings. Before the Palais de Justice stands a statue of Berryer. The pediment and peristyle are decorated with bas reliefs by Guillaume. The outer hall is surrounded by beautiful pillars of red marble. The Bourse has in the vestibule a bas relief representing Marseilles receiving the productions of all parts of the world, and allegorical statues of Marseilles and France. The hall is larger than even that of the Bourse at Paris. The hall of the Chamber of Commerce, at whose cost the whole edifice was built, is remarkable for the magnificence of its mural paintings and gildings. The Hôtel de Ville, an old and unimportant building, stands on the quay to the north of the old harbour. The Palais des Arts de Longchamps, completed in 1870, is a work of consummate taste; it is built at the terminus of the Canal de Marseille, that great work which has metamorphosed the town and its surroundings by bringing into it the waters of the Durance. This canal, which leaves the river opposite Pertuis, has a length of 94 miles, of which more than 15 are underground. It crosses the valley of the Arc, between Aix and Rognac, by the magnificent aqueduct of Roquefavour, comparable with the noblest works of ancient or modern times. The canal then purifies its waters, charged with ooze, in the basins of Réaltort, sets in motion seventy-two mills, which it supplies with upwards of 1200 horse-power, carrying about 200 cubic feet of water per second to the district of Marseilles. Right and left of the Château d'Eau, which occupies the centre of the Palais de Longchamps, and is 128 feet in height, are the picture gallery, a fine collection of ancient and modern works, and the natural history museum, remarkable for its conchological department and the interesting collection of ammonites. Behind are extensive zoological gardens, with the astronomical observatory, one of the most important in France. The museum of antiquities is established in the Palais Borély, in a fine park, recently purchased by the town, at the end of the Prado, and approached by the two finest promenades of the city. It includes a Phœnician collection (containing the remains that support the hypothesis of the Phœnician origin of Marseilles), an Egyptian collection, numerous Greek, Latin, and Christian inscriptions in stone, &c. A building within the city, recently finished, 177 feet by 64, with an imposing façade, contains the school of art and a valuable library. The triumphal arch of Aix, originally dedicated to the victors of the Trocadero, was in 1830 appropriated to the conquests of the empire.

Marseilles contains large hospitals. The Hôtel Dieu in the old town was founded in 1188, and rebuilt in 1593; it has 450 beds. The Hospice de la Charité, in the same neighbourhood, accommodates 600 patients, while at the opposite extremity of the town, near the Prado station, are the modern Hôpital de la Conception (with 800 beds), the military hospital, and the lunatic asylum.

The scientific institutions of the town are also numerous, including a faculty of science, an astronomical observatory, a preparatory school of medicine and pharmacy, a musical conservatoire, a school of art, a lyceum, and many private institutions. The principal learned societies are the academy of science, letters, and art, the medical association, and the geographical, statistical, agricultural, and horticultural societies.

The mean temperature of Marseilles is 58° Fahr.; frost is rare, and snow almost unknown. The heat of summer is tempered during the day by the cooling sea breeze. The most disagreeable wind is the mistral, a violent and cold north-west wind, which blows on an average one hundred and thirty-eight times a year, but has at least the advantage of restoring salubrity to the frequently unhealthy shores of the Mediterranean. The sirocco, a south-east wind, blows some sixty times a year; though hot and parching in summer, it softens the winter climate. The east-south-east wind is cold and damp, and brings rain. The Canal de la Durance has greatly modified the climate of Marseilles and its neighbourhood, for by restoring vegetation it has increased the fogs and rains; there is now an annual rainfall of nearly 24 inches.

Marseilles is at once the largest commercial port of France and a manufacturing town, working up the raw materials brought in by sea from every part of the world. The leading industry is that of soap-making, which occupies sixty factories with 1200 artisans, and annually produces 65,000 tons, valued at £2,000,000 sterling. With this manufacture are connected oil and chemical works; in the former, which employ 2000 to 2500 workmen, 55,000 tons of different oils are produced yearly. The chemical works comprise a dozen mills, manufacturing chiefly the salts of soda and concentrated acids. Two thousand operatives are there employed, and the value of their annual production is estimated at £320,000. There are also three sugar-refineries, producing 65,000 tons of loaf-sugar, of which more than half is re-exported. Sulphur from Sicily too is refined and converted into sticks or flowers of sulphur, to the value of £80,000. Petroleum refining occupies 100 workmen. Metallurgy is another great industry; a large quantity of ore, imported from Elba, Spain, and Algeria, is smelted in the blast furnaces of St Louis in the suburbs. The Mediterranean iron-works and yards, together with other private companies, have large workshops for the construction or repair of marine steam-engines and every branch of iron shipbuilding, employing several thousand workmen. Marseilles is a great centre for the extraction of silver from lead ore; 16,000 tons of lead and 25 tons of fine silver are separated annually. There are 64 flour-mills with 300 sets of stones, and 100 factories prepare semolina and other cereal pastes, while 34 tanyards dress 500,000 sheep skins and 335,000 goat skins. To this list of industries must be added the manufactories of matches, candles, and wax-lights, with brass foundries, glass-works, and manufactures of coral, and of Oriental hosiery.

The port of Marseilles is the centre of numerous lines of steamers. The French company of mail steam packets (*Messageries Maritimes*) despatch their boats regularly to Italy, Egypt, Réunion, India, China, and the far East, as well as to Greece, Turkey, the Black Sea, Smyrna, and Syria. The Transatlantic Company runs its vessels to Algiers, Tunis, Malta, and the coast of Italy, and has also a regular line between Marseilles and New York. Many private companies have services to Corsica, Algiers, the coast of Languedoc and of Spain, and the Italian Riviera. Other lines connect Marseilles with Brazil and La Plata, Havre, and London. Landward there are two lines of railway to Aix, and a third to Toulon. A navigable canal is greatly needed to connect the port directly with the Rhone, in order to avoid the difficulties of egress from the river and to make Marseilles the natural outlet of the rich Rhone basin. The countries with which the greatest traffic is maintained are Algeria, Spain, Italy, Turkey, and the Russian ports on the Black Sea; next in order come England, Austria, the western coast of Africa, Réunion, the Cape, British India, Brazil, the Antilles, China, and Senegambia. From the Black Sea, Turkey, and Algeria come the cereals which form the chief imports in point of bulk; from Italy, Spain, the Levant, China, and Japan the silk, which is the import of greatest value (£4,000,000 yearly). Then follow ores and metals, iron, cast iron, lead, and copper; also wood, raw material for oil manufacture, raw sugar, cattle, wool and cotton, rice, and various dry vegetable foods, petroleum, cocoa, gums, pepper, and other spices, wines and brandies, coal, skins, cod-fish, cheese, and sponges. The principal exports in respect of value are silk, woollen, and cotton fabrics, refined sugars, wines and spirits; those of greatest bulk are cereals in the form of grain or flour, coal, building materials, oil-cakes, iron and other manufactures in metal, wines and spirits, oils, glass and crystal, lead, and coffee.

Of the seagoing tonnage, one-third is under the French flag, but the coasting trade, carried on by French sailors alone, is almost half as large as the ocean trade. The shipowners of the port possess almost seven hundred vessels, without counting the hundreds of fishing boats which ply along the coast.

History.—The Greek colony of Massalia (in Latin, *Massilia*) was founded by the enterprising mariners of Phocæa in Asia Minor, about 600 B.C. The settlement of the Greeks in waters which the Carthaginians jealously reserved for their own commerce was not effected without a naval conflict; it is, indeed, not improbable that the Phœnicians were settled at Marseilles before the Greek period, and that the very name of the town is the Phœnician מְזֻל, "settlement." Whether the judges (שפטים, "suffetes") of the Phœnician sacrificial tablet of Marseilles were the rulers of a city older than the advent of the Phœnicians, or were a sort of consuls for Punic residents in the Greek period, is disputed. The fall of the Ionic cities before the Persians probably sent new settlers to the Ligurian coast and cut off the remote city of Massalia from close connexion with the mother country. Isolated amidst alien populations, the Massaliots made their way by great prudence in dealing with the inland tribes, by the vigilant administration of their oligarchical government, and by frugality and temperance united to remarkable commercial and naval enterprise. Their colonies spread east and west along the coast from Monaco to Cape St Martin in Spain, carrying with them the worship of Artemis; the inland trade, in which wine was an important element, can be traced by finds of Massalian coins right across Gaul and through the Alps as far as Tyrol. The Massaliot Pytheas (330–320 B.C.) passed the pillars of Hercules and visited the coasts of Gaul, Britain, and Germany. The great rival of Massalian trade was Carthage, and in the Punic wars the city took the side of Rome, and was rewarded by Roman assistance in the subjugation of the native tribes of the Ligurian mountains. In the war of Cæsar and Pompey the aristocratic town took the side of the latter, and made a courageous but vain resistance to Cæsar. In memory of its ancient services the city, "without which," as Cicero says, "Rome had never triumphed over the Transalpine nations," was still left as a *civitas libera*, but her power was broken and most of her dependencies taken from her. From this time Massalia has little place in Roman history; it became for a time an important school of letters and medicine, but its commercial and intellectual importance gradually declined into insignificance. The town appears to have been Christianized before the end of the 3d century, and its reputation partly revived through the names of Gennadius and Cassian, which give it prominence in the history of Semi-Pelagianism and the foundation of Western monachism.

After the ravages of successive streams of invaders, Marseilles was repeopled in the 10th century under the protection of its viscounts. In 1112 the town bought up their rights, and was formed into a republic, governed by a podestat, who was appointed for life, and exercised his office in conjunction with 3 notables, and a municipal council, composed of 80 citizens, 3 clerics, and 6 principal tradesmen. During the rest of the Middle Ages, however, the higher town was governed by the bishop, and had its harbour at the creek of La Joliette. The southern suburb was governed by the abbot of St Victor, and owned the Port des Catalans. Situated between the two, the lower town, the republic, retained the old harbour, and was the most powerful of the three divisions. The period of the crusades brought great prosperity to Marseilles. The activity of its shipbuilding, the magnitude of its fleet, the importance of its commerce and manufactures, all increased at once. The count of Provence, Raymond Bérenger, Charles of Anjou, and afterwards Alphonso of Aragon, successively attempted to make themselves masters of the town; it suffered at different times from incendiarism, pillage, and massacre during the 13th and 14th centuries, and in the beginning of the 15th. King René, who had made it his winter residence, however, caused trade, arts, and manufactures again to flourish. Under Francis I., the disaffected constable de Bourbon vainly besieged the town with the imperial forces in 1524. During the wars of religion, Marseilles took an active part against the Protestants, and long refused to acknowledge Henry IV. The loss of the ancient liberties of the town brought on new disturbances under the Fronde, which Louis XIV. came in person to suppress. He took the town by storm, and had Fort St Nicolas constructed. Marseilles repeatedly suffered from the plague, and an epidemic raged from May 1720 to May 1721 with a severity for which it is almost impossible to find a parallel; Bishop Belsunce, Chevalier Rose, and others immortalized themselves by their courage and devotion.

During the Revolution the people rose against the aristocracy, who up to that time had governed the commune. In the Terror they rebelled against the convention, but were promptly subdued by General Carteaux. The wars of the empire, by dealing a severe blow to their maritime commerce, excited the hatred of the inhabitants against Napoleon, who accordingly hailed with enthusiasm the return of the Bourbons and the defeat of Waterloo. The news of the latter provoked a bloody reaction in the town against those suspected of imperialism. Since 1815 the prosperity of the city has received a considerable impulse from the conquest of Algeria and the opening of the Suez Canal. The completion of the canal of the Durance has covered with verdure the formerly arid country surrounding the town, and the openings made in the old part of Marseilles have improved its sanitary condition. (G. ME.)

MARSH, George Perkins, LL.D. (1801-1882), American diplomatist and philologist, was born at Woodstock, Vermont, March 17, 1801, graduated at Dartmouth College in 1820, and practised law at Burlington, Vermont, devoting himself also with ardour to philological studies. In 1835 he was elected to the State legislature, and in 1842 he became a member of Congress. In 1849 he was appointed United States minister to Turkey, and in 1852 discharged also a special mission to Greece, returning to Vermont in 1853. In 1861 he became United States minister to Italy, and died in that office at Vallombrosa, July 24, 1882.

His chief published works are a *Compendious Grammar of the Old Northern or Icelandic Language*, 1838, compiled and translated from the grammar of Rask; *The Camel, his Organization, Habits, and Uses*, 1856; *Lectures on the English Language*, 1861; *The Origin and History of the English Language*, 1862; *Man and Nature*, 1864. The last-named work, largely rewritten, was issued under the title *The Earth as Modified by Human Action* in 1874.

MARSHAL (from Old High German *marah*, horse, and *scalc*, care-taker), in its original signification a servant of the royal *manège*, was afterwards a title given in different countries to the holder of various high offices, military and civil. In the time of Philip Augustus the commander of the French forces was called the marshal of France. Under Francis I. the marshals of France became two in number, under Henry III. four, and in the time of Louis XIV. their number was raised to twenty. In England the marshal was a high officer of state as far back as the 12th century. In the end of the 12th and first half of the 13th century the office was conferred on the earls of Pembroke, from whom it passed by female descent to the family of Bigod, earl of Norfolk. The dignity of earl-marshal was afterwards held successively by the Mowbrays, dukes of Norfolk, the Howards, dukes of Norfolk, and the earls of Arundel and Norwich. Under a grant by Charles II. to Henry Howard, earl of Norwich, it has descended to and continues in the line of the existing dukes of Norfolk. The marshal was in feudal times (in conjunction with the constable, a still higher officer) the judge in the court of chivalry, which had cognizance of questions of honour and dignity; and, when the king headed his army in person, it was the marshal who selected the proper spot for the encampment of each noble. The constable's powers and duties were superseded in the reign of Henry VIII.; but the earl-marshal is still the head of the Heralds' College, and appoints the officers of arms. In Scotland (an orthography resembling the French maréchal being adopted) the office of marischal, probably introduced under David I., became from the 14th century hereditary in the family of Keith. The Scottish marischal became an earl under the designation of "earl-marischal" in 1458. Marischal College in Aberdeen was founded and endowed by the munificence of George, 5th earl-marischal. The dignity came to an end by the attainder of George, 10th earl-marischal, in 1716. The military title of field-marshal was at first borrowed by the Germans from the French *maréchal de champs*; and in the Thirty Years' War it meant much what quartermaster-general does now. It was not till last century that the word rose in dignity so as to signify the highest military dignity except that of commander-in-chief. It was adopted into the British military system from Germany,—the first field-marshals being John, duke of Argyll, and George, earl of Orkney, made so by George II. in 1736.

MARSHALL, John (1755-1835), chief justice of the United States, was born in Fauquier county, Virginia, on September 24, 1755. As lieutenant and captain he served in the revolutionary army from 1775 to 1780. In 1781 he began the practice of the law, and two years later removed to Richmond. At various times from 1782 to 1798 he was elected a member of the Virginia legislature, in 1788 a member of the Virginia convention for the ratification of the constitution; in 1797 he was envoy-extraordinary to France, and in 1799 a member of Congress; in 1800 he became secretary of state; and on January 31, 1801, he was appointed to the chief justiceship, which position he held until his death on the 6th of July 1835. Marshall as a lawyer soon rose to the first rank at the Virginia bar, and acquired also a national reputation. In the Virginia convention of 1788 his influence was second only to that of Madison in securing the adoption of the constitution. But, unlike Madison, he continued, under the constitution, to support the administration of Washington and Federalist measures in general. It was as chief justice of the supreme court of the United States, however, that Marshall won lasting fame. His reports, filling about thirty volumes, form a work which time will only render more valued. In the expounding of public law, whether international or State law, his talents found their freest scope. In these departments of jurisprudence general principles rather than authority must be sought by the judge, and in their application Marshall has had no equal upon the American bench. It is the peculiar function of the supreme court of the United States to interpret the constitution and to guard it from the encroachments of both national and State legislation. To this duty Marshall brought his great and just powers of reasoning, as well as those broad views of government which, during the thirty-four years of his judicial career, gave to the constitution the liberal powers which were necessary to its durability. "The constitution," says Judge Story, "since its adoption, owes more to him than to any other single mind for its true interpretation and vindication." See biography by Henry Flanders in his *Lives of the Chief Justices*, vol. ii.

MARSHALL ISLANDS. See Micronesia.

MARSHALLTOWN, the county seat of Marshall County, Iowa, United States, is situated on the Iowa river at the junction of several railways, and in the midst of a grain and stock producing region. Among its numerous industries are sugar-refining, waggon-making, and the manufacture of barbed steel wire for fencing purposes. The population was 3218 in 1870 and 6240 in 1880, and has since increased rapidly.

MARSHMAN, Joshua (1768-1837), a Baptist missionary and Oriental scholar, was born on April 20, 1768, at Westbury Leigh, in Wiltshire, where he received a somewhat defective school education, and afterwards followed the occupation of a weaver until 1794, when he removed to Bristol to take charge of a small school there. Meanwhile he had been diligent in the cultivation of his talents, which were naturally good; and he was already a man of considerable acquirements when in 1799 he was sent by the Baptist Missionary Society to join their establishment at Serampore. Here, in addition to the discharge of his more special duties, he engaged with success in the study of Bengali and Sanskrit, and afterwards of Chinese, and accomplished numerous literary tasks, the more important of which are mentioned below. He received the degree of D.D. from Brown University, U.S.A., in 1811. His death took place at Serampore on December 5, 1837.

Dr Marshman translated into Chinese the book of Genesis, the Gospels, and the Epistles of Paul to the Romans and the Corinthians; in 1811 he published *The Works of Confucius, containing the Original Text, with a Translation*, and in 1814 his *Clavis Sinica*. He was also the author of *Elements of Chinese Grammar, with Preliminary Dissertation on the Characters and Colloquial Mediums of the Chinese*, and was associated with Carey in the preparation of a

Sanskrit grammar and of a Bengali-English dictionary. See J. C. Marshman's *Life and Times of Carey, Marshman, and Ward* (2 vols., 1859).

MARSIGLI (Latinized MARSILIUS), LUIGI FERDINAND, soldier and savant, was born at Bologna, July 10, 1658, and died in the same city, November 1, 1730. After a considerable course of study in mathematics, natural history, and anatomy, he visited Constantinople, and on his return to Christendom offered his services to the emperor Leopold, then at war with the Turks (1682). Wounded and captured in an action on the river Raab, he was sold to a pasha and accompanied him to the siege of Vienna; but in 1684 his friends purchased his release, and at the close of the war he was appointed commissioner for fixing the new Dalmatian boundary. In 1703 he was second in command to the count of Arco when Alt-Breisach was surrendered to the duke of Burgundy; and, though popular opinion acquitted him of blame, Marsigli was cashiered when Arco was condemned to death. Devoting himself to scientific pursuits, he visited Switzerland, and spent a considerable time at Paris and Marseilles. He went to Rome in 1709 at the request of Clement XI., but soon returned to Marseilles to prosecute his investigations into the physical nature of the sea. In 1712 he presented his scientific collections to his native city, and thus gave rise to the Bologna Institute of Science and Art; and about the same time he established a press, including founts of Oriental characters, for printing the publications of the society.

Marsigli's own works were valuable contributions to knowledge, brought out in very handsome style. Best known are his curious physical history of the sea (Italian, Venice, 1711; French, Amsterdam, 1725), with a very laudatory preface by Boerhaave; *L'état militaire de l'Empire Ottoman* (Amsterdam, 1732); and *Danubius Pannonico-Mysicus* (Hague, 1726). This last, of which only three hundred and seventy-five copies were printed, consists of six huge folio volumes illustrated by nearly three hundred maps and engravings, and furnishes an exceedingly elaborate account of the course of the Danube, of the towns and antiquities along its banks, of its birds, beasts, fishes, &c. See Fontenelle's *éloge* in *Mém. de l'Acad. des Sciences*, Paris, 1730; Quincy, *Vie de Mons. le Comte de Marsigli*, Zurich, 1741.

MARSTON, JOHN, was one of the most vigorous satirists and dramatists of the Shakespearean age. He was probably some ten years younger than Shakespeare He has been identified with a gentleman commoner of Brasenose College, Oxford, who entered in 1591, and was admitted B.A. in 1593 as the eldest son of an esquire. If this is the same John Marston that was buried in the Temple Church in 1634, under a tombstone *Oblivioni sacrum*, the identification of him with the poet is most probably right, for one of Marston's most singular poems is a prayer to Oblivion—

"Let others pray
For ever their fair poems flourish may;
But as for me, hungry Oblivion,
Devour me quick."

In the superfluity of learned allusions and Latin quotations in his plays Marston proclaims the fact that he was a university man. He entered the field of letters in 1598, as a satirist, with a *Scourge of Villany*. He was professedly an imitator of Juvenal, but he wrote rather in the spirit of Skelton, and speedily earned something like Skelton's reputation as a coarse ribald buffoon of astonishing energy, girding at the grossest vices of the time in "plain naked words stript from their shirts." There was more of the good-natured chuckling buffoon than of the cynic in Marston's satire, though he did profess unmeasured scorn for the vices and fopperies of his age. The coarse energy of his invective pours out as if he loved strong language more than he hated the subjects of his ridicule. Shakespeare's *Venus and Adonis* was one of Marston's first butts; in his *Pygmalion's Image* (1598) the wooing of Adonis by the queen of love is very roughly but very cleverly parodied. The freshness and vigour of Marston's vein brought him at once into notice. He is mentioned (misspelt as Maxton or Mastone) in Henslowe's *Diary*, in 1599, as "the new poet" receiving payment as part author of a play; and in the same year he was probably ridiculed by Ben Jonson as "Carlo Buffone" in *Every Man out of his Humour*. He and Dekker had a famous quarrel with Jonson arising out of the latter's attack upon them in the *Poetaster* (see DEKKER). The literary enemies were reconciled; Marston forswore literary quarrels, dedicated a play to Jonson in terms of high eulogy, and was conjoined with Jonson and Chapman in the play of *Eastward Ho!* some political allusions in which nearly cost the authors their ears. Marston wrote comparatively few plays, published in quick succession at the following dates:—*Antonio and Mellida* (1602); *Antonio's Revenge* (1602); *The Malcontent* (1604, his first and most powerful play); *The Dutch Courtesan* (1605); *Parasitaster* (1606); *Sophonisba* (1606); *What You Will* (1607). Marston then apparently left off play writing; if he lived till 1634, there is no explanation of his sudden stoppage. There is very little constructive skill in his plays; the plots are uninteresting. He does little more than send a procession of puppets across the stage, one or more of which "gird at" the others—very "loose libertines" and very contemptible some of them—in the author's own rough vein of satire. One scene in *Antonio and Mellida* was much admired by Charles Lamb, and either suggested or was suggested by one of the most powerful situations in *King Lear*. But the passage taken out of the body of the play gives a very misleading idea of its general tenor, or of the general cast of Marston's dramatic work.

MARSYAS was a Phrygian god, whose name has passed into Greek mythology. It is hardly possible to discover the real basis of the legends, as their original form has been so much altered. Marsyas was the god of a small river which rose in a cave in the agora of Celænæ, and flows into the Mæander. In this cave was hung a hide, which according to the story was the skin of Marsyas suspended there by Apollo. When Athene threw away her flute, Marsyas found it, a subject represented by the sculptor Myron. Proud of his skill, Marsyas challenged Apollo with his lyre. Midas the Phrygian king, appointed judge in the contest, preferred the flute-player, and got his ass's ears in reward for his stupidity. The contest and the punishment of Marsyas, who was flayed alive by Apollo, were frequent subjects for Greek art, both vase-painting and sculpture. There can be little doubt that this account has been very much altered from its native Phrygian form by the Attic comic poets, with whom Marsyas was a favourite character. With regard to the Phrygian god it is difficult to say more than that he and Silenus and Midas are associated in legend with Dionysus, and that he must therefore belong to the cycle of legends of Cybele (see Preller, *Gr. Mythol.*, i. 508). The flute was the favourite instrument in the worship of the goddess. Sacrifices were offered by the people of Celænæ to Marsyas, and he helped them against the Galatians (Paus., x. 30). A statue of Marsyas was erected in the Roman Forum and in other towns, and is said to have been a symbol of liberty.

MARTEN,[1] the name of a group of animals constituting

[1] By all old authors of authority, as Ray, Pennant, Shaw, and Fleming, the word is written "Martin," but this form of spelling is now generally reserved by way of distinction for the bird (see MARTIN). The word, as applied to the animal here described, occurs in most Germanic and Romanic languages:—German, *marder*; Dutch, *marter*; Swedish, *mard*; Danish, *maar*; English, *marteron*, *martern*, *marten*, *martin*, and *martlett*; French, *marte* and *martre*; Italian, *martora* and *martorella*; Spanish and Portuguese, *marta*. Its earliest known use is in the form *martes* (Martial, *Ep.* x. 37), but it can scarcely be an old Latin word, as it is not found in Pliny or other classical writers,

a small but well-defined section of the family *Mustelidæ*, belonging to the Arctoid or Bear-like division of the order *Carnivora* (see MAMMALIA, pp. 439, 440 of the present volume).

The genus *Mustela*, as restricted by Cuvier (*Règne Animal*, 1817), contains a very natural assemblage of animals commonly called Martens, Sables, Polecats, Stoats, Ermines, and Weasels, all closely allied in structure and habits. A structural division, however, occurs between the two first-named and all the others, especially shown in the presence of an additional small premolar tooth on each side of each jaw; and, availing himself of this and some other minor characters, Cuvier divided the genus into two subgenera, for the first of which he retained the name of *Mustela*, and to the second assigned that of *Putorius*. Three years later Nilsson (*Skand. Fauna*, 1820) definitely constituted the two groups into genera, applying to the first the name of *Martes*, by which the animals composing it had been generally designated by the Latin-writing zoologists of the preceding century, and keeping *Mustela* for the more typical Weasels and their immediate allies. Later zoologists have been divided between the nomenclature of Cuvier, which has the priority, and that of Nilsson, which on other grounds is preferable. Those who adopt the latter affirm that Cuvier's names, being only used by him in a subgeneric sense, and not binomially, need not be applied generically; but this is contrary to the practice usually followed in such cases. Others avoid the difficulty by not breaking up the genus at all, and so apply the term *Mustela* to all the species. The result is that the generic name of the Martens in modern zoological works oscillates between *Martes* and *Mustela*, according to the views of the writer.

The following characters apply to the restricted group of Martens proper, by whatever name they are called. Body long, slender, and very flexible, though less so than in the true Weasels. Head somewhat triangular; muzzle pointed, the nose extending a little beyond the lips; eyes large and prominent; ears conspicuous, broad, somewhat triangular, rounded at the ends, furred outside and in; limbs short; feet rounded; toes short, five on each foot, all with short, compressed, curved, sharp-pointed claws. Soles densely furred between the naked pads. Tail moderately long, more or less bushy. Outer fur long, strong, and glossy; a very abundant soft under fur.

Vertebræ: C 7, D 14, L 6, S 3, C 18–23. Skull elongated and depressed. Facial portion moderate and rather compressed. Zygomata arched and wide but slender. Postorbital processes small. Auditory bullæ large, but not very globose. Mandible with a strong triangular vertical coronoid process and a well-developed angular process.

Dentition: $i\,\frac{3}{3}$, $c\,\frac{1}{1}$, $p\,\frac{4}{4}$, $m\,\frac{1}{2}$; total 38. Upper incisors in a straight transverse line, rather long and compressed; first and second subequal, third considerably larger. Lower incisors very small, especially the first, and crowded together, the second placed rather behind the others. Canines long and sharp-pointed. Upper premolars: first very small, with simple crown and one root; second and third nearly equal in size and two-rooted, with simple compressed sharp-pointed crowns, with very slightly developed accessory cusps; fourth (the sectorial) with blade consisting chiefly of the central and posterior cusps, the anterior being rudimentary, inner tubercle small and confined to the anterior part of the tooth. True molar tubercular, about twice as wide transversely as in the antero-posterior direction, having an outer, more elevated, but smaller portion, bearing three blunt tubercles; to the inner side of this the crown is contracted, and its surface deeply hollowed; it then expands again into a broad low lobe, with the central part elevated, and a raised, even, semicircular, slightly crenated internal border. Lower premolars: first very small, simple, and one-rooted; second, third, and fourth increasing slightly in size, with high compressed pointed crowns and posterior accessory cusps, best marked in the third. First molar (sectorial) with well-marked bilobed blade,—heel scarcely more than one-third of the length of the tooth, and a very small inner tubercle. Second molar small, single-rooted, with a low, flattened, subcircular or oval tubercular crown.

In geographical distribution the Martens are limited to the northern hemisphere, ranging throughout the greater part of the northern temperate regions of both Old and New Worlds, as far north as conditions of existence suited to their habits are met with, and southwards in America to 35° N. lat., while in Asia one species is met with as far as the island of Java.

The various species appear to be very similar in their habits. They live in woods and rocky places, and are thoroughly arboreal, spending most of their time in trees, although descending to the ground in quest of prey. They climb with great facility, and are agile and graceful in their movements. Some species are said occasionally to resort to berries and other fruit for food, but as a rule they are strictly carnivorous, feeding chiefly on birds and their eggs, small mammals, as squirrels, hares, rabbits, and moles, but chiefly mice of various kinds, of which they destroy great numbers, and occasionally snakes, lizards, and frogs. In proportion to their size they are among the most bloodthirsty of animals, though less so than the true Weasels. The female usually makes her nest of moss, dried leaves, and grass in the hollow of a tree, but sometimes in a hole among rocks or ruined buildings, and produces several young at a birth, usually from four to six. Though wild and untameable to a great degree if captured when fully grown, when taken young they are very docile, and have frequently been made pets of, not having the strong unpleasant odour of the smaller *Mustelidæ*. The common European Marten appears to have been partially domesticated by the Greeks and Romans, and to have been used to keep houses clear from rats and mice before cats were introduced.[1] In the same way, according to Hodgson, an allied species, the Yellow-bellied Weasel (*Mustela kathiah*), "is exceedingly prized by the Nepalese for its service in ridding houses of rats. It is easily tamed; and such is the dread of it common to all murine animals that not one will approach a house where it is domiciled." It is, however, to the great value attached to the pelts of these animals that their importance to man is chiefly due. Though all yield fur of serviceable quality, the commercial value varies immensely, not only according to the particular species from which it is obtained, but according to individual variation, depending upon age, sex, season, and other trifling circumstances. The skins from northern regions are more full and of a finer colour and gloss than those from more temperate climates, as are those of animals killed in winter compared to the same individuals in the summer season. The caprices of fashion have, moreover, set wholly factitious values upon slight shades of colour, recognized and named by experienced furriers, but not indicating any specific or other distinctions

and Martial often introduced foreign words into his Latin. Its etymology has been connected with the German "martern," to torment. A second Romanic name for the same animal is *fuina*, in French *fouine* (see E. Von Marten's "Ueber Thiernamen," in *Der Zoologische Garten*, vol. xi., 1870). The term "Marten Cat," often used, is a misnomer, for though somewhat Cat-like in size, general appearance, and habits, its true affinities are not with the *Felidæ*, but, as stated above, with the Bears.

[1] See Rolleston, "On the Domestic Cats, *Felis domesticus* and *Mustela foina*, of Ancient and Modern Times," *Journal of Anatomy and Physiology*, vol. ii. p. 47, 1868.

of which zoologists have any cognizance. Enormous numbers of animals are annually caught, chiefly in traps, to supply the demand of the fur trade, Siberia and North America being the principal localities from which they are obtained.

With the exception of the Pekan (*M. pennanti*) all the Martens are so much alike in size, general colouring, and cranial and dental characters that the discrimination of the species, and assignment of the proper geographical distribution to each, has been a subject which has sorely perplexed the ingenuity and patience of zoologists. The following description by Dr Elliott Coues of the external characters of the American Pine Marten (*M. americana*) will apply almost equally well to most of the others. "It is almost impossible to describe the colour of the Pine Marten, except in general terms, without going into the details of the endless diversities occasioned by age, sex, season, or other incidents. The animal is 'brown,' of a shade from orange or tawny to quite blackish; the tail and feet are ordinarily the darkest, the head lightest, often quite whitish; the ears are usually rimmed with whitish; on the throat there is usually a large tawny-yellowish or orange-brown patch, from the chin to the fore legs, sometimes entire, sometimes broken into a number of smaller, irregular blotches, sometimes wanting, sometimes prolonged on the whole under surface, when the animal is bicolor like a Stoat in summer. The general 'brown' has a greyish cast, as far as the under fur is concerned, and is overlaid with rich lustrous blackish-brown in places where the long bristly hairs prevail. The claws are whitish; the naked nose pad and whiskers are black. The tail occasionally shows interspersed white hairs, or a white tip."

The species generally recognized as distinct are the following, the first five belonging to the Old and the last two to the New World.

1. *Mustela foina*, Erxleben; the Beech Marten, Stone Marten, or White-breasted Marten.—Distinguished from the following by the greater breadth of the skull, and some minute but constant dental characters, by the dull greyish-brown colour of the fur of the upper parts, and the pure white of the throat and breast. It inhabits the greater part of the Continent of Europe, but is more southern than the next in its distribution, not being found in Sweden or Norway, nor, according to the recent investigations of Mr Alston, in the British Isles, although included in their fauna by all earlier writers.

2. *M. martes*, Linn; *Martes sylvatica*, Nilsson; *M. abietum*, Fleming; the Pine Marten (see figure).—Outer fur rich dark brown; under fur reddish-grey, with clear yellow tips; breast spot usually yellow, varying from bright orange to pale cream-colour or yellowish-white. Length of head and body 16 to 18 inches; of tail (including the hair) 9 to 12 inches. This species is extensively distributed throughout northern Europe and Asia, and was formerly

European Pine Marten (*Mustela martes*). From life.

common in most parts of Great Britain and Ireland. Though commonly called "Pine Marten," it does not appear to have any special preference for coniferous trees, except that, inasmuch as they constitute the greater proportion of the forests of the countries which it inhabits, it is more often met with in them than in any other. With regard to its recent occurrence in the British Isles, Mr Alston writes in *Proc. of Zool. Society of London*, 1879:—

"Although greatly reduced in numbers by persecution, it still maintains its ground in the wilder districts of Scotland, the north of England, Wales, and Ireland; and occasionally specimens are killed in counties where the species was thought to have been long extinct. In Scotland it is still found, though comparatively rarely, in the Lews and in most of the Highland mainland counties, being perhaps most abundant in Sutherland and Ross-shire, especially in the deer forests. In the Lowlands a Marten is now a very great rarity; but a fine example was killed in Ayrshire in the winter of 1875–76. In the north of England Mr W. A. Durnford says the species is 'still plentiful' in the wilder parts of Cumberland, Westmoreland, and Lancashire, and in Lincolnshire several have been recorded, the latest killed in 1865, by Mr Cordeaux.[1] In Norfolk one was shot last year; and I have myself examined a fine example which was shot in Hertfordshire, within 20 miles of London, in December 1872. In Dorsetshire the last is said to have been killed in 1804; but a specimen occurred in Hampshire about forty years ago, and another in Surrey in 1847. In Ireland the following counties were enumerated by Thompson as habitats of this species: Donegal, Londonderry, Antrim, Down, Armagh, Fermanagh, Longford, Galway, Tipperary, Cork, and Kerry. The *Cat-crann* is probably now a rarer animal in Ireland than it was when Thompson wrote; but it still exists in various districts, especially in County Kerry, whence the society has received several living examples; and Professor A. Leith Adams states that it has been seen of late years even in county Dublin."

3. *M. zibellina*, Linnæus; the Sable (German, *Zobel* and *Zebel*; Swedish, *sabel*; Russian, *sobel*, a word probably of Turanian origin).—Closely resembling the last, if indeed differing from it except in the quality of the fur, which is the most highly valued of that of all the group. Found chiefly in eastern Siberia.

4. *M. flavigula*, Boddaert; the Indian Marten.—Inhabits the southern slopes of the Himalayas, the Nilgiri Hills, the interior of Ceylon, the Malay Peninsula, and Java.

5. *M. melampus*, Wagner.—Japan.

6. *M. americana*, Turton; the North-American Sable or Marten.—A species so closely allied to the European Pine Marten and Asiatic Sable that it is very difficult to assign constant distinguishing characters between them. The importance of the fur of this animal as an article of commerce may be judged of from the fact that 15,000 skins were sold in one year by the Hudson's Bay Company as long ago as 1743, and the more recent annual imports into Great Britain have exceeded 100,000. It is ordinarily caught in wooden traps of very simple construction, being little enclosures of stakes or brush in which the bait is placed upon a trigger, with a short upright stick supporting a log of wood, which falls upon its victim on the slightest disturbance. A line of such traps, several to a mile, often extends many miles. The bait is any kind of meat, a mouse, squirrel, piece of fish, or bird's head. It is principally trapped during the colder months, from October to April, when the fur is in good condition, as it is nearly valueless during the shedding in summer. Dr Coues tells us that, notwithstanding the persistent and uninterrupted destruction to which the American Sable is subjected, it does not appear to diminish materially in numbers in unsettled parts of the country. It holds its own partly in consequence of its shyness, which keeps it away from the abodes of men, and partly because it is so prolific, bringing forth six to eight young at a litter. Its home is sometimes a den under ground or beneath rocks, but oftener the hollow of a tree, and it is said frequently to take forcible possession of a squirrel's nest, driving off or devouring the rightful proprietor.

7. *M. pennanti*, Erxleben; the Pekan or Pennant's Marten, also called Fisher Marten, though there appears to be nothing in its habits to justify the appellation. This is the largest species of the group, the head and body measuring from 24 to 30 inches, and the tail 14 to 18 inches. It is also more robust in form than the others, its general aspect being more that of a Fox than a Weasel; in fact its usual name among the American hunters is "Black Fox." Its general colour is blackish, lighter by mixture of brown or grey on the head and upper fore part of the body, with no light patch on the throat, and unlike the other Martens generally darker below than above. It was generally distributed in wooded districts throughout the greater part of North America, as far north as Great Slave Lake, lat. 63° N., and Alaska, and extending south to the parallel of 35°; but at the present time it is almost exterminated in the settled parts of the United States east of the Mississippi.

See Elliott Coues, *Fur-bearing Animals, a Monograph of North American Mustelidæ*, 1877; E. R. Alston, "On the British Martens," *Proceedings of the Zoological Society of London*, 1879, p. 468. (W. H. F.)

MARTIAL (M. VALERIUS MARTIALIS) is a writer to whose merits it is difficult to do justice in the present day. His faults are of the most glaring kind; they are exhibited without the least concealment; and they are of the sort of which modern feeling is most intolerant. Living as he did under perhaps the worst of the many bad emperors who ruled the world in the 1st century, he addresses him and his favourites with the most servile flattery in his lifetime, reviles him immediately after his death (xii. 6), and offers equally fulsome incense at the shrine of his successor. No writer of equal genius has ever shown such an absence of dignity and independence of character in his relation to his richer friends and patrons. He is not ashamed

[1] The *Zoologist* for June 1882 records the recent capture of a Marten in a trap near Bardney in Lincolnshire.

to be dependent on them for gifts of money, for his dinner, and even for his dress. We cannot feel sure that even what seem his sincerest tributes of regard may not be prompted by the hope of payment. Further, there is no book in any literature which, both in expression and in the things treated of, sins so flagrantly against all instincts of propriety. A certain proportion of the epigrams in every book—perhaps one-fifth or one-sixth (in some books the proportion is much larger)—can be read by no class of readers with any other feelings than those of extreme distaste.

These faults are so unmistakable and undeniable that many readers of ancient literature have formed their whole estimate of Martial from them, and have declined to make any further acquaintance with him. Even those who greatly admire his genius, who find the freshest interest in his representation of Roman life and his sketches of manners and character, and who, after admitting the unfavourable first impression which he is bound to make, believe that they still can discern sufficient indications of the better nature which made him a popular and likeable man in his day, do not attempt to palliate his faults, though they may partially account for them by reference to the morals of his age and the circumstances of his life. The time when "the last of the Flavian line was tearing in pieces the half-lifeless world, and Rome was a bondslave to a bald Nero,"[1] was one when literature had either to be silent or to be servile. Martial was essentially a man of letters; there was no other métier for which he was fitted; he was bound either to gain favour by his writings or to starve. Tacitus and Juvenal might have chosen the latter alternative, but they were fortunately spared the necessity of making the choice by the possession of independent means. Even Statius, the contemporary of Martial, whose writings are in other respects irreproachable, is nearly as fulsome in his adulation as Martial. The relation of client to patron had been recognized as an honourable one by the best Roman traditions. No blame had attached to Virgil or Horace on account of the favours which they received from Augustus and Mæcenas, or of the return which they made for these favours in their verse. That old honourable relationship had, however, greatly changed its character between the era of Augustus and that of Domitian. Men of good birth and education, and sometimes even of high official position (Juv., i. 117), were not ashamed to gain or increase their living by the acceptance of money doles to provide their daily meal. "Atria magna colam" is the resource of a man who was too lazy or too incompetent to become an advocate, and who thought himself too much of a gentleman to adopt any mechanical trade. Martial was merely following a general fashion in paying his court to "a lord." "Rex" is the common term used for a patron. He made the best of the custom. In his earlier career he used to accompany his patrons to their villas at Baiæ or Tibur, and to attend their morning levées. Later on he went to his own small country house, near Nomentum, and sent a poem, or a small volume of his poems, as his representative, at the early visit. If his patron was courteous and liberal, he became his friend and entertained him with his wit and social vivacity. If he was mean and exacting, he found in him a subject for his epigrams. The fault of grossness Martial shares with nearly all ancient and many modern writers who treat of life from the baser or more ridiculous side. That he offends worse than perhaps any of them is to be explained, not, apparently, on the ground that he was more of a libertine in his life, but on the ground that he had to amuse a public which had become more corrupt than in any other civilized era. Although there is the most cynical effrontery and want of self-respect in Martial's use of language, there is not much trace of the satyr in him,—much less, many readers will think, than in Juvenal. Neither is it at all true, as is said by historians of Roman literature (W. S. Teuffel, vol. ii. 317, 5), that his epigrams mostly deal with this side of life. At least four-fifths of them are unexceptionable in subject and treatment.

Our knowledge of Martial's life is derived almost entirely from himself. His writings do not, like those of Horace, supply materials for a continuous biography, nor do they lay bare every secret of his heart with the self-absorption of Catullus. But, as he writes frankly about everything that interested him, he has not only painted a very life-like picture, or rather drawn a multitude of very life-like sketches of Roman society in his time, but he has clearly marked his own position in and his own relation to that society. His criticism of men and manners enables us to judge of the standard which he applied to life, of the things which he liked and disliked, and of his own temper and disposition. Reference to public events enables us approximately to fix the date of the publication of the different books of epigrams, and from these dates to determine those of various important events in his life. Thus, as in book x., which was published in 97 or perhaps 98 A.D., he is found celebrating his fifty-seventh birthday (x. 24), the date of his birth may be assigned to the year 40 or 41. The place of his birth was Bilbilis, or Augusta Bilbilis, in Spain, in a "barren and rugged country" near the sources of the Tagus. His name seems to imply that he was born with the rights of Roman citizenship, but he speaks of himself as "sprung from the Celts and Iberians, and a countryman of the Tagus"; and, in contrasting his own masculine appearance with that of an effeminate Greek, he draws especial attention to "his stiff Spanish hair"—

"Hispanis ego contumax capillis" (x. 65).

In an epigram written nearly thirty years after his removal to Rome he piously commends the soul of a little child, Erotion, to whom he was much attached, to his parents Fronto and Flaccilla, who had gone before to the world of shades (v. 34). Their position in life seems to be indicated by such references to his former home as the phrase "saturæ sordida rura casæ" (x. 96). His home was evidently one of rude comfort and plenty, sufficiently in the country to afford him the amusements of hunting and fishing, which he often recalls with a keen sense of pleasure, and sufficiently near the town to afford him the companionship of many comrades, the few survivors of whom he looks forward to meet again after his five and thirty years absence (x. 104). The memories of this old home, of Bilbilis on its mountain site, of the shallow, rapid Salo flowing round the base of the hill ("flectu tenui sed inquieto"), of "Gaius hoary with snow and sacred Vadavero with its broken cliffs," of the ilex-grove of Burado (iv. 55) "which even the laziest traveller walks through," and of other spots the rough names and local associations of which he delights to introduce into his verse, attest the enjoyment which he had in his early life, and were among the influences which kept his spirit thoroughly alive in the midst of the deadening routine of social life in Rome. But his Spanish home could impart, not only the vigorous vitality which was one condition of his success as a wit and poet, but the education which made him so accomplished a writer. The literary distinction obtained by the Senecas, by Lucan, by Quintilian, who belonged to a somewhat older generation, and by his friends and contemporaries Licinianus of Bilbilis, Decianus of Emerita, and

[1] Cum iam semianimum laceraret Flavius orbem
Ultimus, et calvo serviret Roma Neroni.—Juv., iv. 37.

Canius of Gades, proves how eagerly the novel impulse of letters was received in Spain in the first century of the empire, just as a similar impulse had been received in Cisalpine Gaul in the first half of the first century before our era. The success of his countrymen may have been the motive which induced Martial's parents to prepare him for a literary career,—

"At me litterulas stulti docuere parentes" (ix. 73, 7),

and which induced Martial himself to remove to Rome when he had completed his education. This he must have done some time before the fall, in 65 A.D., of Seneca and Lucan, who were probably his earliest patrons. He speaks of the halls of the Pisos and of Seneca as having been opened to him when he first went to Rome (iv. 40); and in epigrams, addressed to his widow nearly thirty years after the death of Lucan, he speaks of him with grateful admiration, and applies to her the word "Regina," "his lady patroness."

Of the details of his life for the first twenty years or so after he came to Rome we do not know much. He published some juvenile poems of which he thought very little in his maturer years, and he laughs at a foolish bookseller who would not allow them to die a natural death (i. 113). Martial had neither youthful passion nor youthful enthusiasm to make him precociously a poet. His faculty ripened with experience and with the knowledge of that social life which was both his theme and his inspiration; and many of his best epigrams are among those written in his last years. From many answers which he makes to the remonstrances of friends,—among others to those of Quintilian,—it may be inferred that he was urged to practise at the bar, but that he preferred his own lazy Bohemian kind of life to more settled and remunerative modes of industry. He made many influential friends and patrons, and secured the favour both of Titus and Domitian. From them he obtained various privileges, among others the "semestris tribunatus," which conferred on him equestrian rank. He failed, however, in his application to the latter for more substantial advantages, although he commemorates the glory of having been invited to dinner by him, and also the fact that he procured the privilege of citizenship for many persons in whose behalf he appealed to him. The earliest of his extant works, that known by the name of *Liber Spectaculorum*, was first published at the opening of the Colosseum in the reign of Titus; but the book as it now stands was given to the world in or about the first year of Domitian, *i.e.*, about 81 A.D. The favour of the emperor procured him the countenance of some of the worst creatures at the imperial court,—among them of the notorious Crispinus, of Parthenius, Earinus, Regulus, and probably of Paris, the supposed author of Juvenal's exile, on whose death Martial afterwards wrote a eulogistic epitaph. The two books numbered xiii. and xiv., and known by the name of *Xenia* and *Apophoreta*,—inscriptions of two lines for presents,—were published between 81 and 86 A.D. In that last year he gave to the world the first two of the twelve books on which his reputation rests. From that time till his return to Spain in 98 A.D. he published a volume almost every year. The first nine books and the first edition of book x. appeared in the reign of Domitian; and book xi. at the end of 96 A.D., shortly after the accession of Nerva. A revised edition of book x., that which we now possess, appeared in 98 A.D., about the time of the entrance of Trajan into Rome. The last book was written after three years' absence in Spain, shortly before his death, which happened about the year 102 or 103 A.D.

These twelve books bring Martial's ordinary mode of life between the age of five-and-forty and sixty very fully before us. His regular home for five-and-thirty years was Rome. He lived at first up three pair of stairs ("et scalis habito tribus sed altis," i. 117), and his rooms overlooked the laurels in front of the portico of Agrippa. He had a small and not very valuable country house near Nomentum, in the Sabine territory, to which he occasionally retired as a refuge from the bores and noises of the city (ii. 38, xii. 57). In his later years he had a small house on the Quirinal, near the temple of Quirinus. At the time when his third book was brought out he had retired for a short time to Cisalpine Gaul, in weariness, as he tells us, of his unremunerative attendance on the levées of the great—

"Non poterat vanæ tædia ferre togæ" (iii. 4).

For a time he seems to have felt the charm of the new scenes which he visited, and in a later book (iv. 25) he contemplates, probably with a reminiscence of Horace (*Od.* ii. 6), the prospect of retiring to the neighbourhood of Aquileia and the Timavus in his old age. But the spell exercised over him by Rome and Roman society was too great to permit of a prolonged absence; and even the epigrams sent from Forum Corneli and the Æmilian Way ring much more of the Roman Forum, and of the streets, baths, porticos, and clubs of Rome, than of the places from which they are dated. So too his motive for his final departure from Rome in 98 A.D. was a weariness of the burdens imposed on him by his social position, and, apparently, the difficulties of meeting the ordinary expenses of living in the metropolis (x. 96); and he looks forward, with a kind of "nostalgia," to a return to the scenes familiar to his youth. The well-known epigram addressed to Juvenal (xii. 18) shows that for a time his ideal was realized; but the more trustworthy evidence of the prose epistle prefixed to book xii. proves that his contentment was of very short duration, and that he could not live happily away from the literary and social pleasures of Rome ("bibliothecas, theatra, convictus"), which supplied both the impulse to his genius and the material on which it could exercise itself. The one consolation of his exile was the society of a lady, Marcella, of whom he writes rather as if she were his patroness,—and it seems to have been a necessity of his being to have always a patron or patroness,—than his wife or mistress. His delight in her society arose from his finding in her one who, though born and bred in this remote province, yet by her natural grace and accomplishment revived for him the charm of Rome.

During his life there, although he never rose to a position of real independence, and had always a hard struggle with poverty, he seems to have known everybody, especially every one of any eminence at the bar or in literature. In addition to Lucan and Quintilian, he numbered among his friends or more intimate acquaintances Silius Italicus, Juvenal, the younger Pliny; and we find a number of other names, such as those of Julius Martialis, Faustinus, Bassus, Decianus, Melior, Stella, &c., of men holding a high social, legal, or literary position, whose society and patronage he enjoyed. The silence which he and Statius, although authors writing at the same time, having common friends, and treating sometimes of the same subjects, maintain in regard to one another may be explained by mutual dislike or want of sympathy. Martial, in many places, shows an undisguised contempt for the artificial kind of epic on which Statius's reputation chiefly rests; and it seems quite natural that the respectable author of the *Thebaid* and the *Silvæ* should feel little admiration for either the life or the works of the Bohemian epigrammatist.

The personal faults of Martial, which deny to his writings, notwithstanding their vivacity, truth, and brilliancy, a place among the best poetry of antiquity, have been sufficiently indicated. It remains to ask, What were those qualities of nature and intellect which enable us to read his best work—even the great body of his work—with the freshest sense of pleasure in the present day?

He had the keenest capacity for enjoyment, the keenest curiosity and power of observation. The ordinary spectacle of Roman life, as it passed before his eyes, was thus vividly apprehended and reproduced by him in all its details; and the many varieties of character which an over-ripe and decaying civilization produces were quickly seized and graphically sketched. He had also a very just discernment. It is rare to find any one endowed with so quick a perception of the ridiculous who is so little of a caricaturist. He was himself singularly free from cant, pedantry, or affectation of any kind. Though tolerant of most vices, he has a hearty scorn of hypocrisy,—of the combination of outward austerity with secret profligacy,—of the man who, while he wears

"Fuscos colores, galbinos habet mores."[1]

There are few better satirists of social and literary pretenders either in ancient or modern times. Living in a very artificial age, he was quite natural, hating pomp and show, and desiring to secure in life only what really gave him pleasure. To live one's own life heartily from day to day without looking before or after, and to be one's self without trying to be that for which nature did not intend him, is the sum of his philosophy. It is the philosophy of a man who has passed the middle of life, who has outlived any illusions he may ever have had, and who is quite content that whatever remains to him in the future should be like his present. Further, while tolerant of much that is bad and base,—the characters of Crispinus and Regulus, for instance,—he shows himself genuinely grateful for kindness and appreciative of excellence. He has no bitterness, malice, or envy in his composition. He professes to avoid personalities in his satire;—"Ludimus innocui" is the character he claims for it. Pliny, in ths short tribute which he pays to him on hearing of his death, says, "He had as much candour as wit and pungency in his writings" (*Ep.* iii. 21).

Honour and sincerity (*fides* and *simplicitas*) are the qualities which he most admires in his friends. Though many of his epigrams indicate a cynical disbelief in the character of women, yet others prove that he could respect and almost reverence a refined and courteous lady. His own life in Rome afforded him no experience of domestic virtue; but his epigrams show that, even in the age which is known to modern readers chiefly from the *Satires* of Juvenal, that virtue was recognized as the purest source of happiness. The tenderest element in Martial's nature seems, however, to have been his affection for children and for his dependants. The pathos with which he has recorded their premature death, combined with his fresh enjoyment of outward nature, give to many of his pieces a rank among the serious poetry of the world—"inter sanctiora carmina,"—to use a phrase of his own.

The permanent literary interest of Martial's epigrams arises not so much from their verbal point or brilliancy, though in these respects they are unsurpassed, as from the amount of human life and character which they contain. There is no truer painter of social manners in antiquity. He enables us better than any other writer to revive the outward spectacle of the imperial Rome which we see in its ruins, and to repeople its streets, shops, porticos, baths, and amphitheatres. If Juvenal enforces the lesson of that time, and has penetrated more deeply into the heart of society, Martial has sketched its external aspect with a much fairer pencil and from a much more intimate contact with it. It is from the immediate impressions and comments of the epigrammatist that the satirist has taken the suggestion of many of his more elaborate pictures and more stern denunciations. But it is not only the peculiarities of Roman customs that live in the writings of Martial. His page, to use his own phrase, "has the true relish of human life" in every age—"hominem pagina nostra sapit." He was to Rome in the decay of its ancient virtue and patriotism what Menander was to Athens in its decline. They were both men of cosmopolitan rather than of a national type, and had a closer affinity to the life of Paris or London in the 18th century than to that of Rome in the days of the Scipios or of Athens in the age of Pericles. The form of epigram was fitted to the critical temper of Rome as the comedy of manners was fitted to the dramatic genius of Greece. Martial professes to be of the school of Catullus, Pedo, and Marsus, and admits his inferiority only to the first. But, though he is a poet of a less pure and genuine inspiration, he is a greater epigrammatist even than his master. He has indeed made that form of art peculiarly his own. He has applied it to the representation of a very much greater number of situations, incidents, and characters, and he has done this with the greatest clearness, terseness, and vivacity of style, and with a masterly command over all his metres, except the pure hexameter, in which no other writer has been able to treat the familiar matters of the day with the light touch of Horace. Martial, except where he is flattering the emperor,—and then we may sometimes suspect an undercurrent of irony,—is one of the most natural and sensible as he is one of the wittiest and most brilliant of writers. He fails, perhaps, more often in his wit than in his sense. He is full of the happiest phrases, which express admirably for all times, without over-subtlety and without triteness, the judgment and impressions of life formed by direct contact with it, and taken neither from books nor from the opinions of other men, of a thorough man of the world, who had yet some feelings and sensibilities to which men of the world are generally strangers. He wrote naturally because he was completely in harmony with the life of his age. As this is the explanation of his grave offences, it should also be recognized as contributing to his merits as a writer.

Owing probably to the reasons which have excluded his writings from school education, little has been done for the criticism or explanation of Martial for about two centuries. There is a good edition of the text by Schneidewin in the Teubner series of classics. For English readers the *Selected Epigrams of Martial*, by H. H. Stephenson, and the *Martialis Epigrammata Selecta*, by Messrs Paley and Stone, may be recommended as a good introduction to the study of this poet. An edition of book i., with a Latin commentary by J. Flach, has lately appeared at Tübingen. Further information about him may be obtained in a work by A. Brandt, *De Martialis poetæ vita et scriptis* (Berlin, 1853), and in Friedländer's *Sittengeschichte Roms*; and an excellent criticism on his writings is to be found among the prose works of Lessing. (W. Y. S.)

MARTIAL LAW. See Military Law.

MARTIGUES, chief place of a canton in the department of Bouches-du-Rhône, France, stands on the southern shore of the lagoon of Berre, and at the eastern extremity of that of Caronte, by which the former is connected with the Mediterranean. Divided into three quarters by canals with numerous bridges, the place has sometimes been called the Venice of Provence. It has a harbour of 10 acres, an iron foundry, workshops for maritime constructions, oil manufactures, and chemical works; the principal industry, however, consists in the preparation of "boutargue," which is obtained from the roes of the grey mullet caught in the lagoons, and rivals Russian caviare. The population in 1876 was 8053.

[1] "Whose dress is of a dull colour, his morals a pale green."

Built in 1232 by Raymond Bérenger, count of Provence, Martigues was made a viscountship by Joanna I., queen of Naples. Henry IV. made it a principality, in favour of a princess of the house of Luxembourg. It afterwards passed into the hands of the duke of Villars.

MARTIN[1] (French, *Martinet*), the *Hirundo urbica* of Linnæus and *Chelidon urbica* of modern ornithologists, a bird very well known throughout Europe, including even Lapland, where it is abundant, retiring in winter to the south of Africa.[2] It also inhabits the western part of Asia, and appears from time to time in large flocks in India; but the boundaries of its range and those of at least one of its Eastern congeners cannot as yet be laid down. The Martin (or House-Martin, as it is often called, to distinguish it from the Sand-Martin presently to be mentioned) commonly reaches its summer-quarters a few days later than the SWALLOW (*q.v.*), whose habits its own so much resemble that heedless persons often disregard the very perceptible differences between them, the Martin's white rump and lower parts being conspicuous as it flies or clings to its "loved mansionry" attached to our houses, for, as Shakespeare wrote—

> "No jutty, frieze,
> Buttress, nor coign of vantage, but this bird
> Hath made his pendent bed and procreant cradle."
> —*Macbeth*, act i. sc. 6.

This nest, made of the same material as the Swallow's, is, however, a far more difficult structure to rear, and a week or more is often occupied in laying its foundations—the builders clinging to the wall while depositing the mud of which it is composed. But, the base once securely fixed, the superstructure is often quickly added till the whole takes the shape of the half or quarter of a hemisphere, and a lining of soft feathers, mixed with a few bents or straws, fits it for its purpose. The Martin sets about building very soon after its return, and a nest that has outlasted the winter's storms is almost at once reoccupied; though if a new nest be needed its construction often involves great delay, for any excess of wet or drought retards the operation, and the work is generally placed in such an exposed situation that heavy driving rains will frequently wash away the half-dried walls. However, the bird mostly perseveres against these and other untowardnesses, contriving in the course of the summer to raise a second or, rarely, a third brood of offspring—though it is certain that the latest broods often die in the nest—apparently through failure of food. Yet what seem to be adults of this species are observed in England every year so late as November, and there are several instances of its appearance within a few days of the winter solstice; but it is to be remarked that these late birds are almost certainly strangers, and not natives of the locality in which they are seen.

The Sand-Martin, *Hirundo riparia* of Linnæus and *Cotile riparia* of modern writers, differs much in appearance and habits from the former. Its smaller size, mouse-coloured upper surface, and jerking flight ought to render it easily recognizable from the other British *Hirundinidæ*; but through carelessness it is seldom discriminated, and, being the first of the Family to return to its northern home, the "early Swallow" of newspaper-writers would seem to be nearly always of this species. Instead of the clay-built nest of the House-Martin, this bird bores, with a degree of regularity and an amount of labour rarely excelled in its Class, horizontal galleries in a natural or artificial escarpment. When beginning its excavation, it clings to the face of the bank, and with its bill loosens the earth, working from the centre outwards, assuming all sorts of positions—as often as not hanging head downwards. The form of the boring and its length depend much on the nature of the soil; but the tunnel may extend to 4, 6, or even 9 feet. The gallery seems intended to be straight, but inequalities of the ground, and especially the meeting with stones, often cause it to take a sinuous course. At the end is formed a convenient chamber lined with a few grass stalks and feathers, the latter always beautifully arranged, and upon them the eggs are laid. The Sand-Martin has several broods in the year, and is much more regular than other *Hirundinidæ* in its departure for the south. The kind of soil needed for its nesting-habits makes it a somewhat local bird; but no species of the Order *Passeres* has a geographical range that can compare with this. In Europe it is found nearly to the North Cape, and thence to the Sea of Okhotsk. In winter it visits many parts of India, and South Africa to the Transvaal territory. In America its range is even more extraordinary, extending (due regard being of course had to the season of the year) from Melville Island to Caiçara in Brazil, and from Newfoundland to Alaska.

The Purple Martin of America,[3] *Hirundo* or *Progne purpurea*, requires some remarks as being such a favourite bird in Canada and in the United States. Naturally breeding in hollow trees, it readily adapts itself to the nest-boxes which are very commonly set up for its accommodation; but its numbers are in some years and places subject to diminution in a manner which has not yet been satisfactorily explained. The limits of its range in winter are not determined, chiefly owing to the differences of opinion as to the validity of certain supposed kindred species found in South America; but according to some authorities it reaches the border of Patagonia, while in summer it is known to inhabit lands within the Arctic Circle. The male is almost wholly of a glossy steel-blue, while the female is much duller in colour above, and beneath of a brownish-grey.

Birds that may be called Martins[4] occur almost all over the world except in New Zealand, which is not regularly inhabited by any member of the Family. The ordinary Martin of Australia is the *Hirundo* or *Hylochelidon nigricans* of most ornithologists, and another and more beautiful form is the Ariel or Fairy-Martin of the same country, *Hirundo* or *Lagenoplastes ariel*. This last builds of mud a bottle-shaped nest, as does also the Rock-Martin of Europe, *Hirundo* or *Biblis rupestris*; but space fails wherein to tell more of these interesting birds. (A. N.)

MARTIN, ST, bishop of Tours, was born of heathen parents at Sabaria (*Stein am Anger*) in Pannonia, about the year 316. When ten years of age he became a catechumen, and at fifteen, contrary to his own inclination, he entered the army. It was while he was stationed at Amiens that he divided his cloak with the beggar, and on the following night had the vision of Christ making known to his angels this act of charity to Himself on the part of "Martinus, still a catechumen." Soon afterwards he received baptism, and, two years later, having been permitted to leave the army, he joined Hilary of Poitiers, who wished to make him a deacon, but at his own request ordained him to the humbler office of an exorcist. In the course of the years that followed he undertook a journey to Pannonia for the purpose of converting his parents, and was successful in bringing his mother within the pale of

[1] The older English form, Martlet (French, *Martelet*), is, except in heralds' language, almost obsolete, and when used is now applied in some places to the SWIFT (*q.v.*).

[2] Since the publication of the account of this species in Yarrell's *British Birds* (ed. 4, ii. p. 354), Mr Gurney has informed the writer of a specimen obtained out of a migratory flock flying very high on the Qua'qua' river, lat. 19° 10′ S., by the expedition of Messrs Jameson and Ayres, 23d October 1880.

[3] In 1840 an example is said to have been killed at Kingstown in Ireland, the skin of which is in the Dublin Museum of Science and Art.

[4] The *Martin* of French colonists (in the Old World) is an *Acridotheres*, one of the STARLINGS (*q.v.*).

the church. For some time, doubtless during the Arian troubles, he lived, along with a presbyter friend, an ascetic life on the desert island of Gallinaria near Genoa; in 360 he was again with Hilary at Poitiers, and founded in the neighbourhood the monasterium Locociagense (Licugé). Here his miracles, which included more than one case of restoring the dead to life, were very numerous, and made him so famous that in 371 the people of Tours insisted on having him for their bishop. In this capacity he was extremely zealous and energetic in seeking to extirpate idolatry from his diocese and from France, and by example as well as by precept he did much for the spread of the monastic system. To obtain the privacy that he required for the maintenance of his personal religion, he established the monastery of Marmoutier-les-Tours (Martini monasterium) on the banks of the Loire. At Treves, in 385, he was importunate in his entreaties that the lives of the Priscillianist heretics should be given them, and he ever afterwards refused to hold ecclesiastical fellowship with those bishops who had sanctioned their execution. He died at Candes about the year 400, and is commemorated by the Roman Church on November 11 (duplex). He is the patron saint of France, and of the cities of Mainz and Würzburg. The *Life* by his disciple Sulpicius Severus is practically the only source we have for his biography, but it is full of legendary matter and chronological inaccuracies. The feast of St Martin (Martinmas) took the place of an old pagan festival, and inherited some of its usages (such as the Martinsmännchen, Martinsfeuer, Martinshorn, and the like, in various parts of Germany); by this circumstance is most probably to be explained the fact that he is regarded as the patron of drinking and jovial meetings, as well as of reformed drunkards.

MARTIN I., pope, succeeded Theodore I., in June or July 649. He had previously acted as papal apocrisiarius at Constantinople, and was held in high repute for learning and virtue. Almost his first official act was to summon a synod (the first Lateran) for dealing with the Monothelite heresy. It met in the Lateran church, was attended by one hundred and five bishops (chiefly from Italy, Sicily, and Sardinia, a few being from Africa and other quarters), held five sessions or "secretarii" from the 5th to the 31st of October 649, and in twenty canons condemned the Monothelite heresy, its authors, and the writings by which it had been promulgated. In this condemnation were included, not only the "Ecthesis" or exposition of faith of the patriarch Sergius for which the emperor Heraclius had stood sponsor, but also the "Typus" of Paul, the successor of Sergius, which had the support of the reigning emperor (Constans II.). Martin was very energetic in publishing the decrees of his Lateran synod in an encyclical, and Constans replied by enjoining his exarch to seize the pope, should he persist in this line of conduct, and send him prisoner to Constantinople. These orders were found impossible of execution for a considerable space of time, but at last Martin was arrested in the Lateran (June 15, 653), hurried out of Rome, and conveyed first to Naxos and subsequently to Constantinople (September 17, 654). After suffering an exhausting imprisonment and many public indignities, he was ultimately banished to Cherson, where he arrived on March 26, 655, and died on the 16th of September following. His successor was Eugenius I. A full account of the events of his pontificate will be found in Hefele's *Conciliengeschichte*, vol. iii., 1877.

MARTIN II. See Marinus I.

MARTIN III. See Marinus II.

MARTIN IV., pope from 1281 to 1285, was the successor of Nicholas III. He was a native of Touraine, born about 1210, and his proper name was Simon de Brion. After holding various offices at Rouen and Tours, he was made chancellor of France by Louis IX. in 1260, and cardinal by Urban IV. in 1261. He acted as legate for this pope and also for his successor Clement IV. in the negotiations for the assumption of the crown of Sicily by Charles of Anjou, and he is supposed also to have stimulated the ambition of Philip III. for the imperial dignity in 1273. After the death of Nicholas III. (August 1280) Charles of Anjou was able to secure the election of Cardinal Simon by the conclave at Viterbo (February 22, 1281). The Romans declined to receive him within their walls, and he was crowned at Orvieto. At the instance of Charles, whose tool he had become, he in November 1281 excommunicated the emperor Michael Palæologus, who stood in the way of the French projects against Greece, —an act by which the union of the Eastern and Western churches was rendered impossible. For three years after the Sicilian Vespers in 1282 all the spiritual and material resources at his command were in vain employed on behalf of his patron against Peter of Aragon. He died at Perugia on March 25, 1285, and was succeeded by Honorius IV.

MARTIN V. (Otto di Colonna), pope from 1417 to 1431, was elected on St Martin's day at Constance by a conclave consisting of twenty-three cardinals and thirty delegates of the council, which after deposing John XXIII. had long experienced much perplexity from the conflicting claims of Gregory XII. and Benedict XIII. The son of Agapito Colonna and Catarina Conti, born about 1368, he belonged to one of the oldest and most distinguished families of Rome, became apostolic protonotary under Urban VI., was created cardinal-deacon by Innocent VII., and in 1410 was the delegate of Alexander V. to hear the appeal which had been taken in that year to the papal see by John Huss. He was justly esteemed for his moderation, learning, uprightness, and business capacity, but he failed to achieve, as he might have done, the honour of being a reforming pope. His first act after his election was to publish a brief confirming all the regulations made by his predecessors with regard to the papal chancery,—regulations which had long been the subject of just complaint. When the "nations" of the council pressed their plans for reform, Martin submitted a counter scheme, and ultimately entered into negotiations for separate concordats, for the most part vague and illusory, with Germany, England, and France. He left Constance at the close of the council (May 1418), but travelled slowly through Italy, lingered at Florence, and did not venture to enter Rome until September 1420, when his first task was to seek to restore it to the prosperity and order to which it had become a stranger. In accordance with the decree of Constance, confirmed by himself, ordering that councils should be held every five years, he in 1423 summoned the council which met at Pavia and afterwards at Siena; it was somewhat poorly attended, and this circumstance gave the pope a pretext for dissolving it as soon as it had come to the resolution that "internal church union by reform ought to take precedence of external union." It was prorogued for seven years, and then met at Basel; shortly after its opening Martin died of apoplexy, on February 20, 1431. His successor was Eugenius IV.

MARTIN, John (1789-1854), a popular English painter, was born at Haydon Bridge, near Hexham, on the 19th of July 1789. On account of his early interest in art he was apprenticed by his father to a coachbuilder to learn heraldic painting, but owing to a quarrel the indentures were cancelled, and he was placed under Bonifacio Musso, an Italian artist, father of the well-known enamel painter Charles Musso. With his master Martin removed to London in 1806, where he married at the age of nineteen, and led a struggling life, supporting himself by giving drawing lessons, and by painting in water colours, and on china and glass. His leisure was occupied in the study of perspective and architecture. His first picture, Sadak in Search of the Waters of Oblivion, was executed in a month. It was exhibited in the Royal Academy of 1812, and sold for fifty guineas. It was followed by the Expulsion (1813), Paradise (1813), Clytie (1814), and Joshua (1815). In 1821 appeared the famous Belshazzar's Feast, which excited much favourable and hostile comment, and was awarded a prize of £200 at the British Institution, where the Joshua had previously carried off a premium of £100. Then came the Destruction of Herculaneum (1822), the Creation (1824), the Eve of the Deluge (1841), and a long series of other Biblical and imaginative subjects, many of which are widely known through engravings. In 1832–33 Martin received £2000 for drawing and engraving a fine series of designs to Milton, and along with Westall he produced a set of Bible illustrations. He was also much occupied with schemes for the improvement of London, and published various pamphlets and plans dealing with the metropolitan water supply, sewage, dock, and railway systems. During the last four years of his life he was engaged upon his large subjects of the Judgment, the Day of Wrath, and the Plains of Heaven. He was attacked with paralysis while painting, and died in the Isle of Man on the 17th of February 1854.

The bold originality of Martin's productions startled and attracted the public, but they are without the qualities of solid execution and truth to nature upon which a lasting fame in the arts must be built. His figures are badly drawn, his colouring is hot and unpleasant. To most of his professional brethren his works seemed theatrical and tricky; and the best lay critics of his time, like Charles Lamb, were disposed to deny that they evinced true imaginative power. His popularity may be said to have culminated in 1828, the year of his Fall of Nineveh; since then it has been gradually declining.

MARTINA FRANCA, a city of Italy in the province of Lecce, 18 miles north of Taranto, on a hill near the sources of the Tara. It was a fief of the Caraccioli family, and dates from a comparatively modern epoch. The ducal palace is one of the finest buildings of its kind in the south of Italy, somewhat similar in style of architecture to the Palazzo Pamfili in Naples. The population of the city was 13,088 in 1861; that of the commune has increased from 16,637 in that year to 19,257 in 1881.

MARTINEAU, Harriet (1802–1876), English woman of letters, was born at Norwich, where her father was a manufacturer. The family was of Huguenot extraction, but had adopted Unitarian views. Her education, which included Latin and French, as well as domestic accomplishments, was received partly at home, and partly under a Mr Perry, to whose lessons in logical English composition she ascribed something of her later clearness of thought and statement. The atmosphere of her home was industrious, intellectual, and austere; she herself was clever, weakly, and unhappy, and was, moreover, already growing deaf. At the age of fifteen the state of her health and temper led to a prolonged visit to her father's sister, Mrs Kentish, who kept a school at Bristol. Here, in the companionship of amiable and talented people, her life became happier. Here, also, she fell under the influence of the Unitarian minister, Dr Carpenter, from whose instructions, she says, she derived "an abominable spiritual rigidity and a truly respectable force of conscience strangely mingled together." From 1819 to 1830 she again resided chiefly at Norwich. The first part of this period was mainly spent in quiet and almost secret study and in needlework. About her twentieth year her deafness became confirmed, and she habitually from that time used an ear trumpet. In 1821 she began to write anonymously for the *Monthly Repository*, a Unitarian periodical, and was assured by her brother that authorship was her proper career. A little later she published *Devotional Exercises and Addresses, Prayers, and Hymns.*

In 1826 her father died, leaving a bare maintenance to his wife and daughters. His death had been preceded by that of his eldest son, and was shortly followed by that of the young man to whom Harriet was engaged. Mrs Martineau and her daughters soon after lost all their means by the failure of the house where their money was placed. Harriet had to earn her living, and, being precluded by her deafness from teaching, took up authorship in earnest and toiled with incredible industry. She reviewed for the *Repository* at the rate of £15 a year, wrote stories (afterwards collected as *Traditions of Palestine*), gained in one year (1830) three essay-prizes of the Unitarian Association, and eked out her income by needlework. In 1831 she was seeking a publisher for a series of tales designed as *Illustrations of Political Economy.* After many failures she accepted very disadvantageous terms, and the first number appeared amidst gloomy prognostications from the publisher. The sale, however, was immediate and enormous, the demand increased with each new number, and from that time her literary success was secured. In 1832 she moved to London; she at once became the fashion, and her acquaintance was eagerly sought. Till 1834 she continued to be occupied with her political economy series and with a supplemental series of *Illustrations of Taxation.* Four stories dealing with the poor-law came out about the same time. These tales, direct, lucid, written without any appearance of effort, and yet practically effective, display the characteristic qualities of their author's style. In 1834, when the whole series was complete, Miss Martineau paid a long visit to America. Here her open adhesion to the Abolitionist party, then small and very unpopular, gave great offence, which was deepened by the publication, soon after her return, of *Society in America* and a *Retrospect of Western Travel.* An article in the *Westminister Review*, "The Martyr Age of the United States," introduced English readers almost for the first time to the struggles of the Abolitionists. In these American writings Miss Martineau shows less than her usual calmness and judicial common sense, but it will scarcely be denied that there was some ground for her vehemence. The American books were followed by a novel, *Deerbrook*,—a story of middle class country life, lacking the delicate humour of Miss Austen or the touch of farce that enlivens Miss Edgeworth's tales, but delightfully clear in style, wholesome in spirit, and well sustained in point of interest. To the same period belong two or three little handbooks, forming parts of a *Guide to Service.* The veracity of her *Maid of all Work* led to a widespread belief, which she regarded with some complacency, that she had once been a maid of all work herself.

In 1839, during a visit to the Continent, Miss Martineau's health, which had long been bad, broke down entirely. She retired to solitary lodgings in Tynemouth, and remained a prisoner to her couch till 1844. She was still busy, and, besides a novel (*The Hour and the Man*), published some tales for children, and *Life in the Sick-room.* These volumes contain some of her best work, and possess a charm of tender feeling to balance the somewhat cold rationality that predominates in most of Miss Martineau's writing. During this illness she for a second time declined a pension on the civil list, fearing to compromise her political independence. Her letter on the subject was published, and some of her friends raised a small annuity for her soon after.

In 1844 Miss Martineau underwent a course of mesmerism, and in a few months was restored to health. Her recovery excited much discussion and controversy.

She herself felt no doubt either of its reality or of its being due to mesmerism, and not unnaturally resented the incredulity of others. She eventually published an account of her case in sixteen *Letters on Mesmerism*, a proceeding which caused great offence to some members of her family. On finding herself set free from the bondage of ill-health, she removed to Ambleside, where she built herself the house in which the greater part of her after life was spent. In 1845 she published three volumes of *Forest and Game Law Tales*, in which the method of her political economy series was again applied. In 1846 she made an Eastern tour with some friends. She was abroad for eight months, visiting Egypt, Palestine, and Syria, and on her return published *Eastern Life*. The tendency of this work is to display humanity passing through one after another of the world's historic religions, the conception of the Deity and of Divine government becoming at each step more and more abstract and indefinite. The ultimate goal Miss Martineau believed to be a philosophic atheism, but this belief she did not expressly declare in *Eastern Life*, considering it to be outside the province of that book. She published about this time *Household Education*, expounding the modern theory, in which freedom and rationality, rather than command and obedience, are regarded as the most effectual instruments of education. Her practical interest in all schemes of instruction led her to start a series of lectures, addressed at first to the school children of Ambleside, but afterwards extended, at their own desire, to their elders. The subjects of these lectures were sanitary principles and practice, the histories of England and North America, and the scenes of her Eastern travels. At the request of Mr Charles Knight she wrote for him, in 1849, *The History of the Thirty Years' Peace*,—a characteristic instance of Miss Martineau's remarkable powers of labour. "From the first opening of the books to study for the history to the depositing of the MS. of the first volume at press was," she says, "exactly six months. The second volume took six months to do."

In 1851 Miss Martineau edited a volume of *Letters on the Laws of Man's Nature and Development*. Its form is that of a correspondence between herself and Mr H. G. Atkinson (in which the latter has much the larger share), and it expounds that doctrine of philosophical atheism to which Miss Martineau had, in *Eastern Life*, depicted the course of human belief as tending. The existence of a first cause is not denied, but is declared unknowable, and the authors, while regarded by others as denying it, certainly considered themselves to be affirming the doctrine of man's moral obligation. Mr Atkinson was a zealous exponent of mesmerism, and the prominence given to the topics of mesmerism and clairvoyance no doubt tended to heighten the disapprobation with which the book was received. The reviewers were almost unanimous in condemnation, and the publication caused a lasting division between Miss Martineau and some of her friends.

The new philosophical bent of her studies directed Miss Martineau's attention to the works of Comte, and she undertook a condensed English version of the *Philosophie Positive*. It appeared in 1853, and to most readers is more useful and intelligible than the original. She had begun in the previous year to write articles, chiefly biographical, for the *Daily News*. Among these were the *Letters from Ireland*, written during a visit to that country in the summer of 1852. She also wrote a considerable number of essays upon different manufactures for *Household Words*, and another series for the same periodical upon the treatment of blindness, deafness, idiotcy, &c., besides a *Guide to Windermere*, followed afterwards by a *Complete Guide to the Lakes*. She had been for many years a contributor to the *Westminster Review*, and was one of the little band of supporters whose pecuniary assistance, in 1854, prevented its extinction or forced sale. In the early part of 1855 Miss Martineau found herself suffering from heart disease. Having always felt it one of her duties to write her autobiography, and believing the time before her to be but brief, she now at once set about this task, and on its completion caused the book to be printed that it might be ready for speedy publication at her death. But her life, which she supposed to be so near its close, was prolonged for other twenty years, her death not taking place until 1876.

These years were by no means idle. She continued to contribute to the *Daily News*, for which she wrote in all more than 1600 articles, and to the *Westminster Review*, as well as to other papers, and her biographical sketches were collected and reprinted from the *Daily News* in a volume which has justly become one of the best-known of her works. In point of style it is probably the most excellent of them all. The form and method leave nothing to be desired, and the perception of character is shrewd, sincere, and, roughly speaking, reliable. But in reading the book we feel that the biographies, divided by the editor into groups of royal, political, &c., fall far more naturally into two larger classes,—the biographies of persons whom Miss Martineau liked, and the biographies of persons whom she disliked. All are doubtless in a sense true, as all photographs are true, but the difference between a flattering and an unflattering photograph is considerable.

She also produced two books on the government of India, and was continually occupied in promoting schemes of reform and benevolence. Her poorer neighbours owed much to her kindly and enlightened efforts, and her servants found in her a friend as well as a mistress. Her long and busy life bears the consistent impress of two leading characteristics,—industry and sincerity. Her work was invariably sound, and its motive invariably respectable. The verdict which she records on herself in the autobiographical sketch left to be published by the *Daily News* is probably very near to that which will be recorded by future judgment. She says,—"Her original power was nothing more than was due to earnestness and intellectual clearness within a certain range. With small imaginative and suggestive powers, and therefore nothing approaching to genius, she could see clearly what she did see, and give a clear expression to what she had to say. In short, she could popularize while she could neither discover nor invent." Her judgment on large questions was clear and sound, and was always the judgment of a mind naturally progressive and Protestant. Mentally she was a true daughter of her Huguenot ancestors. But it is impossible to read her autobiography without suspecting that she was subject to considerable prejudices, especially in her judgment of persons, and that her temper, particularly in earlier life, was unamiable, hard, and unforgiving. She seems, indeed, to have possessed the sort of disposition which shows to much greater advantage in its relation to juniors, inferiors, and dependants than in its relations to elders and superiors, and which therefore appears more amiable in the closing than in the opening years of life. Her autobiography reveals also a weakness which was perhaps unavoidable. The publication of her political economy tales brought her into great and sudden notice; many persons of high position, official and otherwise, desired to enlist her advocacy on the part of their particular projects. She found her help much courted, and much help eagerly proffered to her. Her deafness, which suffered her to hear only what was directly addressed to herself, assisted to make her a central figure, and to induce the belief that hers was one of the most potent if not actually the most potent voice in English politics. Her deafness was in another direction probably advantageous. It led her to find solitude easier than most companionship, and saved her from many distractions of attention. It may indeed fairly be surmised that but for her deafness she could never have found time to achieve the amazing quantity of work that she did, while the courageous, cheerful, and unobtrusive spirit in which she bore her infirmity remains an example and an encouragement to all her fellow-sufferers. (C. BL.)

MARTINI, Giovanni Battista (1706-1784), the most learned musician of the 18th century, was born at Bologna on April 25, 1706. His father, Antonio Maria Martini, a violinist, taught him very early the elements of music, and to play the violin; at a later period he learned singing and harpsichord playing from Padre Pradieri, and counterpoint from Antonio Riccieri. Having received his education in classics from the fathers of the oratory of San Filippo Neri, he afterwards entered upon a noviciate at the Franciscan monastery at Lago, at the close of which he was received into that order on September

11, 1722. Continuing his studies in the theory and practice of music with great zeal, he in 1725, though only nineteen years of age, received the appointment of chapel-master in the Franciscan church at Bologna, where his compositions soon attracted much attention. At the invitation of amateurs and professional friends he now opened a school of musical composition at which in the course of his long life several celebrated musicians were trained, including Paolucci, Sabbatini, Ruttini, Zanotti, Sarti, Ottani, and Stanislas Mattei; as a teacher he consistently declared his preference for the traditions of the old Roman school of musical composition (see MUSIC). Padre Martini was a zealous and indefatigable collector of musical literature, and is alleged to have been the possessor of the most extensive musical library ever formed. After a lingering illness he died at Bologna on August 4, 1784. His *Elogio* was published by Pietro della Valle at Bologna in the same year.

The greater number of Martini's sacred compositions remain unprinted. The Liceo of Bologna possesses the MSS. of two oratorios; and a requiem, with some other pieces of church music, are now in Vienna. *Litaniæ atque antiphonæ finales B. V. Mariæ* were published at Bologna in 1734, as also twelve *Sonate d'intavolatura*; six *Sonate per l'organo ed il cembalo* in 1747; and *Duetti da Camera* in 1763. Martini's most important works are his *Storia della Musica* (Bologna, 1757–81) and his *Saggio di Contrapunto* (Bologna, 1774–75). The former, of which the three published volumes relate wholly to ancient music, and thus represent a mere fragment of the author's vast plan, exhibits immense reading and industry, but it is written in a dry and unattractive style, and is overloaded with matter which cannot be regarded as historical. At the beginning and end of each chapter occur puzzle-canons, some of which are exceedingly difficult; Cherubini solved the whole of them. The *Saggio* is a very learned and valuable work, containing an important collection of examples from the best masters of the old Italian and Spanish schools, with excellent explanatory notes. It treats chiefly of the tonalities of the plain chant, and of counterpoints constructed upon them. Besides being the author of several controversial works, Martini drew up a *Dictionary of Ancient Musical Terms*, which appeared in the second volume of G. B. Doni's *Works*; he also published a treatise on *The Theory of Numbers as applied to Music.*

MARTINI, SIMONE (1283–1344), called also Simone di Martino, and more commonly, but not correctly, Simon Memmi,[1] was born in 1283. He followed the manner of painting proper to his native Siena, as improved by Duccio, which is essentially different from the style of Giotto and his school, and the idea that Simone was himself a pupil of Giotto is therefore wide of the mark. The Sienese style is less natural, dignified, and reserved than the Florentine; it has less unity of impression, has more tendency to pietism, and is marked by exaggerations which are partly related to the obsolescent Byzantine manner, and partly seem to forebode certain peculiarities of the fully developed art which we find prevalent in Michelangelo. Simone, in especial, tended to an excessive and rather affected tenderness in his female figures; he was more successful in single figures and in portraits than in large compositions of incident. He finished with scrupulous minuteness, and was elaborate in decorations of patterning, gilding, &c.

The first known fresco of Simone is the vast one which he executed in the hall of the Palazzo Pubblico in Siena,—the Madonna Enthroned, with the Infant, and a number of angels and saints; its date is 1315, at which early period of his life he was already an artist of repute throughout Italy. In S. Lorenzo Maggiore of Naples he painted a life-sized picture of King Robert crowned by his brother, Lewis, bishop of Toulouse; this also is extant, but much damaged. In 1320 he painted for the high altar of the church of St Catharine in Pisa the Virgin and Child between six saints; above are archangels, apostles, and other figures. The compartmented portions of this work are now dispersed, some of them being in the academy of Siena. Towards 1321 he executed for the church of St Dominic in Orvieto a picture of the bishop of Savona kneeling before the Madonna attended by saints, now in the Fabricceria of the cathedral. Certain frescos in Assisi in the chapel of St Martin, representing the life of that saint, ascribed by Vasari to Puccio Capanna, are now, upon strong internal evidence, assigned to Simone. He painted also, in the south transept of the lower church of the same edifice, figures of the Virgin and eight saints. In 1328 he produced for the Sala del Consilio in Siena a work of a very different character—a striking equestrian portrait of the victorious general Guidoriccio Fogliani de' Ricci.

Simone had married in 1324 Giovanna, the daughter of Memmo (Guglielmo) di Filippuccio. Her brother, named Lippo Memmi, was also a painter, and was frequently associated with Simone in his work; and this is the only reason why Simone has come down to us with the family-name Memmi. They painted together in 1333 the Annunciation which is now in the Uffizi gallery. Simone kept a bottega (or shop), undertaking any ornamental work commissioned of him, and his gains were large. In 1339 he settled at the papal court in Avignon, where he made the acquaintance of Petrarch and Laura; and he painted for the poet a portrait of his lady, which has not come down to us; it gave occasion for two of Petrarch's sonnets, in which Simone is highly eulogized. He also illuminated for the poet a copy of the Comment of Servius upon Virgil, now preserved in the Ambrosian library of Milan. He was largely employed in the decorations of the papal buildings in Avignon, and several of his works still remain—in the cathedral, in the hall of the consistory, and, in the two chapels of the palace, the stories of the Baptist, and of Stephen and other saints. One of his latest productions (1342) is the picture of Christ Found by his Parents in the Temple, now in the Liverpool Gallery. Simone died in Avignon in July 1344.

From this account of Simone's principal works it will be perceived that those with which his name and fame are most generally identified are no longer regarded as his. These are the compositions, in the Campo Santo of Pisa, from the legend of S. Ranieri, and the Assumption of the Virgin; and the great frescos in the Cappellone degli Spagnuoli, in S. Maria Novella, Florence, representing the Triumph of Religion through the work of the Dominican order, &c. Some of the works in question can be proved to have been done many years after Simone's death, and the others belong to a different school and style of art.

MARTINIQUE, one of the West India islands, belonging to the chain of the Lesser Antilles, and constituting a French colony, lies 33 miles south of Dominica and 22 north of Saint Lucia, between 14° 23′ and 14° 52′ N. lat. and 63° 6′ and 63° 31′ W. long. The greatest length is 43 miles, the mean width 19; and the surface comprises 244,090 acres, or 380 square miles. A cluster of volcanic mountains in the north, a similar group in the south, and a line of lower heights between them, form the backbone of the island, which culminates in the north-west in Mont Pelée (4430 feet), and has altogether a much more irregular and strongly marked relief than it presents to the eye,—the deep ravines and precipitous escarpments with which it abounds being reduced in appearance to gentle undulations by the drapery of the forests. Of the numerous streams which traverse the few miles of country between the watershed and the sea, about seventy or eighty

[1] The ordinary account of this celebrated early Sienese painter is that given by Vasari, and since repeated in a variety of forms. Modern research shows that it is far from correct, the incidents being erroneous, and the paintings attributed to Simone in various principal instances not his. We follow the authority of Messrs Crowe and Cavalcaselle.

are of considerable size, and in the rainy season become deep and too often destructive torrents. The east coast of the island, exposed to the full sweep of the Atlantic, is a succession of inlets, headlands, islands, and rocks; the south coast is much more regular, but bold and steep; and the west alone presents, in the bay of Fort de France, a stretch of mangrove swamp. Of the total area, about 83,990 acres are under cultivation, 83,843 occupied by forest and savanna, and 68,837 by fallow. On an average, according to the returns for 1874-78 inclusive, 47,440 acres are devoted to the sugar crop, 1290 to coffee, 640 to cotton, and 1660 to cocoa. The mean annual temperature is 81° in the coast region,—the monthly mean for June being 83°, and that of January 77°. Of the annual rainfall of 87 inches, August has the heaviest share (11·3 inches), though the rainy season extends from June to October; March, the lowest, has 3·7. Martinique enjoys a remarkable immunity from hurricanes; half a century may pass without serious disaster from such a visitation. In 1878 there were 162,861 inhabitants (77,782 males, 85,079 females) in the island, which is thus nearly as densely peopled as Belgium. Since 1848 the increase amounts to about 42,800. Of the twenty-five communes, fourteen have more than 5000 inhabitants; the largest are Saint Pierre (23,909), Fort de France (15,414), Lamentin (13,409), and François (10,297). The great mass of the population consists of Creole negroes and half-castes of various grades, ranging from the "Saccatra," who has hardly retained any trace of Caucasian blood, to the so-called "Sangmêlé," with his mere suspicion of negro commixture. Marriage is frequently ignored, and of the births no less than 66 per cent. are illegitimate.

Fort de France, the chief town, a place of about 11,000 inhabitants, stands on a bay on the west coast. Since the earthquake of 1839 nearly all the houses are of wood, and have only one story; the streets are laid out with great regularity. An abundant supply of water was introduced in 1856. St Pierre, the commercial centre of the island, with about 20,000 inhabitants, lies farther north on the same coast. It consists of a lower and an upper town,—the one close and unhealthy, and the other for the most part well-ventilated and pleasant.

Martinique, also called Madiana or Mantinino, was discovered by Columbus 15th June 1502. It was at that time inhabited by Caribs (Galibis) who had expelled or incorporated an older stock. In 1635 a Norman captain, D'Enambuc, from St Christopher's, took possession of the island, and in 1637 his nephew Duparquet became captain-general of the colony, now numbering seven hundred men. In 1654 welcome was given to three hundred Jews expelled from Brazil, and by 1658 there were at least five thousand people exclusive of the Caribs, who were soon after exterminated. Purchased by the French Government from Duparquet's children for 120,000 livres, Martinique was assigned to the West India Company, but in 1674 it became part of the royal domain. The *habitants* (French landholders) at first devoted themselves to the cultivation of cotton and tobacco; but in 1650 sugar plantations were commenced, and in 1726 the coffee plant was introduced by Desclieux, who, when water ran short during his voyage to the island, shared his scanty allowance with his seedlings. Slave labour having been introduced, there were 72,000 blacks in the island by 1736. Martinique has several times been occupied by the English. Captured by Rodney in 1762, it was next year restored to the French; but after the conquest by Sir John Jervis and Sir Charles Grey in 1794 it was retained for eight years; and, seized again in 1809, it was not surrendered till 1814.

See Renouard, *Stat. de la Martinique*, 1822; Sidney Daney, *Hist. de la Martinique*, 1846; E. Rufz, *Études hist. et stat. sur la population de la Martinique*; Pardon, *La Martinique*, 1877; H. Rey, *Étude sur la col. de la Martinique*, 1881.

MARTINSBURG, a town of the United States, the capital of Berkeley county, West Virginia, lies on a plateau above the Tuscarora Creek, in the Shenandoah valley, 80 miles west of Washington. A station on the Baltimore and Ohio Railroad, and a terminus of the Cumberland Valley Railway, Martinsburg is the seat of extensive machine-shops belonging to the former company, which were sacked by the Confederates in 1861. The population, 4863 in 1870, was 6335 in 1880.

MARTIUS, Carl Friedrich Philipp von (1794–1868), a well-known German botanist and traveller in Brazil. He studied in the university of Erlangen, and on graduating M.D. in 1814 published as his thesis a critical catalogue of plants in the botanic garden of the university. He afterwards devoted himself to botanical study, and in 1817 he and Spix were sent to Brazil by the king of Bavaria. They travelled from Rio Janeiro through several of the southern and eastern provinces of Brazil, and ascended the river Amazon to Tabatinga, as well as some of its larger affluents. In 1820 they returned to Europe with rich collections of plants and animals, as also with stores of information on the geography, ethnology, and products of Brazil. In 1820 he was appointed conservator of the botanic garden at Munich, and in 1826 professor of botany in the university there, and held both offices till 1854, when he resigned them.

While a student Martius had published papers in various scientific periodicals, and he continued to do so during his whole life. After his return from Brazil he devoted his chief attention to the flora of that country, and in addition to numerous short papers he published the *Nova Genera et Species Plantarum Brasiliensium* (1823–32, 3 vols.) and *Icones selectæ Plantarum Cryptogamicarum Brasiliensium* (1827), both works being finely illustrated. An account of his travels in Brazil appeared in 3 vols. 4to, 1823–31, with an atlas of plates, and is regarded as one of the most valuable works of travel of the present century. Probably the work by which he is best known is his *Historia Palmarum* (1823–50) in 3 large folio volumes, of which one describes the palms discovered by himself in Brazil. In 1840 he began the *Flora Brasiliensis* with the assistance of the most distinguished European botanists, who undertook monographs of the various orders. Latterly Dr Eichler was associated with him in the editorship of this work, which is still going on, though over eighty parts have appeared. He also edited several works on the zoological collections made in Brazil by Spix, after the death of the latter in 1826. On the outbreak of potato disease in Europe he investigated the state of the diseased plants, and in 1842 published his observations. He also published independent works and short papers on the aborigines of Brazil, on their civil and social condition, on their past and probable future, on their diseases and medicines, and on the languages of the various tribes, especially the Tupi.

MARTOS, a town of Spain, in the province of Jaen, is situated on the slope of a steep hill, which is surmounted by a ruined castle, 16 miles west-south-west of Jaen. The streets are steep, narrow, crooked, and ill-paved; the public buildings are of the usual order, and present no feature calling for special remark. The surrounding district is specially productive of oil, and in the neighbourhood of the town are two sulphurous springs much resorted to in cases of cutaneous disease. Population in 1877, 14,654.

Martos perhaps stands on or near the site of the *Tucci* of Ptolemy. By Ferdinand III. it was taken from the Moors in 1225, and given to the knights of Calatrava; it was there that the brothers Carvajal, commanders of the order, were in 1410 executed by command of Ferdinand IV. after he had been "summoned" by them to a meeting at the Divine judgment seat. O'Donnell here gained a victory over the royalist troops in 1854.

MARTYN, Henry (1781–1812), a celebrated missionary, was born on February 18, 1781, at Truro, Cornwall. He came of a mining family, and his father John Martyn was a "captain" or mine-agent at Gwennap. He received his education at the grammar school of his native town under the famous Dr Cardew, entered St John's College, Cambridge, in the autumn of 1797, and in 1801, a month before he was twenty years old, was declared senior wrangler, obtaining soon after the first Smith's prize. In the following year he was chosen a fellow of his college. In the autumn of 1801 he was introduced to Charles Simeon, whose ardent disciple he soon became. It was his intention to devote himself to the bar, but in the October term of 1802 he chanced to hear Simeon speaking of the vast amount of good done in India by a single missionary, William Carey; some time afterwards he read the life of the devoted David Brainerd, the enthusiastic apostle of the Indians of North America, and, "filled with a holy emulation," resolved to devote his energies to the work of a Christian missionary. On October 22, 1803, he was ordained deacon at Ely, and afterwards priest, and served as Simeon's curate at the church of Holy Trinity, taking charge of the neighbouring parish of Lolworth. Still full of the thought of working in heathen lands, he designed to volunteer for the Church Missionary Society, but a sudden disaster in Cornwall deprived him and his unmarried sister of all the provision their father had made for them, and rendered it necessary that he should obtain a salary that would support her as well as himself. He accordingly applied for, and obtained, a chaplaincy under the East India Company. He left for India on July 5, 1805.

For some months he was chiefly located at Aldeen, near Serampore; in October 1806 he proceeded to Dinapore, where he laboured for a time amongst the Europeans, and soon found himself able to conduct divine worship among the natives in their own vernacular language, and to establish schools for their instruction. At the end of April 1809 he was ordered up to Cawnpore, where he made his first attempt to preach to the heathen in his own compound, and had to endure frequent interruptions "amidst groans, hissings, curses, blasphemies, and threatenings"; nevertheless he pursued his work among the hundreds who crowded round him, consoling himself that, if he should never see a native convert, God "might design by his patience and continuance in the work to encourage other missionaries." Meanwhile the great business of his life was being diligently carried on. Day after day he occupied himself with learning new languages, and had already, during his residence at Dinapore, been engaged in revising the sheets of his Hindustani version of the New Testament. He now translated the whole of the New Testament into Hindi also, and into Persian twice over. He translated the Psalms into Persian, the Gospels into Judæo-Persic, and the prayer book into Hindustani, in spite of the constant interruptions caused by excessive weakness of body, and "the pride, pedantry, and fury of his chief moonshee Sabat." Ordered by the doctors to take a sea voyage for his health, he got leave to go to Persia and correct his Persian New Testament, whence he made up his mind to go on to Arabia, and there compose an Arabic version. Accordingly, on October 1, 1810, having seen his work at Cawnpore crowned, on the previous day, by the opening of a church, he left for Calcutta, whence he departed on January 7, 1811, for Bombay, which he reached on his thirtieth birthday. From Bombay he set out for Bushire, bearing letters from Malcolm to men of position there, as also at Shiraz and Ispahan. After a killing journey from the coast he reached Shiraz, and was soon plunged into discussion with the disputants of all classes, "Sufi, Mohammedan, Jew, and Jewish-Mohammedan, even Armenian, all anxious to test their powers of argument with the first English priest who had visited them." Having made an unsuccessful journey to Tebriz to present the shah with his translation of the New Testament, he was seized with a fever, which so thoroughly prostrated his energies that, after a temporary recovery, he found it necessary to seek a change of climate. On September 12, 1812, he started with two Armenian servants, crossed the Araxes, rode from Tebriz to Erivan, from Erivan to Kars, from Kars to Erzeroum, from Erzeroum to Chiflik, urged on from place to place by his cruel Tartar guide, and, though the plague was raging at Tokat, he was compelled to stop there from utter prostration caused by fever. On the 6th of October he died, either from the plague or from the weakness of the disorders which harassed him from day to day.

By his valuable labours as a translator Martyn had placed portions of the Scriptures within the reach of all who could read over one-fourth of the habitable globe, and during his brief life he earned for himself a foremost place among modern missionaries. Macaulay's lines, written in 1818, testify to the impression made by his enthusiastic career of self-devotion.

See Sargent, *Memoir of the Rev. Henry Martyn, B.D.*, 1819; Wilberforce, *Journals and Letters of the Rev. Henry Martyn*, 1837; Kaye, *Christianity in India*, 1859; Yonge, *Pioneers and Founders*, 1874; and *The Church Quarterly* for October 1881.

MARTYROLOGY, a catalogue or list of martyrs, arranged according to the succession of their anniversaries, and sometimes including an account of their lives and sufferings. The corresponding word in the Greek Church is *Menologion* or *Analogion*; from the *Menologia* the *Synaxaria* are compiled. The custom of paying honour to the memory of those who had "witnessed the good confession" in perilous times established itself very early in the Christian church, and one particular manner of commemoration was formally recognized by at least one ecclesiastical synod before the end of the 4th century; in the 47th canon of the third synod of Carthage (397 A.D.) it is decreed "liceat legi Passiones Martyrum quum anniversarii eorum dies celebrantur." Apart from the still extant *Depositio Martyrum* contained in the work of the chronographer of 354, edited in 1850 by Mommsen, the oldest "martyrologies" of which anything is known are the ἀρχαίων μαρτυρίων συναγωγή, or collection of records of past persecutions, to which Eusebius more than once alludes as having been made by himself, and the treatise *On the Martyrs of Palestine*, by the same author, the full text of which has been preserved in an ancient Syriac version edited by Cureton. Next to the general martyrology of Eusebius, in chronological order, it has been usual to place the calendar of saints' days referred to in a letter, attributed to Jerome, which purports to be written in answer to bishops Chromatius and Heliodorus, who had asked him to search the archives of Eusebius with the view of enabling them to observe the saints' days with more regularity. This epistle is now admitted to be spurious; ultimately, however, a so-called *Martyrologium Hieronymianum* came into existence, but it is not so much a single martyrology as a rude patchwork derived from many ancient church calendars. In its present form it is a meagre list of names and places, but may be said to lie at the foundation of all subsequent Western calendars. Almost contemporary with its last recension is what is known as the *Parvum Martyrologium Romanum*, found by Ado of Vienne about 850; in it many of the dates are changed, and for the first time days are assigned to the chief characters of Scripture. To nearly the same date must be assigned the independent compilation of Bede, which has reached us, however, only as enlarged by subsequent editors. The 9th century was very fertile in martyrologies, among which may be mentioned that of Florus, subdeacon of Lyons (*c.* 830), who was the first editor of Bede, that of Hrabanus Maurus, an attempted further improvement on Bede and Florus, that of Ado, an enlargement of Florus, but based on the *Parvum Martyrologium Romanum*, that of Usuard of Paris, the epitomizer of Ado, and that of Notker of St Gall, based on Ado and Hrabanus. The *Martyrologium Romanum* was published by Baronius at the command of Pope Gregory XIII. in 1586; the enlarged edition by Rosweyd appeared at Antwerp in 1613. The Cistercian *Martyrology* appeared at Rome in 1733 and 1748. The best-known Greek *Menologion* is that prepared in the 9th century by command of the emperor Basilius Macedo; it was edited in 1727 by Cardinal Hannibal Urbini. An ancient Syriac martyrology, entitled "the names of our lords the martyrs and victors, with their days on which they won crowns," written in 412, has been edited, with an English translation, by Professor W. Wright, in the *Journal of Sacred*

Literature (1866). See *Catal. Syr. MSS. Br. Mus.*, ii. 632.

MARULLUS, Michael Tarchaniota (*ob.* 1500), one of the most brilliant scholars of the golden age of Florentine learning, was born at Constantinople, and at an early age, on the fall of his native city, was brought to Ancona in Italy, where he became the friend and pupil of Pontanus, with whom his name is associated by Ariosto (*Orl. Fur.*, xxxvii. 8). He was a soldier and a poet, and in the latter capacity published epigiams and *hymni naturales.*[1] Marullus took no part in the work of translation, then so favourite an exercise of scholars, but he was understood to be planning some great work when he perished, 10th April 1500, in the river Cecina near Volterra. Of other incidents in his life his feud with Politian and his marriage to the beautiful and learned Alexandra Scala, whom he praises in his poems, may be noticed. The name of Marullus is now perhaps most familiar from the brilliant emendations on Lucretius which he left unpublished, and which were used for the Juntine edition. See especially Munro's *Lucretius*, 2d ed., p. 6 *sq.*

MARUM (in Dutch Marwm), Martin Van (1750–1837), a distinguished Dutch man of science, born at Delft. Though his fame rests chiefly on his electrical researches, he took a prominent position in many departments of natural science. He graduated at Groningen in medicine and philosophy, and his numerous papers take up subjects connected with botany, chemistry, hygiene, natural history, and technology, as well as with his more special department, natural philosophy. In early life his father, who was a skilled mathematician, gave him a thorough training in the one really indispensable science. After his doctorate he for some time attached himself to the celebrated botanist Camper. He then commenced medical practice in Haarlem, but seems to have been too busy with original work to pay proper attention to his numerous patients. He devoted himself mainly to lecturing on physical subjects; and, after a brief interval, his extensive knowledge and methodical habits led to his being made secretary of the scientific society of his adopted city. For this post he was specially fitted; and, under his active guidance, the society was advanced to the position of one of the most noted in Europe. He soon became professor of physics, and was entrusted with the care of the celebrated Teyler collection (now the Musée Teyler). He caused to be constructed for this, by Cuthbertson, the gigantic electrical machine which, for a long period, was the most powerful in the world. He also effected great improvements in air-pumps and other pneumatic machines. Though his name is not associated with any discovery of the very first order, the number and variety of his researches (especially in connection with electricity) are remarkable. So also is the practical mode in which he regarded his results, always when at all possible from the technological point of view. The work by which he is best known is his *Treatise on Electricity* (Groningen, 1776), in which all that had then been discovered in that science was carefully methodized. Van Marum was a man of quiet but active disposition, and of simple habits and tastes, which probably conduced in no small measure to the extreme length and usefulness of his life.

MARUTSE-MABUNDA, a kingdom in South Africa, stretching from 18° to 14° 25′ S. lat. and from about 22° to 28° 25′ E. long., with an area estimated at 123,590 square miles. It all belongs to the basin of the Zambesi, and by far the greater proportion lies to the north of that river, which forms its south-eastern boundary from the mouth of the Linyanti to the mouth of the Kafue, a distance of about 350 miles. The kingdom thus includes the main part of the territory formerly subject to the Makololo empire, which broke up on the death of Sekeletu in 1864. Of country and people Dr Holub gives a very favourable report. Abundance of water, a fertile soil, and a genial climate render easy the work both of husbandry and cattle-breeding. The chief crop is Kaffre corn, red and white; the hemp-like kleen-korn or *rosa*, maize, water-melons, sugar-cane, ground-nuts, two kinds of beans, and *manza* are also cultivated. "September and October are the usual months for sowing; but gourds, leguminous plants, and tobacco are sown any time up to December, the growth of the two latter crops being so rapid that they often ripen by January, whilst Kaffre corn and maize are ready by February." Upwards of fifty kinds of wild fruit are used by the people as food. Salt has to be imported, and is consequently within the reach only of the wealthier classes. Besides the two great tribes which give their name to the kingdom, there are a large number of vassal tribes of numerical importance—Masupias, Matongas, Makalakas—all considered in the light of slaves by the rulers. The prevailing language is the Sesuto of the nearly extirpated Makololos. See Holub, *Seven Years in South Africa*, 1881.

MARVELL, Andrew (1621–1678), was born on March 31, 1621, at the parsonage of Winestead in Holderness. He was educated at Hull grammar school by his father, who had obtained high position in that town, until his admission to Trinity College, Cambridge, on December 14, 1633. There he became ensnared by the Jesuits, who at that time were keen to secure youths of promise at the universities, and by them, probably in the beginning of 1638, was taken to London; but he was recaptured by his father, and again received into Trinity on April 13 of the same year. He appears to have contributed to the *Musa Cantabrigiensis* in 1637; and beyond this nothing is known or even conjectured as to his college career. In 1640 his father was drowned under remarkable circumstances, an event which appears to have entirely unsettled him, for by an entry in the College Conclusion book, dated September 24, 1641, we find that he was adjudged by the seniority to have forfeited the benefits of the college. He used his liberty during the next four years to travel through the Continent, remaining abroad until 1646. It has been assumed that during this journey Marvell became acquainted with Milton, but a comparison of dates shows that this is an error. His first employment was in 1650, as tutor to Lord Fairfax's daughter. During his stay at Nunappleton were written the *Poems of the Country* and some of the *Poems of Imagination and Love.* In 1652 he was in communication with Milton, to whom he had probably been introduced by Fairfax, and was by him sent on February 21 to President Bradshaw with a letter urging his appointment as assistant Latin secretary to himself. The post was, however, otherwise filled up, and he was provided instead with another tutorship, that of Cromwell's nephew, Mr Dutton. This has been wrongly stated by several writers as not occurring until six years later. In 1657 the secretaryship again fell vacant, and was then conferred upon him, but he held office for a year only, and no record of his work appears in the calendar of state papers. Marvell accepted the Commonwealth as a practical fact, and the rule of Cromwell as the only guarantee for government at once tolerant and strong. But he never lost his belief in the monarchical theory. His line "'Tis godlike good to save a falling king" is well known; and throughout his most vehement invective against corruption there is a great tenderness and desire to spare the king.

[1] Two books of epigrams appeared first without date; an enlarged edition, with two additional books, published in 1497, contains also the so-called hymns.

The assistant secretaryship opened the way to public life, and in 1658 Marvell was elected member for Kingston-upon-Hull in Richard Cromwell's parliament. From 1663 to 1665 he acted as secretary to Lord Carlisle's embassy to Muscovy, Sweden, and Denmark; and this is the only official post he ever filled during the reign of Charles. With the exception of this and of shorter unexplained intervals of travel, Marvell was constant in his parliamentary attendance to the day of his death. He seldom spoke in the House, some five or six times in all, but his parliamentary influence is amply established by other evidence; and his correspondence with his constituents, from 1660 to 1678, forms a source of information all the more valuable because by a resolution passed at the Restoration the publication of the proceedings of the House without leave was forbidden. He made it a point of duty to write at each post—that is, every two or three days—both on local interests and on all matters of public interest. The discreet reserve of these letters, natural at a time when the post-office was a favourite source of information to the Government, contrasts curiously with the freedom of the few private letters which state opinions as well as facts. Marvell's constituents, in their turn, were not unmindful of their member. He makes frequent references to their presents, usually of Hull ale and of salmon, and he regularly drew from them the wages of a member, six and eightpence a day during session.

During these years Marvell wrote a good deal of verse, chiefly satire, often very coarse, but always vigorous and full of an honest hatred at corruption. He chose verse merely as being the usual vehicle of satire, and cared little about form. "He plucked a cudgell from the nearest hedgerow, careless if it became fuel after it had served his turn." It was very different with his prose satires. His peculiar talent was first displayed in the mock *King's Speech*, issued in 1675. This is written in a vein of genial banter, perhaps the greatest tribute to the influence which the bonhomie of Charles exercised even over such men as Marvell. But his tone soon changed, and *The Growth of Popery and Arbitrary Power*, published in the year of his death, is a grave indictment of the conduct of ministers of the crown, and, by implication, of Charles himself, since the Restoration. So shrewdly did this strike the conscience of the king that a proclamation, of which Marvell takes laughing notice, offered a large reward for the discovery of the author.

As a political pamphleteer Marvell holds a high place; as a satirist he stands still higher. Tolerance in religion was his creed, and this creed had been lately attacked by a clergyman seeking promotion, Dr Parker, afterwards bishop of Oxford, who asserted in their most extravagant form the claims of the civil magistrate over the consciences of subjects in matters of external religion. Marvell's reply, *The Rehearsal Transprosed*, is a masterpiece of prolonged banter. It contains passages of lofty indignation, hearty laughter, coarse vituperation; but the prevailing tone is that of grave and ironical banter. The effect, as witnessed to by Anthony Wood, Burnet, and other contemporary writers, was to set the whole public "from the king to the tradesman" in a laugh against Parker. This stung him to an ill-tempered rejoinder, affording Marvell a second opportunity, of which he availed himself so well that no more was heard from his opponent; and Swift was shortly afterwards able to say that people remembered Parker's book only by Marvell's answer. Marvell's second controversial work, *Mr Smirke, or the Divine in Mode*, was written in the same strain and under similar circumstances, and obtained a success fully equal to that of the *Rehearsal Transprosed*. It was a defence of Croft, bishop of Hereford, against a violent attack by Dr Turner, the High Church master of St John's, Cambridge. Prefixed to it was a "short historical essay concerning general councils," intended to show the folly of religious impositions. Several other writings, often ascribed to him, more especially the *Parliamenti Angliæ Declaratio*, *A Sensible Question and an Usefull Answer*, and the *Flagellum Parliamentarium*, were certainly not his.

As a humorist, then, and as a great "parliament man," no name is of more interest to a student of the reign of Charles II. than that of Marvell. But other qualities entitle him to still higher respect. To a personal charm so great, to wit so brilliant, to learning so extensive, and to sympathies so wide that he was at the same time dear to John Milton and courted by Charles II., he joined the rarest quality of that evil time, a robust and intrepid rectitude. In the very heyday of political infamy, at a time when he says passionately "we are all venal cowards except some few," and when opposition to the court was likely to be resented by personal violence of the brutalest kind, he, a needy man, obliged to accept wages from his constituents, tempted in winning phrases from royal lips by his old schoolfellow Danby, and with nothing to gain from the court by purity, kept his political virtue unspotted and unsuspected. The meaning of this fact can barely be felt by any one who has not read with minute care the annals of that time. When the grossest forms of self-indulgence were the ordinary habits of town life, Marvell was a temperate man, in spite of Aubrey's witness that he "kept bottles of wine at his lodgings and would drink liberally by himself to refresh his spirits and exalt his muse." Lastly, in the worst times of parliamentary violence, he stood forward throughout his career as the champion of moderate and tolerant measures. His person corresponded singularly with his mind, so far as can be judged from the portrait by Hannemann and from the few words of John Aubrey—"He was of a middling stature, pretty strong set, roundish faced, cherry cheeked, hazel eyed, brown haired. In his conversation he was modest and of very few words."

He died suddenly in 1678 on his return from Hull to take his seat in August. That he was poisoned, and at the instigation of the court, has been roundly asserted, naturally enough, though without the slightest foundation. The matter has been finally set at rest by a very interesting letter by Dr Samuel Gee in the *Athenæum* for March 7, 1874.

The following works may be consulted on Marvell:—*Life and Works*—(1) by Thomas Cooke, 2 vols., 1726 (there is a reprint by Thomas Davies in 1772); (2) by Captain Thomson, 3 vols. 4to, 1776; (3) by John Dove, 1832; (4) by Edwin Paxton Hood, 1853; and essays by Hartley Coleridge in *Lives of the Northern Worthies*, Henry Rogers in his collected *Essays*, and an anonymous author in the *Cornhill Magazine* for July 1869, and in the *Saturday Review* for April 26, 1873. All these authorities are mentioned, collated, and corrected in the very important and laborious work of Mr Grosart, whose book, in spite of its excessive mannerism and one or two curious inaccuracies, is indispensable to the student of Marvell's correspondence and career. (O. A.)

MARWAR. See JODHPUR.

MARY[1] (Μαρία, Μαριάμ), the mother of Jesus, at the time when the gospel history begins, had her home in

[1] The name (Heb. מִרְיָם), that of the sister of Moses and Aaron, is of uncertain etymology; many interpretations have been suggested, including "stella maris," which, though it has attained considerable currency through Jerome (the *Onomasticon*), may be at once dismissed. It seems to have been very common among the Jews in New Testament times; besides the subject of the present notice there are mentioned (1) "Mary (the wife) of Clopas," who was perhaps the mother of James "the little" (ὁ μικρός) and of Joses (see vol. xiii. pp. 552, 553); (2) Mary Magdalene, *i.e.*, of Magdala; (3) Mary of Bethany, sister of Martha and Lazarus; (4) Mary the mother of Mark (see MARK); and (5) Mary, an otherwise unknown benefactress of the apostle Paul (Rom. xvi. 6).

Galilee, at the village of Nazareth. Of her parentage nothing is recorded in any extant historical document of the 1st century, for the genealogy in Luke iii. (*cf.* i. 27) is manifestly that of Joseph. In early life she became the wife of JOSEPH (*q.v.*) and also the mother of our Lord (see JESUS[1]); that she afterwards had other children is a natural inference from Matt. i. 25, which the evangelists, who frequently allude to "the brethren of the Lord," are at no pains to obviate. The few incidents mentioned in Scripture regarding her show that she followed our Lord to the very close of His earthly career with unfailing motherliness, but the "Magnificat" assigned to her in Luke i. is the only passage which would distinctly imply on her part a high prophetic appreciation of His divine mission. She was present at the crucifixion, where she was commended by Jesus to the care of the apostle John, (John xix. 26, 27), Joseph having apparently died before this time. (It would be idle to inquire why "the brethren of the Lord," who, whatever their relationship to Mary, must at least have been nearer than John, were ignored in this arrangement.) Mary is mentioned in Acts i. 14 as having been among those who continued in prayer along with the apostles at Jerusalem during the interval between the ascension and pentecost. There is no allusion in the New Testament to the time or place of her death.

The subsequent growth of ecclesiastical tradition and belief regarding Mary will be traced most conveniently under the separate heads of (1) her perpetual virginity, (2) her absolute sinlessness, (3) her peculiar relation to the Godhead, which specially fits her for successful intercession on behalf of mankind.

Her Perpetual Virginity.—This doctrine, as has already been pointed out, was, to say the least, of no importance in the eyes of the evangelists, and so far as extant writings go there is no evidence of its having been anywhere taught within the pale of the catholic church of the first three centuries. On the contrary, to Tertullian the fact of Mary's marriage after the birth of Christ is a useful argument for the reality of the Incarnation against Gnostic notions, and Origen relies upon the references to the Lord's brethren as disproving the Docetism with which he had to contend. The ἀειπαρθενία, though very ancient, is in reality a doctrine of non-catholic origin, and first occurs in a work proscribed by the earliest papal *Index Librorum Prohibitorum* (attributed to Gelasius) as heretical,—the so-called *Protevangelium Jacobi*, written, it is generally admitted, within the 2d century. According to this very early source, which seems to have formed the basis of the later *Liber de Infantia Mariæ et Christi Salvatoris* and *Evangelium de Nativitate Mariæ*, the name of Mary's father was Joachim (in the *Liber de Infantia* a shepherd of the tribe of Judah, living in Jerusalem); he had long been married to Anna her mother, whose continued childlessness had become a cause of much humiliation and sorrow to them both. The birth of a daughter was at last angelically predicted to each parent separately. From her third to her twelfth year "Mary was in the temple as if she were a dove that dwelt there, and she received food from the hand of an angel." When she became of nubile age a guardian was sought for her by the priests among the widowers of Israel "lest she should defile the sanctuary of the Lord"; and Joseph, an elderly man with a family, was indicated for this charge by a miraculous token. Some time afterwards the annunciation took place; when the Virgin's pregnancy was discovered, Joseph and she were brought before the high priest, and, though asserting their innocence in all sincerity, were acquitted only after they had been tried with "the water of the ordeal of the Lord" (Numb. v. 11). Numerous details regarding the birth at Bethlehem are then given. The perpetual physical virginity of Mary, naively insisted upon in this apocryphon, is alluded to only with a half belief and a "some say" by Clement of Alexandria (*Strom.*, vii. 16), but became of much importance to the leaders of the church in the 4th century, as for example to Ambrose, who sees in Ezek. xliv. 1–3 a prophetic indication of so great a mystery.[2] Those who continued to believe that Mary, after the miraculous birth of Jesus, had become the mother of other children by Joseph came accordingly to be spoken of as her enemies,—Antidicomarianitæ (Epiphanius) or Antidicomaritæ (Augustine),—and the first-mentioned author devotes a whole chapter (chap. 78) of his great work upon heresies to their confutation. For holding the same view Bonosus of Sardica was condemned by the synod of Capua in 391. To Jerome the perpetual virginity not only of Mary but even of Joseph appeared of so much consequence that while a young man he wrote (387) the long and vehement tract *Against Helvidius*, in which he was the first to broach the theory (which has since gained wide currency) that the brethren of our Lord were children neither of Mary by her husband, nor of Joseph by a former marriage, but of another Mary, sister to the Virgin and wife of Clopas or Alphæus. At last the epithet of ἀεὶ παρθένος was authoritatively applied to the Virgin by the council of Chalcedon in 451, and the doctrine implied has ever since been an undisputed point of orthodoxy both in the Eastern and in the Western church, some even seeking to hold the Anglican Church committed to it on account of the general declaration (in the *Homilies*) of concurrence in the decisions of the first four general councils.

Her Absolute Sinlessness.—While much of the apocryphal literature of the early sects in which she is repeatedly spoken of as "undefiled before God" would seem to encourage some such doctrine as this, many passages from the acknowledged fathers of the church could be cited to show that it was originally quite unknown to catholicism. Even Augustine repeatedly asserts that she was born in original sin (*De Gen. ad lit.*, x. 18); and the *locus classicus* regarding her possible immunity from actual transgression, on which the subsequent doctrine of Lombardus and his commentators was based, is simply an extremely guarded passage (*De Nat. et Grat.*, chap. 36) in which, while contradicting the assertion of Pelagius that many had lived free from sin, he wishes exception to be made in favour of "the holy Virgin Mary, of whom out of honour to the Lord I wish no question to be made where sins are treated of,—for how do we know what mode of grace wholly to conquer sin may have been bestowed upon her who was found meet to conceive and bear Him of whom it is certain that He had no sin." A writer so late as Anselm (*Cur Deus Homo*, ii. 16) declares that "the Virgin herself whence He (Christ) was assumed was conceived in iniquity, and in sin did her mother conceive her, and with original sin was she born, because she too sinned in Adam in whom all sinned," and the same view was expressed by Damian. The growth of the modern Roman doctrine of the immaculate conception from the time in the 12th century when the canons of Lyons sought to institute a festival in honour of her "holy conception," and were remonstrated with by Bernard, has been already sketched elsewhere (see IMMACULATE CONCEPTION).

[1] Vol. xiii. 656 *sq.*, where (p. 659) sufficient reference is made to the coarse view of this event taken by the later hostile Judaism (a view supposed by some to be alluded to even in John viii. 41). We learn from Origen that the story about the soldier Panthera (Πανθήρα) was already upheld by Celsus. The Ebionites and other heretical sects, as is well known, maintained the paternity of Joseph.

[2] *De Inst. Virg.*, "quæ est hæc porta nisi Maria? . . . per quam Christus intravit in hunc mundum, quando virginali fusus est partu et genitalia virginitatis claustra non solvit."

The epithets applied to her in the Greek Church are such as ἀμόλυντος, πάναγνος, ἁγία; but in the East generally no clear distinction is drawn between immunity from actual sin and original sinlessness.

Her Peculiar Relation to the Godhead, which specially fits her for Successful Intercession on Behalf of Mankind.—It seems probable that the epithet θεοτόκος ("Mother of God") was first applied to Mary by theologians of Alexandria towards the close of the 3d century; but it does not occur in any genuine extant writing of that period, unless we are to assign an early date to the apocryphal *Transitus Mariæ*, in which the word is of frequent occurrence. In the 4th century it is met with frequently, being used by Eusebius, Athanasius, Didymus, and Gregory of Nazianzus,—the latter declaring that the man who believes not Mary to have been θεοτόκος has no part in God (*Orat.*, li. p. 738).[1] If, as is not unlikely, its use was first recommended by a desire to bring into prominence the divinity of the Incarnate Word, there can be no doubt that latterly the expression came to be valued as directly honourable to Mary herself and as corresponding to the greatly increased esteem in which she personally was held throughout the catholic world, so that, when Nestorius and others began to dispute its propriety in the following century, their temerity was resented, not as an attack upon the established orthodox doctrine of the Nicene creed, but as threatening a more vulnerable and more tender part of the popular faith. It is sufficient in illustration of the drift of theological opinion to refer to the first sermon of Proclus, preached on a certain festival of the Virgin (πανήγυρις παρθενική) at Constantinople about the year 430 or to that of Cyril of Alexandria delivered in the church of the Virgin Mary at the opening of the council of Ephesus in 431. In the former the orator speaks of "the holy Virgin and Mother of God" as "the spotless treasure-house of virginity, the spiritual paradise of the second Adam; the workshop in which the two natures were welded together . . . . the one bridge between God and men";[2] in the latter she is saluted as the "mother and virgin," "through whom (δι' ἧς) the Trinity is glorified and worshipped, the cross of the Saviour exalted and honoured, through whom heaven triumphs, the angels are made glad, devils driven forth, the tempter overcome, and the fallen creature raised up even to heaven." The response which such language found in the popular heart was sufficiently shown by the shouts of joy with which the Ephesian mob heard of the deposition of Nestorius, escorting his judges with torches and incense to their homes, and celebrating the occasion by a general illumination. The causes which in the course of the preceding century had led to this exaltation of the Mother of God in the esteem of the catholic world are not far to seek. On the one hand the solution of the Arian controversy, however correct it may have been theoretically, undoubtedly had the practical effect of relegating the God-man redeemer for ordinary minds into a far away region of "remote and awful Godhead," so that the need for a mediator to deal with the very Mediator could not fail to be felt. On the other hand, it must be accepted as a fact abundantly proved by history that the religious instincts of mankind are very ready to pay worship, in grosser or more refined forms, to the idea of womanhood; at all events many of those who became professing Christians at the political fall of paganism entered the church with such instincts (derived from the nature-religions in which they had been brought up) very fully developed. Probably it ought to be added that the comparative colourlessness with which the character of Mary is presented not only in the canonical gospels but even in the most copious of the apocrypha left greater scope for the untrammelled exercise of devout imagination than was possible in the case of Christ, in the circumstances of whose humiliation and in whose recorded utterances there were many things which the religious consciousness found difficulty in understanding or in adapting itself to. At all events, from the time of the council of Ephesus, to exhibit figures of the Virgin and Child became the approved expression of orthodoxy, and the relationship of motherhood in which Mary had been formally declared to stand to God[3] was instinctively felt to give the fullest and freest sanction of the church to that invocation of her aid which had previously been resorted to only hesitatingly and occasionally. Previously to the council of Ephesus, indeed, the practice had obtained complete recognition, so far as we know, in those circles only in which one or other of the numerous redactions of the *Transitus Mariæ* passed current.[4] There we read of Mary's prayer to Christ: "Do Thou bestow Thine aid upon every man calling upon, or praying to, or naming the name of Thine handmaid"; to which His answer is, "Every soul that calls upon thy name shall not be ashamed, but shall find mercy and support and confidence both in the world that now is and in that which is to come in the presence of My Father in the heavens." But Gregory of Nazianzus also, in his panegyric upon Justina, mentions with incidental approval that in her hour of peril she "implored Mary the Virgin to come to the aid of a virgin in her danger."[5] Of the growth of the Marian cultus, alike in the East and in the West, after the decision at Ephesus it would be impossible to trace the history, however slightly, within the limits of the present article. Justinian in one of his laws bespeaks her advocacy for the empire, and he inscribes the high altar in the new church of St Sophia with her name. Narses looks to her for directions on the field of battle. Heraclius bears her image on his banner. John of Damascus speaks of her as the sovereign lady to whom the whole creation has been made subject by her son. Peter Damian recognizes her as the most exalted of all creatures, and apostrophizes her as deified and endowed with all power in heaven and in earth, yet not forgetful of our race.[6] In a word, popular devotion gradually developed the entire system of doctrine and practice which Protestant controversialists are accustomed to call by the name of Mariolatry. With reference to this much-disputed phrase it is always to be kept in mind that the directly authoritative documents,

[1] See Gieseler (*KG.*, Bd. i. Abth. 1), who points out instances in which anti-Arianizing zeal went so far as to call David θεοπάτωρ, and James ἀδελφόθεος.

[2] Labbé, *Conc.*, vol. iii. p. 51. Considerable extracts are given by Augusti (*Denkw.* iii.); see also Milman (*Lat. Christ.*, i. 185), who characterizes much of it as a "wild labyrinth of untranslatable metaphor."

[3] The term θεοτόκος does not actually occur in the canons of Ephesus. It is found, however, in the creed of Chalcedon.

[4] It is true that Irenæus (*Hær.*, v. 19, 1) in the passage in which he draws his well-known parallel and contrast between the first and second Eve (comp. Justin, *Dial. c. Tryph.*, 100), to the effect that, "as the human race fell into bondage to death by a virgin, so is it rescued by a virgin," takes occasion to speak of Mary as the "advocata" of Eve; but it seems certain that this word is a translation of the Greek συνήγορος, and implies hostility and rebuke rather than advocacy.

[5] It is probable that the commemorations and invocations of the Virgin which occur in the present texts of the ancient liturgies of "St James" and "St Mark" are due to interpolation. In this connexion ought also to be noted the chapter in Epiphanius (*Hær.*, 79) against the "Collyridians," certain women in Thrace, Scythia, and Arabia, who were in the habit of worshipping the Virgin (ἀεὶ παρθένον) as a goddess, the offering of a cake (κολλυρίδα τινα) being one of the features of their worship. He rebukes them for offering the worship which was due to the Trinity alone; "let Mary be held in honour, but by no means worshipped." The cultus was probably a relic of heathenism; compare Jerem. xliv. 19.

[6] "Numquid quia ita deificata, ideo nostræ humanitatis oblita es? Nequaquam, Domina. . . . Data est tibi omnis potestas in cœlo et in terra. Nil tibi impossibile." Serm. de Nativ. Mariæ, ap. Gieseler, *KG.*, Bd. ii. Abth. 1.

alike of the Greek and of the Roman Church, distinguish formally between "latria" and "dulia," and declare that the "worship" to be paid to the mother of God must never exceed that superlative degree of "dulia" which is vaguely described as "hyperdulia." On the other hand, it must be remembered that the comparative reserve shown by the council of Trent in its decrees, and even in its catechism,[1] on this subject has not been observed by individual theologians, and in view of the fact of the canonization of some of these (such as Liguori),—a fact guaranteeing the absence of erroneous teaching from their writings,—it does not seem unfair to hold the Roman Church responsible for the natural interpretations and just inferences which may be drawn even from apparently exaggerated expressions in such works as the well-known *Glories of Mary* and others frequently quoted in controversial literature. A good résumé of recent Catholic developments of the cultus of Mary is to be found in Pusey's *Eirenicon*.

The following are the principal feasts of the Virgin in the order in which they occur in the ecclesiastical year. (1) That of the Presentation (*Præsentatio B. V. M.*, τὰ εἰσόδια τῆς θεοτόκου), to commemorate the beginning of her stay in the temple, as recorded in the *Protevangelium Jacobi* (see above). It is believed to have originated in the East sometime in the 8th century, the earliest allusion to it being made by George of Nicomedia (9th century); Manuel Comnenus made it universal for the Eastern empire, and in the modern Greek Church it is one of the five great festivals in honour of the Deipara. It was introduced into the Western Church late in the 14th century, and, after having been withdrawn from the calendar by Pius V., was restored by Sixtus V., the day observed both in East and West being November 21. It is not mentioned in the English calendar. (2) The Feast of the Conception (*Conceptio B. V. M.*, *Conceptio Immaculata B. V. M.*, σύλληψις τῆς ἁγίας Ἄννης), observed by the Roman Catholic Church on December 8, and by all the Eastern churches on December 9, has already been explained (see IMMACULATE CONCEPTION); in the Greek Church it only ranks as one of the middle festivals of Mary. (3) The Feast of the Purification (*Occursus*, *Obviatio*, *Præsentatio*, *Festum SS. Simeonis et Annæ*, *Purificatio*, *Candelaria*, ὑπαπαντή, ὑπαντή) is otherwise known as CANDLEMAS (*q.v.*). (4) The Feast of the Annunciation of the Virgin Mary (*Annunciatio*, Εὐαγγελισμός); see ANNUNCIATION. It may be mentioned that at the Toledan council in 656 it was decreed that this festival should be observed on December 18, in order to keep clear of Lent. (5) The Feast of the Visitation (*Visitatio B. V. M.*) was instituted by Urban VI., promulgated in 1389 by Boniface IX., and reappointed by the council of Basel in 1441 in commemoration of the visit paid by Mary to Elizabeth. It is observed on July 2, and has been retained in the English calendar. (6) The Feast of the Assumption (*Dormitio*, *Pausatio*, *Transitus*, *Depositio*, *Migratio*, *Assumptio*, κοίμησις, μετάστασις, ἀνάληψις) has reference to the apocryphal story related in several forms in various documents of the 4th century condemned by Pope Gelasius. Their general purport is that as the time drew nigh for "the most blessed Virgin" (who is also spoken of as "Holy Mary," "the queen of all the saints," "the holy spotless Mother of God") to leave the world, the apostles were miraculously assembled round her deathbed at Bethlehem on the Lord's day, whereupon Christ descended with a multitude of angels and received her soul. After "the spotless and precious body" had been laid in the tomb, "suddenly there shone round them (the apostles) a miraculous light," and it was taken up into heaven. The first Catholic writer who relates this story is Gregory of Tours (*c.* 590); Epiphanius two centuries earlier had declared that nothing was known as to the circumstances of Mary's death and burial; and one of the documents of the council of Ephesus implies a belief that she was buried in that city. The Sleep of the Theotokos is observed in the Greek Church as a great festival on August 15; the Armenian Church also commemorates it, but the Ethiopic Church celebrates her death and burial on two separate days. The earliest allusion to the existence of such a festival in the Western Church seems to be that found in the proceedings of the synod of Salzburg in 800; it is also spoken of in the thirty-sixth canon of the reforming synod of Mainz, held in 813. It was not, however, at that time universal, being mentioned as doubtful in the capitularies of Charlemagne. It ought to be observed that the doctrine of the bodily assumption of the Virgin into heaven, although extensively believed, and indeed flowing as natural theological consequence from that of her sinlessness, has never been declared to be "de fide" by the Church of Rome, and is still merely a "pia sententia." (7) The Nativity of Mary (*Nativitas*, γενέθλιον τῆς θεοτόκου), observed on September 8, is first mentioned in one of the homilies of Andrew of Crete (*c.* 750), and along with the feasts of the Purification, the Annunciation, and the Assumption, it was appointed to be observed by the synod of Salzburg in 800, but seems to have been quite unknown at that time in the Gallican Church, and even two centuries later it was by no means general in Italy. In the Roman Church a large number of minor festivals in honour of the Virgin are locally celebrated; and all the Saturdays of the year as well as the entire month of May are also regarded as sacred to her. (J. S. BL.)

[1] The points taught in the catechism are—that she is truly the Mother of God, and the second Eve, by whose means we have received blessing and life; that she is the Mother of Pity, and very specially our advocate; that her merits are highly exalted, and that her dispositions towards us are extremely gracious; that her images are of the utmost utility. In the *Missal* her intercessions (though alluded to in the canon and elsewhere) are seldom directly appealed to except in the Litany and in some of the later offices such as those for September 8, and for the Festival of the Seven Sorrows (decreed by Benedict XIII. in 1727). Noteworthy are the versicles in the office for December 8 (The Feast of the Immaculate Conception), "Tota pulchra es, Maria, et macula originalis non est in te," and "Gloriosa dicta sunt de te, Maria, quia fecit tibi magna qui potens est."

MARY I., queen of England (1516–1558), unpleasantly remembered as "the Bloody Mary" on account of the religious persecutions sanctioned under her reign, was a woman whose private history demands no less compassion than her policy as queen (if indeed it was her own) merits the condemnation of a more humane and tolerant age. She was the daughter of Henry VIII. and Catherine of Aragon, born in the earlier years of their married life, when as yet no cloud had darkened the prospect of Henry's reign. Her birth occurred at Greenwich on Monday the 18th February 1516, and she was baptized on the following Wednesday, Cardinal Wolsey standing as her godfather. She seems to have been a singularly precocious child, and is reported in July 1520, when she was little more than four years of age, as entertaining some visitors by a performance on the virginals. When she was little over nine she was addressed in a complimentary Latin oration by commissioners sent over from Flanders on commercial matters, and replied to them in the same language "with as much assurance and facility as if she had been twelve years old" (Gayangos, iii. pt. 1, 82). Her father, against whom it cannot be said that he depreciated learning, had taken care to give her an excellent education, and was proud of her achievements. About the same time that she replied to the commissioners in Latin he was arranging that she should learn Spanish, Italian, and French. A great part, however, of the credit of her early education was undoubtedly due to her mother, who not only consulted the Spanish scholar Vives upon the subject, but was herself Mary's first teacher in Latin. She was also well instructed in music, and among her principal recreations as she grew up was that of playing on the virginals and lute.

It was a misfortune that she shared with many other high-born ladies in those days that her prospects of life were made a matter of sordid bargaining from the first. Political alliances to be cemented by marriages between persons who were at the time mere infants—or perhaps, more shameful still, between a child and a superannuated debauchee—are among the most repulsive features of the times. Mary was little more than two years old when she was proposed in marriage to the dauphin, son of Francis I. Three years afterwards the French alliance was broken off, and she was affianced to her cousin the young emperor Charles V. by the treaty of Windsor. No one, perhaps, seriously expected either of these arrangements to endure; and, though we read in grave state papers of some curious compliments and love tokens (really the mere counters of diplomacy) professedly sent by the girl of nine to the powerful cousin whom she had never seen, not many years passed away before Charles released himself from this engagement and made a more convenient match. In 1526 a rearrangement was made of the royal household, and it was thought right to give Mary an establishment of her own along with a council on the borders of Wales, for the better government of the Marches. For some years she accordingly kept her court at Ludlow, while new arrangements were made for the disposal of her hand in connexion with the latest turn in the tortuous game of diplomacy. She was now proposed as a wife, not for the dauphin as before, but for his father Francis I., who had just been redeemed from captivity at Madrid, and who was only too glad of an alliance with England to mitigate the severe conditions imposed on him by the emperor. Wolsey, however, on this occasion, only made use of the princess as a bait to enhance the terms of the compact, and left Francis free in the end to marry the emperor's sister.

It was during this negotiation, as Henry afterwards pretended, that the question was first raised whether Henry's own marriage with Catherine was a lawful one. The bishop of Tarbes, who was one of the ambassadors sent over by Francis to ask the princess in marriage, had, it was said, started an objection that she might possibly be considered illegitimate on account of her mother having been once the wife of her father's brother. The statement was a mere pretence to shield the king when the unpopularity of the divorce became apparent. It is not only extremely improbable in itself, but is proved to be untrue by the strongest evidence, for we have pretty full contemporary records of the whole negotiation. On the contrary, it is quite clear that Henry, who had already for some time conceived the project of a divorce, kept the matter a dead secret, and was particularly anxious that the French ambassadors should not know it, while he used his daughter's hand as a bait for a new alliance. The alliance itself, however, was actually concluded by a treaty dated Westminster, the 30th April 1527, in which it was provided, as regards the Princess Mary, that she should be married either to Francis himself or to his second son Henry, duke of Orleans. But the real object was only to lay the foundation of a perfect mutual understanding between the two kings, which Wolsey soon after went into France to confirm.

During the next nine years the life of Mary, as well as that of her mother, was rendered miserable by the conduct of Henry VIII. in seeking a divorce. During the most of that period mother and daughter seem to have been kept apart, and, though sometimes living at no great distance from each other, were strictly forbidden to see each other. Of the two it may be that Queen Catherine had the hardest trial; but Mary's was scarcely less severe. Removed from court and treated as a bastard, she was, on the birth of Anne Boleyn's daughter, required to give up the dignity of princess and acknowledge the illegitimacy of her own birth. On her refusal her household was broken up, and she was sent to Hatfield to act as lady-in-waiting to her own infant sister. Nor was even this the worst of her trials; her very life was in danger from the hatred of Anne Boleyn. Her health, moreover, was indifferent, and even when she was seriously ill, although Henry sent his own physician Dr Buttes to attend her, he declined to let her mother visit her. So also at her mother's death in January 1536 she was forbidden to take a last farewell of her. But in May following another change occurred which seemed to promise some kind of relief. Anne Boleyn, the real cause of all her miseries, fell under the king's displeasure and was put to death. Mary was then urged to make a humble submission to her father as the means of recovering his favour, and, after a good deal of correspondence with the king's secretary Cromwell, she actually did so. The terms exacted of her were bitter in the extreme, but there was no chance of making life tolerable otherwise, if indeed she was permitted to live at all; and the poor friendless girl, absolutely at the mercy of a father who could brook no contradiction, at length subscribed an act of submission, acknowledging the king as supreme, repudiating the pope's authority, and confessing that the marriage between her father and mother "was by God's law and man's law incestuous and unlawful."

No act, perhaps, in the whole of Henry's reign gives us a more painful idea of his revolting despotism. Mary was a high-spirited girl, and undoubtedly popular. All Europe looked upon her at that time as the only legitimate child of her father, but her father himself compelled her to disown the title and pass an unjust stigma on her own birth and her mother's good name. Nevertheless Henry was now reconciled to her, and gave her a household in some degree suitable to her rank. During the rest of the reign we hear little about her except in connexion with a number of new marriage projects taken up and abandoned successively, one of which, to the count palatine Philip, duke of Bavaria, was specially repugnant to her in the matter of religion. Her privy purse expenses for nearly the whole of this period have been published, and show that Hatfield, Beaulieu or Newhall in Essex, Richmond, and Hunsdon were among her principal places of residence. Although she was still treated as of illegitimate birth, it was believed that the king, having obtained from parliament the extraordinary power to dispose of the crown by will, would restore her to her place in the succession, and three years before his death she was so restored by statute, but still under conditions to be regulated by her father's will.

Under the reign of her brother Edward VI. she was again subjected to severe trials, which at one time made her seriously meditate taking flight and escaping abroad. Edward himself indeed seems to have been personally not unkind to her, but the religious revolution in his reign assumed proportions such as it had not done before, and Mary, who had done sufficient violence to her own convictions in submitting to a despotic father, was not disposed to yield an equally tame obedience to authority exercised by a factious council in the name of a younger brother not yet come to years of discretion. Besides, the cause of the pope was naturally her own. In spite of the forced declaration formerly wrung from herself, no one really regarded her as a bastard, and the full recognition of her rights depended on the recognition of the pope as head of the church. Hence, when Edward's parliament passed an Act of Uniformity enjoining services in English and communion in both kinds, the law appeared to her totally void of authority, and she insisted on having mass in her own private chapel under the old form. When ordered to desist, she appealed for protection to the emperor Charles V., who, being her cousin, intervened for some time not ineffectually, threatening war with England if her religious liberty was interfered with. But Edward's court was composed of factions of which the most violent eventually carried the day. Lord Seymour, the admiral, was attainted of treason and beheaded in 1549. His brother, the Protector Somerset, met with the same fate in 1552. Dudley, duke of Northumberland, then became paramount in the privy council, and easily obtained the sanction of the young king to those schemes for altering the succession which led immediately after his death to the usurpation of Lady Jane Grey. Dudley had, in fact, overawed all the rest of the privy council, and when the event occurred he took such energetic measures to give effect to the scheme that Lady Jane was actually recognized as queen for some days, and Mary had even to fly from Hoddesden into Norfolk. But the country was really devoted to her cause, as indeed her right in law was unquestionable, and before many days she was royally received in London, and took up her abode within the Tower.

Her first acts at the beginning of her reign displayed a character very different from that which she still holds in popular estimation. Her clemency towards those who had taken up arms against her was altogether remarkable. She released from prison Lady Jane's father, Suffolk, and had difficulty even in signing the warrant for the execution of Northumberland. Lady Jane herself she fully meant to spare, and did spare till after Wyatt's formidable insurrection. Her conduct, indeed, was in every respect conciliatory and pacific, and so far as they depended on her personal character the prospects of the new reign might have appeared altogether favourable. But unfortunately her position was one of peculiar difficulty, and the policy on which she determined was far from judicious. Inexperienced in the art of governing, she had no trusty councillor but Gardiner; every other member of the council had been more or less implicated in the conspiracy against her. And though she valued Gardiner's advice she was naturally led to rely even more on that of her cousin, the emperor, who had been her mother's friend in adversity, and had done such material service to herself in the preceding reign. Following the emperor's guidance she determined almost from the first to make his son Philip her husband, though she was eleven years his senior. She was also strongly desirous of restoring the old religion and wiping out the stigma of illegitimacy passed upon her birth, so that she might not seem to reign by virtue of a mere parliamentary settlement.

Each of these different objects was attended by difficulties or objections peculiar to itself; but the marriage was the most unpopular of all. A restoration of the old religion threatened to deprive the new owners of abbey lands of their easy and comfortable acquisitions; and it was only with an express reservation of their interests that the thing was actually accomplished. A declaration of her own legitimacy necessarily cast a slur on that of her sister Elizabeth, and cut her off from the succession. But the marriage promised to throw England into the arms of Spain and place the resources of the kingdom at the command of the emperor's son. The Commons sent her a deputation to entreat that she would not marry a foreigner, and when her resolution was known insurrections broke out in different parts of the country. Suffolk, whose first rebellion had been pardoned, proclaimed Lady Jane Grey again in Leicestershire, while young Wyatt raised the county of Kent and actually besieged the queen in her own palace at Westminster. In the midst of the danger Mary showed great intrepidity, and the rebellion was presently quelled; after which, unhappily, she got leave to pursue her own course unchecked. She married Philip, restored the old religion, and got Cardinal Pole to come over and absolve the kingdom for its past disobedience to the Holy See.

But the misgivings of those who had disliked the Spanish match were more than sufficiently justified by the course of events. Mary yielded a loyal and womanly devotion to a husband who did not too greatly esteem the treasure of her person. Her health, which was feeble before, was bad for the remainder of her days, and she fell under a delusion at first that it was owing to an approaching confinement. Disappointment and vexation probably added to her helplessness. The resources of the kingdom were at Philip's command, and he even took ships of the English fleet to escort his father the emperor, on his abdication, to Spain. More extraordinary still, he ultimately succeeded in committing England to a war against France, when France had made an alliance with the pope against him as king of Spain; so the very marriage which was to confirm England in the old religion led to a war against the occupant of the see of Rome. And it was this war with France which produced the final calamity of the loss of Calais which sank so deeply into Mary's heart some months before she died.

The cruel persecution of the Protestants, which has cast so much infamy upon her reign, began about six months after her marriage; and it is not difficult to see that it was greatly due to the triumph of ideas imported from the land of the Inquisition. Rogers, the first of the martyrs, was burnt on the 4th February 1555. Hooper, bishop of Gloucester, had been condemned six days before, and suffered the same fate upon the 9th. From this time the persecution went on uninterrupted for more than three years, numbering among its victims Ridley, Latimer, and Cranmer. It seems to have been most severe in the eastern and southern parts of England, and the largest number of sufferers was naturally in the diocese of Bonner, bishop of London. From first to last nearly three hundred victims are computed to have perished at the stake; and their fate certainly created a revulsion against Rome that nothing else was likely to have effected. How far Mary herself—who during the most part of this time, if not the whole time, was living in the strictest seclusion, sick in body and mind, hysterical and helpless—was personally answerable for these things, it is difficult to say. To her, no doubt, the propagators of heresy were the enemies of mankind, and she had little cause to love them from her own experience. Yet perhaps she hardly realized the full horror of what was done under her sanction. But there can be little doubt what effect it had upon the people; and when Mary breathed her last, on the 17th November 1558, the event was hailed with joy as a national deliverance. (J. GA.)

MARY II. (1662–1694), queen of England, was the eldest daughter of James, duke of York (afterwards James II. of England), by his first wife Anne Hyde, and was born in London on April 30, 1662. Having been educated in the Protestant faith, she was married to William, prince of Orange, on November 4, 1677. After the events of 1688 she followed her husband to England, and was proclaimed by the convention joint sovereign with him on February 13, 1689. She died of small-pox on December 28, 1694 (o.s.). See Burnet's *Essay upon the Life of Queen Mary*, and the article WILLIAM III.

MARY (1542–1587), queen of Scots, daughter of King James V. and his wife Mary of Lorraine, was born in December 1542, a few days before the death of her father, heart-broken by the disgrace of his arms at Solway Moss, where the disaffected nobles had declined to encounter an enemy of inferior force in the cause of a king whose systematic policy had been directed against the privileges of their order, and whose representative on the occasion was an unpopular favourite appointed general in defiance of their ill-will. On the 9th of September following the ceremony of coronation was duly performed upon the infant. A scheme for her betrothal to Edward, prince of Wales, was defeated by the grasping greed of his father, whose obvious ambition to annex the crown of Scotland at once to that of England aroused instantly the general suspicion and indignation of Scottish patriotism. In 1548 the queen of six years old was betrothed to the dauphin Francis, and set sail for France, where she arrived on the 15th of August. The society in which the child was thenceforward reared is known to readers of Brantôme as well as that of imperial Rome at its worst is known to readers of Suetonius or Petronius,—as well as that of papal Rome at its worst is known to readers of the diary kept by the domestic chaplain of Pope Alexander VI. Only in their pages can a parallel be found to the gay and easy record which reveals without sign of shame or suspicion of offence the daily life of a court compared to which the court of King Charles II. is as the court of Queen Victoria to the society described by Grammont. Debauchery of all kinds, and murder in all forms, were the daily matter of excitement or of jest to the brilliant circle which revolved around Queen Catherine de' Medici. After ten years' training under the tutelage of the woman whose main instrument of policy was the corruption of her own children, the queen of Scots, aged fifteen years and five months, was married to the eldest and feeblest of the brood on April 24, 1558. On the 17th of November Elizabeth became queen of England, and the princes of Lorraine—Francis the great duke of Guise, and his brother the cardinal—induced their niece and her husband to assume, in addition to the arms of France and Scotland, the arms of a country over which they asserted the right of Mary Stuart to reign as legitimate heiress of Mary Tudor. Civil strife broke out in Scotland between John Knox and the queen-dowager,—between the self-styled "congregation of the Lord" and the adherents of the regent, whose French troops repelled the combined forces of the Scotch and their English allies from the beleaguered walls of Leith, little more than a month before the death of their mistress in the castle of Edinburgh, on the 10th of June 1560. On the 25th of August Protestantism was proclaimed and Catholicism suppressed in Scotland by a convention of states assembled without the assent of the absent queen. On the 5th of December Francis II. died; in August 1561 his widow left France for Scotland, having been refused a safe-conduct by Elizabeth on the ground of her own previous refusal to ratify the treaty made with England by her commissioners in the same month of the preceding year. She arrived nevertheless in safety at Leith, escorted by three of her uncles of the house of Lorraine, and bringing in her train her future biographer, Brantôme, and Chastelard, the first of all her voluntary victims. On the 21st of August she first met the only man able to withstand her; and their first passage of arms left, as he has recorded, upon the mind of John Knox an ineffaceable impression of her "proud mind, crafty wit, and indurate heart against God and His truth." And yet her acts of concession and conciliation were such as no fanatic on the opposite side could have approved. She assented, not only to the undisturbed maintenance of the new creed, but even to a scheme for the endowment of the Protestant ministry out of the confiscated lands of the Church. Her half-brother, Lord James Stuart, shared the duties of her chief counsellor with William Maitland of Lethington, the keenest and most liberal thinker in the country. By the influence of Lord James, in spite of the earnest opposition of Knox, permission was obtained for her to hear mass celebrated in her private chapel,—a licence to which, said the Reformer, he would have preferred the invasion of ten thousand Frenchmen. Through all the first troubles of her reign the young queen steered her skilful and dauntless way with the tact of a woman and the courage of a man. An insurrection in the north, headed by the earl of Huntly under pretext of rescuing from justice the life which his son had forfeited by his share in a homicidal brawl, was crushed at a blow by the Lord James against whose life, as well as against his sister's liberty, the conspiracy of the Gordons had been aimed, and on whom, after the father had fallen in fight and the son had expiated his double offence on the scaffold, the leading rebel's earldom of Murray was conferred by the gratitude of the queen. Exactly four months after the battle of Corrichie, and the subsequent execution of a criminal whom she is said to have "loved entirely," had put an end to the first insurrection raised against her, Pierre de Boscosel de Chastelard, who had returned to France with the other companions of her arrival, and in November 1562 had revisited Scotland, expiated with his head the offence or the misfortune of a second detection at night in her bed-chamber. In the same month, twenty-five years afterwards, the execution of his mistress, according to the verdict of her contemporaries in France, avenged the blood of a lover who had died without uttering a word to realize the apprehension which (according to Knox) had before his trial impelled her to desire her brother "that, as he loved her, he would slay Chastelard, and let him never speak word." And in the same month, two years from the date of Chastelard's execution, her first step was unconsciously taken on the road to Fotheringay, when she gave her heart at first sight to her kinsman Henry, Lord Darnley, son of Matthew Stuart, earl of Lennox, who had suffered an exile of twenty years in expiation of his intrigues with England, and had married the niece of King Henry VIII., daughter of his sister Margaret, the widow of James IV., by her second husband, the earl of Angus. Queen Elizabeth, with the almost incredible want of tact or instinctive delicacy which distinguished and disfigured her vigorous intelligence, had recently proposed as a suitor to the queen of Scots her own low-born favourite, Lord Robert Dudley, the widower if not the murderer of Amy Robsart; and she now protested against the project of marriage between Mary and Darnley. Mary, who had already married her kinsman in secret at Stirling Castle with Catholic rites celebrated in the apartment of David Rizzio, her secretary for correspondence with France, assured the English ambassador, in reply to the protest of his mistress, that the marriage would not take place for three months, when a dispensation from the pope would allow the cousins to be publicly united without offence to the church. On the 29th of July 1565 they were accordingly remarried at Holyrood. The hapless and worthless bridegroom had already incurred the hatred of two powerful enemies, the earls of Morton and Glencairn; but the former of these took part with the queen against the forces raised by Murray, Glencairn, and others, under the nominal leadership of Hamilton, duke of Chatelherault, on the double plea of danger to the new religion of the country, and of the illegal proceeding by which Darnley had been proclaimed king of Scots without the needful constitutional assent of the estates of the realm. Murray was cited to attend the "raid" or array levied by the king and queen, and was duly denounced by public blast of trumpet for his non-appearance. He entered Edinburgh with his forces, but failed to hold the town against the guns of the castle, and fell back upon Dumfries before the advance of the royal army, which was now joined by James Hepburn, earl of Bothwell, on his return from a three years' outlawed exile in France. He had been accused in 1562 of a plot to seize the queen and put her into the keeping of the earl of Arran, whose pretensions to her hand ended only when his insanity could no longer be concealed. Another new adherent was the son of the late earl of Huntly, to whom the forfeited honours of his house were restored a few months before the marriage of his sister to Bothwell. The queen now appealed to France for aid; but Castelnau, the French ambassador, replied to her passionate pleading by sober and earnest advice to make peace with the malcontents. This counsel was rejected, and in October 1565 the queen marched an army of 18,000 men against them from Edinburgh; their forces dispersed in face of superior numbers, and Murray, on seeking shelter in England, was received with contumely by Elizabeth, whose half-hearted help had failed to support his enterprise, and whose intercession for his return found at first no favour with the queen of Scots. But the conduct of the besotted boy on whom at their marriage she had bestowed the title of king began at once to justify the enterprise and to play into the hands of all his enemies alike. His father set him on to demand the crown matrimonial, which would at least have assured to him the rank and station of independent royalty for life. Rizzio, hitherto his friend and advocate, induced the queen to reply by a reasonable refusal to this hazardous and audacious request. Darnley at once threw himself into the arms of the party opposed to the policy of the queen and her secretary,—a policy which at that moment was doubly and trebly calculated to exasperate the fears of the religious and the pride of the patriotic. Mary was invited if not induced by the king of Spain to join his league for the suppression of Protestantism; while the actual or prospective endowment of Rizzio with Morton's office of chancellor, and the projected attainder of Murray and his allies, combined to inflame at once the anger and the apprehension of the Protestant nobles. According to one account, Darnley privately assured his uncle George Douglas of his wife's infidelity; he had himself, if he might be believed, discovered the secretary in the queen's apartment at midnight, under circumstances yet more unequivocally compromising than those which had brought Chastelard to the scaffold. Another version of the pitiful history represents Douglas as infusing suspicion of Rizzio into the empty mind of his nephew, and thus winning his consent to a deed already designed by others. A bond was drawn in which Darnley pledged himself to support the confederates who undertook to punish "certain privy persons" offensive to the state, "especially a stranger Italian called Davie"; another was subscribed by Darnley and the banished lords, then biding their time in Newcastle, which engaged him to procure their pardon and restoration, while pledging them to ensure to him the enjoyment of the title he coveted, with the consequent security of an undisputed succession to the crown, despite the counter claims of the house of Hamilton, in case his wife should die without issue,—a result which, intentionally or not, he and his fellow conspirators did all that brutality could have suggested to accelerate and secure. On the 9th of March the palace of Holyrood was invested by a troop under the command of Morton, while Rizzio was dragged by force out of the queen's presence and slain without trial in the heat of the moment. The parliament was discharged by proclamation issued in the name of Darnley as king; and in the evening of the next day the banished lords, whom it was to have condemned to outlawry, returned to Edinburgh. On the day following they were graciously received by the queen, who undertook to sign a bond for their security, but delayed the subscription till next morning under plea of sickness. During the night she escaped with Darnley, whom she had already seduced from the party of his accomplices, and arrived at Dunbar on the third morning after the slaughter of her favourite. From thence they returned to Edinburgh on the 28th of March, guarded by two thousand horsemen under the command of Bothwell, who had escaped from Holyrood on the night of the murder, to raise a force on the queen's behalf with his usual soldierly promptitude. The slayers of Rizzio fled to England, and were outlawed; Darnley was permitted to protest his innocence and denounce his accomplices; after which he became the scorn of all parties alike, and few men dared or cared to be seen in his company. On the 19th of June a son was born to his wife, and in the face of his previous protestations he was induced to acknowledge himself the father. But, as Murray and his partisans returned to favour and influence no longer incompatible with that of Bothwell and Huntly, he grew desperate enough with terror to dream of escape to France. This design was at once frustrated by the queen's resolution. She summoned him to declare his reasons for it in presence of the French ambassador and an assembly of the nobles; she besought him for God's sake to speak out, and not spare her; and at last he left her presence with an avowal that he had nothing to allege. The favour shown to Bothwell had not yet given occasion for scandal, though his character as an adventurous libertine was as notable as his reputation for military hardihood; but as the summer advanced his insolence increased with his influence at court and the general aversion of his rivals. He was richly endowed by Mary from the greater and lesser spoils of the church; and the three wardenships of the border, united for the first time in his person, gave the lord high admiral of Scotland a position of unequalled power. In the gallant discharge of its duties he was dangerously wounded by a leading outlaw, whom he slew in single combat; and while yet confined to Hermitage Castle he received a visit of two hours from the queen, who rode thither from Jedburgh and back through 20 miles of the wild borderland, where her person was in perpetual danger from the freebooters whom her father's policy had striven and had failed to extirpate. The result of this daring ride was a ten days' fever, after which she removed by short stages to Craigmillar, where a proposal for her divorce from Darnley was laid before her by Bothwell, Murray, Huntly, Argyle, and Lethington, who was chosen spokesman for the rest. She assented on condition that the divorce could be lawfully effected without impeachment of her son's legitimacy; whereupon Lethington undertook in the name of all present that she should be rid of her husband without any prejudice to the child,—at whose baptism a few days afterwards Bothwell took the place of the putative father, though Darnley was actually residing under the same roof, and it was not till after the ceremony that he was suddenly struck down by a sickness so violent as to excite suspicions of poison. He was removed to Glasgow, and left for the time in charge of his father; but on the news of his progress towards recovery a bond was drawn up for execution of the sentence of death which had secretly been pronounced against the twice-turned traitor who had earned his doom at all hands alike. On the 22d of the next month (January 1567) the queen visited her husband at Glasgow and proposed to remove him to Craigmillar Castle, where he would have the benefit of medicinal baths; but instead of this resort he was conveyed on the last day of the month to the lonely and squalid shelter of the residence which was soon to be made memorable by his murder. Between the ruins of two sacred buildings, with the town-wall to the south and a suburban hamlet known to ill fame as the Thieves' Row to the north of it, a lodging was prepared for the titular king of Scotland, and fitted up with tapestries taken from the Gordons after the battle of Corrichie. On the evening of Sunday, February 9, Mary took her last leave of the miserable boy who had so often and so mortally outraged her as consort and as queen. That night the whole city was shaken out of sleep by an explosion of gunpowder which shattered to fragments the building in which he should have slept and perished; and next morning the bodies of Darnley and a page were found strangled in a garden adjoining it, whither they had apparently escaped over a wall, to be despatched by the hands of Bothwell's attendant confederates.

Upon the view which may be taken of Mary's conduct during the next three months depends the whole debatable question of her character. According to the professed champions of that character, this conduct was a tissue of such dastardly imbecility, such heartless irresolution, and such brainless inconsistency as for ever to dispose of her time-honoured claim to the credit of intelligence and courage. It is certain that just three months and six days after the murder of her husband she became the wife of her husband's murderer. On the 11th of February she wrote to the bishop of Glasgow, her ambassador in France, a brief letter of simple eloquence, announcing her providential escape from a design upon her own as well as her husband's life. A reward of two thousand pounds was offered by proclamation for discovery of the murderer. Bothwell and others, his satellites or the queen's, were instantly placarded by name as the criminals. Voices were heard by night in the streets of Edinburgh calling down judgment on the assassins. Four days after the discovery of the bodies, Darnley was buried in the chapel of Holyrood with secrecy as remarkable as the solemnity with which Rizzio had been interred there less than a year before. On the Sunday following, Mary left Edinburgh for Seton Palace, 12 miles from the capital, where scandal asserted that she passed the time merrily in shooting-matches with Bothwell for her partner against Lords Seton and Huntly; other accounts represent Huntly and Bothwell as left at Holyrood in charge of the infant prince. Gracefully and respectfully, with statesmanlike yet feminine dexterity, the demands of Darnley's father for justice on the murderers of his son were accepted and eluded by his daughter-in-law. Bothwell, with a troop of fifty men, rode through Edinburgh defiantly denouncing vengeance on his concealed accusers. As weeks elapsed without action on the part of the royal widow, while the cry of blood was up throughout the country, raising echoes from England and abroad, the murmur of accusation began to rise against her also. Murray, with his sister's ready permission, withdrew to France. Already the report was abroad that the queen was bent on marriage with Bothwell, whose last year's marriage with the sister of Huntly would be dissolved, and the assent of his wife's brother purchased by the restitution of his forfeited estates. According to the *Memoirs* of Sir James Melville, both Lord Herries and himself resolved to appeal to the queen in terms of bold and earnest remonstrance against so desperate and scandalous a design; Herries, having been met with assurances of its unreality and professions of astonishment at the suggestion, instantly fled from court; Melville, evading the danger of a merely personal protest without backers to support him, laid before Mary a letter from a loyal Scot long resident in England, which urged upon her consideration and her conscience the danger and disgrace of such a project yet more freely than Herries had ventured to do by word of mouth; but the sole result was that it needed all the queen's courage and resolution to rescue him from the violence of the man for whom, she was reported to have said, she cared not if she lost France, England, and her own country, and would go with him to the world's end in a white petticoat before she would leave him. On the 28th of March the privy council, in which Bothwell himself sat, appointed the 12th of April as the day of his trial, Lennox, instead of the crown, being named as the accuser, and cited by royal letters to appear at "the humble request and petition of the said Earl Bothwell," who, on the day of the trial, had four thousand armed men behind him in the streets, while the castle was also at his command. Under these arrangements it was not thought wonderful that Lennox discreetly declined the danger of attendance, even with three thousand men ready to follow him, at the risk of desperate street fighting. He pleaded sickness, asked for more time, and demanded that the accused, instead of enjoying special favour, should share the treatment of other suspected criminals. But, as no particle of evidence on his side was advanced, the protest of his representative was rejected, and Bothwell, acquitted in default of witnesses against him, was free to challenge any persistent accuser to the ancient ordeal of battle. His wealth and power were enlarged by gift of the parliament which met on the 14th and rose on the 19th of April,—a date made notable by the subsequent supper at Ainslie's tavern, where Bothwell obtained the signatures of its leading members to a document affirming his innocence, and pledging the subscribers to maintain it against all challengers, to stand by him in all his quarrels, and finally to promote by all means in their power the marriage by which they recommended the queen to reward his services and benefit the country. On the second day following Mary went to visit her child at Stirling, where his guardian, the earl of Mar, refused to admit more than two women in her train. It was well known in Edinburgh that Bothwell had a body of men ready to intercept her on the way back, and carry her to Dunbar,—not, as was naturally inferred, without good assurance of her consent. On the 24th of April, as she approached Edinburgh, Bothwell accordingly met her at the head of eight hundred spearmen, assured her (as she afterwards averred) that she was in the utmost peril, and escorted her, together with Huntly, Lethington, and Melville, who were then in attendance, to Dunbar Castle. On the 3d of May Lady Jane Gordon, who had become countess of Bothwell on February 22d of the year preceding, obtained, on the ground of her husband's infidelities, a separation which, however, would not under the old laws of Catholic Scotland have left him free to marry again; on the 7th, accordingly, the necessary divorce was pronounced, after two days' session, by a clerical tribunal which ten days before had received from the queen a special commission to give judgment on a plea of somewhat apocryphal consanguinity alleged by Bothwell as the ground of an action for divorce against his wife. The fact was studiously evaded or concealed that a dispensation had been granted by the archbishop of St Andrews for this irregularity, which could only have arisen through some illicit connexion of the husband with a relative of the wife between whom and himself no affinity by blood or marriage could be proved. On the day when the first or Protestant divorce was pronounced, Mary and Bothwell returned to Edinburgh with every prepared appearance of a peaceful triumph. Lest her captivity should have been held to invalidate the late legal proceedings in her name, proclamation was made of forgiveness accorded by the queen to her captor in consideration of his past and future services, and her intention was announced to reward them by further promotion; and on the same day (May 12th) he was duly created duke of Orkney and Shetland. The duke, as a conscientious Protestant, refused to marry his mistress according to the rites of her church; and she, the chosen champion of its cause, agreed to be married to him, not merely by a Protestant, but by one who before his conversion had been a Catholic bishop, and should therefore have been more hateful and contemptible in her eyes than any ordinary heretic, had not religion as well as policy, faith as well as reason, been absorbed or superseded by some more mastering passion or emotion. This passion or emotion, according to those who deny her attachment to Bothwell, was simply terror,—the blind and irrational prostration of an abject spirit before the cruel force of circumstances and the crafty wickedness of men. Hitherto, according to all evidence, she had shown herself on all occasions, as on all subsequent occasions she indisputably showed herself, the most fearless, the most keen-sighted, the most ready-witted, the most high-gifted and high-spirited of women; gallant and generous, skilful and practical, never to be cowed by fortune, never to be cajoled by craft; neither more unselfish in her ends nor more unscrupulous in her practice than might have been expected from her training and her creed. But at the crowning moment of trial there are those who assert their belief that the woman who on her way to the field of Corrichie had uttered her wish to be a man, that she might know all the hardship and all the enjoyment of a soldier's life, riding forth "in jack and knapscull"—the woman who long afterwards was to hold her own for two days together without help of counsel against all the array of English law and English statesmanship, armed with irrefragable evidence and supported by the resentment of a nation—showed herself equally devoid of moral and of physical resolution; too senseless to realize the significance and too heartless to face the danger of a situation from which the simplest exercise of reason, principle, or courage must have rescued the most unsuspicious and inexperienced of honest women who was not helplessly deficient in self-reliance and self-respect. The famous correspondence produced next year in evidence against her at the conference of York may have been, as her partisans affirm, so craftily garbled and falsified by interpolation, suppression, perversion, or absolute forgery as to be all but historically worthless. Its acceptance or its rejection does not in any degree whatever affect, for better or for worse, the rational estimate of her character. The problem presented by the simple existence of the facts just summed up remains in either case absolutely the same.

That the coarse and imperious nature of the hardy and able ruffian who had now become openly her master should no less openly have shown itself even in the first moments of their inauspicious union is what any bystander of common insight must inevitably have foreseen. Tears, dejection, and passionate expressions of a despair "wishing only for death," bore fitful and variable witness to her first sense of a heavier yoke than yet had galled her spirit and her pride. At other times her affectionate gaiety would give evidence as trustworthy of a fearless and improvident satisfaction. They rode out in state together, and if he kept cap in hand as a subject she would snatch it from him and clap it on his head again; while in graver things she took all due or possible care to gratify his ambition, by the insertion of a clause in their contract of marriage which made their joint signature necessary to all documents of state issued under the sign-manual. She despatched to France a special envoy, the bishop of Dumblane, with instructions setting forth at length the unparalleled and hitherto ill-requited services and merits of Bothwell, and the necessity of compliance at once with his passion and with the unanimous counsel of the nation,—a people who would endure the rule of no foreign consort, and whom none of their own countrymen were so competent to control, alike by wisdom and by valour, as the incomparable subject of her choice. These personal merits and this political necessity were the only pleas advanced in a letter to her ambassador in England. But that neither plea would avail her for a moment in Scotland she had ominous evidence on the thirteenth day after her marriage, when no response was made to the usual form of proclamation for a raid or levy of forces under pretext of a campaign against the rievers of the border. On the 6th or 7th of June Mary and Bothwell took refuge in Borthwick Castle, twelve miles from the capital, where the fortress was in the keeping of an adherent whom the diplomacy of Sir James Melville had succeeded in detaching from his allegiance to Bothwell. The fugitives were pursued and beleaguered by the earl of Morton and Lord Hume, who declared their purpose to rescue the queen from the thraldom of her husband. He escaped, leaving her free to follow him or to join the party of her professed deliverers. But whatever cause she might have found since marriage to complain of his rigorous custody and domineering brutality was insufficient to break the ties by which he held her. Alone, in the disguise of a page, she slipped out of the castle at midnight, and rode off to meet him at a tower two miles distant, whence they fled together to Dunbar. The confederate lords on entering Edinburgh were welcomed by the citizens, and after three hours' persuasion Lethington, who had now joined them, prevailed on the captain of the castle to deliver it also into their hands. Proclamations were issued in which the crime of Bothwell was denounced, and the disgrace of the country, the thraldom of the queen, and the mortal peril of her infant son were set forth as reasons for summoning all the lieges of the chief cities of Scotland to rise in arms on three hours' notice and join the forces assembled against the one common enemy. News of his approach reached them on the night of June 14, and they marched before dawn with 2200 men to meet him near Musselburgh. Mary meanwhile had passed from Dunbar to Haddington, and thence to Seton, where 1600 men rallied to her side. On the 15th of June, one month from their marriage day, the queen and Bothwell, at the head of a force of fairly equal numbers but visibly inferior discipline, met the army of the confederates at Carberry Hill, some six miles from Edinburgh. Du Croc, the French ambassador, obtained permission through the influence of Maitland to convey to the queen the terms proposed by their leaders,—that she and Bothwell should part, or that he should meet in single combat a champion chosen from among their number. Bothwell offered to meet any man of sufficient quality; Mary would not assent. As the afternoon wore on their force began to melt away by desertion and to break up for lack of discipline. Again the trial by single combat was proposed, and thrice the proposal fell through, owing to objections on this side or on that. At last it was agreed that the queen should yield herself prisoner, and Bothwell be allowed to retire in safety to Dunbar with the few followers who remained to him. Mary took leave of her first and last master with passionate anguish and many parting kisses; but in face of his enemies, and in hearing of the cries which burst from the ranks, demanding her death by fire as a murderess and harlot, the whole heroic and passionate spirit of the woman represented by her admirers as a spiritless imbecile flamed out in responsive threats to have all the men hanged and crucified, in whose power she now stood helpless and alone. She grasped the hand of Lord Lindsay as he rode beside her, and swore "by this hand" she would "have his head for this." In Edinburgh she was received by a yelling mob, which flaunted before her at each turn a banner representing the corpse of Darnley with her child beside it invoking on his knees the retribution of Divine justice. From the violence of a multitude in which women of the worst class were more furious than the men she was sheltered in the house of the provost, where she repeatedly showed herself at the window, appealing aloud with dishevelled hair and dress to the mercy which no man could look upon her and refuse. At nine in the evening she was removed to Holyrood, and thence to the port of Leith, where she embarked under guard, with her attendants, for the island castle of Lochleven. On the 20th a silver casket containing letters and French verses, miscalled sonnets, in the handwriting of the queen, was taken from the person of a servant who had been sent by Bothwell to bring it from Edinburgh to Dunbar. Even in the existing versions of the letters, translated from the lost originals and retranslated from this translation of a text which was probably destroyed in 1603 by order of King James on his accession to the English throne,—even in these possibly disfigured versions, the fiery pathos of passion, the fierce and piteous fluctuations of spirit between love and hate, hope and rage and jealousy, have an eloquence apparently beyond the imitation or invention of art. Three days after this discovery Lord Lindsay, Lord Ruthven, and Sir Robert Melville were despatched to

Lochleven, there to obtain the queen's signature to an act of abdication in favour of her son, and another appointing Murray regent during his minority. She submitted, and a commission of regency was established till the return from France of Murray, who, on the 15th of August, arrived at Lochleven with Morton and Athole. According to his own account, the expostulations as to her past conduct which preceded his admonitions for the future were received with tears, confessions, and attempts at extenuation or excuse; but when they parted next day on good terms she had regained her usual spirits. Nor from that day forward had they reason to sink again, in spite of the close keeping in which she was held, with the daughters of the house for bedfellows. Their mother and the regent's, her father's former mistress, was herself not impervious to her prisoner's lifelong power of seduction and subjugation. Her son George Douglas fell inevitably under the charm. A rumour transmitted to England went so far as to assert that she had proposed him to their common half-brother Murray as a fourth husband for herself; a later tradition represented her as the mother of a child by him. A third report, at least as improbable as either, asserted that a daughter of Mary and Bothwell, born about this time, lived to be a nun in France. It is certain that the necessary removal of George Douglas from Lochleven enabled him to devise a method of escape for the prisoner on March 25, 1568, which was frustrated by detection of her white hands under the disguise of a laundress. But a younger member of the household, Willie Douglas, aged eighteen, whose devotion was afterwards remembered and his safety cared for by Mary at a time of utmost risk and perplexity to herself, succeeded on May 2d in assisting her to escape by a postern gate to the lake-side, and thence in a boat to the mainland, where George Douglas, Lord Seton, and others were awaiting her. Thence they rode to Seton's castle of Niddry, and next day to Hamilton Palace, round which an army of 6000 men was soon assembled, and whither the new French ambassador to Scotland hastened to pay his duty. The queen's abdication was revoked, messengers were despatched to the English and French courts, and word was sent to Murray at Glasgow that he must resign the regency, and should be pardoned in common with all offenders against the queen. But on the day when Mary arrived at Hamilton Murray had summoned to Glasgow the feudatories of the crown, to take arms against the insurgent enemies of the infant king. Elizabeth sent conditional offers of help to her kinswoman, provided she would accept of English intervention and abstain from seeking foreign assistance; but the messenger came too late. Mary's followers had failed to retake Dunbar Castle from the regent, and made for Dumbarton instead, marching two miles south of Glasgow, by the village of Langside. Here Murray, with 4500 men, under leaders of high distinction, met the 6000 of the queen's army, whose ablest man, Herries, was as much distrusted by Mary as by every one else, while the Hamiltons could only be trusted to think of their own interests, and were suspected of treasonable designs on all who stood between their house and the monarchy. On the 13th of May the battle or skirmish of Langside determined the result of the campaign in three quarters of an hour. Kirkaldy of Grange, who commanded the regent's cavalry, seized and kept the place of vantage from the beginning, and at the first sign of wavering on the other side shattered at a single charge the forces of the queen, with a loss of one man to three hundred. Mary fled 60 miles from the field of her last battle before she halted at Sanquhar, and for three days of flight, according to her own account, had to sleep on the hard ground, live on oatmeal and sour milk, and fare at night like the owls, in hunger, cold, and fear. On the third day from the rout of Langside she crossed the Solway, and landed at Workington in Cumberland, May 16, 1568. On the 20th Lord Scrope and Sir Francis Knollys were sent from court to carry messages and letters of comfort from Elizabeth to Mary at Carlisle. On June 11th Knollys wrote to Cecil at once the best description and the noblest panegyric extant of the queen of Scots,—enlarging, with a brave man's sympathy, on her indifference to form and ceremony, her daring grace and openness of manner, her frank display of a great desire to be avenged of her enemies, her readiness to expose herself to all perils in hope of victory, her delight to hear of hardihood and courage, commending by name all her enemies of approved valour, sparing no cowardice in her friends, but above all things athirst for victory by any means at any price, so that for its sake pain and peril seemed pleasant to her, and wealth and all things, if compared with it, contemptible and vile. What was to be done with such a princess, whether she were to be nourished in one's bosom, above all whether it could be advisable or safe to try any diplomatic tricks upon such a lady, Knollys left for the minister to judge. It is remarkable that he should not have discovered in her the qualities so obvious to modern champions of her character,—easiness, gullibility, incurable innocence and invincible ignorance of evil, incapacity to suspect or resent anything, readiness to believe and forgive all things. On the 15th of July, after various delays interposed by her reluctance to leave the neighbourhood of the border, where on her arrival she had received the welcome and the homage of the leading Catholic houses of Northumberland and Cumberland, she was removed to Bolton Castle in North Yorkshire. During her residence here a conference was held at York between her own and Elizabeth's commissioners and those appointed to represent her son as king of Scots. These latter, of whom Murray himself was the chief, privately laid before the English commissioners the contents of the famous casket. On the 24th of October the place of the conference was shifted from York to London, where the inquiry was to be held before Queen Elizabeth in council. Mary was already aware that the chief of the English commissioners, the duke of Norfolk, was secretly an aspirant to the peril of her hand; and on October 21st she gave the first sign of assent to the suggestion of a divorce from Bothwell. On the 26th of October the charge of complicity in the murder of Darnley was distinctly brought forward against her in spite of Norfolk's reluctance and Murray's previous hesitation. Elizabeth, by the mouth of her chief justice, formally rebuked the audacity of the subjects who durst bring such a charge against their sovereign, and challenged them to advance their proofs. They complied by the production of an indictment under five heads, supported by the necessary evidence of documents. The number of English commissioners was increased, and they were bound to preserve secrecy as to the matters revealed. Further evidence was supplied by Thomas Crawford, a retainer of the house of Lennox, tallying so exactly with the text of the casket letters as to have been cited in proof that the latter must needs be a forgery. Elizabeth, on the close of the evidence, invited Mary to reply to the proofs alleged before she could be admitted to her presence; but Mary simply desired her commissioners to withdraw from the conference. She declined with scorn the proposal made by Elizabeth through Knollys, that she should sign a second abdication in favour of her son. On January 10, 1569, the judgment given at the conference acquitted Murray and his adherents of rebellion, while affirming that nothing had been proved against Mary,—a verdict accepted by Murray as equivalent to a practical recognition of his office as regent for the infant king. This position he was not long to hold; and the fierce exultation of Mary at the news of his murder gave to those who believed in her complicity with the murderer, on whom a pension was bestowed by her unblushing gratitude, fresh reason to fear, if her liberty of correspondence and intrigue were not restrained, the likelihood of a similar fate for Elizabeth. On January 26, 1569, she had been removed from Bolton Castle to Tutbury in Staffordshire, where proposals were conveyed to her, at the instigation of Leicester, for a marriage with the duke of Norfolk, to which she gave a graciously conditional assent; but the discovery of these proposals consigned Norfolk to the Tower, and on the outbreak of an insurrection in the north Mary, by Lord Hunsdon's advice, was again removed to Coventry, when a body of her intending deliverers was within a day's ride of Tutbury. On the 23d of January following Murray was assassinated; and a second northern insurrection was crushed in a single sharp fight by Lord Hunsdon. In October Cecil had an interview with Mary at Chatsworth, when the conditions of her possible restoration to the throne in compliance with French demands were debated at length. The queen of Scots, with dauntless dignity, refused to yield the castles of Edinburgh and Dumbarton into English keeping, or to deliver up her fugitive English partisans then in Scotland; upon other points they came to terms, and the articles were signed October 16. On the same day Mary wrote to Elizabeth, requesting with graceful earnestness the favour of an interview which might reassure her against the suggestion that this treaty was a mere pretence. On November 28 she was removed to Sheffield Castle, where she remained for the next fourteen years in charge of the earl of Shrewsbury. The detection of a plot, in which Norfolk was implicated, for the invasion of England by Spain on behalf of Mary, who was then to take him as the fourth and most contemptible of her husbands, made necessary the reduction of her household and the stricter confinement of her person. On May 28, 1572, a demand from both houses of parliament for her execution as well as Norfolk's was generously rejected by Elizabeth; but after the punishment of the traitorous pretender to her hand, on whom she had lavished many eloquent letters of affectionate protestation, she fell into "a passion of sickness" which convinced her honest keeper of her genuine grief for the ducal caitiff. A treaty projected on the news of the massacre of St Bartholomew, by which Mary should be sent back to Scotland for immediate execution, was broken off by the death of the earl of Mar, who had succeeded Lennox as regent; nor was it found possible to come to acceptable terms on a like understanding with his successor Morton, who in 1577 sent a proposal to Mary for her restoration, which she declined, in suspicion of a plot laid to entrap her by the policy of Sir Francis Walsingham, the most unscrupulously patriotic of her English enemies, who four years afterwards sent word to Scotland that the execution of Morton, so long the ally of England, would be answered by the execution of Mary. But on that occasion Elizabeth again refused her assent either to the trial of Mary or to her transference from Sheffield to the Tower. In 1581 Mary accepted the advice of Catherine de' Medici and Henry III. that she should allow her son's title to reign as king of Scotland conjointly with herself when released and restored to a share of the throne. This plan was but part of a scheme including the invasion of England by her kinsman the duke of Guise, who was to land in the north and raise a Scottish army to place the released prisoner of Sheffield beside her son on the throne of Elizabeth. After the overthrow of the Scottish accomplices in this notable project, Mary poured forth upon Elizabeth a torrent of pathetic and eloquent reproach for the many wrongs she had suffered at the hands of her hostess, and pledged her honour to the assurance that she now aspired to no kingdom but that of heaven. In the spring of 1583 she retained enough of this saintly resignation to ask for nothing but liberty, without a share in the government of Scotland; but Lord Burghley not unreasonably preferred, if feasible, to reconcile the alliance of her son with the detention of his mother. In 1584 the long-suffering earl of Shrewsbury was relieved of his fourteen years' charge through the involuntary good offices of his wife, whose daughter by her first husband had married a brother of Darnley; and their orphan child Arabella, born in England, of royal descent on the father's side, was now, in the hopeful view of her grandmother, a more plausible claimant than the king or queen of Scots to the inheritance of the English throne. In December 1583 Mary had laid before the French ambassador her first complaint of the slanders spread by Lady Shrewsbury and her sons, who were ultimately compelled to confess the falsehood of their imputations on the queen of Scots and her keeper. It was probably at the time when a desire for revenge on her calumniatress made her think the opportunity good and safe for discharge of such a two-edged dart at the countess and the queen that Mary wrote, but abstained from despatching, the famous and terrible letter in which, with many gracious excuses and professions of regret and attachment, she transmits to Elizabeth a full and vivid report of the hideous gossip retailed by Bess of Hardwick regarding her character and person at a time when the reporter of these abominations was on friendly terms with her husband's royal charge. In the autumn of 1584 she was removed to Wingfield Manor under charge of Sir Ralph Sadler and John Somers, who accompanied her also on her next removal to Tutbury in January 1585. A letter received by her in that cold, dark, and unhealthy castle, of which fifteen years before she had made painful and malodorous experience, assured her that her son would acknowledge her only as queen-mother, and provoked at once the threat of a parent's curse and an application to Elizabeth for sympathy. In April 1585 Sir Amyas Paulet was appointed to the office of which Sadler, accused of careless indulgence, had requested to be relieved; and on Christmas Eve she was removed from the hateful shelter of Tutbury to the castle of Chartley in the same county. Her correspondence in cipher from thence with her English agents abroad, intercepted by Walsingham and deciphered by his secretary, gave eager encouragement to the design for a Spanish invasion of England under the prince of Parma,—an enterprise in which she would do her utmost to make her son take part, and in case of his refusal would induce the Catholic nobles of Scotland to betray him into the hands of Philip, from whose tutelage he should be released only on her demand, or if after her death he should wish to return, nor then unless he had become a Catholic. But even these patriotic and maternal schemes to consign her child and reconsign the kingdom to the keeping of the Inquisition, incarnate in the widower of Mary Tudor, were superseded by the attraction of a conspiracy against the throne and life of Elizabeth. Anthony Babington, in his boyhood a ward of Shrewsbury, resident in the household at Sheffield Castle, and thus subjected to the charm before which so many victims had already fallen, was now induced to undertake the deliverance of the queen of Scots by the murder of the queen of England. It is maintained by those admirers of Mary who assume her to have been an almost absolute imbecile, gifted with the power of imposing herself on the world as a woman of unsurpassed ability, that, while cognizant of the plot for her deliverance by English rebels and an invading army of foreign auxiliaries, she might have been innocently unconscious that this conspiracy involved the simultaneous assassination of Elizabeth. In the conduct and detection of her correspondence with Babington, traitor was played off against traitor, and spies were utilized against assassins, with as little scruple as could be required or expected in the diplomacy of the time. As in the case of the casket letters, it is alleged that forgery was employed to interpolate sufficient evidence of Mary's complicity in a design of which it is thought credible that she was kept in ignorance by the traitors and murderers who had enrolled themselves in her service,—that one who pensioned the actual murderer of Murray and a would-be murderer of Elizabeth was incapable of approving what her keen and practised intelligence was too blunt and torpid to anticipate as inevitable and inseparable from the general design. In August the conspirators were netted, and Mary was arrested at the gate of Tixall Park, whither Paulet had taken her under pretence of a hunting party. At Tixall she was detained till her papers at Chartley had undergone thorough research. That she was at length taken in her own toils even such a dullard as her admirers depict her could not have failed to understand; that she was no such dastard as to desire or deserve such defenders the whole brief course of her remaining life bore consistent and irrefragable witness. Her first thought on her return to Chartley was one of loyal gratitude and womanly sympathy. She cheered the wife of her English secretary, now under arrest, with promises to answer for her husband to all accusations brought against him, took her new-born child from the mother's arms, and in default of clergy baptized it, to Paulet's Puritanic horror, with her own hands by her own name. The next or the twin-born impulse of her indomitable nature was, as usual in all times of danger, one of passionate and high-spirited defiance, on discovering the seizure of her papers. A fortnight afterwards her keys and her money were confiscated, while she, bedridden and unable to move her hand, could only ply the terrible weapon of her bitter and fiery tongue. Her secretaries were examined in London, and one of them gave evidence that she had first heard of the conspiracy by letter from Babington, of whose design against the life of Elizabeth she thought it best to take no notice in her reply, though she did not hold herself bound to reveal it. On the 25th of September she was removed to the strong castle of Fotheringay in Northamptonshire. On the 6th of October she was desired by letter from Elizabeth to answer the charges brought against her before certain of the chief English nobles appointed to sit in commission on the cause. In spite of her first refusal to submit, she was induced by the arguments of the vice-chamberlain, Sir Christopher Hatton, to appear before this tribunal on condition that her protest should be registered against the legality of its jurisdiction over a sovereign, the next heir of the English crown.

On the 14th and 15th of October 1586 the trial was held in the hall of Fotheringay Castle. Alone, "without one counsellor on her side among so many," Mary conducted the whole of her own defence with courage incomparable and unsurpassable ability. Pathos and indignation, subtlety and simplicity, personal appeal and political reasoning, were the alternate weapons with which she fought against all odds of evidence or inference, and disputed step by step every inch of debatable ground. She repeatedly insisted on the production of proof in her own handwriting as to her complicity with the project of the assassins who had expiated their crime on the 20th and 21st of the month preceding. When the charge was shifted to the question of her intrigues with Spain, she took her stand resolutely on her right to convey whatever right she possessed, though now no kingdom was left her for disposal, to whomsoever she might choose. One single slip she made in the whole course of her defence; but none could have been more unluckily characteristic and significant. When Burghley brought against her the unanswerable charge of having at that moment in her service, and in receipt of an annual pension, the instigator of a previous attempt on the life of Elizabeth, she had the unwary audacity to cite in her justification the pensions allowed by Elizabeth to her adversaries in Scotland, and especially to her son. It is remarkable that just two months later, in a conversation with her keepers, she again made use of the same extraordinary argument in reply to the same inevitable imputation, and would not be brought to admit that the two cases were other than parallel. But except for this single instance of oversight or perversity her defence was throughout a masterpiece of indomitable ingenuity, of delicate and steadfast courage, of womanly dignity and genius. Finally she demanded, as she had demanded before, a trial either before the estates of the realm lawfully assembled, or else before the queen in council. So closed the second day of the trial; and before the next day's work could begin a note of two or three lines hastily written at midnight informed the commissioners that Elizabeth had suddenly determined to adjourn the expected judgment and transfer the place of it to the star-chamber. Here, on the 25th of October, the commissioners again met; and one of them alone, Lord Zouch, dissented from the verdict by which Mary was found guilty of having, since the 1st of June preceding, compassed and imagined divers matters tending to the destruction of Elizabeth. This verdict was conveyed to her, about three weeks later, by Lord Buckhurst and Robert Beale, clerk of the privy council. At the intimation that her life was an impediment to the security of the received religion, "she seemed with a certain unwonted alacrity to triumph, giving God thanks, and rejoicing in her heart that she was held to be an instrument" for the restoration of her own faith. This note of exultation as in martyrdom was maintained with unflinching courage to the last. She wrote to Elizabeth and the duke of Guise two letters of almost matchless eloquence and pathos, admirable especially for their loyal and grateful remembrance of all her faithful servants. Between the date of these letters and the day of her execution wellnigh three months of suspense elapsed. Elizabeth, fearless almost to a fault in face of physical danger, constant in her confidence even after discovery of her narrow escape from the poisoned bullets of household conspirators, was cowardly even to a crime in face of subtler and more complicated peril. She rejected with resolute dignity the intercession of French envoys for the life of the queen-dowager of France; she allowed the sentence of death to be proclaimed, and welcomed with bonfires and bell-ringing throughout the length of England; she yielded a respite of twelve days to the pleading of the French ambassador, and had a charge trumped up against him of participation in a conspiracy against her life; at length, on the 1st of February 1587, she signed the death-warrant, and then made her secretaries write word to Paulet of her displeasure that in all this time he should not of himself have found out some way to shorten the life of his prisoner, as in duty bound by his oath, and thus relieve her singularly tender conscience from the guilt of bloodshed. Paulet, with loyal and regretful indignation, declined the disgrace proposed to him in a suggestion "to shed blood without law or warrant"; and on the 7th of February the earls of Shrewsbury and Kent arrived at Fotheringay with the commission of the council for execution of the sentence given against his prisoner. Mary received the announcement with majestic tranquillity, expressing in dignified terms her readiness to die, her consciousness that she was a martyr for her religion, and her total ignorance of any conspiracy against the life of

Elizabeth. At night she took a graceful and affectionate leave of her attendants, distributed among them her money and jewels, wrote out in full the various legacies to be conveyed by her will, and charged her apothecary Gorion with her last messages for the king of Spain. In these messages the whole nature of the woman was revealed. Not a single friend, not a single enemy, was forgotten; the slightest service, the slightest wrong, had its place assigned in her faithful and implacable memory for retribution or reward. Forgiveness of injuries was as alien from her fierce and loyal spirit as forgetfulness of benefits; the destruction of England and its liberties by Spanish invasion and conquest was the strongest aspiration of her parting soul. At eight next morning she entered the hall of execution, having taken leave of the weeping envoy from Scotland, to whom she gave a brief message for her son; took her seat on the scaffold, listened with an air of even cheerful unconcern to the reading of her sentence, solemnly declared her innocence of the charge conveyed in it and her consolation in the prospect of ultimate justice, rejected the professional services of Richard Fletcher, dean of Peterborough, lifted up her voice in Latin against his in English prayer, and when he and his fellow-worshippers had fallen duly silent prayed aloud for the prosperity of her own church, for Elizabeth, for her son, and for all the enemies whom she had commended overnight to the notice of the Spanish invader; then, with no less courage than had marked every hour and every action of her life, received the stroke of death from the wavering hand of the headsman.

Mary Stuart was in many respects the creature of her age, of her creed, and of her station; but the noblest and most noteworthy qualities of her nature were independent of rank, opinion, or time. Even the detractors who defend her conduct on the plea that she was a dastard and a dupe are compelled in the same breath to retract this implied reproach, and to admit, with illogical acclamation and incongruous applause, that the world never saw more splendid courage at the service of more brilliant intelligence, that a braver if not "a rarer spirit never did steer humanity." A kinder or more faithful friend, a deadlier or more dangerous enemy, it would be impossible to dread or to desire. Passion alone could shake the double fortress of her impregnable heart and ever active brain. The passion of love, after very sufficient experience, she apparently and naturally outlived; the passion of hatred and revenge was as inextinguishable in her inmost nature as the emotion of loyalty and gratitude. Of repentance it would seem that she knew as little as of fear, having been trained from her infancy in a religion where the Decalogue was supplanted by the Creed. Adept as she was in the most exquisite delicacy of dissimulation, the most salient note of her original disposition was daring rather than subtlety. Beside or behind the voluptuous or intellectual attractions of beauty and culture, she had about her the fresher charm of a fearless and frank simplicity, a genuine and enduring pleasure in small and harmless things no less than in such as were neither. In 1562 she amused herself for some days by living "with her little troop" in the house of a burgess of St Andrews "like a burgess's wife," assuring the English ambassador that he should not find the queen there,—"nor I know not myself where she is become." From Sheffield Lodge, twelve years later, she applied to the archbishop of Glasgow and the cardinal of Guise for some pretty little dogs, to be sent her in baskets very warmly packed,—"for besides reading and working, I take pleasure only in all the little animals that I can get." No lapse of reconciling time, no extent of comparative indulgence, could break her in to resignation, submission, or toleration of even partial restraint. Three months after the massacre of St Bartholomew had caused some additional restrictions to be placed upon her freedom of action, Shrewsbury writes to Burghley that "rather than continue this imprisonment she sticks not to say she will give her body, her son, and country for liberty"; nor did she ever show any excess of regard for any of the three. For her own freedom of will and of way, of passion and of action, she cared much; for her creed she cared something; for her country she cared less than nothing. She would have flung Scotland with England into the hellfire of Spanish Catholicism rather than forego the faintest chance of personal revenge. Her profession of a desire to be instructed in the doctrines of Anglican Protestantism was so transparently a pious fraud as rather to afford confirmation than to arouse suspicion of her fidelity to the teaching of her church. Elizabeth, so shamefully her inferior in personal loyalty, fidelity, and gratitude, was as clearly her superior on the one all-important point of patriotism. The saving salt of Elizabeth's character, with all its wellnigh incredible mixture of heroism and egotism, meanness and magnificence, was simply this, that, overmuch as she loved herself, she did yet love England better. Her best though not her only fine qualities were national and political, the high public virtues of a good public servant; in the private and personal qualities which attract and attach a friend to his friend and a follower to his leader, no man or woman was ever more constant and more eminent than Mary Queen of Scots. (A. C. S.)

MARYBOROUGH, a town of Queensland, Australia, in the county of March, on the left bank of the Mary river, 25 miles from its mouth, about 180 miles north of Brisbane, in 25° 35′ S. lat. and 152° 43′ E. long. It is the principal shipping port for an extensive district, communicating by steamer and coach with Brisbane and (since 1881) by railway with the Gympie gold-fields, 54 miles to the south. A large shipbuilding yard, saw-mills, distilleries, breweries, and soap-works are among the industrial establishments of the town, and extensive sugar factories exist in the neighbourhood. Besides a handsome court-house and town-hall, the public buildings comprise a hospital, a school of arts with a considerable library, and immigration barracks. Gas-lighting and water from the Tinana creek were both introduced in 1879. The population of the census district in 1876 was 8608, that of the municipal area about 7000. Maryborough had only about 600 inhabitants in 1860; the municipality dates from 1861, and was reincorporated in 1875.

MARYLAND

MARYLAND, one of the thirteen original States of the American Union, lies between the parallels of 37° 53′ and 39° 43′ 26″ N. lat., and 75° 4′ and 79° 33′ W. long. It is bounded on the N. by Pennsylvania and Delaware; E. by Delaware and the Atlantic Ocean; and S. and W. by Virginia and West Virginia. The total area of the State is 12,210 square miles, of which about 2350 square miles are covered by the waters of the Chesapeake Bay and of the Potomac and other rivers. Plate

Topography.—The configuration of the State is very irregular. Its extreme length east and west is about 200 miles, and its breadth varies from 4 to 120 miles. The coast-line has no harbours; but a narrow beach and a shallow lagoon, called Sinepuxent Bay, extend along its entire length. The central geographical feature of the State is the Chesapeake Bay, the greatest inlet in the United States, and one which is navigable throughout for the largest vessels. The bay at its ocean mouth, between Cape Charles and Cape Henry, is 12 miles wide; it extends north and south about 200 miles; its breadth at

the widest point is 40 miles, and its average breadth is 10 miles. It contains many islands, and its shore-line, which is extremely irregular, is deeply indented with estuaries. That part of the State which lies between the bay on the west and the State of Delaware and the ocean on the east is locally known as the Eastern Shore. The surface of this region is for the most part level, and but little raised above the sea. The peninsula between the Potomac river and the west shore of the bay constitutes another geographical division similar in its general features to the Eastern Shore. Its surface, however, is more undulating, and on the north-west it rises to a ledge of Primitive rocks which runs from the Potomac river at a point about 10 miles above Washington city north-east to the Susquehanna river, and separates the tide-water portion of the State from the third division. This latter region gradually rises as it extends westward until it culminates in the mountains of the great Appalachian range, which are called, in Maryland, the Blue Ridge and the Alleghanies. The principal rivers of the Eastern Shore are the Pocomoke, Nanticoke, Choptank, and Elk. These are rather estuaries than rivers, and are not navigable for any distance from their mouths. The Susquehanna flows into the bay at its head, and is navigable for a few miles. On the western shore are the Potomac, navigable for 125 miles, to Washington city, the Patuxent,—the largest river which is altogether within the State,—navigable for small vessels for 40 miles, and the Patapsco, on which Baltimore city is situated, navigable for 22 miles. The tide rises and falls in all these rivers. With the exception of the Youghiogheny, all the Maryland streams flow into the Chesapeake Bay.

Geology and Minerals.—A great diversity of geological formation is found in Maryland. The lower part of the Eastern Shore is an alluvial plain, and the numerous islands in the bay are composed of similar alluvial deposits. The northern part of the Eastern Shore, beginning at the Choptank river, is a Tertiary formation, whose strata of sands and clays overspread deposits of marl, which is of great value as a fertilizer. The peninsula on the western shore of the bay belongs to the same Tertiary formation, which, towards the north-west, gives place to a range of metamorphic rocks. This belt of rocks, which includes a strip of New Red Sandstone, enters the State near the head of the bay, and extends south-west to the Potomac, with an average breadth of about 20 miles. The principal rocks are gneiss, talc-slates, limestone, granite, serpentine, and divers hydrated magnesian silicates. The limestone supplies a marble highly valued as a building material, and the serpentine rocks yield the valuable metallic element of chromium, which has been extensively and profitably worked. Oxides of iron occur in gneiss, and the Jurassic clays contain the brown hæmatite ores from which iron is manufactured. These ores were worked even during the colonial period, and in 1751 Maryland exported 2950 tons of pig iron to England. Bog iron ore is also found on the Eastern Shore. Beds of different kinds of clays which are used in the manufacture of bricks, porcelain, &c., are abundant, and veins of copper ore are also worked. Passing westward of the metamorphic rocks, we meet a wide belt of Silurian and Devonian formation, and the first ridge of the Appalachian range, beyond which lies the broad Hagerstown valley resting upon Trenton limestone. Numerous parallel ridges, enclosing valleys of great fertility, and belonging to the Middle Silurian, Devonian, and Carboniferous formations, follow. This belt of lines of elevation nearly parallel with the ocean, which is a characteristic of the Appalachian chain, has, in Maryland, an average breadth of about 40 miles, and trends to the south-west. The mountainous region, which extends to the western extremity of the State, but with elevations rarely exceeding 2500 feet, begins at Cumberland, and here the Silurian and Devonian formations give place to the Carboniferous. This portion of Maryland is one of the most important bituminous coal regions in America. There are several coal-fields with horizontal seams lying near the surface, but the most considerable is that of the George's Creek valley between Dan's Mountain on the east and Savage Mountain on the west. This narrow valley, about 20 miles long, contains the "big seam" of bituminous coal, of the extraordinary thickness of 14 feet. The Maryland coal is unequalled in the manufacture of iron and the generation of steam. The number of tons mined in 1881 was 2,261,918, and it is estimated that 550 square miles of Coal-measures remain. This Carboniferous formation also contains deposits of iron ore which are extensively worked.

Climate, Soil, &c.—The climate of Maryland is equable and salubrious, except in some of the lower counties on the bay, which, in summer, are subject to malarious exhalations. The mean annual temperature in the southern part of the State is 56°, in the middle 54°, and in the western 50°. The mean temperature at Baltimore is in spring 53°·8, in summer 76°·2, in autumn 57°·1, in winter 36°·2. The mean annual temperature is 55°·9. The mean annual barometer is 30·064 inches, and the annual rainfall 41·94 inches. The death-rate in the State is 1·81 per cent. In Baltimore city it was 19·34 per 1000 in 1879, and 24·7 in 1880.

The soil of the Eastern Shore, and of the peninsula on the western shore of the bay, is composed of sand and clay, and when properly cultivated is very productive. Much attention is there bestowed upon the growth of peaches and other fruits. The land in the central part of the State, and in the valleys of the mountainous part, is of great fertility. The original forest still covers a considerable area of the western portion. There are about one hundred species of trees in the State. The deciduous oaks, hickory, chestnut, walnut, cedar, and beech trees are especially abundant. The bay and its estuaries contain inexhaustible beds of the finest oysters, yielding many thousand bushels annually.[1] There are several kinds of tortoises, the most highly esteemed of which are the *Malaclemys palustris* and the *Ptychemys rugosa.* At least eighty kinds of edible fishes abound in the waters of the State, and swimming birds are very numerous.

Population, Divisions.—The State is divided into twenty-three counties and the corporation of Baltimore city. The counties are — Alleghany, Anne Arundel, Baltimore, Calvert, Caroline, Carroll, Cecil, Charles, Dorchester, Frederick, Garrett, Harford, Howard, Kent, Montgomery, Prince George's, Queen Anne, St Mary's, Somerset, Talbot, Washington, Wicomico, and Worcester. There are five cities—Baltimore, the metropolis of the State, and the seventh city in the United States (population in 1880, 332,313; in 1870, 267,354), Cumberland (population in 1880, 10,693), Frederick (8659), Hagerstown (6627), and Annapolis (6498), the capital of the State, and the seat of the naval academy of the United States.

The body of 200 emigrants who colonized Maryland in 1634 had increased twenty-five years later to 12,000. In 1671 the population was 20,000; in 1715, 30,000; in 1748, 130,000, of whom 36,000 were negroes; in 1761, 164,007 (including 49,675 negroes); in 1775, 200,000; in 1782, 254,050 (including 83,362 negroes). The growth of population as exhibited by the decennial census returns of the United States is as follows:—

[1] In 1880 the amount of capital invested in the Maryland oyster business was $6,245,876; the number of persons employed, 24,377; and the oysters taken, 10,569,012 bushels.

Years	White.	Free Coloured.	Slaves.	Total.

1870	605,497	175,397	...	780,894
1880	724,693	210,250	...	934,943

In 1880 the native-born were 852,137, and the foreign-born 82,806. There were 10,569 more females than males. The number of males of twenty-one years of age and over was 232,106, of whom 144,586 were native white, 38,936 foreign white, and 48,584 coloured. The number of persons over the age of ten years who were unable to read and write was 134,488. The number of families in Maryland was 175,318 ; dwellings, 155,070 ; persons to a square mile (land surface), 94·82; families to a square mile, 17·78; dwellings to a square mile, 15·73 ; acres to a person, 6·75 ; acres to a family, 35·99 ; persons to a dwelling, 6·03 ; persons to a family, 5·33.

Agriculture, Manufactures, Commerce.—The following statistics relating to agricultural labour in Maryland are those of the census of 1880. The number of farms was 40,517 (the rate of increase since 1870 being 50 per cent.) ; 27,978 farms were occupied by the owners, 3878 were rented for a fixed money rental, and 8661 were rented for shares of produce. In 19,920 farms the number of acres under cultivation was less than 100, and only 805 farms were of or above 500 acres' extent. The staple crops are tobacco, maize, and wheat, and the average cash value per acre of crops was $17.82. In the production of tobacco Maryland ranks as the seventh State in the Union. The acreage devoted to it was 38,174 ; the production was 26,082,147 ℔ ; and the value of the crop in the farmers' hands was $1,825,750. The cereal production was as follows :—Barley, 226 acres, 6097 bushels ; buckwheat, 10,294 acres, 136,667 bushels ; Indian corn, 664,928 acres, 15,968,533 bushels ; oats, 101,127 acres, 1,794,872 bushels; rye, 32,405 acres, 288,067 bushels; wheat, 569,296 acres, 8,004,864 bushels. The live stock on the farms, June 1, 1880, was as follows :—horses, 117,796 ; mules and asses, 12,561 ; working oxen, 22,246 ; milch cows, 122,907 ; other cattle, 117,387 ; sheep, 171,184 ; swine, 335,408.

The statistics of the iron and steel industries for 1880 showed that the number of establishments in Maryland was twenty-three ; capital, $4,962,125 ; number of hands, 2763 ; wages paid, $905,090 ; value of materials, $2,888,574 ; value of products, $4,470,050. The production of pig iron was 59,664 tons. The cotton manufactures had 2325 looms, 125,014 spindles, used 46,947 bales of cotton, and employed 4159 hands. Baltimore stands eighth in the list of manufacturing cities in the United States. The number of establishments in that city is 3596 ; capital $35,760,108 ; average number of hands employed 55,201 ; annual product $75,621,388.

The large foreign commerce of the State is conducted almost wholly through the port of Baltimore, although there are two other ports of entry. In 1881 the number of foreign vessels arriving was 1307 ; in 1880, 1508. The number of foreign clearances in 1881 was 1179 ; in 1880, 1633. The number of vessels registered in the State is 1788. The chief imports are iron, coffee, and salt ; the chief exports, tobacco, petroleum, and grain. The grain elevators at Baltimore have a capacity of 6,150,000 bushels. In 1880 the value of the foreign imports was $18,643,245, and that of the foreign exports $74,398,971. The aggregate exchanges at the Baltimore clearing house in 1881 were $732,448,141. There are one hundred and fifty-two fire and marine insurance companies doing business in the State. In 1881 these received $1,680,109 in premiums, and paid losses amounting to $1,015,658. The twenty-nine life insurance companies in the State received in 1881 $1,116,540 in premiums, and paid losses amounting to $895,092.

Railways and Canals.—The Baltimore and Ohio Railway, incorporated in 1827, is one of the chief lines of communication between the seaboard and the Western States. The number of miles of all railways in operation wholly within the State is 1048. The Chesapeake and Ohio Canal, begun in 1828, and completed in 1845, at a cost of $11,375,000, extends from Cumberland, along the left bank of the Potomac, to Georgetown, in the District of Columbia, a distance of 184 miles. It there crosses the river by an aqueduct and continues to Alexandria, Va. Its depth is 6 feet, and its width varies from 52 to 70 feet. The Chesapeake and Delaware Canal, connecting the Chesapeake and Delaware Bays, is 12 miles long, 66 feet wide, 10 feet deep, and cost $3,547,561.

Revenue, Debts, Taxation.—The total amount of the funded debt of the State on September 30, 1881, was $11,257,560. About one-half of this debt bears interest at 5 per cent., and the remainder at 6 per cent. As an offset to this debt the State owns interest-paying securities amounting to $3,461,085, and non-productive property valued at 25 million dollars. The property assessed for purposes of State taxation in 1881 was valued at $461,459,939, and the State tax was 18¾ cents on each $100. The total receipts of the State from all sources were $1,996,641. The debt of Baltimore city, on January 1, 1882, was $36,381,351. The city owns productive property worth $15,304,596, and unproductive property valued at $5,150,780. The property assessed for city taxation was valued at $247,230,189, and the city tax was $1·37 on each $100. The debts of the cities and counties, exclusive of Baltimore, amount to nearly two million dollars.

Social Statistics.—In 1881 the average number of convicts in the State penitentiary was 545, nearly one-half of whom were sentenced for larceny. The convicts are employed upon profitable labour, and the institution is not only self-supporting, but is a source of revenue to the State. The State house of correction received in 1881 414 prisoners, most of whom were sentenced for short terms. Provision is made for juvenile offenders in houses of reformation and similar establishments. The number of inmates in the almshouses in 1879 was 2384. The M'Donogh Industrial School has an endowment of $861,968, and educates and supports about fifty poor boys annually. The State extends its aid to a hospital for the insane (with 400 inmates), an asylum for the blind, two deaf and dumb asylums, and other charitable institutions. In 1880 there were one hundred and thirty-eight periodicals published in the State. The principal religious denominations are the Methodist, Roman Catholic, Episcopalian, Presbyterian, and Baptist.

Education and Libraries.—Maryland has an excellent system of free public schools supported by State, county, and municipal taxation. In 1881 the number of schools was 2039, the number of pupils 158,909, the number of teachers 3180, and the total expenses $1,604,580. The schools are managed by school commissioners who, in the counties, are appointed by the judges of the circuit courts, and in Baltimore city are elected by the city council. There is also a State board of education, invested with comprehensive visitorial powers. A number of higher educational institutions are maintained in part by the State. The principal of these are the normal school at Baltimore, St John's College at Annapolis (founded in 1783), the Western Maryland, Maryland Agricultural, Baltimore Female, Washington, and Frederick colleges. In 1881 these colleges had 723 students and 56 instructors, and received from the State $40,300. In Baltimore are two medical colleges—the college of physicians and surgeons, with 10 professors and 330 students, and the medical school of the university of Maryland, with 10 instructors and 200 students. There are also two dental colleges in the State. The law school of the university of Maryland has 4 instructors and 60 students. The Johns Hopkins University, at Baltimore, which has an endowment of more than 3 million dollars, was opened in 1876. It has 34 professors and associates, 20 fellows, 155 students, and 12,000 volumes in its library. The buildings of the Johns Hopkins Hospital, which has a similar endowment of more than 3 million dollars, are now (1882) being erected. The Peabody Institute, which has $1,300,000 in productive funds, the gift of George Peabody, was founded in 1857. It embraces a lecture department, a conservatory of music, a gallery of fine arts, and a library. The library, containing 75,459 volumes in 1882, is designed to be a collection of such books as are not ordinarily accessible to scholars. The Pratt Public Library, endowed with one million dollars, was founded in 1882.

Administration.—The chief executive officer of the State is the governor, who is elected for the term of four years, and receives a salary of $4500 per annum. He is invested with power to grant pardons and reprieves except in cases of impeachment, and a three-fifths vote of the legislature is necessary to overcome his veto of an Act. The legislature, called the General Assembly, meets biennially, and its sessions are limited by the constitution to ninety days. It is composed of a senate, elected for four years (one-half being chosen every second year), and a house of delegates, elected for two years. The present number of senators is 26, and of delegates 91. The judicial power of the State is vested in a court of appeals, consisting of 8 judges, in a circuit court and an orphans' court for each county, in six courts of record for Baltimore city, and in justices of the peace. The judges are elected by the people for fifteen years, and retire upon attaining the age of seventy years. The justices of the peace are appointed by the governor, with the consent of the senate. The law officers are an attorney-general for the State, and a State's attorney for each county, who is the prosecuting officer in all criminal cases. The local affairs of the counties are managed by county commissioners elected for two years, and those of each city by a mayor and city council. All elections are by ballot, and every male citizen of the United States who has been a resident of the State for one year and of the district in which he offers to vote for six months preceding the election is entitled to be registered as a voter. The present constitution was adopted in 1867. Maryland is represented in the national congress by two senators and six representatives. The arms of the State are those prescribed by Lord Baltimore for the province in 1648, viz. :—quarterly—1st and 4th, paly of six, or and sable, a bend counterchanged ; 2d and 3d, quarterly, argent and gules, a cross botonny, counterchanged; crest (which is placed upon a helmet, showing five bars, over a count palatine's coronet), on a ducal coronet proper two pennons, dexter or, the other sable, staves gules; motto, *Fatti maschii parole femine*; supporters, a ploughman and fisherman, proper. On the great seal a mantle doubled with ermine surrounds the arms and supporters, as above, and upon a border encircling the seal is engraven the legend, *scuto bonæ voluntatis tuæ coronasti nos.*

History.—The charter of Maryland, which constituted the first proprietary government established in America, was obtained from Charles I. by Sir George Calvert, the first Lord Baltimore, who had been one of the principal secretaries of state to James I. Lord Baltimore died before the patent passed the seals, and it was issued to his son the second Lord Baltimore on June 20, 1632. The name Maryland (*Terra Mariæ*) was bestowed upon the colony by Charles I. in honour of his queen Henrietta Maria. In 1633 Lord Baltimore despatched a number of emigrants, under the command of his brother Leonard Calvert, to colonize the territory. They settled at St Mary's on the 27th March 1634, and the first legislative assembly, which was composed of all the freemen of the province, met in February 1635. Before the grant of the charter a trading station had been established, by William Clayborne of Virginia, upon Kent Island, in Chesapeake Bay, and the early years of the colony were greatly disturbed by contests with him, in which, however, Lord Baltimore was finally successful. The Baltimores were Catholics, and Maryland was designed to be a place of refuge for English Catholics, but, from the earliest period, religious toleration for all Christians was proclaimed and practised. Maryland has always claimed the honour of having been the first government in which liberty in matters of faith was established by law. Under the charter by which Maryland was made a province of the empire Baltimore was the owner of the soil, and enjoyed all the rights that had ever been exercised by a count palatine. The laws of the provincial assemblies which received his assent were not subject to the revision of the crown. In 1652 the parliamentary commissioners deposed Lord Baltimore's officers, and appointed a Puritan council to govern the province. After several years of contest between the proprietary and Puritan parties, the power of the former was finally re-established. At the time of the Revolution of 1688 the failure of Lord Baltimore's deputies to proclaim William and Mary gave an opportunity to the disaffected Protestants in the province to incite a revolt, which resulted in the overthrow of their feudal lord. The king and queen approved of this colonial Protestant revolution, and Maryland was taken directly under the government of the crown. The Church of England was then established, and disabilities imposed upon Catholics and dissenters. Maryland remained a royal colony until 1714, when, upon the death of the third Lord Baltimore, his son, who was a Protestant, was recognized as the proprietary. The province was governed by the Baltimores until the revolution of 1776. The original charter limits included all the present State of Delaware and a large part of Pennsylvania. The grant to William Penn conflicted with that of Maryland, and a controversy between the two colonies began in 1682, and was not concluded until 1760, when the Penns, armed with a decision of the privy council and a decree in chancery, were successful. "Mason and Dixon's line"—famous in American politics—was established between the provinces in 1763–67. During the war for independence Maryland furnished her full quota of troops, but refused to ratify the articles of confederation until those colonies which had claims to western lands surrendered them to the general Government. Washington resigned his commission as commander-in-chief to the colonial congress at Annapolis in December 1783. Maryland ratified the constitution of the United States on the 28th April 1788, and in 1790 ceded to the United States 60 square miles of territory, where the national capital is situated. At the outbreak of the civil war Maryland was a slave-holding State, and popular sentiment was divided between the North and the South, but the decisive measures adopted by the Federal Government made it impossible for the State to leave the Union. The history of the State has been written by M'Mahon (1831), Bozman (1837), M'Sherry (1849), and Scharf (1879). The Maryland Historical Society at Baltimore has a large collection of colonial and revolutionary MSS., newspapers, and historical works, and has published numerous essays upon questions of local history. (W. T. B.)

MARYPORT, a market and seaport town of Cumberland, England, is situated on the Irish Sea, 29 miles southwest from Carlisle. It is irregularly built, partly on a cliff and partly on the sea-shore. The streets are spacious, but there are no public buildings of importance. The town until 1750 consisted of a few huts called Ellenfoot, when a harbour was constructed by Humphrey Senhouse, which gave a great impulse to its prosperity. The principal exports are coal to Ireland and pig-iron to the Continent, the principal imports timber and general merchandise. Shipbuilding is carried on to a small extent. In 1881 the number of vessels that entered from foreign and colonial ports was 72, of 35,241 tons burden; the number that cleared 120, of 60,840 tons burden. The coasting trade is much more important, the number of vessels that entered being 1805, of 215,332 tons burden, and the number that cleared 1753, of 187,290 tons. There are rope and sailcloth works, iron foundries, and saw-mills, also brewing and tanning. The population of the urban sanitary district in 1871 was 7443, and in 1881 it was 8177. There was a Roman camp in the neighbourhood of Maryport, and the district is rich in Roman antiquities.

MASACCIO (1402-1429). Tommaso Guidi, son of a notary, Ser Giovanni di Simone Guidi, of the family of the Scheggia, who had property in Castel S. Giovanni di Val d'Arno, was born in 1402, and acquired the nickname of Masaccio, which may be translated "Lubberly Tom," in consequence of his slovenly dressing and deportment. He loved to be alone and at home, neglected "appearances" of all sorts, and was constantly wool-gathering when not intently occupied with his work; he had no vices, however, and would always do a good turn to an acquaintance. From childhood he showed a great inclination for the arts of design, and he is said to have studied under his contemporary Masolino da Panicale. In 1421, or perhaps 1423, he was enrolled in the guild of the speziali (druggists) in Florence, in 1424 in the guild of painters. His first attempts in painting were made in Florence, and then in Pisa. Next he went to Rome, still no doubt very young; although the statement that he returned from Rome to Florence, in 1420, when only eighteen or nineteen, seems incredible, considering what were the works which he undertook in the papal city. These included a series of frescos still extant in a chapel of the church of S. Clemente, a Crucifixion, and scenes from the life of St Catherine and of St Clement, or perhaps some other saint. Though much inferior to his later productions, these paintings are, for naturalism and propriety of representation, in advance of their time. Some critics, however, consider that the design only, if even that, was furnished by Masaccio, and the execution left to an inferior hand; this appears highly improbable, as Masaccio, at his early age, can scarcely have held the position of a master laying out work for subordinates; indeed Vasari says that Lubberly Tom was held in small esteem at all times of his brief life. In the crucifixion subject the group of the Maries is remarkable; the picture most generally admired is that of

Catherine, in the presence of Maxentius, arguing against and converting eight learned doctors. After returning to Florence, Masaccio was chiefly occupied in painting in the church of the Carmine, and especially in that "Brancacci chapel" which he has rendered famous almost beyond rivalry in the annals of painting.

The chapel had been built early in the 15th century by Felice Michele di Piuvichese Brancacci, a noble Florentine. Masaccio's work in it began probably in 1423, and continued at intervals until he finally quitted Florence in 1428. There is a whole library-shelf of discussion as to what particular things were done by Masaccio and what by Masolino, and long afterwards by Filippino Lippi, in the Brancacci chapel, and also as to certain other paintings by Masaccio in the Carmine. He began with a trial piece, a majestic figure of St Paul, not in the chapel; this has perished. A monochrome of the Procession for the Consecration of the Chapel, regarded as a wonderful example, for that early period, of perspective and of grouping, has also disappeared, though there is some suspicion that it might yet, with due pains and research, be recovered; it contained portraits of Brunelleschi, Donatello, and many others. In the cloister of the Carmine was discovered in recent years a portion of a fresco by Masaccio representing a procession; but this, being in colours and not in monochrome, does not appear to be the Brancacci procession. As regards the works in the Brancacci chapel itself, the prevalent opinion now is that Masolino, who used to be credited with a considerable portion of them, did either nothing, or at the utmost the solitary compartment which represents St Peter restoring Tabitha to life, and the same saint healing a cripple. The share which Filippino Lippi bore in the work admits of little doubt; to him are due various items on which the fame of Masaccio used principally to be based—as for instance the figure of St Paul addressing Peter in prison, which Raphael partly appropriated; and hence it may be observed that an eloquent and often-quoted outpouring of Sir Joshua Reynolds in praise of Masaccio ought in great part to be transferred to Filippino. What Masaccio really painted in the chapel appears with tolerable certainty to be as follows, and is ample enough to sustain the high reputation he has always enjoyed:—(1) The Temptation of Adam and Eve; (2) Peter and the Tribute-Money; (3) The Expulsion from Eden; (4) Peter Preaching; (5) Peter Baptizing; (6) Peter Almsgiving; (7) Peter and John Curing the Sick; (8) Peter Restoring to Life the Son of King Theophilus of Antioch was begun by Masaccio, including the separate incident of Peter Enthroned, but a large proportion is by Filippino; (9) the double subject already allotted to Masolino may perhaps be by Masaccio, and in that case it must have been one of the first in order of execution. A few words may be given to these pictures individually. (1) The Temptation shows a degree of appreciation of nude form, corresponding to the feeling of the antique, such as was at that date unexampled in painting. (2) The Tribute-Money, a full, harmonious, and expressive composition, contains a head reputed to be the portrait of Masaccio himself,—one of the apostles, with full locks, a solid resolute countenance, and a pointed beard. (3) The Expulsion was so much admired by Raphael that, with comparatively slight modifications, he adopted it as his own in one of the subjects of the Logge of the Vatican. (5) Peter Baptizing contains some nude figures of strong naturalistic design; that of the young man, prepared for the baptismal ceremony, who stands half-shivering in the raw air, has always been a popular favourite, and an object of artistic study. (8) The restoration of the young man to life has been open to much discussion as to what precise subject was in view, but the most probable opinion is that the legend of King Theophilus was intended.

In 1427 Masaccio was living in Florence with his mother, then for the second time a widow, and with his younger brother Giovanni, a painter of no distinction; he possessed nothing but debts. In 1428 he was working, as we have seen, in the Brancacci chapel. Before the end of that year he disappeared from Florence, going, as it would appear, to Rome, to evade the importunities of creditors. Immediately afterwards, in 1429, when his age was twenty-seven, he was reported dead. Poisoning by jealous rivals in art was rumoured, but of this nothing is known. The statement that several years afterwards, in 1443, he was buried in the Florentine church of the Carmine, without any monument, seems to be improbable, and to depend upon a confused account of the dates, which have now, after long causing much bewilderment, been satisfactorily cleared up from extant documents.

It has been said that Masaccio introduced into painting the plastic boldness of Donatello, and carried out the linear perspective of Paolo Uccello and Brunelleschi (who had given him practical instruction), and he was also the first painter who made some considerable advance in atmospheric perspective. He was the first to make the architectural framework of his pictures correspond in a reasonable way to the proportions of the figures. In the Brancacci chapel he painted with extraordinary swiftness. The contours of the feet and articulations in his pictures are imperfect; and his most prominent device for giving roundness to the figures (a point in which he made a great advance upon his predecessors) was a somewhat mannered way of putting the high lights upon the edges. His draperies were broad and easy, and his landscape details natural, and superior to his age. In fact, he led the way in representing the objects of nature correctly, with action, liveliness, and relief. Soon after his death, his work was recognized at its right value, and led to notable advances; and all the greatest artists of Italy, through studying the Brancacci chapel, became his champions and disciples.

Of the works attributed to Masaccio in public or private galleries hardly any are authentic. The one in the Florentine Academy, the Virgin and Child in the Lap of St Anna, is an exception. The so-called portrait of Masaccio in the Uffizi Gallery is more probably Filippino Lippi; and Filippino, or Botticelli, may be the real author of the head, termed a Masaccio, in the London National Gallery.

MASANIELLO (an abbreviation of Tommaso Aniello or Anello) was the leader of the Neapolitan revolt in July 1647. For many years the Spanish Government, in straits for money, had exacted large sums from the Two Sicilies, although the privileges granted by Ferdinand and Charles V. had exempted them both from taxes on the necessaries of life and from all external payments whatever. Now, however, under Philip III. and Philip IV., the exactions, heavy in themselves, were made more oppressive by being farmed out to contractors, while the sums raised were usually conveyed to Spain and spent on purposes often having no connexion with Naples. Meantime the industrial classes were scourged by the excesses of the nobility and the lawlessness of banditti. At length, at the end of 1646, the duke of Arcos demanded a million ducats in gold; and it was resolved after much opposition to raise it from fruit, one of the most important articles of food to a southern people. Petitions delayed but did not remove the tax; on June 6 a toll-house was actually blown up, but the viceroy did not give way. The discontent was fomented by Genovino, who had been chosen "elect of the people" (that is, of the district of the city where the common people had the right of voting) in 1619 by the duke of Osuna's influence, and had been employed by him as an agitator. After the duke's recall he had been long in prison, and then returned to Naples and became a priest. He selected for his purpose Masaniello, a fisherman of Naples, then twenty-seven years old, well built, intelligent, and very popular in the city. He was so poor, we are told, that he was usually obliged to content himself with selling paper to wrap up the fish that others sold. He had special cause too for hatred to the taxes: his wife had tried to smuggle a bag of flour into the city as an infant; she had been imprisoned, and his scanty possessions had barely sufficed to pay her fine. The temporary success of a rising at Palermo had stirred the people to a sense of their power, and very little was wanted to produce an explosion. On July 16, the feast of S. Maria del Carmine, it was customary to make a sort of castle which was defended by one body of youths armed with sticks and stormed by another. Masaniello had been chosen captain of one of these parties, and got together four hundred young men, with whom he had already raised the cry of "Down with the taxes" when the crisis was precipitated by a quarrel. On Sunday the 7th a dispute arose in the market (on which Masaniello's house looked) whether the gardeners or the buyers of their fruit should pay the tax. Finally the owner of the fruit (said to have been a kinsman of Masaniello) upset his basket, saying he would sooner let the people have it for nothing than pay the tax. Masaniello came up; the tax collectors were pelted with fruit and then with stones, and the toll-house was burnt with cries of—"The king of Spain and plenty; down with misgovernment and taxes." The viceroy attempted without effect to quiet the people by promises; his carriage was surrounded, and he escaped with difficulty to St Elmo. Meanwhile the populace broke open the prisons, and released all charged with offences against the customs. In the evening, by advice of Genovino, a meeting elected officers, and decided on their demands. Masaniello was chosen captain, with one Perrone, who had been in the service of Maddaloni, and at another time a captain of banditti, as his lieutenant. Next day the people went in search of arms; many houses of persons who had made themselves obnoxious to the people, and especially of tax farmers, were sacked, and their contents burnt; but most of the historians of the time state that there were few attempts to appropriate anything, and those few were immediately punished. The duke of Maddaloni, a man of lawless life, but a decided opponent of the viceroy, was selected as a likely intermediary with the people. The latter demanded the original charter granted by Charles V., which was said to have wrongfully come into the viceroy's own hands, the removal of all taxes imposed since Charles V.'s death, and that the elect of the people should have as many votes as the representatives of the nobles. All was granted; but the viceroy made entrenchments to guard the approaches to the castle. Next day the sacking of tax farmers' houses went on. The viceroy attempted to cheat the people by sending documents simply drawn up by himself; and then their rage burst out. Maddaloni was seized and given into custody, but escaped in the night by Perrone's connivance. The people were summoned to arms. The cardinal archbishop Filomarino, who did his best to mediate between the parties all through, came to them from the viceroy, and it was arranged that he should bring them the document. The seizure of arms went on, and Masaniello marching out of the city disarmed and took prisoners four hundred soldiers, while another body of people did the same with six hundred German mercenaries. On Wednesday Perrone made his appearance at the head of three hundred bandits partly mounted, and fired upon Masaniello, but without injuring him. The people rushed upon them, and they were killed almost without exception. Some confessed to having been instigated by Maddaloni, and a price was set upon his head. His brother Giuseppe Caraffa was found in a monastery and killed, and his head and foot were set upon pikes. A new elect of the people was chosen, Arpaia, who had been a partisan of Genovino's in the duke of Osuna's time, and had been condemned to the galleys. On Thursday Maddaloni's house was plundered and his property placed in a heap in the market under guard. The castle being short of provisions, Masaniello sent some as a present to the viceroy. The Neapolitan galleys, under Gianettino Doria, arrived the same day, and Masaniello refused permission to land or to come nearer than a mile to the shore, but sent provisions on board. In fact he was now undisputed master of the city, not only organizing the military force in it with surprising ability, but dispensing strict though severe justice. Often he sat inside his little house on the market, sword or loaded gun in hand, while petitions and complaints were handed to him on the end of a pike through the window; yet he still went barefoot, dressed as a simple fisherman. The people having assembled consulted together on the terms of agreement; it was settled by the advice of Genovino that Masaniello should show the articles agreed on to the duke at the palace (he would not risk himself in the castle), and that the viceroy should afterwards swear to them in the cathedral. Towards evening the procession set out, Masaniello in a dress of cloth of silver pressed upon him by the archbishop. An immense concourse of armed men, estimated at one hundred and forty thousand, lined the way or accompanied him. Before them went a trumpet proclaiming *Viva il rè di Spagna ed il fedelissimo popolo di Napoli.* Before entering the palace he exhibited the charter brought by the archbishop, and charged them not to lay down their arms till they had received the confirmation of their rights from the king of Spain. "If I do not return in an hour," he added, "wreck the city." He was received by the viceroy as an equal. All the conditions were agreed to, the chief being—that the elect of the people should have as many votes as the nobles; that all taxes should be removed except those already existing in Charles V.'s time; that the viceroy should get the articles ratified by the king within three months; that no punishment should be inflicted on those who had taken part in the rising; and that the people should keep their arms till the ratification. On the Friday Masaniello dismissed most of his followers to their work, keeping a patrol of four men and a corporal in each street. Next day the ceremony in the cathedral took place; the duke of Canjano read the articles, Masaniello meanwhile correcting and explaining, and the viceroy solemnly swore to observe them. Then Masaniello tore off his rich dress; it was time, he said, to return to his fish. And indeed from this time began his ruin. For a week the care of a city, with hundreds of thousands of inhabitants, had rested upon him; he had been general, judge, legislator, and during the whole time he had hardly slept or eaten, the latter through dread of poison; no wonder if the fisherman's brain reeled under all this. His justice had been severe, but hitherto it had struck men who deserved punishment, the oppressor, the robber, the hired cut-throat; henceforth every one who ventured to contradict him risked his life, and the only man who could persuade him to mercy was the good archbishop. Five hundred in all, it is said, were put to death by his order; though it is probable that they were few compared to the lives taken a short time afterwards by the viceroy in defiance of his plighted word. Next day in fact the duke set to work; Genovino was made president of the chamber in order to detach him from Masaniello, for which he was the more ready as Masaniello was no longer the tool he wanted. Genovino had already prevented the demand for the surrender of St Elmo, which could easily have been enforced, as the fort was not provisioned. Carlo and Salvatore Cataneo with two others offered to the viceroy to murder Masaniello, and he welcomed their services. On Sunday Masaniello gave orders for laying down arms and submitting to the viceroy, which were obeyed in some quarters of the city before they could be recalled. He tried in vain to get the viceroy to accompany him to Posilippo, where he drank deeply, and in reckless extravagance threw gold into the water to be dived for. Next day his violence continued; he struck his followers in the street, and condemned several of his officers to death for not immediately executing his orders. He cut out the head from a picture of Maddaloni and set it on a pike. Vitale his secretary, sent on a message to the viceroy, talked of his intention to raise a million ducats for the king by means of forced gifts from the rich; Vitale was detained in the castle on some pretext, and on leaving next morning was killed by the people of the quarter, who had returned to their allegiance. On Tuesday the 16th, the feast of S. Maria del Carmine, Masaniello went up into the pulpit, and in a wild harangue recapitulated his services. He knew, he said, his death was near at hand; then tearing open his dress he showed his body emaciated by fatigue and want of food. After some more wild talk he was disarmed and confined in a cell in the monastery. There the quiet seems to have restored him; but his assassins soon broke in; he turned to meet them; five shots were at once fired, and he fell dead. His head was cut off and carried through the streets, while his body was dragged about for a while and then buried outside the city. Next day some boys went and dug up the body, washed it, and took the head from the guard in charge of it. The Neapolitans forgot the excesses of the last few days, and only remembered the leader who had won them their great victory. People plucked out his hairs and preserved them as relics, some even prayed to him as a saint. All the priests of the city officiated at the funeral, and even the viceroy was represented by eight of his pages. (G. H. B.)

MASAYA, a town in Nicaragua, Central America, on the east side of the Lake of Masaya, about 55 miles south-east of Managua, and 25 miles north-west of Granada. The population, mostly of Indian blood, is estimated at 15,000 or 18,000; but, as nearly every house has its orchard or garden, the buildings are spread over a much larger area than this would suggest. Previous to 1871, when a steam-pump was erected, all the water required had to be carried from the lake, which lies 340 feet below the level of the town. The volcano of Masaya on the opposite side of the lake was active at the time of the conquest of Nicaragua in 1522, and the conquerors, thinking the lava they saw was gold, had themselves lowered into the crater at the risk of their lives; it had a great eruption in 1670, and began to smoke again in 1860.

MASCARA, a fortified town of Algeria in the province of Oran, 60 miles south-east of Oran, lies at a height of 1900 feet above the sea, on the southern slope of the first chain of the Atlas mountains, and occupies two small hills separated by the Oued Toudman. The walls, upwards of 2 miles in circuit, and strengthened by bastions and towers, give the place a somewhat imposing appearance; the French part of the town is substantial and clean; and among the public buildings are three mosques (one used as a church, another as a granary), a large hospital, a small theatre, and the usual establishments attaching to the seat of a sub-prefect and the centre of a military subdivision. A public garden of 10 acres has been laid out in the ravine. The population was 9442 in 1866, and 9240 in 1872.

Mascara (*i.e.*, place of soldiers) was the capital of a beylik during the Spanish occupation of Oran from the 16th to the close of the 18th century; but for the most of that period it occupied a site about 2 miles distant from the present position. On the removal of the bey to Oran its importance rapidly declined; and it was quite an insignificant place when in 1832 Abd-el-Kádir, who had been born in the neighbourhood, chose it as the seat of his power. It was laid in ruins by the French under Marshal Clausel and the duke of Orleans in 1835, and, being again occupied by Abd-el-Kádir in 1838, was again captured in 1841 by Bugeaud and Lamoricière.

MASCARENE ISLANDS, or MASCARENHAS, a group in the Indian Ocean to the east of Madagascar, consisting of Mauritius (Île de France), Réunion (Bourbon), and Rodriguez. Mauritius and Rodriguez belong to Great Britain, Réunion to France. The collective title is derived from the Portuguese navigator Garcia Mascarenhas, by whom Bourbon, at first called Mascarenhas, was discovered in 1505.

MASCARON, JULES, was born at Marseilles in 1634, and died at his diocesan city of Agen in 1703. His father was an advocate, and he was himself intended for the law, but he preferred the church. As a member of the Oratorian congregation he preached in different provincial towns, beginning with Saumur, and in all produced a great effect. Then he went to Paris and quickly established his reputation at a time when the court, dissolute enough in manners, had already begun to exercise its connoisseurship in matters of sacred eloquence. Several complimentary speeches of Louis XIV. to Mascaron are handed down by tradition. He was not, however, in the ordinary sense a courtier; or if so he was a very bold and adroit one. In Lent 1669 he preached before the king against adultery in the strongest terms. Either from respect for him or to get rid of him Louis made him bishop of Tulle, but he still continued occasionally to preach and to deliver *oraisons funèbres* before the court. His reputation for these was so high that the king not unfrequently indicated subjects to him himself. His crowning success in this way was his funeral sermon on Turenne in 1675. He was afterwards translated to Agen, where he died, as has been said; but his appointment was not a banishment, and he was summoned more than once to preach before the court, notably in his sixtieth year, when Louis is said to have remarked to him, "Votre eloquence n'a pas vieilli." Mascaron, though the contemporary of Bossuet, belongs to an older school of oratory. His style is unequal, and his taste not always sure, but occasionally he has much vigour. Besides the Turenne address his funeral sermon on the chancellor Séguier ranks as his chief performance. These, with other similar pieces, were collected and edited by Father Borde, a member of the author's own congregation, in 1740.

MASCHERONI, LORENZO (1750–1800), an Italian geometer, was professor of mathematics at the university of Pavia, and published a variety of mathematical works, the best-known of which is his *Geometria del Compasso* (Pavia, 1797), a body of constructive geometry in which the use of the circle alone is postulated. Many of the solutions are most ingenious, and some of the constructions of considerable practical importance.

The English reader will find a copious extract from Mascheroni's work in Leslie's *Geometry*, 3d ed., p. 204. There is a French translation by Carette (Paris, 1798), who also wrote a biography of Mascheroni.

MASINISSA, a Numidian prince whose history is closely intertwined with that of the wars between Rome and Carthage. With true barbarian fickleness, and a keen eye to his own interests, he espoused now one side now the other, inclining however on the whole decidedly in favour of Rome, so much so indeed as to be spoken of by Roman orators and historians as "a most faithful ally of the Roman people." He was the son of a Numidian king or chief, Gala, whose dominions coincided with the eastern portions of Numidia, and thus bordered on Carthaginian territory, or what is now Tunis. He was educated, like many of the Numidian chiefs, at Carthage, learnt Latin and Greek, it is said, and was in short an accomplished as well as a naturally clever man. Although his kingdom was nominally independent of Carthage, it really stood to it in a relation of vassalage; it was directly under Carthaginian influences, and was imbued to a very considerable extent with Carthaginian civilization. It was to this that Masinissa owed his fame and success; he was a barbarian at heart, but he had a varnish of culture, and to this he added the craft and cunning in which Carthaginian statesmen were supposed to excel. While yet a young man, he drove his neighbour Syphax, prince of western Numidia, out of the country now known as Algiers, and forced him to fly to the Moors in the extreme west of Africa. Soon afterwards he appears in Spain, fighting for Carthage with a large force of Numidian cavalry against the Romans under the two Scipios. The defeat of the Carthaginian army in 206 B.C., which for a time at least gave the Romans complete mastery of the south of Spain, led him to desert his old allies and to cast in his lot with the fortunes of Rome. The famous Scipio Africanus is said to have cultivated his friendship and done all he could to secure his services for his country. Masinissa now quitted Spain for a while for Africa, and was again engaged in a war with Syphax, in which he was so decidedly worsted that he found himself at last merely the head of a small band of marauders, and was obliged to confine his movements to the coast. Scipio's arrival in Africa in 204 gave him another chance, and no sooner had he joined the Roman general than he quite crushed his old enemy, Syphax, and captured Cirta (Constantineh), the capital of Syphax. Here occurs the romantic story of Sophonisba, daughter of the Carthaginian Hasdrubal, who had been promised in marriage to Masinissa, but who had subsequently become the wife of Syphax. Masinissa, it is said, wedded her immediately after his victory, but was required by Scipio to dismiss her as a Carthaginian, and consequently an enemy to Rome. To save her from such humiliation he sent her poison, with which she destroyed herself. Masinissa was now accepted as a thoroughly loyal ally of Rome, and was confirmed by Scipio in the possession of his hereditary kingdom. In the decisive battle of Zama, 202 B.C., which witnessed Hannibal's downfall, he commanded the cavalry on Scipio's right wing, and materially assisted the Roman victory. For his services on that great day he had given him, under a treaty with Rome, the kingdom of Syphax with its capital Cirta, and thus under Roman protection he became master of the whole of Numidia, and his dominions completely enclosed the Carthaginian territories, now straitened and reduced at the close of the Second Punic War.

Masinissa was still far from satisfied, and it would seem that he almost had thoughts of annexing Carthage itself with the connivance of Rome. He spared no opportunity to harass and annoy the city by pressing unfair claims to some of its best and oldest possessions, and threatening perpetual encroachments. In a war which soon followed he was successful; the remonstrances of Carthage with Rome on the behaviour of their ally were answered by deputing Scipio to arbitrate in the quarrel, but, as though intentionally on the part of Rome, no definite settlement was arrived at, and thus the relations between Masinissa and the Carthaginians were still unfriendly. Rome, it is certain, deliberately favoured her ally's unjust claims with the view of keeping Carthage weak. Masinissa too was cunning enough to retain the friendship and good opinion of the Roman people by helping them with liberal supplies in their wars in the East, with Perseus of Macedon and with Antiochus. As soon as Carthage seemed to be recovering herself, and some of Masinissa's partisans were driven from the city into exile, his policy was to alarm the fears of Rome, till at last, in 149, war was declared, the Third Punic War, which ended in the final and utter overthrow of Carthage. The king bore some part in the negotiations which preceded the war, and died soon after its commencement in 148 B.C., after a life of ninety and a reign of sixty years.

Masinissa was an able ruler and a decided benefactor to Numidia, the resources of which he developed, while he converted a people which had been little better than a plundering tribe into a settled and civilized population, and out of robbers and marauders made efficient and disciplined soldiers. To his sons he bequeathed a well-stored treasury, a formidable army, and even a fleet. Cirta, his capital, became a famous centre of Phœnician civilization. In fact Masinissa changed for the better the whole aspect of a great part of northern Africa. He had much of the Arab nature, was singularly temperate, and equal to any amount of fatigue. His fidelity to Rome was not the fidelity of principle, but merely that of temporary expediency; it is in the really good work he did for his country that the noblest side of his character comes into display.

For Masinissa, Livy and Sallust's *Jugurtha* must be specially consulted by scholars. English readers may be referred to a very full article in Smith's *Dictionary of Classical Biography*; also to Mommsen's *History of Rome* and Niebuhr's *Lectures*.

MASK, or MASQUE. See DRAMA, vol. vii. p. 431 *sq.*

MASKELYNE, NEVIL (1732-1811), astronomer-royal at Greenwich for nearly half a century, was born in London October 6, 1732. The great solar eclipse of 1748 seems to have made a deep impression upon him; and after studying divinity at Trinity College, Cambridge, of which he was elected a fellow in 1756, he determined to devote himself wholly to astronomy. He early became intimate with Bradley, and in 1761 was deputed by the Royal Society to make observations of the transit of Venus at St Helena. During the voyage he introduced into navigation the determination of longitude by lunar distances, a method which Mayer's recently published tables had made practically possible. In 1763 he undertook a voyage to Barbados to test Harrison's watches, which, however, he reported to be inferior to the method of lunars for determining longitude. In 1765 he succeeded Bliss as astronomer-royal, and thereafter devoted himself with singular energy to the duties of his office, which he held till his death, February 9, 1811.

Maskelyne's first contribution to astronomical literature was "A Proposal for Discovering the Annual Parallax of Sirius," published in 1760 in the *Philosophical Transactions*, in which also most of his later original memoirs appeared—*e.g.*, his observations of the transit of Venus (1761 and 1769), observations on the tides at St Helena (1762), astronomical observations at St Helena (1764) and at Barbados (1764). In 1763 he published a small octavo, *The British Mariner's Guide*, which contains the valuable suggestion that, in order to facilitate the finding of longitude at sea, lunar distances should be calculated beforehand for each year and published in a form accessible to navigators. This suggestion, the germ of the *Nautical Almanac*, was approved of by the Government, and under the care of Maskelyne the *Nautical Almanac* for 1767 was published in 1766. During the remainder of his life Maskelyne continued to superintend the publication of this invaluable annual, the *Nautical Almanac* for 1815 being the last which he prepared. Another valuable service which he rendered astronomy was his inducing the Government to print his observations annually. Flamsteed's and Bradley's observations had been private property, and were published as such. The result of Maskelyne's action was the accumulation and rapid dissemination of a long series of observations which from their continuity and accuracy have been of inestimable value to astronomers, and form along with the *Nautical Almanac* his most lasting monument. The whole work of the observatory was carried on by him and his one assistant in a most methodical manner, Greenwich being in point of organization second to none amongst the observatories of the day. He introduced several improvements in the use of the instruments, being, for example, the first astronomer who measured to tenths of a second; and he prevailed upon the Government to replace Bird's mural quadrant, which had become untrustworthy, by a repeating circle of 6 feet in diameter. The new instrument was constructed by Troughton; but Maskelyne did not live to see it completed. In 1772 he suggested to the Royal Society the famous Schehallion experiment for the determination of the earth's density. Forty years previously Bouguer had demonstrated by experiment that Chimborazo in South America affected the direction of the plumb-line quite appreciably; but his observations were not made with sufficient care to deduce therefrom any trustworthy result. Maskelyne's experiments were made in 1774 (see *Philosophical Transactions* for 1775), the apparent difference of latitude between two stations on opposite sides of the mountain being compared with the real difference of latitude obtained by triangulation. From Maskelyne's observations Hutton deduced by laborious calculations that the density of the earth was 4·5 times that of pure water. Playfair subsequently estimated with greater accuracy the mass of Schehallion, and obtained 4·7 for the earth's mean density. Maskelyne also took a great interest in various geodesical operations, notably the measurement of the length of a degree of latitude in Maryland and Pennsylvania (*Philosophical Transactions*, 1769), which was carried out by Mason and Dixon in 1766-68, and later the determination of the relative longitude of Greenwich and Paris (*Philosophical Transactions*, 1787). Cassini, Legendre, and Méchain conducted the triangulation on the French side; on the English side the work was carried on under the superintendence of General Roy. This triangulation was the beginning of the great trigonometrical survey which has since been extended all over the country. A volume of *Selections* (London, 1812) contains several papers that were published by Maskelyne as additions to the *Nautical Almanac*. His observations fill three large folio volumes, and many of them were reprinted in Vince's *Astronomy*.

MASKINONGE. See PIKE.

MASOLINO DA PANICALE (1383–*c.* 1440). The life and art-work of this Florentine painter were related by Vasari in a form which is partly demonstrated and partly inferred to be highly incorrect. We shall follow the account supplied, and in many respects carefully vouched, by Messrs Crowe and Cavalcaselle.

Masolino (a name which corresponds to "Tommy") was said to have been born at Panicale di Valdelsa, near Florence. It is more probable, however, that he was born in Florence itself, his father, Cristoforo Fini, who was an "imbiancatore" or whitewasher, having been domiciled in the Florentine quarter of S. Croce. There is reason to believe that Tommaso, nicknamed Masolino, was a pupil of the painter Starnina, and was principally influenced in style by Antonio Veneziano; he may probably enough have become in the sequel the master of Masaccio. His birth took place in 1383; his death later than 1429, perhaps as late as 1440. The only works which can with certainty be assigned to him are a series of wall paintings executed towards 1428, commissioned by Cardinal Branda Castiglione, in the church of Castiglione d'Olona, not far from Milan, and another series in the adjoining baptistery. The first set is signed as painted by "Masolinus de Florentia." It was recovered in 1843 from a coating of whitewash, and is not a little damaged; its subject-matter is taken from the lives of the Virgin and of Sts Lawrence and Stephen. The series in the baptistery relates to the life and death of John the Baptist. The reputation of Masolino had hitherto rested almost entirely upon the considerable share which he was supposed to have had in the celebrated frescos of the Brancacci chapel, in the church of the Carmine in Florence; he was regarded as the precursor of Masaccio, and by many years the predecessor of Filippino Lippi, in the execution of a large proportion of these works. Now, however, from a comparison of the Castiglione with the Brancacci frescos, and from other data, it is greatly doubted whether Masolino had any hand at all in the latter series. Possibly he painted in the Brancacci chapel certain specified subjects which are now either destroyed or worked over. Of other and still existing subjects, hitherto assigned to Masolino on the authority of Vasari and later writers, the authorship is now more reasonably ascribed to Masaccio,—except only that one compartment, that which represents in one half Peter reviving Tabitha (or curing Petronilla), and in the other half Peter and John healing a cripple, remains in suspenso between Masaccio and Masolino. In the Castiglione frescos there is some tenderness of expression, and the nude figures are studied with an amount of care superior to their epoch; generally the parts are well made out, but without unity of composition, or mastery of perspective, or of contrast and chiaroscuro. The merit of these works is not to be compared with that of the Brancacci frescos, unless in the single instance above excepted.

The now ascertained facts of Masolino's life are that towards 1423 he entered the service of Filippo Scolari, the Florentine-born obergespan of Temeswar in Hungary, that he stayed in consequence some time in that country, and that, returning towards 1427 to Italy, he painted the works in Castiglione. Thus he resettled in Lombardy, not in Florence; nor is there anything to show that he returned to his Tuscan home at a later date.

MASON, FRANCIS (1799–1874), an American missionary, son of a shoemaker in York, England, was born April 2, 1799. After emigrating to the United States in 1818, he practised there the trade he had learned from his father; but, having studied languages with his minister at Canton, Massachusetts, he in 1827 entered the Newton theological institution. In 1830 he was sent by the American Missionary Union to labour among the Karens in Burmah, where he translated the Bible into two dialects of their language, and also conducted a training college for native preachers and teachers. In 1852 he published a book of great value on the fauna and flora of British Burmah, of which an improved edition appeared in 1860 under the title *Burmah, its People and Natural Products.* He was also the author of a grammar and vocabulary of the Pali language, besides various translations from it and other Indian dialects. He died at Rangoon, March 3, 1874. See his autobiography, *The Story of a Working Man's Life, with Sketches of Travel*, 1870.

MASON, GEORGE HEMMING (1818–1872), A.R.A., was born at Whitley, in 1818, the eldest son of a Staffordshire county gentleman. Intended for the medical profession, he studied for five years under Dr Watt of Birmingham; but he had no taste for science; all his thoughts were given to art. In 1844 he abandoned medicine and travelled for a time on the Continent, visiting France, Germany, and Switzerland, and finally settling in Rome. His pencil was busy with the picturesque scenery that surrounded him, and with hardly any instruction, except that received from nature and from the Italian pictures that met his eye, he gradually acquired the painter's skill. At least two important works are referable to this period,—Ploughing in the Campagna, shown in the Royal Academy of 1857, and In the Salt Marshes, Campagna, exhibited in the following year. After Mason's return from the Continent, in 1858, when he settled at Wetley Abbey, he continued to paint Italian subjects from studies made during his foreign tour, and then his art began to touch, in a wonderfully tender and poetic way, the peasant life of his native England, and especially of his native Staffordshire, and the homely landscape in the midst of which that life was set. The first picture of this class was Wind on the Wolds, and it was followed—along with much else—by the painter's three greatest works—the Evening Hymn, 1868, a band of Staffordshire mill-girls, seen, their figures dark against the sunset, returning from their work, singing as they walk; Girls Dancing by the Sea, 1869; and the Harvest Moon, 1872. Mason had long suffered from heart disease, which carried him off on the 22d of October 1872. In his work he laboured under the double disadvantage of feeble and uncertain health, and a want of thorough art-training, and consequently his pictures were never produced easily, or without strenuous and long-continued effort. His art is great in virtue of the solemn pathos which pervades it, of the dignity and beauty which it reveals in rustic life, of its keen perception of noble form and graceful motion and of rich effects of colour and subdued light. In *motif* and treatment it has most in common with the art of Millet and Jules Breton, and of Frederick Walker among Englishmen. An interesting collection of Mason's pictures was brought together by the Burlington Club shortly after his death.

MASON, WILLIAM (1725–1797), was about the beginning of the last quarter of the 18th century one of the most eminent of living poets, but his eminence was owing to the lowness of the poetic level at the time. He is now held in remembrance, not by his poetry, but by his having been the friend, the literary executor, and the biographer of Gray. Born in 1725, the son of a Yorkshire clergyman, entered of St John's College, Cambridge, in 1742, he took his bachelor's degree in 1745, and seems to have at once decided steadily on a literary career, reading little or nothing, Gray says, but writing abundance. Pope died in 1744, and the aspiring young poet lamented him as "Musæus" in a careful imitation of Milton's *Lycidas*, showing an ear for the music of verse and considerable skill in weaving words together, but not a spark of original force. By his *Musæus* (1747) Mason attracted the

notice of Gray, and through his influence was elected a fellow of Pembroke College. Mason was Gray's attached friend, admirer, and poetical pupil to the end of the greater poet's life. More fancy than judgment, and indolence in reading, were the chief faults that Gray found in his young friend. With his usual penetration, Gray discerned the defects of intellect that lie at the root of the weakness of Mason's poetry. He was painstaking enough and more than enough with his verses, his epithets, his phrases, his figures of speech, his rhymes; but he was deficient in energy of thought, his intellectual grasp was feeble, and he accepted and polished the easy suggestions of fancy instead of exerting himself to find exact expression for his subject. For a modest youth, as Gray describes him, he formed a great ambition, nothing less than the reconciliation of the modern with the ancient drama, to be effected by the strict observance of the unities and the restoration of the chorus. His *Elfrida*, a tragedy published in 1752 in pursuance of this ambition, is constructed elaborately upon deeply considered principles, but the principles are drawn from pedantic books and not from the dramatic needs of men, as may be judged from the dramatist's opinion that Shakespeare, "in compliance merely with the taste of the time, showed a disregard of all the necessary rules of the drama." *Elfrida* is highly "incorrect" in two respects—one venial in a play, the other fatal; it abounds in anachronistic allusions and moral improbabilities. Mason's second attempt, *Caractacus* (published in 1759), is much stronger in construction and situation, but he did not possess the rare art of making his characters speak out of their own thoughts; they only speak as Mason the poet might have done in their circumstances if his fancy had been quite cool. Both *Elfrida* and *Caractacus* were acted in 1776, when Mason had made a considerable reputation by his *English Garden* (a poem in blank verse, first book published in 1772), his *Heroic Epistle to Sir W. Chambers* in 1773, and his *Memoirs of Gray* in 1775. The plays were not successful; Mason did not expect success; his plays were intended to be read as poems. The manager perhaps had hopes from the novelty of the choruses of Saxon maidens and Druids. The second book of the *English Garden* was issued in 1777, the third in 1779, the fourth in 1782. Mason took orders in 1754, and soon afterwards was presented to the vicarage of Ashton in Yorkshire, the canonry of York, the prebend of Driffield, and the precentorship of York cathedral. Ashton was his residence till his death in 1797.

MASON AND DIXON'S LINE, a line in the United States between Pennsylvania on the north and Delaware, Maryland, and West Virginia on the south, coinciding with 39° 43′ 26″·3 N. lat., and famous for a long time as the limit between the "free" and the "slave" States. It derives its name from Charles Mason, F.R.S. (1730–87), and Jeremiah Dixon, two English astronomers who, between 1763 and 1767, surveyed the line for 244 miles west from the Delaware river, leaving only 36 miles of the Pennsylvania boundary to be fixed in 1782–84. This line must not be confounded, as has often been done, with the parallel of 36° 30′ N. lat., which was assigned by the "Missouri compromise" of 1820 as the limit to the north of which slavery could not be introduced.

MASS. See EUCHARIST and MISSAL.

MASSA, or, to distinguish it from several places of the same name, MASSA CARRARA, a city of Italy, the chief town of the province of Massa, lies on the left bank of the Frigido, a small stream falling into the Gulf of Genoa about 3 miles lower down. It is 78½ miles south-east of Genoa by rail, and 26 miles north of Pisa. The ancient part of the city stands on a hill. Among the objects of interest it is sufficient to mention the old ducal palace, the new cathedral (erected instead of the building destroyed by Elisa Bacciocchi because it interfered with the view from the palace windows), the technical school, and the academy of science and literature, originally known as Dei Derelitti. Like Carrara, Massa is largely engaged in the marble trade; it also manufactures silk, oil, and paper. The population of the city was 4786 in 1871; that of the commune was 15,017 in 1861 and 18,031 in 1881.

Massa is first mentioned in the 9th century. About the close of the 10th it was bestowed by Otho the Great on the bishops of Luni, and in consequence it came to be distinguished for a time as Massa Lunense. From the bishops it passed to the marquises of Luni (hence *Massa del Marchese*), and more particularly to a branch of the Malaspina family. After a period in which Lucca, Pisa, the Visconti, the Fieschi, and others were successively in possession it returned, under Florentine protection, to Alberico Malaspina, and finally through the marriage of Ricciarda Malaspina with Lorenzo Cybo became (1519) *Massa Cybea.* Raised under Alberico Cybo from being little better than a feudal village to the rank of a fortified town, Massa was in 1568 made the capital of a principality by Maximilian II., and in 1664 the capital of a duchy by Leopold I. By the marriage of Maria Teresa dei Cybei with Duke Ercole III. of Modena it passed to the Este family; and after the period of the French Revolution, during which it formed part of the duchy of Lucca assigned to Napoleon's sister and brother-in-law, it was restored by the congress of Vienna to Beatrice, duchess of Modena. Massa was made an episcopal see only in 1828, though the design of giving it this dignity had been entertained and almost realized in 1757. The total area of the duchy of Massa and Carrara was 62 square miles, of which 35 belonged to Massa.

See Repetti, *Diz. della Toscana*; Viani, *Memorie della famiglia Cybo*; Musellini, *Ricciarda Malaspina e Lorenzo Cybo*; and Farsetti, *Ragion. storico int. della città di Massa.*

MASSACHUSETTS

MASSACHUSETTS, an Indian name originally applied to a small hillock bordering on Boston Harbour, and thence to a neighbouring tribe of Indians. It is the chief political division of New England, and one of the original thirteen States of the American Union. It lies for the most part between 40° and 42° 45′ N. lat., and 70° 30′ and 73° 30′ W. long. Plate IX.

Physical Description.—Its area, of about 7800 square miles, forms in the main a parallelogram, of 160 miles east and west, 50 miles north and south,—with a projection at the south-east and a lesser one at the north-east, which gives a breadth of 90 miles at this part, where it borders upon the ocean, while the general irregularity of this coast-line gives a sea frontage of about 250 miles. No large navigable river flows in any part, though the Connecticut river, bisecting the State during 50 miles of its course, and fed within it by several lateral streams, has been made navigable for small craft. The Housatonic, a lesser stream, flows parallel with the Connecticut, farther west. The two valleys are separated by the Hoosac range (1200 to 1600 feet high) of the Berkshire Hills, a part of the Appalachian system, and a continuation of the Green Mountains of Vermont. These, with the Taconic range on the western side of the Housatonic valley, of which the highest peak is Greylock, or Saddleback (almost 3500 feet), in the extreme north-west corner of the State, form the only considerable elevated land. Bordering on the Connecticut, Mount Tom (1200 feet) and a few other hills form conspicuous landmarks. Wachusett (2018 feet), farther east, rises from a level country. The Blue Hills in Milton are the nearest elevation to the coast, and are conspicuous to navigators approaching Boston.

The Merrimac runs for 35 miles through the north-east corner of the State, and affords valuable water-power at Lowell, Lawrence, and Haverhill. A few small streams, useful for mill purposes and irrigation, seek the ocean through Boston, Buzzard's, and Narragansett Bays, running for the most part through a rolling country. The south-east parts of the State are level,—with a slightly elevated ridge (Manomet) south of Plymouth,—sandy in soil, with tracts of forest, largely white pine, and well watered by ponds. Between Plymouth and Buzzard's Bay there is the most considerable region of untamed soil in the State, where deer are occasionally seen.

South of Cohasset the shore is sandy, with a few isolated rocky ledges and boulders. About Boston, and to the north of it, the shore is rocky and picturesque. Massachusetts Bay is a name now applied to the gulf of which the outer limits are Cape Cod and Cape Ann; but in early days it was applied to the enclosed lesser bay on its western side, now called Boston Harbour, the finest roadstead on the coast. The extreme hook of the Cape Cod peninsula forms Provincetown Harbour, which is an excellent and capacious port of refuge for vessels approaching Boston. Salem Harbour is the most considerable other haven on the bay; while on Buzzard's Bay New Bedford has a good harbour.

The principal islands lie off the southern coast. The largest is Martha's Vineyard, 21 miles long, with an average breadth of 5 or 6. It has in Holmes's Hole a spacious harbour, much frequented by wind-bound vessels seeking a passage round Cape Cod. The island is interesting as the scene of Mayhew's missionary efforts among the Indians, and it still harbours a remnant of a tribe. It has a population (4300 in 1880) formerly dependent wholly upon the sea; and of late years it has become a summer resort of much popularity. Farther east, Nantucket, an island of triangular shape, 15 miles long and 11 wide at its eastern end, is likewise the home of a seafaring folk (population in 1880, 3727), who still retain in some degree primitive habits, though summer visitors are more and more affecting its life. Nantucket Shoals, south-east of the island, is a large sandbank dangerous to navigation.

Flora and Fauna.—The original native trees and plants did not vary from what is common to New England and northern New York. The presence of a dense population has driven some out, and brought in others, including some noxious weeds. The larger wild animals have disappeared except an occasional deer; but small game still runs, and even within the municipal limits of Boston wild foxes are occasionally killed. No very large birds frequent the State, though a stray eagle is sometimes seen. Reptiles of a harmless kind are found, and three kinds of venomous snakes,—the latter even near Boston, particularly in the Blue Hills of Milton. Fish are abundant on the coast, and the cod is sometimes used as an emblem of the State, a figure of one hanging in the Representatives' Chamber at the State House. The artificial propagation and preservation of salmon and other edible pond and river fish have been of late carried on successfully under the supervision of a State commission

Geology.—Professor N. S. Shaler of Harvard University says: "Geologically as well as topographically, the State is divided into four districts, which extend farther than the State limits. In the south-eastern part the whole of Cape Cod and Plymouth county is made up of rearranged glacial drift. Westward, from the shore region to the Connecticut, the rocks are of the Laurentian, Cambrian, and Carboniferous ages. The Connecticut river flows through a basin of Triassic rocks, abounding in reptilian footprints. West of this basin, to the New York line, the surface is occupied by an extensive series of highly metamorphosed rocks, the age of which is doubtful; but the series is certainly as old as the Silurian. The whole surface of the State was greatly affected by the last glacial period, as much so as Scotland or Sweden.

"The economic resources are limited. An area of about 250 square miles in the south-eastern part of the State shows Carboniferous rocks, containing several coals. The deep drift coating, the profoundly dislocated character of the beds, and the graphitic nature of the coals have made mining unsuccessful. Mines of silver-bearing lead have at times been worked in the north-eastern shore districts, and in the Connecticut valley, but without profit. Emery is now successfully worked in the western district. There are also deposits of hematite iron ores all along the border of New York, which are considerably worked. There are numerous quarries of sienite in the eastern parts of the State, some of red sandstone in the Connecticut valley, and of white marble in the western regions."

Climate.—The climate is a trying one, showing great extremes (20° Fahr. below and 100° above), with about 42 inches of rainfall. The mean average temperature of Boston is 48° Fahr. In the interior it is a trifle lower. Changes are often sudden, and the passage from winter to summer is by a rapid spring. The ocean tempers the climate considerably on the seaboard. Boston harbour has been frozen over in the past, but steam-tugs plying constantly prevent now the occurrence of such obstruction.

Agriculture.—The soil, except in some of the valleys, can hardly be called naturally fertile; and sandy barrens are common in the south-eastern parts. High cultivation, however, has produced valuable market-gardens about Boston and the larger towns; and industry has made the tilling of the earth sustaining in most other parts; while the average sterility of the soil has doubtless had a strong influence in developing a sturdy yeomanry in the rural regions.

In 1875 671,131 tons of hay were cut. On the seaboard some extensive salt marshes yield a hay which is much prized. The corn crop diminished one half from 1855 to 1875. The State produced in 1880 1,797,593 bushels of Indian corn, 15,768 of wheat, 645,159 of oats, 80,128 of barley, 213,716 of rye, 67,117 of buckwheat. In 1879 the average cash value per acre of principal farm-crops was $26·71, which amount is exceeded only in Rhode Island. In the Connecticut valley tobacco is grown, 3358 acres being given to it in 1880, producing 5,369,436 lb, which gives the State the thirteenth rank in the Union. In forty years the sheep have fallen from 384,614 to 65,123 in 1880; and in the same year there were 139,861 horses and 174,859 cows. In 1880 there were 38,406 farms, of which 35,266 were owned by occupants. Most of them were between 20 and 500 acres each, nearly 12,000 having over 100 acres.

The Population and its Condition.—The State is divided into twelve congressional districts, each entitled to one representative in the Federal Congress, and representing from 151,000 to 181,000 inhabitants. It is divided also into 346 towns, and these are grouped into 14 counties, with an aggregate in 1880 of 1,783,085 inhabitants, of whom the native-born are 1,339,594, and the foreign-born 443,491. This population was divided into 379,710 families, living in 281,188 dwellings, with nearly 222 persons to the square mile, and less than an average of 3 acres to each person. Nearly every fifth person is a voter. The total vote in the presidential campaign of 1880 was 282,512. The number of persons born within Massachusetts, and living in 1880 out of the State, but within the limits of the United States, was 1,356,295. The population at past censuses has been—

1790	378,787	1840	737,699
1800	422,845	1850	994,514
1810	472,040	1860	1,231,066
1820	523,159	1870	1,457,351
1830	610,408	1880	1,783,085

There were, in 1880, 31 cities and towns of over 10,000 inhabitants.

Births and Deaths.—It is calculated that to every 1000 inhabitants the births are more than 23, the marriages about 8, the deaths 18¼, the excess of births over deaths being nearly 5. In 1880 44,217 were born, and 15,538 couples were married, while 35,292 persons died, at an average age of thirty-two years. Taking persons over twenty years of age, the deaths in $37\frac{3}{12}$ years were 187,264, with an average age of 51·42. During sixteen years the average age at death of all conditions was 30·18 years. In twenty years the birth-rate to 1000 persons was 26·2, the death-rate 19·7.

Health.—A board of health, lunacy, and charity supervises the public hygiene, and the institutions for the insane and paupers. By their reports of 1880 it appears that the prominent causes of death are for the ages from birth to five—diarrhœa, diphtheria, pneumonia, scarlet fever, and obscure diseases of the brain and intestines; from five to ten—infectious diseases and obscure diseases of childhood; from ten to fifteen—diphtheria, consumption, and typhoid fever; from fifteen to twenty—consumption and typhoid fever; from thirty upward—pneumonia and heart disease, with cancer from forty to sixty. Paralysis and apoplexy gain after forty, and after seventy the greatest portion die of old age. The twelve principal causes of fatality in all ages are placed in this order:—consumption, pneumonia, diphtheria, heart disease, old age, cholera infantum, paralysis, cancer, scarlet fever, cephalitis, bronchitis, and apoplexy; and by these disorders 60 per cent. of all deaths occur. Intermittent fever was known in the earlier history of the State, but in this century, before 1877, was practically unknown, except in the form of an occasional epidemic; but since that date it has made rapid progress in the western parts.

Paupers.—Other tables of the same board show that in July 1880 19,318 paupers were receiving, wholly or in part, local or State support; and the same was true of about 3000 insane persons. The average number of inmates of these charitable establishments (State, city, and town) in 1880 was 7467 persons. At public and private insane asylums there were 4398 cases within the year.

Immigration.—The immigrants from Europe during the year ending September 30, 1880, were 33,636 in number, of whom one-third were Irish, and the males in comparison with the females were as 18 to 15. A large part of this influx merely passed through the State to the west.

Business and Finance; Commerce and Manufactures.—Up to 1830 the commerce of the State found various outlets besides Boston; but since then this city has more and more absorbed the whole foreign trade. The whaling business still remained to other ports, and at one time gave occupation to a thousand ships. The introduction of petroleum gradually diminished this resource of the lesser ports.

The packing of pork and beef was formerly centred in Boston; but, while now a similar business tenfold as large is done, it has been greatly exceeded in the west. For many years Massachusetts controlled a vast lumber trade, drawing upon the forests of Maine, but the growth of the west has changed the old channels of trade, and Boston carpenters now make large use of western lumber. The American trade with China and India was begun in Salem, and was next controlled in Boston, till this also was lost some years ago to New York. In commercial relations the chief port of Massachusetts attained its highest influence about forty years ago, when it was selected as the American terminus of the first steamship line (Cunard) connecting England with the United States, but Boston lost the commercial prestige, then won, by the failure of the State to develop railway communication with the west, so as to equal the development effected by other cities. It was between 1840 and 1850 that the cotton manufactures of Massachusetts began to assume large proportions; and about the same time the manufacture of boots and shoes centred here, and has ever since maintained its prominence, much more than one-half of all boots and shoes manufactured in the country being the product of this State. Again, ice and granite became important articles of export; and Quincy granite, from 1849, was sent to various southern ports, having an importance as a building-stone which it has hardly lost now, with the later multiplication of varieties of such stones. Medford ships began to be famed shortly after the beginning of the century, and by 1845 that town employed one quarter of all the shipwrights in the State. From 1840 to 1860 Massachusetts-built ships competed successfully for the carrying trade of the world. Before 1840 500 tons made a large ship, but after the discovery of gold in California the size of ships increased rapidly, and the lines of their models were more and more adapted to speed. The limit of size was reached in an immense clipper of 4555 tons, and the greatest speed attained in a passage from San Francisco to Boston in seventy-five days, and from San Francisco to Cork in ninety-three days. The development of steam navigation for the carrying of large cargoes has driven this fleet from the sea. Hardly 18 per cent. of the exports and imports through Massachusetts is now carried in American bottoms. The grain elevators, which pour corn in bulk into ships at Boston to-day for European markets, are the result of the first attempt at such transportation, made in 1843, when citizens of Massachusetts sent corn to starving Ireland.

Coastwise steam lines, supported by Massachusetts capital, had run to Philadelphia and Baltimore for some years before the civil war broke up other less successful ones, which had connected ports further south. When the war and steam navigation put an end to the supremacy of Massachusetts wooden ships, much of the capital which had been employed in navigation was turned into developing railroad facilities, and coastwise steam lines. An effort to establish a European steam line failed. In 1872 the great fire in Boston, destroying $72,000,000 worth of property, made large drains upon the capital of the State, and several years of depression in business followed, to be succeeded by an era of business prosperity still continuing. The imports of Boston—practically of Massachusetts—for 1880 were $68,649,664; the exports, $69,178,764. In 1880 322 steamships sailed from Boston for European ports. In 1880 180 steam craft were owned in Massachusetts, with a capacity of 48,917 tons. Massachusetts had in 1880 a fleet of 376 sail of cod-fishing vessels, manned by 4185 men,—three quarters of all belonging to one port, Gloucester. In mackerel catching 239 vessels are employed. In 1882 20,117 persons were actively engaged in the fisheries, and it was estimated that 100,000 people depended on them for support. The capital invested is $14,334,450, and the product is worth $8,141,750. The total tonnage of the State in 1881 was 430,182, which gave the State rank after New York and Maine. In 1880, of 39,921 business houses, 329 failed, with liabilities at $3,336,954.

A general Act of 1870, with supplements of later years, allows of the incorporation of companies under it, and in 1880 such corporations, so organized, had $30,150,255 capital,—and this was in some part money disengaged of late years from navigation and its attendant branches of trade.

While the capital of the State may not have developed even yet, as it might, all that is possible for a system of railway communication with the west, it has fostered, and made possible, large facilities in the States of the Mississippi valley and beyond, which may in time so enlarge the terminal facilities of the State's chief port as to make it a more important outlet for export of the produce of the west, and give it a distinction justly its due from its geographical position.

In the working of ores the State is not prominent. Five furnaces in 1880 yielded 19,000 tons of pig iron. In wool, the Boston market is the largest in the country. The State has far more spindles (4,465,290) in cotton manufacture than any other State, and not much short of half the number in the whole United States (10,921,147). She employs in this business 62,794 hands, or about one third of the entire force so employed in the United States.

Massachusetts is the only State in the east, manufacturing textile fabrics, where ten hours is the operative's day; and it is reported by the State bureau of statistics that, equal grades being considered, as much is produced under her system, per man, loom, or spindle, as in States where eleven hours or more is the rule, and that the Massachusetts operative earns as much or more per day. Canadian French now constitute a considerable proportion of the factory hands. In certain departments of labour Chinese are beginning to find employment.

Formerly farmers' daughters of native stock were much employed in factories. Operatives of foreign birth or parentage have taken in great part their places; and those of native stock have sought other occupations,—largely in the manufacturing of small wares in the cities, and particularly in departments of trade where skilled labour is essential. Household service is seldom now done, as it formerly was, by women of native stock,—persons of Irish, Swedish, and Scottish origin, with many from Nova Scotia and New Brunswick, taking their places.

Railways.—The report of the Railroad Commissioners for 1880 shows twenty-nine street railways; capital, $6,144,000; assets, $10,173,079·84; total income, $3,711,378·18; expenses, $3,003,024·87; length of roads, 240 miles; miles run, 12,516,363; passengers carried, 68,631,842.

Of steam railways there were 3044 miles of single track, of which 1893 were main lines; and 27,057 Massachusetts stockholders held $78,806,559·95 capital stock of the total of $118,738,871·58; and 21,615 persons were employed. The total income of these roads was $35,140,374·77; and the dividends declared were $5,987,718·64. Total passengers carried, 45,151,152; freight carried, 17,221,567 tons. There were to passengers in 1880 nine fatal and fifteen other accidents; and one hundred and fifty-seven other persons were injured on the roads.

The Hoosac Tunnel—after that of Mont Cenis the longest in the world, 5¾ miles in length—pierces the Hoosac mountain in the north-west corner of the State, and opens a second direct railway communication with western lines, that of the Boston and Albany having been long without a rival. It cost $9,000,000, the State lending its credit, and was built between 1855 and 1874.

Savings Banks, &c.—In 1880 the number of open accounts was 706,395; amount of deposits, $218,047,922·37 (only exceeded in New York); amount of earnings, $11,894,710·60; ordinary dividends, $7,957,887·09; annual expenses, $581,274·35; number of outstanding loans (none exceeding $3000) 32,320, aggregating $34,203,951·81. The number of banks in 1880 was 164, against 22 in 1834. The number of co-operative saving fund and loan associations was 16, with $372,462·31 assets.

National Banks.—The report of the comptroller of the currency for 1880 says: "The thirteen States having the largest capital [in national banks] are Massachusetts, New York, Pennsylvania, &c. . . . in the order named." In 1879 the capital of national banks in Massachusetts was $94,748,172, that of New York being $85,706,942. In 1881 there were 242 such banks, with $95,605,000 capital, and $525,827 dividends, and in 1880 they issued $3,693,885 in circulating bills,—Pennsylvania with $2,036,890 coming next.

A report to the commissioner of internal revenue, for the six months ending May 31, 1880, shows Massachusetts to have 218 banking and trust companies, private bankers, and savings banks (not organized under the national law), with an aggregate capital of $5,638,099; average deposits to the amount of $208,822,039. These banks also held investments in United States bonds, amounting to $22,909,377.

Public Debt, &c.—The public debt of the State, January 1, 1881, was $32,799,464; the sinking funds, $13,050,192·20; the trust funds $2,890,650·92. The total taxable value was $1,927,855,430·09. The taxes produced $4,950,000. The rate of State taxation is much smaller than that of any other State. The State receipts were on account of revenue $7,881,198; on account of funds, $5,616,418, or $13,497,616 in all.

The Boston stock exchange stands next to New York in the extent of the securities in which it deals.

Citizens of Massachusetts (16,855 in number) hold 45,138,750 of the United States bonds, and the proportion of holders (23·04 per cent.) to the population of the State is in excess of that of all other States; New York, which is next, shows 20·24 per cent.

In 1881 the State contributed $2,699,681 as internal revenue to the Federal treasury, being a twelfth rank among the States and Territories.

Social Statistics.—Intellectual Life.—No statement of the influence which Massachusetts has exerted upon the American people, through intellectual activity and even through vagary, is complete without an enumeration of the names which, to Americans at least, are the signs of this influence and activity. In science, John Winthrop, the most eminent of colonial scientists; Benjamin Thompson (Count Rumford); Nathaniel Bowditch, the translator of Laplace; Benjamin Peirce; and Morse the electrician; not to include an adopted citizen in Louis Agassiz. In history, Winthrop and Bradford laid the foundations of her story in the very beginning; but the best example of the colonial period is Thomas Hutchinson, and in our day, Bancroft, Sparks, Palfrey, Prescott, Motley, and Parkman. In poetry, the pioneer of the modern spirit in American verse was Richard Henry Dana; and later came Bryant, Longfellow, Whittier, Lowell, and Holmes. In philosophy, and the science of living, Jonathan Edwards, Franklin, Channing, Emerson, and Theodore Parker. In oratory, James Otis, Fisher Ames, Josiah Quincy, jun., Webster, Choate, Everett, Sumner, Winthrop, and Wendell Phillips. In fiction, Hawthorne and Mrs Stowe, not to embrace the living and younger names of Howells and Aldrich. In law, Story, Parsons, and Shaw In polite scholarship, Ticknor and Hillard. In art, Copley, Gilbert Stuart, Washington Allston, William M. Hunt, Horatio Greenough, W. W. Story, and Thomas Ball. What in America was called the "transcendental movement"—which sprang out of German affiliations, and swept in its train many scholarly persons, and resulted in the well-known community of Brook Farm, under the leadership of the late Dr George Ripley—was a growth of Massachusetts, and in passing away it left, instead of traces of an organization, a sentiment and an aspiration for what was called a higher thinking, which gave Emerson his friendly sympathizers. It might go without saying that a community which fostered such persons and feelings was not at all times free from riotous and unbalanced ideas, which could inaugurate too many departures from the common course of wisdom.

Education.—Of the 307,321 children between five and fifteen in Massachusetts, 281,757 attend the public schools, in addition to 25,020 over fifteen, and 1833 under five; while 27,370 of all ages attend charitable, reformatory, and private schools. The public schools are 5570 in number; the academies and private schools, 423. The cost of maintaining the public schools is $5,156,731 per annum. This expenditure is exceeded only in the States of New York, Illinois, Pennsylvania, and Ohio. It is a little more in Iowa. A board of education (the governor, lieutenant-governor, and eight others) have the general charge, and their secretary acts as superintendent of the State system in conjunction with local superintendents and committees. Women are eligible to these positions, and among the teachers of the public schools they are largely in excess,—7462 women and 1133 men; and of the combined number (8595) 2228 had attended normal schools. The male teachers on an average receive $67·54 per month; the women, $30·59. The system includes common, high, and normal schools, with one normal art school, and various evening, industrial, and truant schools. No discrimination is made as to race, colour, or religious views. The average attendance is 89 per cent. of the membership. Two-fifths of one per cent. of the native population are illiterate. The State normal schools, where the teachers are trained, are five in number, besides the art school. The attendance upon them was 841 in 1880. Some of the cities and towns maintain their own training schools. Meetings of teachers are held once a month or oftener in various parts of the State, for comparison of views and experience.

The high schools are 215 in number, with 18,758 pupils and 491 teachers; and other secondary instruction is given in the business colleges, private academic schools, and the more distinctive preparatory schools, which send their graduates to the colleges. Of these last the most important is Harvard College, the chief department of what is known as Harvard University, which includes in addition various professional schools, and other colleges of special studies. This university in 1882 had 1382 students, with a staff of 200 officers and instructors; and of these students 823 belong to the academic department (Harvard College), where they are allowed wide latitude in the choice of the studies pursued. The classes of undergraduates are recruited largely from the State; but the establishment of examinations for admission in distant cities, like Philadelphia, Cincinnati, St Louis, and San Francisco, is increasing the proportion who come from other parts of the country. Harvard University is mainly at Cambridge, 3 miles from Boston, but some of the departments are in the latter city.

In the extreme west of the State is Williams College, which in 1880 had 227 students; and in the Connecticut valley is Amherst College, with 339 students. Boston University, in its several departments, had 510 students in 1880; and Tufts College, a few miles from Boston, an institution supported by the Universalist sect, had 63 students. Two Roman Catholic colleges are maintained,—Boston College with 80 students, and College of the Holy Cross, at Worcester, of about the same size. Of the various institutions for the instruction of women, two rank with the colleges for men,—Smith College at Northampton, and Wellesley College, not far from Boston. The income of college funds ($425,958) is only exceeded in New York ($710,164).

For agricultural students there are two schools,—one supported by the State at Amherst, and the Bussey Institution, a department of Harvard University. In technological science there is special instruction given in the Massachusetts Institute of Technology (Boston), the Lawrence Scientific School (of Harvard University), the Free Institute of Industrial Science (Worcester), and the School of all Sciences (Boston University). In theology, nearly three hundred students in 1880 were divided among the schools at Andover (Congregational), at Boston (in connexion with the university, Methodist), at Cambridge (Harvard University, non-sectarian, and an independent Episcopal school), at Somerville (Tufts College, Universalist), at Newton (Baptist), and at Waltham (New Church). In law there are schools in connexion with both Boston and Harvard universities; and the same is true of medicine, that of the former being of homœopathic tendency. The State is also supplied with special schools of various other sorts, particularly those for deaf mutes, the blind, and the feeble-minded, in which noteworthy methods have been employed with success.

In 1880 the United States patent office issued letters to an average of one inhabitant of the State in every 1333, a degree of inventive energy only exceeded in Connecticut, where the proportion is one in 1020.

The total receipts of the post-office in 1880 were $2,484,692, an amount only exceeded by New York, Ohio, Pennsylvania, and Illinois, while the State stands seventh in population.

The Press.—The earliest printing in the British colonies was done at Cambridge in this State, where, in 1640, the first book was printed, which is known as the "Bay Psalm-Book," being a version of the Psalms, for singing, made in the colony. Cambridge still retains its pre-eminence in the University and Riverside presses. A printing-house was not set up in Boston till 1674. In the early part of this century book printing was done at various country presses; but at present it is all done in Boston, which, with New York and Philadelphia, is now a principal centre of the American book trade.

A single number of two separate ventures to scatter public intelligence had appeared in Boston in 1689 and 1690; but the first regular newspaper was not established till 1704, when the *Boston Newsletter* became the pioneer of the American newspaper press. There is at present no newspaper of much influence printed outside of Boston, except the *Springfield Republican*; and even the Boston newspapers are generally held to be behind those of New York and Chicago in enterprise and power.

In 1880 there were 35 daily newspapers, with 33 others (having an annual circulation for dailies of 86,304,851; for weeklies, &c., of 10,204,537), and 392 periodicals of all kinds issued.

Libraries.—The State is the most richly provided with public collections of books (apart from school libraries) of any in the Union. In the number of volumes the public library of Boston (404,201 in 1882) probably stands at the head of all in the country, though the library of Congress closely follows. Each of these libraries fills its enumeration, however, with large numbers of duplicates,—that at Washington from those received under the Copyright Act, and that of Boston from the extensive provision of extra copies for its ten popular departments, largely counterparts of each other. It is accordingly probable that the library of Harvard University (nearly 300,000 volumes), which has but few duplicates, outranks all others in the country in the count of titles, as it is much the largest of all American academic collections. Of the eight largest libraries in the United States, three are in Massachusetts, the Boston Athenæum, one of the best of the class of proprietary libraries, being counted with the two already named. The State led in the founding of city and town libraries, supported by public taxes, thirty years ago, and has instituted more of them than exist in all the other States combined. After the one at Boston, that at Worcester is the best-known. Collections of fair proportions are attached to the lesser colleges, Amherst, Williams, and Wellesley. The special historical libraries of the American Antiquarian Society at Worcester, the Massachusetts Historical Society, the New England Historic Genealogical Society, and Congregational Library, at Boston, added to the departments of the Harvard and Boston libraries, make Massachusetts exceedingly rich in books upon American history. No one of her libraries has the resources of the rarest of early Americana which will be found in the private collection of the late John Carter-Brown at Providence, and in the Lenox library at New York; but, with access to such private collections as that of Charles Deane at Cambridge, the student of American history is probably at less disadvantage in Massachusetts than in any other library centre in the States, though the value of the Peter Force collection in the library of Congress is not to be forgotten. In science, sections of the Boston public library and the Harvard library are of the most importance, though in physics and natural history the collections of the American Academy of Arts and Sciences (Boston) and of the Boston Society of Natural History may well supplement them. In private libraries the State may claim numbers, rather than individual richness, and is probably surpassed by New York in signal collections. The State itself, in the State House, has a collection of considerable value, confined for the most part to law, public documents, and American history.

Crime.—A board of prison commissioners (three men and two women) report in 1880 3821 persons in confinement, 2070 in county prisons, and 1751 in other institutions. In 1879 there were 16,211 sentences for drunkenness; and during the last twenty years 60 per cent. of all sentences for crime were traceable to liquor, or 340,814, in that time, out of 578,458 sentences. Of this aggregate, 332,495 were against chastity, morality, and decency; 55,327 against property; and 1656 (felonious) and 81,440 (not felonious) against persons. Seventy-five per cent. of criminals are between the ages of eighteen and forty-five.

Fires and Insurance.—The fires in 1880 were 1722 in number (of which 596 were total), causing an aggregate loss of $4,454,221, of which 71 per cent. was paid by insurance companies. The causes were in 383 cases reported unknown, and in 294 incendiary.

In life insurance, six Massachusetts companies have gross assets of $32,939,505 and gross liabilities of $27,546,554; while companies organized without the State and doing business within it have $369,996,657 assets and $328,105,152 liabilities.

Government, Militia, &c.—The State, under the federal constitution, sends two senators to the Congress of the United States, and the most eminent men who have thus represented the commonwealth have been John Quincy Adams, Daniel Webster, Rufus Choate, Edward Everett, and Charles Sumner. The State is also entitled to twelve members of the National House of Representatives.

The executive department of the State Government is confided to a governor, who is aided by a lieutenant-governor, and eight others, representing so many divisions of the State, who, with the governor and lieutenant-governor, constitute the executive council. They are chosen yearly. There are also a secretary of the commonwealth, a treasurer, and auditor. An attorney-general is the State's law officer. The governor, as commander-in-chief of the State militia, has a military staff.

The judges are all appointed by the governor, with the advice and consent of his council, and hold office during good behaviour. The highest court is the supreme judicial court, which has a chief justice and six associate justices. Among the eminent jurists who have been at the head of this court are John Adams, Theophilus Parsons, and Lemuel Shaw. A superior court, with a chief justice and ten associate justices, was established in 1859. Each county has its own courts of probate and insolvency. Various larger cities and towns have police and municipal courts; while groups of towns have district courts.

The legislative departments are the senate, of forty members, chosen by senatorial districts; and a house of representatives, of two hundred and forty members, chosen by districts within the counties. These two bodies form the general court so-called, which is chosen yearly, and it elects its own officers. It meets in the State House, at Boston, a structure prominently placed on the highest point of land in that city, its dome serving as an apex to the elevation of its sky-line. It was built in 1795–97, but has been enlarged since. Before it are statues of Daniel Webster, by Powers, and Horace Mann, by Miss Stebbins, and within are Chantrey's toga-draped statue of Washington (placed there in 1828), and Thomas Ball's statue of John A. Andrew,—the latter the most eminent of the recent governors, whose term of service covered the period of the civil war (1861–65), and who acquired the sobriquet of the "great war governor."

Of the incumbents of the twelve principal offices of the Federal Government, this State has furnished, since the organization under the constitution, 34,—a number exceeded by Virginia (40), Pennsylvania (36), and New York (35).

The enrolled militia (every able-bodied male between eighteen and forty-five years of age in 1880) were 238,762 in number,—the active volunteer militia numbering 334 officers and 4436 enlisted men, organized in two brigades, besides two unattached corps of cadets, one the governor's bodyguard.

History.—It is possible that the coasts of Massachusetts were visited by the Northmen, and by the earliest navigators who followed Cabot, but the evidence is that of conjecture only. Gosnold left the earliest trace of English acquaintance on its shores, when he discovered and named Cape Cod in 1602. Pring and Champlain later tracked them, but the map of Champlain is hardly recognizable. The first sufficient explorations for cartographical record were made by John Smith in 1614, and his map was long the basis—particularly in its nomenclature—of later maps. Permanency of occupation, however, dates from the voyage of the "Mayflower," which brought about a hundred men, women, and children, who had mostly belonged to an English sect of Separatists, originating in Yorkshire, but who had passed a period of exile for religion's sake in Holland. In the early winter of 1620 they made the coast of Cape Cod; they had intended to make their landfall farther south, within the jurisdiction of the Virginia Company, which had granted them a patent; but stress of weather prevented their doing so. Finding themselves without warrant in a region beyond their patent, they drew up and signed, before landing, a compact of government, which is accounted the earliest written constitution in history. After some exploration of the coast they made a permanent landing, December 21, 1620 (new style), at Plymouth, a harbour which had already been so named on Smith's map in 1616. A subsequent patent from the council for New England, upon whose territory they were, confirmed to them a tract of land which at present corresponds to the south-east section of the State. They maintained their existence as a colony, though never having a charter direct from the crown, till 1691, when, under what is termed the Provincial Charter, Plymouth colony was annexed to Massachusetts.

The Massachusetts Company had been formed in England in 1628 for the purpose of promoting settlements in New England. There had been various minor expeditions, during the few years since Smith was on the coast, before this company, in the Puritan interests, had sent over, in 1628, John Endicott, with a party, to what is now Salem. In 1630 the government of the company, with questionable right, transferred itself to their territory, and under the lead of John Winthrop laid the foundations anew of the Massachusetts colony, when they first settled Boston in the autumn of that year. Winthrop remained the governor of the colony, with some interruptions, till his death in 1649, his first rejection coming from a party of theological revolt which chose Henry Vane (later Sir Henry Vane) to the office. The early history was rendered unquiet at times by wars with the Indians, the chief of which were the Pequot War in 1637, and Philip's War in 1675–76; and for better combining against these enemies, Massachusetts, with Connecticut, New Haven, and New Plymouth, formed a confederacy in 1643, considered the prototype of the larger union of the colonies which conducted the War of the Revolution (1775–82). The struggle with the crown, which ended in independence, began at the foundation of the colony, with assumptions of power under the charter,—which the colonial government was always trying to maintain, and the crown was as assiduously endeavouring to counteract. Theological variances and differences of political views led to some emigration of the early colonists to Rhode Island. To secure "more room" led others to go to Connecticut, where they established a bulwark against the Dutch of New York. An inroad of the Quakers disturbed their peace for several years, and led to violent laws against all such aggressive dissentients. After more than a half century of struggle, the crown finally annulled the charter of the colony in 1685, and after a brief temporary sway of Joseph Dudley, a native of the colony, as president of a provisional council, Sir Edmund Andros was sent over with a commission to unite New York and New England under his rule. His government was espoused by a small church party, but was intensely unpopular with the bulk of the people; and, before news arrived of the landing of William of Orange in England, the citizens of Boston rose in revolution (1689), deposed Andros, imprisoned him, and re-established their old colonial form of government. Then came a struggle, carried on in England by Increase Mather as agent of the colony, to secure such a form of government, under a new charter, as would preserve as many as possible of their old liberties. Plymouth colony, acting through its agent in London, endeavoured to secure a separate existence by royal charter, but accepted finally union with Massachusetts when association with New York became the alternative. The province of Maine was also united in the new provincial charter of 1691, and Sir William Phips came over with it, commissioned the first royal governor. He was a native of Maine, a rough sailor, who had got his knighthood because he had raised treasure from a Spanish wreck in the West Indies. He was a parishioner of Mather in Boston, and, it was thought, received the appointment through Mather's influence.

Throughout the continuance of the government under the provincial charter, there was a constant struggle between the prerogative party, headed by the royal governor, and the popular party, who cherished recollections of their practical independence under the colonial charter, and who were nursing the sentiments which finally took the form of resistance in 1775. The popular majority kept up the feeling of hostility to the royal authority in recurrent combats in the legislative assembly over the salary to be voted to the governor. These antagonisms were from time to time forgotten in the wars with the French and Indians, and early in Phips's administration by the unfortunate austerities of the Salem witchcraft delusion. During the earl of Bellomont's administration, New York was again united with Massachusetts, under the same executive. The scenes of the recurrent wars were mostly distant from Massachusetts proper, either in Maine or on Canadian or Acadian territory, although some savage inroads of the Indians were now and then made on the exposed frontier towns, as, for instance, upon Deerfield in 1704, and upon Haverhill in 1708. Phips, who had succeeded in an attack on Port Royal, had ignominiously failed when he led the Massachusetts fleet against Quebec in 1690. The later expedition of 1711 was no less a failure. The most noteworthy administration was that of William Shirley (1741–49 and 1753–56), who at one time was the commanding officer of the British forces in North America. He made a brilliant success of the expedition against Louisburg in 1745, William Pepperell, a Maine officer, being in immediate command. Shirley with Massachusetts troops also took part in the Oswego expedition of 1755; and Massachusetts proposed, and lent the chief assistance in, the expedition to Nova Scotia in 1755, which ended in the removal of the Acadians. Her officers and troops played an important part in the Crown Point and second Louisburg expedition (1758).

The beginning of the active opposition to the crown may be placed in the resistance, led by James Otis, to the issuing of writs to compel citizens to assist the revenue officers, followed later by the outburst of feeling at the imposition of the Stamp Act, when Massachusetts took the lead in confronting the royal power. The governors put in office at this time by the crown were not of conciliatory temperaments, and the measures instituted in parliament served to increase bitterness of feeling. Royal troops sent to Boston irritated the populace, who were highly excited at the time, when an outbreak, known as the Boston massacre, occurred in 1770, and a file of the garrison troops, in self-defence, shot down a few citizens among the crowd which assailed them. The merchants combined to prevent the importation of goods which by law would yield the crown a revenue; and the patriots, as the anti-prerogative party called themselves, opened communication with those of the other colonies through "committees of correspondence," a method of the utmost advantage thereafter in forcing on the revolution, by intensifying the resistance of the towns in the colony, and by inducing the leaguing of the other colonies. In 1773 a party of citizens, disguised as Indians, and instigated by popular meetings, boarded some tea-ships in the harbour of Boston, and, to prevent the landing of their taxable cargoes, threw them into the sea,—an act known in history as the "Boston tea-party." Parliament in retaliation closed the port of Boston,—a proceeding which only aroused more bitter feeling in the country towns, and enlisted the sympathy of the other colonies. The governorship was now given to General Thomas Gage, who commanded the troops which had been sent to Boston. Everything foreboded an outbreak. Most of the families of the highest social position were averse to extreme measures, and a large number were not won over and became expatriated loyalists. The popular agitators, at whose head was Samuel Adams,—with whom John Hancock, an opulent merchant, and one of the few of the richer people who deserted the crown, leagued himself,—forced on the movement, which became war in April 1775, when Gage sent an expedition to Concord and Lexington to destroy military stores accumulated by the patriots. This detachment, commanded by Lord Percy, was assaulted, and returned with heavy loss. The country towns now poured in their militia to Cambridge, opposite Boston; troops came from neighbouring colonies, and a Massachusetts general was placed in command of the irregular force which, with superior numbers, at once shut the royal army up in Boston. An attempt of the provincials to seize a commanding hill in Charlestown brought on the battle of Bunker Hill (June 17, 1775), in which the provincials were driven from the ground, although they lost much less heavily than the royal troops. Washington, chosen by the continental congress to command the army, arrived in Cambridge in July 1775, and, stretching his lines around Boston, forced its evacuation in March 1776. The State was not again the scene of any conflict during the war. Generals Knox and Lincoln were the most distinguished officers contributed by the State to the revolutionary army. Out of an assessment at one time upon the States of $5,000,000 for the expenses of the war, Massachusetts was charged with $820,000, the next highest being $800,000 for Virginia. Of the 231,791 troops sent by all the colonies into the field, reckoning by annual terms, Massachusetts sent 67,907, the next highest being 31,939 from Connecticut, Virginia only furnishing 26,678.

After the outbreak of the war a provisional government was in power till a constitution was adopted in 1780, when John Hancock became the first governor. His most eminent successors have been Samuel Adams (1794–97), Elbridge Gerry (1810–12), Edward Everett (1836–40), and John A. Andrew (1861–66). Governor Bowdoin in 1786 put down an insurrection known as Shay's Rebellion. The Federal Constitution was accepted by Massachusetts by a small majority, and its rejection was at one time imminent. But Massachusetts became a strong Federal State, and suffered heavily under the Embargo Act of 1807, which was laid in the interests of the democratic party. The sentiment of the State was also against the war with England in 1812–14; but much of the naval success of the war was due to Massachusetts sailors. In an apportionment of troops at the time, out of 100,000 Massachusetts was to furnish 10,000,—Pennsylvania with 14,000, New York 13,500, and Virginia 12,000, now exceeding her quota.

During the interval till the outbreak of the civil war of 1861, Massachusetts was foremost in political change or progress. She opposed the policy which led to the Mexican War; but the State sent one regiment (1057 men) into the field, under the command of Caleb Cushing. The Liberty party, forerunner of the Freesoil and Republican parties, arose among her people, led on by such men as William Lloyd Garrison and Wendell Phillips. The Federal domination had been succeeded by the Whig rule in the State, and when its greatest exponent, Daniel Webster, died in 1852, the Freesoil party was gathering force, and after an interval became the Republican party, with new affiliations, which drew off a majority of the old Whig party. This last political organization expired under the operation,—as it lost also its minority by their joining the Democratic ranks. Charles Sumner became the most eminent exponent of the new party, and he became the State's senator in the Federal Congress. The feelings which grew up and the movements that were fostered, till they rendered the civil war inevitable, received something of the same impulse from Massachusetts which she had given a century before to the feelings and movements forerunning the revolution. When the war broke, it was her troops who first received hostile fire in Baltimore, and, turning their mechanical training to account, opened the obstructed railroad to Washington. In the war which was thus begun, she built, equipped, and manned many vessels for the Federal navy, but during the early years of the conflict she was not allowed any credit for these sailors on her quota of men; and, when allowance was finally made in 1864, she showed a record of 22,360 men who had since 1861 enlisted in the navy. In 1862, out of 300,000 men called for, Massachusetts was required to furnish 15,000. During the war all but twelve small towns furnished troops in excess of what was called for, the excess throughout the State amounting in all to over 15,000 men, while the total recruits to the Federal army were 159,165 men, of which less than 1200 were raised by draft. The State, as such, and the towns spent $42,605,517·19 in the war; and private contributions of citizens are reckoned in addition at about $9,000,000. This does not include the aid to families of soldiers, paid then and later by the State.

Since the close of the war the State has remained generally steadfast in adherence to the principles of the Republican party, and has continued to develop its resources. Navigation, which was formerly the distinctive feature of its business prosperity, has, under the pressure of laws and circumstances, given place to manufactures, and the developing of carrying facilities on the land rather than on the sea. (J. WI.)

MASSÉNA, ANDRÉ (1758–1817), duke of Rivoli, prince of Essling, and marshal of France, the greatest soldier and greatest general of all Napoleon's marshals, and the one man who with education and ambition might have been Napoleon's rival, was the son of a small wine merchant, it is said of Jewish origin, and was born at Nice on May 6, 1758. His parents were very poor, and he began life as a cabin boy. He did not care much for the sea, and in 1775 enlisted in the Regiment Royal Italien, a regiment of Italians in the pay of France. He quickly rose to be under-officer-adjutant; but, finding his birth would prevent his ever getting a commission, he left the army in 1789, retired to his native city, and married. At the sound of war, however, and the word republic, his desire to see service increased, and he once more left Italy, and joined the 3d battalion of the volunteers of the Var in 1792. In those days when men elected their officers, and nearly all the old commissioned officers were dead or had emigrated, promotion to a man with a knowledge of his drill was rapid, and by April 1793 Masséna was chef de bataillon, or colonel. His regiment was one of those in the army of General Anselme, which was ordered to occupy Nice, and his knowledge of the country, of the language, and of the people was so useful that in December he was already general of division. In command of the advanced guard he won the battle of Saorgio in August 1794, capturing ninety guns, and after many successes he at last, on November 23, 1795, with the right wing of the army of Italy, won the great victory of Loano, in which four thousand Austrians and Sardinians were put hors de combat. In Bonaparte's great campaigns of 1796 and 1797 Masséna was his most trusted general of division; in each battle he won fresh laurels, until the crowning victory of Rivoli, from which he afterwards took his title. It was during this campaign that Bonaparte gave him the title of *enfant chéri de la victoire*, which he was to justify till he met the English in 1810. Masséna's next important service was in command of the army in Switzerland, which united the army in Germany under Moreau, and that in Italy under Joubert. There he proved himself a great general; the archduke Charles and Suwaroff had each been successful in Germany and in Italy, and now turned upon Masséna in Switzerland. That general held his ground well against the archduke, and then suddenly, leaving Soult to face the Austrians, he transported his army to Zürich, where, on September 26, 1799, he entirely defeated Suwaroff, taking two hundred guns and five thousand prisoners. His campaign and battle placed his reputation on a level with that of his compatriot Bonaparte, and he might have made the revolution of Brumaire, but he was sincerely attached to the republic, and had no ambition beyond a desire to live well and have plenty of money to spend. Bonaparte, now first consul, sent him to Genoa to command the débris of the army of Italy, and he nobly defended Genoa from February to June to the very last extremity, giving time for Bonaparte to strike his great blow at Marengo. He now went to Paris, where he sat in the Corps Législatif in 1803, and defended Moreau, but where Napoleon took his measure, and did not interfere with him. In 1804 he was made one of the first marshals of France of the new régime, and in 1805 was decorated with the Grand Eagle of the Legion of Honour. In that year Napoleon needed an able general to keep in check the archduke Charles in Italy, while he advanced through Germany with the grand army. Masséna was chosen; he kept the archduke occupied till he got news of the surrender of Ulm, and then on October 30th utterly defeated him in the battle of Caldiero. After the peace of Pressburg had been signed, Masséna was ordered to take possession of the kingdom of Naples, and to place Joseph Bonaparte on the throne. This task done, Napoleon summoned Masséna to Poland, where he as usual distinguished himself, and where he for the time gave up his republican principles, and was made duke of Rivoli. In the campaign of 1809 he covered himself with glory at Landshut and at Eckmühl, and finally at the little village of Essling, which he held with such determination that Napoleon had some right to call his otherwise complete defeat of Aspern a victory. When the retreat to the island of Lobau was ordered, it was Masséna who covered the broken regiments, and held the *tête du pont*; and on the field of Wagram it was Masséna who, though too ill to ride, directed from his carriage the movements of the right wing, and recovered the honour of France. For his great services he was created prince of Essling, and given the princely castle of Thouars. He was then ordered to Spain to "drive the English into the sea." The campaigns of 1810 and 1811, the advance to and the retreat from Torres Vedras, are well known from Napier's history, who does full justice to Wellington's great opponent. Masséna himself ascribed his failure to the frequent disobedience of his three subordinate generals Ney, Reynier, and Junot, and with some justice; but he alone could have stayed so long before the lines, and could have made the long halt at Santarem, which checked Wellington so thoroughly. The retreat was as finely conducted as the advance, and would have been even more triumphant had Ney obeyed orders. Even then he was again ready to try his fortune, and nearly defeated Wellington at Fuentes d'Oñoro, though much hampered by Bessières. Recalled with ignominy, his prestige gone, the old marshal felt he had a right to complain of Ney and of Napoleon himself, and, it is said, opened communications with Fouché, and the remnant of the republican party. Whether this be true or not, Napoleon gave his greatest marshal no more employment in the field, but made him merely commandant of the 8th military division, with his headquarters at Marseilles. This command he still held at the restoration of the Bourbons, when Louis XVIII. confirmed him in it, and gave him letters of naturalization, as if the great leader of the French armies had not ceased to be an Italian. When Napoleon returned from Elba, Masséna, probably by the advice of Fouché, kept Marseilles quiet to await events, the greatest service he could do the royalists, but afterwards imputed to him as a fault. After the second restoration Masséna was summoned to sit on the court martial which tried Marshal Ney, but, though he had been on bad terms with that general, and attributed his own disgrace to him, the old soldier would not be his comrade's judge. This refusal was used by the royalists to cruelly attack the marshal, against whom they raked up every offence they could think of, and whose victories they forgot. This annoyance shortened his life, and on the 4th April 1817 the old hero died. He was buried in Père-la-Chaise, with only the word "Masséna" upon his tombstone.

In private life indolent, greedy, rapacious, ill-educated, morose, on the field of battle Masséna was a man of genius, prompt in resource, indefatigable, perfectly brave, and never knowing when he was beaten. Italian he always was in his indolence, but in his quickness of resource a real compatriot of Napoleon himself.

See Thiébault's *Éloge funèbre*, and Koch's *Mémoires de Masséna*, 4 vols., 1849, a most valuable work, and most carefully compiled. See also the military histories of the epoch, but in reading Napier's pictures of him and Soult it is well to remember that author's personal friendship with the latter.

MASSILLON, a city of the United States, in Stark county, Ohio, is situated on the Tuscarawas, a head stream of the Muskingum, communicates with Lake Erie by the Ohio canal, and forms an important junction for various lines of railway. It is well known for its coal-mines and white sandstone quarries; and it also contains blast furnaces, rolling mills, foundries, machine-shops, grist mills, and extensive establishments for the manufacture of agricultural implements, glass, and paper. The population, 3819 in 1860, was 6838 in 1880.

MASSILLON, Jean Baptiste, was born at Hyères on June 24, 1663, and died at Clermont on September 28, 1742. He was thus, except Saint-Simon and Fontenelle, the longest-lived of the men of the Siècle de Louis Quatorze. It is noteworthy that, like the majority of the great pulpit orators of his own and the preceding generation, he was a southerner. His father, François Massillon, was a notary, and he appears to have been well educated. In 1681 he joined the congregation of the Oratory, which at that time had a high reputation. But, although he had thus chosen an order where the rules were by no means strict, he was not anxious for easy living or secular renown. The credit which he received for his first efforts at preaching startled him, and he sought a much more severe discipline, one indeed which is said to have been of Trappist rigour. Accident, however, made his literary and oratorical talents known to the Cardinal de Noailles, who determined that the church should not lose so well qualified a defender. In obedience to the cardinal, Massillon left the abbey of Septfonds, rejoined the Oratory, and was introduced to the Parisian seminary of Saint Magloire in 1696 He was soon set to work to preach in the Paris churches, and his reputation spread rapidly from city to court. He preached before Louis XIV. for the first time in Advent 1699. He made a profound impression, and it is reported that his generous elder, Bourdaloue, from whom Massillon himself had learnt much, said of him, "He must increase, but I must decrease." His fame, however, did not lead to immediate preferment. In the first place, the Oratorians were on bad terms with the Jesuits, and were considered too liberal to suit the reign of gloomy pietism and severe orthodoxy in which Louis's dissolute life closed. In the second, Massillon was neither a flatterer, nor did he resort to the abrupt denunciation of vice which had succeeded in the case of some of his predecessors. Indeed, in the last years of the reign there was nothing (so far as the king was concerned) to denounce, unless it were an excess of orthodoxy. Louis's famous saying that other preachers made him pleased with them, but that Massillon made him displeased with himself, may have been merely a *mot*, but it may also have expressed an involuntary truth. However this may be, Massillon, who perhaps desired no office, received none as long as the old king lived. The regency was much more favourable to him, and in 1717 he was nominated to the see of Clermont, with the additional honour of being commissioned to preach the next year's *Petit Carême* or series of short Lent sermons before the young Louis XV. Bishop in 1717, Lent preacher in 1718, Massillon received in 1719 a yet further honour, though this time a secular one, by being elected to the Academy. Various causes, however, combined to remove him from Paris. His own standard of duty was high, and he was not likely in any case to have acquiesced in the position of a non-resident bishop; the court grew more and more dissolute; and his advance in years must have somewhat disqualified him from preaching and travelling. He delivered but few sermons in Paris after the *Petit Carême*, and preached there for the last time in 1723, when he pronounced the funeral oration of the duchess-dowager of Orleans. The twenty years of life which remained to him were spent at Clermont, where he was distinguished for all good works, especially for exacting the minimum of episcopal dues and expending the maximum on charity.

Massillon's works are made up for the most part of sermons, lectures, synodal addresses, and the like. They have been repeatedly edited, and are easily accessible in two large volumes published by Didot. As a pulpit orator, if not as a theologian, Massillon probably deserves the highest rank among Frenchmen. His style is very nearly perfect, uniting the polish of the later age of Louis XIV. with the vigour of the earlier. His thoughts are original and just, and the arrangement of his discourses lucid and orderly without being unduly scholastic. He has usually been contrasted with his predecessor Bourdaloue, the latter having the credit of vigorous denunciation, Massillon of gentle persuasiveness. But few preachers can have excelled him in vigour when he chose to be stern. Besides the *Petit Carême*, his sermons on the Prodigal Son, on Death, for Christmas Day, for the Fourth Sunday in Advent, may be cited as perhaps his masterpieces. But in truth Massillon is singularly free from inequality. His great literary power, his reputation for benevolence, and his known toleration and dislike of doctrinal disputes caused him to be much more favourably regarded than most churchmen by the *philosophes* of the 18th century. He acquired the surname of the Racine of the pulpit, but extreme purity of style is almost the only point of contact between the two writers.

MASSINGER, Philip (1584-1640), one of the most prolific, scholarly, and powerful dramatists among the immediate successors of Shakespeare. He was born in 1584, went to Oxford (St Alban's Hall) in 1602, and left in 1606. This is all that is known of his early life, except that his father, as appears from the dedication of one of his plays (*The Bondman*), was in the service of the Herberts. That his father's service was not menial is proved by his having once been the bearer of letters from the earl of Pembroke to the queen. The industry of antiquaries has discovered only one little fact about Massinger between his leaving Oxford in 1606 and his having a comedy performed at court in 1621. This fact is that he joined with two dramatists, Field and Daborne, in asking an advance of £5 from the theatrical capitalist, Henslowe. This painful request, the date of which is conjectured to be about 1614, sets forth that the three petitioners were "in unfortunate extremitie." In his part of the document Massinger says that he has "ever found" Henslowe "a true loving friend." The expression seems to point to his having been connected with plays and players for some considerable time. After 1621 many of his plays were acted and published; but from the tone of his dedications it is to be inferred that he was often in straits. The entry in the parish register of St Saviour's—"March 20, 1639-40—buried Philip Massinger, a stranger"—may mean only that Massinger was not a resident in the parish; but it is sadly out of keeping with the dramatist's place in the respect of posterity.

In the barrenness of authentic fact, conjecture has been busy with Massinger's life and character. One of the questions that have been raised about him,—whether or not he was a Roman Catholic,—leads to other questions that have more than a personal interest. Attempts to fix the political or the religious creed of a dramatist are generally fanciful; as a rule, when a critic finds an opinion expressed by one of a dramatist's personages with exceptional and striking force, he jumps to the conclusion that the dramatist must have held this opinion himself as a ruling conviction. The evidence that Massinger was a Roman Catholic at a time when the creed was held under pains and penalties is of a more serious kind, though not conclusive. It rests upon three of his plays, *The Virgin Martyr* (printed in 1622, acted before 1620), *The Renegado* (acted in 1624), and *The Maid of Honour* (printed in 1632, but probably acted earlier). In the first of these Massinger was assisted by Dekker. Whether or not the author was a Roman Catholic, it is certain that only a Roman Catholic audience could be expected to enter into the spirit of these plays and applaud at the end; and they are very remarkable theatrical phenomena to have appeared in the reign of James.

The *Virgin Martyr*, founded on the martyrdom of Dorothea in the time of Diocletian, is, in effect, an old miracle play in five acts. The devil himself appears on the stage,—first in human shape as the servant of a persecutor, hunting out victims and instigating the most cruel tortures; afterwards in "a fearful shape" with fire flashing round him. The page of the martyr Dorothea is an angel in disguise, who also appears in his own proper shape before the end of the play. Dorothea is tortured on the stage in the most revolting fashion, dragged about by the hair, kicked, beaten with cudgels, but her page Angelo stands by, and she is miraculously preserved from hurt. Other miracles are performed on the stage. A persecutor falls down in a fit when about to proceed to subject the martyr's constancy to the foulest trials. In the last act a basket of fruit from paradise is brought on, and the chief persecutor eating of it is wholly changed in spirit, and drives away his diabolic servant by holding up a cross of flowers. At the close the martyrs appear in white robes, transfigured. The *Virgin Martyr* further resembles the miracle play in the coarseness of the comic scenes intended to illustrate the power of the devil over the most base and grovelling natures. The tone of the play throughout is serious and lofty; the passions of the persecutors and the heroic devotion of the martyrs are given with great dramatic force. This is a very remarkable play to have appeared suddenly amidst the run of secular pieces. It seems to have been popular, and was several times reprinted before the Restoration. That the *Renegado* should have found favour is still more remarkable. In itself it is a powerfully constructed play, strong in character and incident. Massinger's leaning to Roman doctrine is supposed to be shown by his making one of his heroines—a converted Turk, a sultan's sister—experience complete spiritual transformation after receiving the rite of baptism. But there is a more suggestive and stranger fact than this. The hero of the piece, Francisco, is a Jesuit priest, treated with profound respect throughout, a man of noble unselfish aims, running all risks to save and gain souls, exercising the strongest moral influence for the wisest and most benevolent purposes. Francisco's influence pervades the play, and is crowned with triumph at the end. He sails back to Venice with a noble lady rescued from the infidel, her virtue protected by an amulet during her captivity, a renegade military hero restored to his country and the church, a noble Venetian rescued from spiritual and physical perils, the beautiful sister of the sultan converted to Christianity. That a London audience should have tolerated this glorification of a Jesuit within twenty years of the Gunpowder Plot is an extraordinary fact, of which the explanation is still to seek. In the *Maid of Honour* the heroine relieves a highly complicated situation at the end by taking the veil, giving a third of her property to a nunnery, a third for pious uses, and a third to an honest, faithful, but to her unattractive lover. For this she is held up as "to all posterity a fair example for noble maids to imitate." Only an audience of very pious Catholics could have sympathized with such a conclusion.

Such plays show that Massinger, if not a Roman Catholic, was at least not blinded by the popular hatred of them, but could dwell in rapt admiration on what was noble and lofty in the motives supplied by the Roman Church. The strange thing is that he found a manager to produce these plays, or an audience to tolerate them. It may be doubted whether Massinger was ever a popular dramatist. His poverty is not indeed conclusive on this point, for the prices paid for plays were so small that a dramatist could hardly make a livelihood by play writing, unless he was also an actor or a theatrical manager. But the best qualities of his plays appeal rather to thoughtful politicians, moralists, and students of character than to the simple feelings of the ordinary playgoer Only one of them, *A New Way to Pay Old Debts* (printed 1633), has kept the stage, and that chiefly because the leading character, Sir Giles Overreach, a sort of commercial Richard III., a compound of "the lion and the fox," provides many opportunities for a great actor. Like all Massinger's plays, it is most ingenious and effective in construction, but in this as in others he has been more intent upon the elaboration of a plot and the exhibition of a ruling passion than upon winning the love and admiration of his audience for heroes and heroines. The other personages besides Sir Giles are either conventional comic figures, or dim, feebly outlined, uninteresting characters. The reformed prodigal and the two pairs of lovers who outwit the cunning diplomatist by simple means seem poor, joyless, bloodless phantoms when put side by side with the rich life of Shakespeare's youthful lovers and reckless scapegraces; they are mere foils to Overreach; their life is not displayed, it is only indicated in the dialogue. With the exception of this play, all Massinger's have been relegated to the study since his own time. The *Fatal Dowry* (printed 1632), in which Massinger had the assistance of Field, was partially resuscitated by Rowe, being made the basis of the *Fair Penitent*. In Massinger's own judgment, the *Roman Actor* was "the most perfect birth of his Minerva." It is in effect a study of the tyrant Domitian, and of the results of despotic rule on the despot himself and his court; the intrigues and counter intrigues, the rise of sycophancy, the fall of honesty, the growth of the appetite for blood, the growth and final triumph of the spirit of revenge, are exhibited with great power. Among the dramatists of that great period, Massinger comes next to Shakespeare in the art of opening and developing a plot. The *Bondman*, the *Duke of Milan*, and the *Great Duke of Florence* are also favourable specimens of Massinger's power. But what was said by one of his admirers in the dedication of the *City Madam* is perfectly true, that, "though he composed many plays, he wrote none amiss." The manners and the characters are always clearly conceived, although the dramatist's strength is put forth in the portrayal of some one ruling passion. The action always marches forward steadily, with as little as possible of irrelevant digression; so steadily in fact is the main purpose pursued as to produce a certain air of labour and constraint. The language is never mean, and never turgid; in impassioned situations it wants fire and directness. If the stage were ever deliberately employed as an historical school, frequented by audiences anxious to get a clear and vivid impression of important situations, going to the theatre not to be interested against their will but willing to be interested, the dramas of Massinger would furnish excellent models.

Several of Massinger's plays are no longer extant. Eight of them were among those destroyed by Warburton's cook. The most recent edition of those remaining, nineteen in number, is Cunningham's (1870). Gifford edited Massinger with great care. (W. M.)

MASSORAH (מַסֹּרָה), better MASSORETH (מַסֹּרֶת), a late Hebrew word meaning "tradition," is the technical term specially applied to the tradition by which Jewish scholars (Massorets, בַּעֲלֵי הַמַּסֹּרֶת) sought to fix the correct writing and reading of the text of the Old Testament. An oral tradition on disputed points of this sort naturally existed from the early days of the Jewish schools, but the use of a written Massorah in notes on the margin of Bibles, at the end of Biblical codices or of the individual books contained in them, or in separate works appears to have followed the introduction of the vowel points, and to have been influenced by similar labours of Syrian scholars. See HEBREW LANGUAGE, vol. xi p. 600

MASSOWAH, or MESOWAH, a town on the Abyssinian coast of the Red Sea, on a small coral island of the same name, in 15° 30′ N. lat. and 39° 30′ E. long. The height of the island is from 20 to 25 feet above the sea, the length does not exceed $\frac{1}{2}$ mile, and the breadth is about $\frac{1}{4}$ mile The western half is occupied by the town; in the eastern half are Mohammedan burying-grounds and dismantled cisterns. Most of the dwelling-houses are mere straw huts; the mosque, the Roman Catholic church, the Government buildings and custom-house, and the residences of the principal merchants are of stone. Water was formerly scarce, and had for the most part to be carried from the mainland; but in 1872 an ancient aqueduct from Mokullu was restored, and continued by an embankment to the town. Besides the original Ethiopians, who speak a Tigré dialect corrupted with Arabic, the population, estimated at from 5000 to 6000, comprises Arabs from Yemen and Hadramaut, Gallas and Somalis, and Hindus from Surat. The trade, which consists mainly in exporting hides, butter, Abyssinian coffee, and civet, and importing European and Indian cotton goods and silks, increased in value from about £65,000 per annum in 1865 to from £240,000 to £280,000 between 1879 and 1881.

The island of Massowah (locally Base) has probably been inhabited from a very early date. It was at Massowah (Matzua, as they called it) that the Portuguese landed in 1542 under Christovão da Gama. Captured by the Turks in 1557, the island has remained more or less strictly a Turkish possession ever since. A military colony of Bosnians settled at Arkiko was appointed, not only to defend it in case of attack from the mainland, but to keep it supplied with water in return for $1400 per month from the town's customs. For some time in the close of last century Massowah was held by the sherif of Mecca, and it afterwards passed under Mehemet Ali of Egypt. The Turks were reinstated about 1850, but in 1865 they handed the island back to Egypt for an annual tribute of $2\frac{1}{2}$ million piastres.

See *Bruce's Travels*, vol. iv.; Heuglin in Petermann's *Mittheilungen*, 1860; Rassam, *Brit. Mission to Abyssinia*, 1869; Pennazzi in *Nuova Antologia*, July 1880.

MASSYS, or MATSYS, QUINTIN (1466–1530), was born at Louvain, where he first learned a mechanical art. During the greater part of the 15th century the centres in which the painters of the Low Countries most congregated were Bruges, Ghent, and Brussels. Towards the close of the same period Louvain took a prominent part in giving employment to workmen of every craft. It was not till the opening of the 16th century that Antwerp usurped the lead which it afterwards maintained against Bruges and Ghent, Brussels, Mechlin, and Louvain. Quintin Massys was one of the first men of any note who gave repute to the guild of Antwerp. A legend still current relates how the smith of Louvain was induced by affection for the daughter of an artist to change his trade and acquire proficiency in painting. A less poetic but perhaps more real version of the story tells that Quintin had a brother with whom he was brought up by his father Josse Massys, a smith, who held the lucrative offices of clockmaker and architect to the municipality of Louvain. It came to be a question which of the sons should follow the paternal business, and which carve out a new profession for himself. Josse the son elected to succeed his father, and Quintin then gave himself to the study of painting. But it is not improbable that as he lived in an age when single individuals were cunning in various branches of design, Quintin was equally familiar with the chisel and file or the brush and pencil. We are not told expressly from whom Quintin learned the profession in which he acquired repute, but his style seems necessarily derived from the lessons of Dierick Bouts, who took to Louvain the mixed art of Memling and Van der Weyden. When he settled at Antwerp, at the age of twenty-five, he probably had a style with an impress of its own, which certainly contributed most importantly to the revival of Flemish art on the lines of Van Eyck and Van der Weyden. What particularly characterizes Quintin Massys is the strong religious feeling which he inherited from earlier schools. But that again was permeated by realism which frequently degenerated into the grotesque. Nor would it be too much to say that the facial peculiarities of the boors of Van Steen or Ostade have their counterparts in the pictures of Massys, who was not, however, trained to use them in the same homely way. From Van der Weyden's example we may trace the dryness of outline and shadeless modelling and the pitiless finish even of trivial detail, from the Van Eycks and Memling through Dierick Bouts the superior glow and richness of transparent pigments, which mark the pictures of Massys. The date of his retirement from Louvain is 1491, when he became a master in the guild of painters at Antwerp. His most celebrated picture is that which he executed in 1508 for the joiners' company in the cathedral of his adopted city. Next in importance to that is the Maries of Scripture round the Virgin and Child, which was ordered for a chapel in the cathedral of Louvain. Both altar-pieces are now in public museums, one at Antwerp, the other at Brussels. Both challenge attention for the qualities which have already been described. They display great earnestness in expression, great minuteness of finish, and a general absence of effect by light or shade. As in early Flemish pictures, so in those of Massys, superfluous care is lavished on jewellery, edgings, and ornament. To the great defect of want of atmosphere such faults may be added as affectation, the result of excessive straining after tenderness in women, or common gesture and grimace suggested by a wish to render pictorially the brutality of jailers and executioners. Yet in every instance an effort is manifest to develop and express individual character. This tendency in Massys is chiefly illustrated in his pictures of male and female market bankers (Louvre and Windsor), in which an attempt is made to display concentrated cupidity and avarice. The other tendency to excessive emphasis of tenderness may be seen in two replicas of the Virgin and Child at Berlin and Amsterdam, where the ecstatic kiss of the mother is quite unreal. But in these examples there is a remarkable glow of colour which takes us past many defects. Expression of despair is strongly exaggerated in a Lucretia at the museum of Vienna. On the whole the best pictures of Massys are the quietest; his Virgin and Christ or Ecce Homo and Mater Dolorosa (London and Antwerp) display as much serenity and dignity as seems consistent with the master's art. A telling example of his partiality for grotesque character in face is an Epiphany in the collection of Mr H. R. Hughes in England. His skill as a portrait painter has not been sufficiently admired, probably because most of his likenesses have ceased to be identified with his name. Egidius at Longford, which drew from Sir Thomas More a eulogy in Latin verse, is but one of a numerous class, to which we may add the portrait of Maximilian of Austria in the gallery of Amsterdam, a masterpiece which at some future period may afford a clue to other works of similar treatment in English and Continental galleries. Massys in this branch of practice was much under the influence of his contemporaries Lucas of Leyden and Mabuse. His tendency to polish and smoothness excluded to some extent the subtlety of modulation remarkable in Holbein and Dürer. There is reason to think that he was well acquainted with both these German masters. He probably met Holbein more than once on his way to England. He saw Dürer at Antwerp in 1520. Quintin died at Antwerp in 1530. The puritan feeling which slumbered in him was fatal to some of his relatives. His sister Catherine and her husband suffered at Louvain in 1543 for the then capital offence of reading the Bible, he being decapitated, she buried alive in the square fronting the cathedral.

Quintin's son, Jan Massys, inherited the art but not the skill of his parent. The earliest of his works, a St Jerome, dated 1537, in the gallery of Vienna, the latest, a Healing of Tobias, of 1564, in the museum of Antwerp, are sufficient evidence of his tendency to substitute imitation for original thought.

MASTER AND SERVANT. These are scarcely to be considered as technical terms in law. The relationship which they imply is created when one man hires the labour of another for a term. Thus it is not constituted by merely contracting with another for the performance of a definite work, or by sending an article to an artificer to be repaired, or engaging a builder to construct a house. Nor would the employment of a man for one definite act of personal service—*e.g.*, the engagement of a messenger for a single occasion—generally make the one master and the other servant. It was held, however, in relation to the offence of embezzlement, that a drover employed on one occasion to drive cattle home from market was a servant within the statute. (See article EMBEZZLEMENT for definition of "clerk" or "servant" in that connexion.) On the other hand, there are many decisions limiting the meaning of "servants" under wills giving legacies to the class of servants generally. Thus "a person who was not obliged to give his whole time to the master, but was yet in some sense a servant," was held not entitled to share in a legacy to the servants. These cases are, however, interpretations of wills where the intention obviously is to benefit domestic servants only. And so in other connexions questions may arise as to the exact nature of the relations between the parties—whether they are master and servant, or principal and agent, or landlord and tenant, or partners, &c.

The terms of the contract of service are for the most part such as the parties choose to make them, but in the absence of express stipulations terms will be implied by the law. Thus, "where no time is limited either expressly or by implication for the duration of a contract of hiring and service, the hiring is considered as a general hiring, and in point of law a hiring for a year." But "in the case of domestic and menial servants there is a well-known rule, founded solely on custom, that their contract of service may be determined at any time by giving a month's warning or paying a month's wages, but a domestic or other yearly servant, *wrongfully* quitting his master's service, forfeits all claim to wages for that part of the current year during which he has served, and cannot claim the sum to which his wages would have amounted had he kept his contract, merely deducting therefrom one month's wages. Domestic servants have a right by custom to leave their situations at any time on payment of a calendar month's wages in advance, just as a master may discharge them in a similar manner" (Manley Smith's *Law of Master and Servant*, chaps. ii. and iii.). The master's right to chastise a servant for dereliction of duty (which appears to be still recognized in some American cases) is no longer sustained in English law, unless perhaps in the case of servants under age, to whom the master stands *in loco parentis*.

The following are assigned by Manley Smith as in general sufficient grounds for discharging a servant:—(1) wilful disobedience of any lawful order; (2) gross moral misconduct; (3) habitual negligence; (4) incompetence or permanent disability caused by illness.

A master has a right of action against any person who deprives him of the services of his servant, by enticing him away, harbouring or detaining him after notice, confining or disabling him, or by seducing his female servant. Indeed the ordinary and only available action for seduction in English law is in form a claim by a parent for the loss of his daughter's services.

The death of either master or servant in general puts an end to the contract. A servant wrongfully discharged may either treat the contract as rescinded and sue for services actually rendered, or he may bring a special action for damages for the breach. A master is bound to provide food (but apparently not medical attendance) for a servant living under his roof, and wilful breach of duty in that respect is a misdemeanour under 24 & 25 Vict. c. 100.

A servant has no right to demand "a character" from an employer, and if a character be given it will be deemed a privileged communication, so that the master will not be liable thereon to the servant unless it be false and malicious. A master by knowingly giving a false character of a servant to an intending employer may render himself liable—should the servant for example rob or injure his new master.

For penalties incurred by personating masters and giving false certificates of character, or by persons offering themselves as servants with false or forged certificates, see 32 Geo. III. c. 56.

Reference may be made to the article on LABOUR AND LABOUR LAWS for the cases in which special terms have been introduced into contracts of service by statute (*e.g.*, Truck Act), and for the recent legislation on the subject generally, including the Employers' Liability Act, 1880.

The master's liability on the contracts of his servant depends on altogether different principles from those on which his liability for negligence has been justified. It is substantially a case of liability as principal for the acts of an agent. The main question in all cases is whether the alleged agent had authority to make a contract for his principal, and in the relation of master and servant there may be any variety of circumstances giving rise to that presumption. Here the rights of third persons have to be considered, and the master will be held liable to them wherever he has "by words, conduct, or demeanour held out his servant as a general agent, whether in all kinds of business or in transacting business of a particular kind,"—even if the servant should act contrary to express orders. For example, a horse-dealer sending his servant to market with a horse to sell will be liable on the servant's warranty, although he has been positively ordered not to warrant; whereas an owner sending a stranger to sell would not be liable on a warranty given contrary to express directions.

MASTIC, or MASTICH, a resinous exudation obtained from the lentisk, *Pistacia Lentiscus*, an evergreen shrub of the natural order *Anacardiaceæ*. The lentisk or mastic plant is indigenous to the Mediterranean coast region from Syria to Spain, but grows also in Portugal, Morocco, and the Canaries. Although experiments have proved that excellent mastic might be obtained in other islands in the archipelago, the production of the drug has been, since the time of Dioscorides, almost exclusively confined to the island of Scio. The mastic districts of that island are for the most part flat and stony, with little hills and few streams. The shrubs are about 6 feet high. The resin is contained in the bark and not in the wood, and in order to obtain it numerous vertical incisions are made, during June, July, and August, in the stem and chief branches. The resin speedily exudes and hardens into roundish or oval tears, which are collected, after about fifteen days, by women and children, in little baskets lined with white paper or cotton wool. The ground around the trees is kept hard and clean, and flat pieces of stone are often laid beneath them to prevent any droppings of resin from becoming contaminated with dirt. The collection is repeated three or four times between June and September, a fine tree being found to yield about 8 or 10 ℔ of mastic during the season. Besides that obtained from the incisions, mastic of very fine quality spontaneously exudes from the small branches. The harvest is affected by showers of rain during the period of collection, and the trees are much injured by frost, which is, however, of rare occurrence in the districts where they grow.

Four qualities of mastic are recognized by the dealers in Scio.

1. *Cake*, consisting of large pieces, sold chiefly for use in the seraglios, being chewed by women of all ranks throughout the Turkish empire, for the purpose of imparting an agreeable odour to the breath. This quality is worth 120 to 130 piastres per oke (of 2·83 ℔) or even more.
2. *Large tears*, worth 90 to 100 piastres.
3. *Small tears*, valued at 75 to 80 piastres.
4. Mastic mixed with fragments of leaves and sand, chiefly consumed in the manufacture of the Turkish liqueur, or mastic brandy, called *raki*, and other cordials.

The third sort, in small tears, is that which is chiefly exported to England, the first and second qualities being sent to Turkey, especially Constantinople, also to Trieste, Vienna, and Marseilles. These varieties are known to the dealers as κυλιστό, φλισκάρι, πῆττα, and φλοῦδα respectively.

Mastic still forms the principal revenue of Scio. In 1871, 28,000 ℔ of picked and 42,000 ℔ of common were exported from that island, the former being worth 6s. 10d. and the latter 2s. 10d. per ℔. The average price in London varies from 2s. 6d. to 4s. 6d. per ℔.

During the 15th, 16th, and 17th centuries mastic enjoyed a high reputation as a medicine, and formed an ingredient in a large number of medical compounds, but its use in medicine is now almost obsolete.

Mastic occurs in English commerce in the form of roundish tears about the size of peas, some of them, however, being oblong or pear-shaped. They are transparent, with a glassy fracture, of a pale yellow or faint greenish tinge, which darkens slowly by age. When chewed they rapidly soften, by which character they are easily distinguished from Sandarac resin, which while bearing a strong resemblance to mastic occurs in tears of a more cylindrical shape. The mastic which has been imported of late years presents a bright glassy appearance from having been washed free from dust.

Mastic is soluble in turpentine, chloroform, ether, acetone, and oil of cloves; but cold alcohol dissolves only 90 per cent. of it. The soluble portion is called *Alpha resin* ($C^{20}H^{32}O^{3}$), and possesses acid properties. The insoluble portion, *Beta resin* or *Masticin*, is somewhat less rich in oxygen, and is a translucent colourless tough substance insoluble in caustic alkali.

Pistacia Khinjuk, Stocks, and *P. cabulica*, St., trees growing throughout Sindh, Baluchistan, and Cabul, yield a kind of mastic which is met with in the Indian bazaars under the name of *Mustagi-rúmi*, *i.e.*, Roman mastic. This when met with in the European market is known as East Indian or Bombay mastic. In Algeria *P. atlantica*, Desf., yields a solid resin, which is collected and used by the Arabs as a masticatory. Cape mastic, used by the colonists, but not exported to England, is the produce of *Euryops multifidus*, the resin bush, or *harpuis bosch*, of the Boers,—a plant of the composite order growing abundantly in the Clanwilliam district. Dammar resin is sometimes sold under the name of mastic. The West Indian mastic tree is the *Bursera gummifera*, and the Peruvian mastic is *Schinus Molle*; but neither of these furnishes commercial resins.

MASTODON (from *μαστός*, "nipple," and *ὀδούς*, "tooth"), a name, suggested by the conical or papillary form of the projections on the molar teeth of some of the species, given by Cuvier to a genus of extinct elephant-like animals. Their position in the suborder *Proboscidea* of the great order *Ungulata* has been indicated in the article MAMMALIA (p. 425 of the present volume).

In size, general form, and principal osteological characters the Mastodons resembled the Elephants. It is by the teeth alone that the two groups are to be distinguished, and, as shown in the article just referred to, so numerous are the modifications of these organs in each, and so insensibly do they pass by a series of gradations into one another, that the distinction between the two is an arbitrary and artificial one, though convenient and even necessary for descriptive purposes.

As in other Proboscideans, the teeth of Mastodons consist only of incisors and molars. The incisors or tusks are never more than a single pair in each jaw. In the upper jaw they are always present and of large size, but apparently never so much curved as in some species of Elephant, and they often have longitudinal bands of enamel, more or less spirally disposed upon their surface, which are not met with in Elephants. Lower incisors, never found in true Elephants, are present throughout life in some species of Mastodon, which have the symphysis of the lower jaw greatly elongated to support them (as in *M. angustidens*, *M. pentelici*, and *M. longirostris* (see fig. 1, *C*). In the common American species (*M. ohioticus*, Blumenbach) there were two tusks in the lower jaw in the young of both sexes; these were soon shed in the female, but one of them was retained in the male. In other species no inferior tusks have been found, at all events in adult life (see figure of *M. turicensis*).

The molar teeth are six in number on each side, increasing in size from before backwards, and, as in the Elephants, with a horizontal succession, the anterior teeth being lost before the full development of the posterior teeth, which gradually move forward, taking the place of those that have been destroyed by wear. This process is, however, not so complete as in the true Elephants, and as many as three teeth may be in place in each jaw at one time. There is, moreover, in many species a true vertical succession, affecting either the third, or the third and second, or (in one American species, *M. productus*) the first, second, and third of the six molariform teeth. These three

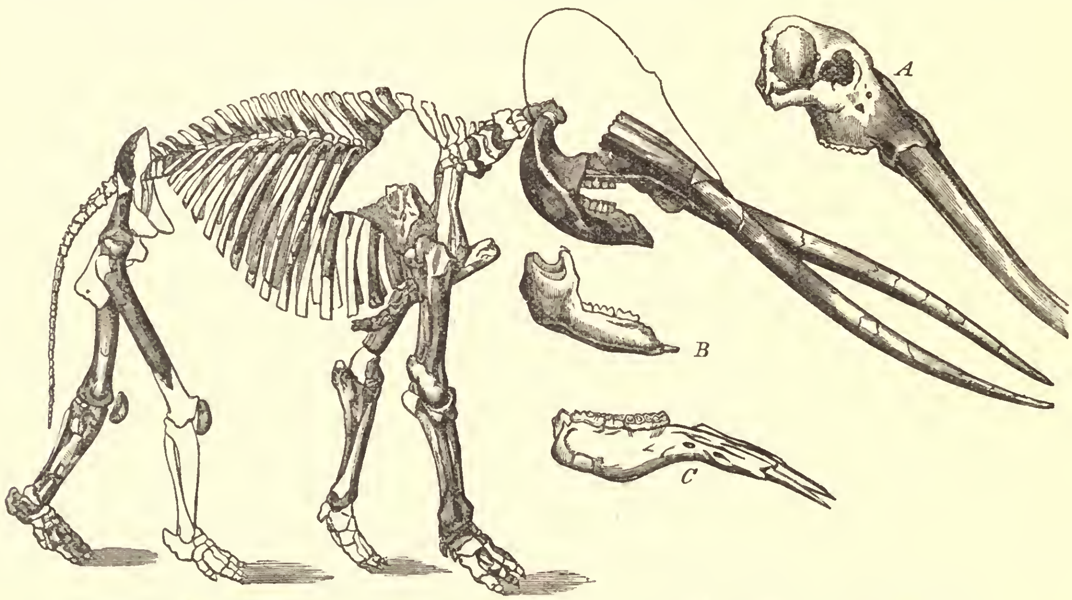

FIG. 1.—*Mastodon turicensis* (Pliocene). From Sismonda. A, B, *M. ohioticus*; C, *M. longirostris*.

are therefore reckoned as milk molars, and their successors as premolars, while the last three, which are never changed, correspond to the true molars of those animals in which the typical dentition is fully developed. The study of the mode of succession of the teeth in the different species of Mastodons is particularly interesting, as it exhibits so many stages of the process by which the very anomalous dentition of the modern Elephants may have been derived by gradual modification from the typical heterodont and diphyodont dentition of the ordinary Mammal. It also shows that the anterior molars of Elephants do not correspond to the premolars of other Ungulates, but to the milk molars, the early loss of which in consequence of the peculiar process of horizontal forward-moving succession does not require, or allow time for, their replacement by premolars. It must be noted, however, that, in the Mastodon in some respects the least specialized in tooth-structure, the *M. ohioticus* of North America, no vertical succession of the molars has yet been observed, although vast numbers of specimens have been examined.

The Mastodons have, generally speaking, fewer ridges on their molar teeth than the Elephants; the ridges are also less elevated, wider apart, have a thicker enamel covering, and scarcely any cementum filling up the space between them. Sometimes (as in *M. ohioticus*) the ridges are simple transverse wedge-shaped elevations, with straight or

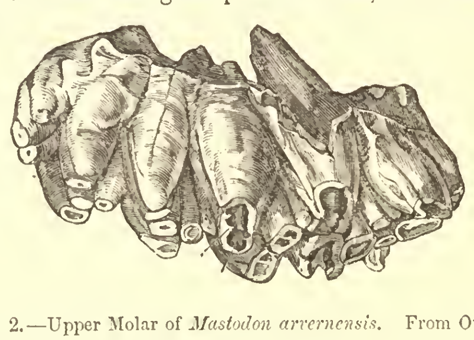

FIG. 2.—Upper Molar of *Mastodon arvernensis*. From Owen.

concave edges. In other species the summits of the ridges are more or less subdivided into conical cusps, and may have accessory cusps clustering around them (as in *M. arvernensis*, see fig. 2). When the apices of these are worn by mastication, their surfaces resemble circles of dentine, surrounded by a border of enamel, and as the attrition proceeds different patterns are produced by the union of the bases of the cusps, a trilobed or trefoil form being characteristic of some species.

Certain of the molar teeth of the middle of the series in both Elephants and Mastodons have the same number of principal ridges, and those in front of them have fewer and those behind a greater number. These teeth were distinguished as "intermediate" molars by Dr Falconer, to whose extensive and conscientious researches we owe much of our knowledge of the structure of this group of animals. In the restricted genus *Elephas* there are only two, the last milk molar and the first true molar (or the third and fourth of the whole series), which are alike in the number of ridges; whereas in the Mastodons there are three such teeth, the last milk molar and the first and second true molars (or the third, fourth, and fifth of the whole series). In the Elephants the number of ridges on the intermediate molars always exceeds five, but in the Mastodons it is nearly always three or four, and the tooth in front has usually one fewer and that behind one more, so that the ridge formula (*i.e.*, a formula expressing the number of ridges on each of the six molar teeth) of most Mastodons can be reduced either to 1, 2, 3, 3, 3, 4 or 2, 3, 4, 4, 4, 5. The former characterizes the section called *Trilophodon*, and the latter that called *Tetralophodon* by Dr Falconer. These divisions are very useful, as under one or the other all the present known species of Mastodon can be ranged, but observations upon a larger number of individuals have shown that the number of ridges upon the teeth is by no means so constant as implied by the mathematical formulæ given above. Their exact enumeration is even difficult in many cases, as "talons" or small accessory ridges at the hinder end of the teeth occur in various stages of development, until they take on the character of true ridges. Transitional conditions have also been shown, at least in some of the teeth, between the trilophodont and the tetralophodont forms, and again between the latter and what has been called a "pentalophodont" type, which leads on towards the condition of dental structure characteristic of the true Elephants.

The range of the genus *Mastodon* in time was from the middle of the Miocene period to the end of the Pliocene in the Old World, when they became extinct; but in America several species—especially the best-known, owing to the abundance of its remains, which has been variously called *M. ohioticus*, *M. americanus*, and *M. giganteus*—survived quite to a late Pleistocene period.

The range in space will be best indicated by the following list of the generally recognized species. 1. Trilophodont series—*M. angustidens, borsoni, pentelici, pyrenaicus, tapiroides* (or *turicensis*), *virgatidens*, from Europe; *M. falconeri* and *pandionis*, from India; *M. ohioticus, obscurus*, and *productus*, North America; and *M. andium* and *humboldtii*, South America. 2. Tetralophodont series—*M. arvernensis, M. dissimilis* and *longirostris*, from Europe; *M. latidens, sivalensis*, and *peramensis*, from India; *M. mirificus*, from North America. The only two of which remains have been found in Great Britain are *M. arvernensis* and *M. borsoni*, both from the crags of Norfolk and Suffolk.

The range of the genus was thus very extensive, and it has even been supposed to reach to Australia, where no Ungulate mammal has ever been proved to exist. This supposition until very recently has been based upon the evidence of a single molar tooth of an animal undoubtedly belonging to *Mastodon*, and alleged to have been brought from near Boree Creek, an affluent of the Lachlan river in the Ashburnham district, New South Wales, by the late Count Strzelecki, and described by Professor Owen in 1844 under the name of *M. australis*. Its identity with the South American *M. andium* has, however, been shown by Dr Falconer, who has thrown grave doubts upon the locality assigned to the specimen. A fragment of a tusk, of the Australian origin of which there is less question, and which presents the characteristic structure only known at present in Elephants and Mastodons, has been lately described by Professor Owen (*Proc. Roy. Soc.*, March 30, 1882). It was found in a drift-deposit of a ravine in a district of Darling Downs, 60 miles to the eastward of Moreton Bay, Queensland. Unfortunately no other portions of the remains of the animal to which it belonged have been discovered.

MASʻÚDY. Abú'l-Ḥasan ʻAlí ibn Ḥosein ibn ʻAlí el-Masʻúdy,[1] was born at Baghdad towards the close of the 9th Christian century. Great part of his life was spent in travel; in 912–13 A.D. he was at Múltán in the Punjab, and also visited Manṣúra. Three years later he was at Baṣra and met Abu Zeid, the geographer whose remarks on the extreme East are comprised in Reinaud's *Relation des Voyages* (Paris, 1845). His writings and those of Masʻúdy are indebted each to the other. In the interval it would seem our traveller had gained that personal acquaintance with Fars and Susiana, and that knowledge of the books of the Persians, of which he speaks in his writings. Once more turning eastward he was at Cambay in 915–16, and soon after at Ṣaimúr. Hence he pushed on to Ceylon and sailed to Madagascar, returning to ʻOmán in 916–17. In the introduction to the *Meadows* he seems also to say that he had journeyed as far as China. A northern journey carried Masʻúdy as far as the Caspian Sea. In 926 he was at Palestine, where his curiosity, not limited by religious prejudice, led him to visit the Christian church and describe its relics. In 943–44 he made a careful study of the ruins of Antioch, and subsequently proceeded to Baṣra. In the same year he composed the *Meadows of Gold*. The last ten years of his life were passed in Syria and Egypt. His last work, *The Indicator and Monitor*, was written 345 A.H., and his death took place in Egypt the same year (956–57 A.D.).[2] The vast journeys of Masʻúdy did not pass beyond the lines of commercial enterprise among the Moslems of those days, when ʻIráḳ was not unjustly held to be the centre of the world, and the arms, the trade, and the religion of Islám penetrated to the remotest parts of Asia and Africa. But Masʻúdy did not travel for gain. His object was to study with his own eyes the peculiarities of every land, and to collect whatever was of interest for archæology, history, and manners. Singularly free from bigotry—he was himself a Moʻtazilite, one of the heretical sect, as they were reckoned, who held the doctrine of man's free will—he was ready to derive information even from the writings of infidel Persians or of a Christian bishop.[3] In the range of his observations and the naive uncritical honesty with which he records them he has naturally suggested comparison with Herodotus, and so competent a judge as Ibn Khaldún gives him the title of imám of Eastern historians, an epithet precisely parallel to that borne by Herodotus among the historians of the West. The parallel, however, must be taken with great deductions. Of the *Meadows*, the work by which Masʻúdy is chiefly known, by far the greater part is an historical compilation, enlivened indeed in some parts by personal recollection of places and the like, but mainly drawn from a vast mass of earlier books[4] which are used in the common paste-and-scissors fashion of Eastern history. Even in the earlier cosmographical chapters the author's vast and miscellaneous reading, which included the Arabic translations of Ptolemy and other Greek writers, is mingled with his original observa-

1 The surname is derived from an ancestor Masʻúd, a Meccan, whose son ʻAbdalla accompanied Mohammed on his flight to Medína, and is often mentioned in the history of the prophet. Details as to the family are given by Reiske, *Ann. Mos.*, vol. i., note 208.

2 See De Sacy, *Chrest.*, 1st ed., ii. 490.

3 In the *Meadows*, iii. 69, he tells us that at Fosṭáṭ (Old Cairo), in 336 A.H., there fell into his hands a chronicle (now lost) by Godmer, bishop of Gironne, which he uses for his narrative.

4 Of these the first chapter gives an interesting catalogue.

tions in that ill-digested style so often characteristic of men of prodigious acquisitive power; and the presentation of facts falls as far short of freshness and the artistic charm of the inimitable Grecian *raconteur* as the shapeless details of universal history, as it appeared to the Moslem, fall short of the epic interest of the great struggle for supremacy between Eran and Hellas.

Mas'údy has himself sketched his literary activity in the opening chapter of the *Meadows* and in his last book *The Indicator*. In his huge *Annals* (*Akhbár el-Zemán*) and in a second work of less extent (*Kitáb el-Awsat*) which followed it he summed up the whole cosmographical and geographical science of his age. These works are lost or known only by fragments, but we possess an abridgment in the author's third great work *The Meadows of Gold and Mines of Precious Stones*, of which there are many MSS. in European libraries. It was printed by Barbier de Meynard with a French translation, 9 vols. 8vo, Paris, 1861-77, and at Búlák in 1867 (2 vols. folio). The first volume of an English translation by Sprenger appeared at London in 1841; but the work was not continued. The Kitáb-el-Tanbíh (*Indicator and Monitor*) exists in MS. at Paris, and has been fully described by De Sacy in *Notices et Extraits*, vol. viii., 1810 (reprinted at the end of the Paris edition of the *Meadows*, where a list of other works of our author is given). See also Quatremère in *Jour. As.* for January 1839, and the article "Masoudy," by Reinaud, in the *Nouv. Biog. Générale*.

MASULIPATAM, the chief town of Kistna district, Madras, India, and a seaport, is situated in 16° 9′ N. lat., 81° 11′ E. long., with a population in 1871 of 36,316. The export trade is partly to Europe; imports are chiefly local. In 1874-75 235 vessels of 106,000 tons burthen visited the port; the exports (oil-seeds and cotton) amounted to £171,400, the imports to £119,600. The town contains the usual district offices, a jail, and several schools, the chief being the high school. It is a flourishing station of the Church Missionary Society.

Masulipatam was the earliest British settlement on the Coromandel coast. An agency was established there in 1611, and a fortified factory in 1622. During the wars of the Carnatic, the English were temporarily expelled the town, which was held by the French for some years. In 1759 the town and fort were carried by storm by Colonel Forde, and it has been held by the British ever since. Weavers form a large portion of the inhabitants of the town, though their trade has greatly declined since the beginning of this century. Their operations, besides weaving, include printing, bleaching, washing, and dressing. In former days the chintzes of Masulipatam had a great reputation abroad for the freshness and permanency of their dyes, the colours becoming brighter after washing than before. There is still a small demand for these articles in Burmah, the Straits, and the Persian Gulf; but steam machinery has nearly beaten the hand-loom out of the field. Another speciality was *metapollams* or kerchiefs for the head; but this industry was ruined by the refusal of the West Indian negroes to wear these kerchiefs after their emancipation. Tartans, ginghams, towels, and table linen are still manufactured to some extent. The importance of the place is now declining, and the garrison was withdrawn in 1865. The heaviest blow to the prosperity of the town was given by the great storm-wave of 1864, which swept over the entire town, and is said to have destroyed 30,000 lives.

MATAMOROS, a city of Mexico, in the province of Tamaulipas, on the southern bank of the Rio Grande, about 35 miles from its mouth, and directly opposite Brownsville in Texas. Built in an open plain, Matamoros has its streets laid out with great regularity; and the general appearance gives evidence at once of its recent rise into importance and of the influence of the architectural fashions of the United States. The principal building is the large but heavy-looking cathedral. An extensive traffic, both legitimate and contraband, is carried on between Matamoros and Brownsville, and in spite of the bar at the mouth of the river, which in foul weather prevents the entrance even of small schooners, the place is not without its value to Mexico as a foreign port. The imports of American and of European goods are valued each at about $1,100,000, with a growing preponderance on the side of the American. Cotton, flax, silk, and woollen goods are the main items in the European list; cottons, leaf tobacco, wheat-flour, machinery, and preserved meats in the American. Hides and skins, live animals, and wool are the principal exports apart from coin and bullion, which are largely smuggled to avoid the export duty. The population is about 20,000.

Founded in the beginning of the century, and named in honour of the Mexican patriot Mariano Matamoros, the city has played a part in all the more recent wars. It was captured by General Taylor of the United States in 1846, was in the hands of the imperialists under Majia in 1864, and was occupied by the French in 1866.

MATANZAS, or SAN CARLOS DE MATANZAS, a city and seaport on the north coast of Cuba, and the chief town of a province, lies 52 miles east of Havana, with which it is connected by rail. It is a well-built place of from 36,000 to 40,000 inhabitants, occupying a fine site at the head of the Bay of Matanzas, and separated from its suburbs Pueblo Nuevo and Versailles by the San Juan on the one hand and the Yamurri on the other. In the centre of the principal square is a statue of Ferdinand VII., and along the east side runs the residence of the commandant. The new theatre is the handsomest building of its kind in Cuba, and the Empresa Academy has the repute of being one of the best educational institutions in the West Indies. As a commercial centre Matanzas ranks next to Havana, having risen rapidly after the removal of the old trade restrictions in 1809. The exports are mainly sugar and molasses. The harbour has been deteriorated by the mud brought down by the San Juan; but the bay is well sheltered from all winds except the north-east, which brings in a heavy sea. Matanzas was founded in 1693 by a number of immigrants from the Canary Islands, and in the same year Bishop Compostello laid the first stone of the cathedral. The city suffered severely from a conflagration in 1845. About 2½ miles to the east are the beautiful stalactite caves of Bellamar, about 3 miles in extent.

MATARÓ, a Mediterranean seaport of Spain, in the province of Barcelona, 21 miles to the north-east of that city, is beautifully situated on the lower slopes and at the foot of the range of hills which skirt the coast, and shelter the town from the cold northern winds. The streets of the new town, lying next the sea, are wide and regularly built; those of the old town, farther up the hill, still preserve much of their ancient character. The parish church of Santa Maria has some good pictures and wood carvings; other prominent public buildings are the theatre, the civil hospital, and the establishments of the Padres Escolapios. There are small schools of navigation and the fine arts. The wine of the neighbourhood, which somewhat resembles port, is shipped in large quantities from Barcelona; and the district furnishes fine roses, strawberries, and similar produce for the Barcelona market. There is a considerable fishery, the products of which are sent inland to Manresa and other places. The leading industries of Mataró are its linen, woollen, and cotton manufactures, especially of canvas and tarpaulin; several hundreds of women are employed in the town and neighbourhood in lace-making; there are also potteries, machine-making, and chemical works, and shipbuilding is carried on to some extent. The railway to Barcelona, opened in October 1848, was the first to be constructed in Spain. Mataró has no artificial harbour, several attempts to make one having failed; the trade is carried on chiefly through Barcelona. The population in 1877 was 17,405. Outside the town is the much-frequented carbonated mineral spring of Argentona.

MATCHES. Till the close of the 18th century flint and steel with tinder box and sulphur-tipped splints of wood—"spunks" or matches—were the common means of obtaining fire for domestic and other purposes. The sparks struck off by the percussion of flint and steel were made to fall among the tinder, which consisted of carbonized fragments of cotton and linen; the entire mass of the tinder was set into a glow, developing sufficient heat to ignite the sulphur with which the matches were tipped, and thereby the splints themselves were set on fire. Instead of tinder, match-paper or touch-paper, a thick bibulous paper impregnated with saltpetre (nitrate of potash), and amadou or German tinder, a thick leathery and porous preparation from the fungus *Polyporus fomentarius*, were often used.

It was not till 1805 that any attempt was made to use chemical agency for the ordinary production of fire. In that year M. Chancel, assistant to Professor Thenard of Paris, introduced an apparatus consisting of a small bottle containing asbestos, saturated with strong sulphuric acid, with splints or matches coated with sulphur, and tipped with a mixture of chlorate of potash and sugar. The matches so prepared, when brought into contact with the sulphuric acid in the bottle, ignited, and thus, by chemical action, fire was produced. It appears also that in the same year phosphorus matches were known in Paris, and in 1809 Derepas proposed to lessen the dangerously great inflammability of the phosphorus match by making an igniting mixture of that element with magnesia. It is also said that M. Derosne made a friction match with a phosphorus tip in 1816. Again in 1823 a phosphorus match was proposed, but it came into little use. In this case the composition consisted of equal parts of phosphorus and sulphur cautiously melted together in a glass tube. The tube was then securely corked, and, to obtain a light, a splint was introduced into the mixture, and a small pellet detached, which on withdrawal and exposure almost spontaneously ignited. In that year (1823) a decided impetus was given to the artificial evolution of fire by the introduction of the Döbereiner lamp, so called after its inventor Professor Döbereiner of Jena. The action of this elegant invention depends on the remarkable property possessed by spongy or highly porous platinum of determining the combination of hydrogen and oxygen and the formation of water at common atmospheric temperatures. In the Döbereiner lamp hydrogen is evolved in a suitable vessel by the action of zinc on acidulated water. The gas so liberated, when required, is passed through a fine orifice by means of a stop-cock, and impinging on a mass of spongy platinum mounted in a frame it combines with oxygen of the air, thereby developing an intense heat, which quickly causes the platinum to glow, and ultimately is sufficiently intense to set the stream of hydrogen itself on fire. The Döbereiner lamp is still occasionally seen, but it is chiefly used in connexion with chemical lectures.

The first really practical friction matches were made in England in 1827, by Mr John Walker, a druggist of Stockton-on-Tees. These were known as "Congreves" after Sir William Congreve, Bart., the inventor of the Congreve rocket, and consisted of wooden splints or sticks of cardboard coated with sulphur and tipped with a mixture of sulphide of antimony, chlorate of potash, and gum. With each box of eighty-four, which was retailed at a shilling, there was supplied a folded piece of glass paper, the folds of which were to be tightly pressed together, while the match was drawn through between them. In 1830 the so-called "Prometheans" were patented by Mr S. Jones of London. These consisted of a short roll of paper with a small quantity of a mixture of chlorate of potash and sugar at one end, a thin glass globule of strong sulphuric acid being attached at the same point. When the sulphuric acid was liberated by pinching the glass globule, it acted on the mixed chlorate and sugar, producing fire.

The phosphorus friction match of the present day was first introduced on a commercial scale in 1833; and it appears to have been made almost simultaneously in several distinct centres. The name most prominently connected with the early stages of the invention is that of Preschel of Vienna, who in 1833 had a factory in operation for making phosphorus matches, fusees, and amadou slips tipped with igniting composition. At the same time also matches were being made by Moldenhauer in Darmstadt; and for a long series of years Austria and the South-German states were the principal centres of the new industry. Improvements in the manufacture have been numerous; and the industry is now carried on with a complete system of ingenious labour-saving machinery. The use of phosphorus as a principal ingredient in the igniting mixture of matches has not been free from very serious disadvantages. It is a deadly poison, the free dissemination of which has led to many accidental deaths, and also to numerous cases of wilful poisoning and suicides. Workers also who are exposed to phosphoric vapours are subject to a peculiarly distressing disease which attacks the jaw, and ultimately produces necrosis of the jaw-bone; it appears, however, that, with scrupulous attention to ventilation and cleanliness, almost all risk of the disease may be avoided. Strenuous efforts have been made by numerous inventors to introduce matches having no phosphorus in their igniting mixture, but hitherto with indifferent success. The most serious objections to the use of phosphorus have, however, been overcome by the discovery of the modified condition of that body known as red or amorphous phosphorus, made by Professor Anton Von Schrötter of Vienna in 1845, and the utilization of that substance in the now well-known "safety matches" invented by Lundström of Sweden in 1855, and first manufactured in the United Kingdom by Bryant & May of London. Red phosphorus is, in itself, a perfectly innocuous substance, and no evil effects arise from freely working the compositions of which it forms an ingredient. The fact again that safety matches ignite only in exceptional circumstances on any other than the prepared surfaces which accompany the box—which surfaces and not the matches themselves contain the phosphorus required for ignition—makes them much less liable to cause accidental fires than the kinds more commonly in use.

Manufacture.—The operations carried on in a match factory may be grouped under the four heads of preparing the splints, dipping the matches, box-making, and filling. The varieties of wood principally used for matches are poplar, aspen, yellow pine, and white pine. Splints are either round or quadrangular, the former having been at one time exceedingly common, when Austrian manufactures ruled the markets; but, now that Sweden is the principal match-manufacturing country, matches are nearly all square in section. For cutting square splints many ingenious machines have been devised, some of which, worked by engine-power, can turn out from 15,000,000 to 17,000,000 splints per day. In Sweden the manufacturers use principally aspen or clean-grained pine wood, preferring sections 12 to 20 inches in diameter, newly felled and full of sap. If dry, the wood must be soaked before it is fit for the operations through which it passes. The timber is cut into blocks about 15 inches long—sufficient for seven matches—and being freed from bark it is fixed in a special form of turning lathe, and by means of a fixed cutting tool acting on its entire length a continuous veneer or band the thickness of a match is cut off. With each revolution of the block the knife advances proportionately to the thickness of the band cut off, and thus a uniformly thick slice is obtained continuously. At the same time eight small knives cut the veneer into seven separate bands each the length of a match, and thus in one operation seven long ribbons of wood the length and thickness of a match are obtained. These ribbons are next broken into lengths of from 6 to 7 feet, knotty pieces are removed, and to cut them into single matches they are fed into a machine which acts somewhat like a straw-chopper. From 120 to 140 bands are acted on in the apparatus, and a ratchet arrangement feeds them forward the thickness of a match at each stroke of the cutter, which thus cuts off 120 to 140 matches per stroke. Worked by hand the machine delivers about 5,000,000 splints per day, and by power it can be run to turn out double that number. The matches are next dried in revolving drums in a heated chamber or stove, and thereafter they are sifted in a kind of partitioned sieve to free them from fragments and splinters. The sifting process also arranges all the splints in parallel order and in uniform quantities, whereby they may be conveniently bundled and prepared for the dipping which next follows. For the dipping process it is necessary to keep each match free from contact with its neighbour, and indeed allow it such a space that each may be fully coated and yet there be no danger of the igniting composition clotting the heads into one mass. To effect this the splints are by an ingenious machine separately arranged at uniform intervals between the lathes of a dipping frame. The dipping frames are made about 18 inches square, and are fitted with 44 movable lathes. Between each pair of lathes 50 splints are inserted by the machine, and when tightened up by screws each frame thus contains $44 \times 50 = 2200$ splints placed at regular intervals, the heads of which are all on the same level. A single attendant can place, by aid of the machine, about 1,250,000 matches in the dipping frames per day. The dipping is done in a stove of masonry which contains three square flat-bottomed shallow pans. In the first the splints are heated so as to facilitate the absorption of paraffin; in the second their points are dipped into molten paraffin scale; and in the third they receive their heads or tips of igniting composition, that mixture being kept in a uniform thin stratum in the pan, or in some cases it is supplied by an endless india-rubber belt which revolves and dips into the composition. A skilful workman can dip from 3500 to 4000 frames, or about 8,000,000 matches, a day. The frames so dipped are afterwards arranged in a heated apartment till the igniting composition is dried, after which the matches are taken out and put up in boxes by hand.

Match splints in the factories of the United Kingdom are generally cut in lengths suitable for two matches, and dealt with in that form throughout. The splint-cutting machine patented by John Jex Long of Glasgow in 1871 differs essentially from the Swedish splint-making machinery above alluded to; it acts on squared blocks two-match length, and is capable of producing up to 17,000,000 matches per day.

The object of dipping in melted paraffin is, of course, to secure more ready ignition of the wood. Sulphur was formerly employed for that purpose; and enormous quantities of the cheaper matches made on the Continent and in America continue to be sulphur dipped. The cheaper kinds are frequently "bundle dipped" in the molten sulphur, after which their points are merely pressed against the igniting composition.

The chief element in the igniting mixture of ordinary matches is still common phosphorus, combined with one or more other bodies which readily part with oxygen under the influence of heat. Chief among these latter substances is chlorate of potash, the body which causes the sharp explosive sound when a common match is struck, and to the use of which there is a strong objection on the Continent from the fear of explosions in dealing with the substance in large quantities. The other oxygen-yielding bodies commonly found in matches are red lead, nitrate of lead, bichromate of potash, and peroxide of manganese. The proportions in which any of these bodies is present in various igniting compositions are kept trade secrets; they vary greatly, as special regard must be given to matches for damp climates, or for ocean transport, and to other considerations. The igniting agents are made into a paste with glue or gum as an adhesive agent, a little fine sand or powdered glass, and some colouring ingredient such as cinnabar, smalt, magenta, or Prussian blue. Matches in which amorphous phosphorus takes the place of the common variety, notwithstanding several obvious advantages, have never come into general use. They were shown in the Great Exhibition of 1851 by Bell & Black of London; and Foster & Warwa of Vienna, one of the earliest match-making firms, long continued to make them, as did also Coigniet Père et Fils of Paris. As made by these and other makers they were difficult to strike, requiring a special rough rubbing surface; the head frequently broke away in the attempt to light them, and when they did inflame it was with explosive violence and a loud spluttering noise. Dr Von Schrötter, the discoverer of amorphous phosphorus, claims to have found a means of preparing combinations of amorphous phosphorus with chlorate of potash and other oxygen-yielding compounds of all degrees of combustibility, and he states that Hochstätter of Frankfort now manufactures matches with amorphous phosphorus composition which may be ignited by rubbing on a cloth surface, which inflame quietly, burn without smell or sparking, are not influenced by damp, and are cheaper than common phosphorus matches. The use of amorphous phosphorus—but on the rubbing surface only and not in the dipping composition (safety matches)—was first suggested by Böttger, but it was not till a patent was secured by Lundström in 1855 that the matches were brought into the market. According to J. G. Gentele, the elements of the dipping mixture for the heads are—chlorate of potash, 32 parts; bichromate of potash, 12; red lead, 32; sulphide of antimony, 24; and the ingredients of a suitable rubbing surface are eight parts of amorphous phosphorus to nine of sulphide of antimony. There is no doubt, however, that here too there is considerable diversity in the composition of the mixtures. Igniting compositions entirely free from phosphorus depend for their moderate degree of efficiency on the use of such agents as chlorate of potash, sulphide of antimony, bichromate of potash, and red lead.

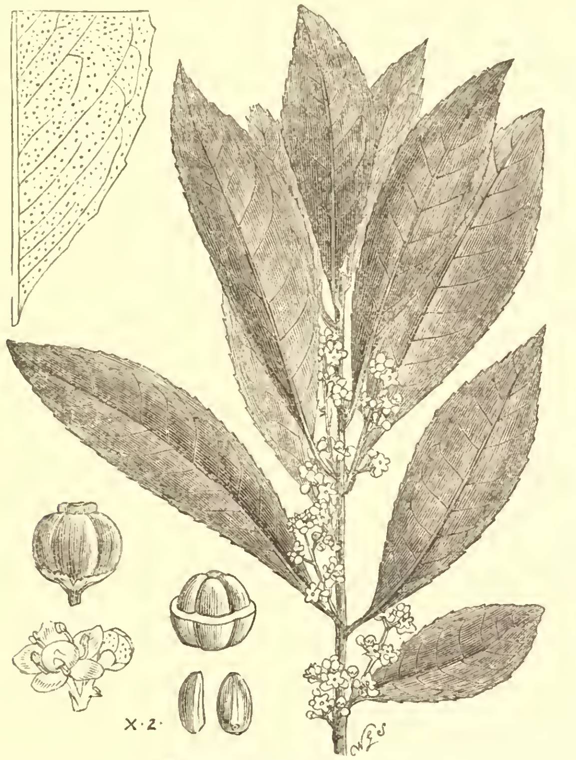
"Vestas" are matches in which short pieces of "wax taper" are used in place of wooden splints. The taper is prepared by drawing a series of wicks or strands of twenty to thirty fine cotton threads through molten stearin, with some proportion of paraffin. The wax quickly hardens on the threads, agglutinating them to irregular hard strands, which are smoothed and rounded to the required size by being drawn through iron plates perforated with holes the size of the required taper. The tapers are cut to the match lengths, and set in dipping frames by special machines. The making of vestas is an industry only second in extent to the wooden match manufacture,—its headquarters being London, Manchester, Marseilles, and the north of Italy. Fusees for the use of smokers are made of strips of thick porous paper saturated with saltpetre and bichromate of potash, and tipped with ordinary composition. They are now almost entirely supplanted by vesuvians, which consist of large oval heads on both ends of a round splint. These heads, made by repeated dipping, consist of a porous mixture of charcoal, saltpetre, cascarilla or other scented bark, glass, and gum, and they also are tipped with common igniting composition.

Ordinary match boxes are made of thin veneers or skillets of wood the same as used in splint making. The blocks used yield skillets the exact size of the box or cover to be made, and the machine which shaves skillets off the block also scores them along the lines by which they must be bent to form the box. The folding, covering with paper, and labelling are operations performed by young girls with remarkable rapidity. In dealing with double splints, the matches are at the boxing stage cut asunder in small bundles with a lever knife by the box filler, who acquires such delicacy of perception that at each operation she seizes and divides the exact quantity required to fill two boxes. A good hand will in this way fill 35 to 40 gross of boxes per day.

It is calculated that in the principal European countries from six to ten matches are used for each inhabitant daily. There is no way by which an exact estimate of the extent of the trade in the United Kingdom can be obtained; but competent authorities believe the yearly value of the matches made to be not less than £1,500,000, and that the makers turn out about 300,000,000 matches daily. Of all the makers Messrs Bryant & May are by far the most extensive; and next comes the Bell & Black company, formed of a combination of makers in London, Glasgow, Manchester, and York. In France the right to manufacture matches is a Government monopoly farmed to the *Compagnie générale des allumettes chimiques* for an annual payment of 16,000,000 francs, with 6 centimes extra per hundred matches in excess of forty milliards sold yearly. The company has concentrated the whole of the manufacture into twelve establishments, the largest of which are at Marseilles. The effect of the monopoly in France is that matches are very costly, and the average consumption per head throughout the country is considerably less than in other countries. Sweden is the country which in recent years has been most intimately identified with the growth of the industry. In that country, including with it Norway, there were in 1880 forty-three match factories, many of them large, that of Jönköping being among the most extensive in the world. The quantity of matches exported that year was about 19,000,000 lb (22,900,000 skal-punds), probably representing 50,000,000,000 matches. The yearly exports have increased four-fold since 1870, and are still rapidly extending. In Germany there are two hundred and twelve factories, which are estimated to make yearly about 60,000,000,000 matches; and Austria-Hungary—the original seat and centre of the manufacture—possesses one hundred and fifty establishments, whence large quantities of matches are exported to Russia, Turkey, Asia Minor, and the neighbouring states of Italy. Throughout Europe about 1200 tons of phosphorus are annually consumed in the manufacture of matches, the greater proportion being produced in England

In the United States a tax of 1 cent per box containing one hundred is levied on matches manufactured in the country, in addition to which there is an *ad valorem* duty of 35 per cent. on all matches imported. The internal revenue tax of a cent per box is subject to a reduction of 10 per cent. to manufacturers, with an additional discount of 5 per cent. on the purchase of the stamps used for the boxes when quantities exceeding in value $50 are purchased at one time. The result of these fiscal arrangements has been to favour large monopolizing companies. Although there are nearly thirty manufactories in the States at present, practically the match trade of the country is in the hands of, or entirely controlled by, the Diamond Match Company of New York, consisting of a combination of large manufacturers. During the year 1881 the revenue derived from the internal tax amounted to $3,272,258, while the customs duty on imported matches yielded no more than $6186, these receipts representing probably a consumption of 40,000,000,000 matches. (J. PA.)

MATÉ, or Paraguay Tea, consists of the dried leaves of *Ilex paraguayensis*, St Hil.,[1] an evergreen shrub or small tree belonging to the same natural order as the common holly, a plant to which it bears some resemblance in size and habit. The leaves are from 6 to 8 inches long, shortly-stalked, oblong wedge-shaped, rounded at the upper end, and finely toothed at the margin. The small white flowers



Maté (*Ilex paraguayensis*).
Portion of plant, half natural size. Flower drupe and nuts, twice natural size. Part of underside of leaf showing minute glands, natural size.

grow in forked clusters in the axils of the leaves; the sepals, petals, and stamens are four in number; and the berry is 4-seeded. The plant grows abundantly in Paraguay, Corrientes, Chaco, and the south of Brazil, forming woods called *yerbales.* One of the principal centres of the maté industry is the Villa Real, a small town above Asuncion on the Paraguay river; another is the Villa de San Xavier, in the district between the rivers Uruguay and Parana.

Although maté appears to have been used from time immemorial by the Indians, the Jesuits were the first to attempt its cultivation. This was commenced at their branch missions in Paraguay and the province of Rio Grande de San Pedro, where some plantations still exist, and furnish the best tea that is made. From this circumstance the names Jesuits' tea, tea of the Missions, St Bartholomew's tea, &c., are sometimes applied to maté. Under cultivation the quality of the tea improves, but the plant remains a small shrub with numerous stems, instead of forming, as in the wild state, a tree with a rounded head. From cultivated plants the leaves are gathered every two or three years, that interval being necessary for restoration to vigorous growth. The collection of maté is, however, chiefly effected by Indians employed for that purpose by merchants, who pay a money consideration to Government for the privilege.

When a yerbal or maté wood is found, the Indians, who usually travel in companies of about twenty-five in number, build wigwams and settle down to the work for about six months. Their first operation is to prepare an open space, called a *tatacua*, about 6 feet square, in which the surface of the soil is beaten hard and smooth with mallets. The leafy branches of the maté are then cut down and placed on the tatacua, where they undergo a preliminary roasting from a fire kindled around it. An arch of poles, or of hurdles, is then erected above it, on which the maté is placed, a fire being lighted underneath. This part of the process demands some care, since by it the leaves have to be rendered brittle enough to be easily pulverized, and the aroma has to be developed, the necessary amount of heat being only learned by experience. After drying, the leaves are reduced to coarse powder in mortars formed of pits in the earth well rammed. Maté so prepared is called *caa gazu* or *yerva do polos*, and is chiefly used in Brazil. In Paraguay and the province of Parana in the Argentine Republic, the leaves are deprived of the midrib before roasting; this is called *caa-miri.* A very superior quality, or *caa-cuys*, is also prepared in Paraguay from the scarcely expanded buds. More recently a different method of drying maté has been adopted, the leaves being heated in large cast iron pans set in brick work, in the same way that tea is dried in China; it is afterwards powdered by machinery.

The different methods of preparation influence to a certain extent the value of the product, the maté prepared in Paraguay being considered the best, that of Oran and Paranagua very inferior. The leaves when dried are packed tightly in serons or oblong packages made of raw hides, which are then carefully sewed up. These shrink by exposure to the sun, and in a couple of days form compact parcels each containing about 200 lb of tea; in this form it keeps well. The tea is generally prepared for use in a small silver-mounted calabash, made of the fruit of *Crescentia Cujete* (Cuca) or of *Cucurbita lagenaria* (Cabaço), usually about the size of a large orange, the tapering end of the latter serving for a handle. In the top of the calabash, or *maté*,[2] a circular hole about the size of a florin is made, and through this opening the tea is sucked by means of a bombilla. This instrument consists of a small tube 6 or 7 inches long, formed either of metal or a reed, which has at one end a bulb made either of extremely fine basket-work or of metal perforated with minute holes, so as to prevent the particles of the tea leaves from being drawn up into the mouth. Some sugar and a little hot water are first placed in the gourd, the yerva is then added, and finally the vessel is filled to the brim with boiling water, or milk previously heated by a spirit lamp. A little burnt sugar or lemon juice is sometimes added instead of milk. The beverage is then handed round to the company, each person being furnished with a bombilla. The leaves will bear steeping about three times. The infusion, if not drunk soon after it is made, rapidly turns black. Persons who are fond of maté drink it before every meal, and consume about 1 oz. of the leaves per day. In the neighbourhood of Parana it is prepared and drunk like Chinese tea. Maté is generally considered disagreeable by those unaccustomed to it, having a somewhat bitter taste; moreover, it is the custom to drink it so hot as to be unpleasant. But in the south-eastern republics it is a much-prized article of luxury, and is the first thing offered to visitors. The *gaucho* of the plains will travel on horseback for weeks asking no better fare than dried beef washed down with copious draughts of maté, and for it he will forego any other luxury, such as sugar, rice, or biscuit. Maté acts as a restorative after great fatigue in the same manner as tea. Since it does not lose its flavour so quickly as tea by exposure to the air and damp, it is more valuable to travellers.

Some writers attribute deleterious effects to its use, while others praise it to an almost incredible degree. Its physiological action does not appear to have been carefully worked out, but its extensive use in countries where tea and coffee are known seems to indicate that it may possess virtues peculiar to itself.

Its properties appear to be chiefly due to theine or caffeine. Analysed by Dr H. Byasson, 100 grains were found to yield

	Grains.
Caffeine	1·850
Glutinous substance or peculiar fatty matter and colouring matter	3·870
Complex glucoside	2·380
Resin	0·630
Inorganic salts, including iron	3·920
Malic acid not estimated.	

[1] Mr J. Miers has proved that *I. curitibensis*, *I. gigantea*, *I. ovalifolia*, *I. Humboldtiana*, and *I. nigropunctata*, besides several varieties of these species, are in general use for preparing maté.

[2] The word *caa* signified the plant in the native Indian language. The Spaniards gave it a similar name, *yerba.* *Maté* comes from the language of the Incas, and originally means a calabash. The Paraguay tea was called at first *yerva do maté*, and then, the *yerva* being dropped, the name *maté* came to signify the same thing.

According to analyses made by Alonzo Robbins it also contains about 1·5 of a peculiar tannin which does not precipitate potassio-tartrate of antimony, nor tan leather. The glutinous substance resembles in consistence common birdlime, and is considered by Byasson to be a compound ether, the alcohol of which would be near cholesterin. Since the beginning of the 17th century maté has been drunk by all classes in Paraguay, and it is now used throughout Brazil and the neighbouring countries. In 1855 the amount of maté annually consumed in South America was estimated by Von Bibra at 15,000,000 lb, and the consumption is now probably three or four times as great; in Brazil it brings in a revenue of about £410,000. In the Argentine Republic alone the consumption is not less than 27,000,000 lb per annum, or about 13 lb per head, while the proportion of tea and coffee consumed is only about 2 lb of the former and ¼ lb of the latter per head. The export of maté from Brazil to foreign countries has also increased from 2,720,475 kilos in 1840 to 5,206,485 kilos in 1850, 6,808,056 kilos in 1860, 9,507,086 kilos in 1870, and 14,063,731 kilos in 1879–80.

MATERA, a city of Italy in the north-east of the province of Potenza, 48 miles from Potenza, on the high road to Bari. Part of it is built on a level plateau and part in deep valleys adjoining, the tops of the campaniles of the lower portions being on a level with the streets of the upper. The principal building is the co-cathedral of the archbishopric of Acerenza and Matera, formed in 1203 by the union of the two bishoprics, dating respectively from 300 and 398. In 1871 the population of the commune was 14,312 (that of the city 14,262), in 1881 15,700.

Under the Normans Matera, the ancient Mateola, was a countship for William Bras de Fer and his successors. It was the chief town of the Basilicata from 1664 till 1811, when the French transferred the administration to Potenza.

MATHEMATICAL DRAWING AND MODELLING. The necessity for geometrical drawings and models is as old as geometry itself. The figure has formed the basis of many a geometrical truth; and demonstration by mere inspection of this has frequently to do service for more rigorous proof. So necessary is this visual representation of an idea that there is hardly a branch of mathematics which does not make use of it in the form of tables, symbols, formulæ, &c. The visual method is especially important in geometry. The figure is to the geometer what the numerical example is to the algebraist—on the one hand limiting the horizon, on the other imparting life to the conception. Herein lies the didactic value of the figure, which is the more indispensable the more elementary the stage of instruction. To be able to dispense with it is a faculty acquired only after a long and special training. The power of mental picturing is a talent which can be so strengthened by use that even a slightly gifted mind may acquire the power of carrying out a series of geometrical operations without the aid of a figure, provided these do not lead into unfamiliar regions. But each new group of ideas which the geometer would master requires a new graphic setting forth, which not even the experienced can dispense with. Drawings are sufficient in plane geometry; but solid geometry requires models, except in specially simple cases, in which delineation by means of perspective or some conventional method may suffice. Then, again, in passing from the geometry of the plane, straight line, and point in space to that of curved surfaces, tortuous curves, &c., new and distinct graphical methods are necessary. The difficulties encountered in understanding new groups of geometrical forms are best removed by a careful study of a small number of characteristic models and drawings. As a means of education, the model is lively and suggestive, forming in this way a completing factor in the course of instruction. We remember the pleasure experienced when, after a discussion which has yielded a series of hardly reconcilable properties of one and the same geometrical figure, a model is exhibited which combined these properties in itself; or the striking manner in which a deformable model either of pasteboard or thread executes its transformations before the eye of the observer and scientific student. The study of the model raises new and unexpected questions, and can even do valuable service in leading to new truths.

In the more elementary departments of plane and solid geometry and descriptive geometry, models are abundant and easily obtainable; but there are comparatively few collections of drawings and models for instruction in higher geometry. There are numerous drawings of algebraic and transcendental curves in the well-known treatises on analytical geometry of Cramer, Euler, Salmon, in Frost's *Curve Tracing*, &c.; but there is still a deficiency in systematic enumerations of the forms of curves and surfaces of a given order or class. In this connexion we may mention Plücker's *System der analytischen Geometrie* (curves of the third order), and Beer's *Enumeratio linearum IV. ordinis*. A graphical representation of all the characteristics of the singular points of an algebraic curve of the fourth order is given in Zeuthen's *Systemer af plane Kurver* (1873). As regards tridimensional figuring, the oldest known models for instruction in the higher geometry are the thread models of skew surfaces constructed about the year 1800 under the direction of G. Monge for the École Polytechnique in Paris. In 1830 Th. Olivier of Paris got the same executed in movable form. The great development in modern times of certain branches especially of the higher geometry has given a new importance to such methods of graphical representation.

Amongst the larger collections we must mention the elegant series of complex surfaces, consisting of twenty-seven items, constructed by the celebrated J. Plücker of Bonn. After Plücker's death copies, not very satisfactory, were made from zinc casts. The collection of plaster and thread models published by Muret of Paris (now Delagrave), and intended for instruction in descriptive geometry, contains many architectural forms. The wire models of tortuous curves by Professor Wiener of Carlsruhe, and the thread-models of developable surfaces by Professor Björling of Lund, merit notice amongst others. Perhaps the largest and most extensive of the collections is that of L. Brill, bookseller in Darmstadt. These represent every department of the higher and applied mathematics. The catalogue embraces some seventy numbers, with over a hundred plaster, thread, and metal models. Several series of this collection were prepared in the mathematical department of the technical college of Munich. In the preparation of these models, involving the development of a comparatively novel art, certain practical lessons were gained, especially in the working of plaster models, to which we may direct attention.

We assume that the preliminary designs are prepared with the aid of board, ruler, square, compasses, and such well-known instruments as are used by the draughtsman.

The material to be employed, whether wire or thread, interlaced pasteboard strips, or plaster, depends upon the special circumstances of each case, and upon the purpose aimed at in the construction of the model. Two bundles of parallel disks of cardboard or metal-sheeting, inclined at an adjustable angle, may be used with advantage in representing a series of different but mutually transformable surfaces. For ruled and developable surfaces the thread model is to be recommended. The surface is enclosed in a cube, or more generally in a region of space bounded by plane walls. Upon these bounding walls are marked the series of points in which they are cut by the generative lines that are to be represented by threads. Through these points the threads are drawn, and parts of the supporting walls are then cut away so as to allow a convenient glance into the interior of the region. The more densely the threads are strung, the liker is the appearance to that of a continuous surface.

In the majority of cases plaster will be found the most convenient substance, being easily worked, and giving a result convenient and clear to the eye. There is the disadvantage, however, that one of the regions of space bounded by a surface is filled up. Should the boundaries of the surface be plane or capable of being turned on the lathe, the desired form is best approximated to by working wood or plaster blocks. Plaster is not easily worked on the lathe, but a plane surface is readily got by rubbing, and if not too dry it may be cut with the knife.

A surface which cannot be conveniently approximated to by the above method may be built up of strips cut to pattern, which are then filled in with some plastic material. To accomplish this, a system of sections either parallel or having a single axis is laid through the region to be filled up; the bounding lines of these sections are calculated or obtained by geometrical construction. Strips of plate zinc are then cut to the required form and fixed securely by cross-pieces or soldered if necessary. Between the interstices of this zinc scaffolding some plastic material is filled in, such as embossing wax or damp clay; and thus the form of the surface is rendered. The substance known in trade as plastilin is especially suitable for use in this way, as it retains its plastic property a long time. The finishing touches are given to the surface by means of a sculptor's style. From the clay model a plaster cast is formed and well dried; and its imperfections are removed by means of plaster-files and other instruments familiar to those who work in plaster. Lines which are to be shown on the model are drawn through points already marked on the original clay model, and engraved with fine files. A galvanoplastic copy of such a plaster model, not too deeply deposited, shows the surface even better than the plaster itself.

MATHEMATICS. Any conception which is definitely and completely determined by means of a finite number of specifications, say by assigning a finite number of elements, is a mathematical conception. Mathematics has for its function to develop the consequences involved in the definition of a group of mathematical conceptions. Interdependence and mutual logical consistency among the members of the group are postulated, otherwise the group would either have to be treated as several distinct groups, or would lie beyond the sphere of mathematics.

As an example of a mathematical conception we may take "a triangle"; regarded without reference to its position in space, this is determined when three elements are specified, say its three sides; or we may take a "colour sensation," which, on Young's theory, is determined when the amounts of the three fundamental colour sensations that enter into it are stated. As an example of a non-mathematical conception we may take "a man," "a mineral," "iron," no one of which admits of being so determined by a finite number of specifications that all its properties can be truly said to be deducible from the definition.

A mathematical conception is, from its very nature, abstract; indeed its abstractness is usually of a higher order than the abstractness of the logician. Thus, for instance, we may neglect the other attributes of a body and consider merely its form; we thus reach the abstract idea of "form." But the form of an irregular fragment of stone does not admit of being finitely specified, and is therefore not susceptible of mathematical treatment. If, however, we have a carefully squared cubical block of granite to deal with, for most practical purposes its form is specified by stating that it is a cube, and assigning one element, viz., an edge of the abstract mathematical cube by which we replace it. This example illustrates at once the limits of mathematical reasoning and the nature of the bearing of mathematics on practice.

A variety of words have been used to denote the dependence of a mathematical conception upon its elements. It is frequently said, for instance, that the conception is a "function" of its elements. One word has recently come into use which is very convenient, inasmuch as it draws attention at once to the fundamental idea involved in mathematical conception and to the prime object of mathematical contemplation, viz., "manifoldness."

Number is involved in the notion of a manifoldness both directly, as any one can see, and also indirectly in a manner which the mind untrained to mathematical thinking does not so readily understand. Take on the one hand the case of a triangle considered without reference to its position but merely as composed of three limited straight lines, it may be completely determined in various ways by assigning three elements. A triangle may therefore be called a triple discrete manifoldness. A plane quadrilateral considered in the same way (being fully determined when four sides and a diagonal are known) is a quintuple discrete manifoldness; and a plane polygon of n sides a $(2n-3)$-ple discrete manifoldness. Consider on the other hand the assemblage of points on a given straight line, they are infinite in number yet so related that any one of them is singled out by assigning its distance from an arbitrarily chosen fixed point on the line. Such an assemblage is called a onefold continuous manifoldness, or simply a onefold manifoldness; another example of the same kind is the totality of instants in a period of time. The assemblage of points on a surface is a twofold manifoldness; the assemblage of points in tridimensional space is a threefold manifoldness; the values of a continous function of n arguments an n-fold manifoldness.

It should be observed that the distinction between discrete and continuous manifoldness is not of necessity inherent in the conception. For one purpose we may treat a conception as a discrete manifoldness, for another as a continuous manifoldness. Thus we have seen that an unlimited straight line may be treated as a onefold continuous manifoldness; but, if we regard it as a whole, and with reference to the fact that its position in space is determined by four data, it becomes a quadruple discrete manifoldness.

The primary, although not the only, operation in the treatment of a discrete manifoldness is numbering or counting; hence arises the pure mathematical science of number, comprehending (abstract) *Arithmetic* and its higher branch commonly called the *Theory of Numbers.* Without entering into a discussion of the definitions and axioms of the science of number, it will be sufficient here to remark that all numerical operations are reducible to three fundamental laws commonly called the commutative, associative, and distributive laws. The four fundamental processes, or four species, as they are sometimes called, two of which, addition and multiplication, are direct, and two, subtraction and division, inverse, are solely defined by and derive their meaning from the three laws of operation just mentioned.

A careful consideration of the methods in vogue for dealing with continuous manifoldness shows that they reduce themselves to two, which may be called the synoptic method and the analytic method. In the synoptic method we deduce the properties of a manifoldness by contemplating it as a whole, aiding our understanding, when it is necessary to do so, by a diagram, a model, or any other concrete device more or less refined according to circumstances. In the analytic method we fix our attention upon the individual elements of the manifoldness, usually defining each element by a definite number of specifications the variation of which leads us from element to element of the given manifoldness. We examine the properties of an element in the most general manner, and from them we predicate the properties of the manifoldness as a whole.

The best and most familiar examples of the synoptic treatment of manifoldness are the different varieties of pure geometry. Among these we may mention the apagogic geometry of the Greeks, which starts with a collection of definitions and axioms, enunciates and proves proposition after proposition with great attention to strict logical form and with continual reference to the grounds of inference, but pays little attention to the ordering of theorems with a view to mutual illustration, and carefully suppresses all traces of the method by which the propositions were or might have been discovered. It is true that the Greeks were in possession of a method, called by them analysis, which had for its object the discovery of geometrical truth. But this consisted merely in taking any proposition suspected to be true and tracing its consequences until one was reached which either contradicted a known proposition or else was true and capable of leading by a direct process of reasoning (synthesis) to the proposition in question. In this we have no trace of the systematic development of geometric truth, and the method was apparently regarded by the ancients themselves as imperfect, for it makes no figure in such of their systematic treatises as have reached us. In somewhat sharp contrast with the Grecian geometry, but still essentially synoptic in method, stand the different varieties of modern geometry,—which aims at greater generality in its definitions, pays less explicit attention to logical form, but arranges geometrical propositions as much as possible in the natural order of development or discovery, and above all makes extensive use of the principle of continuity. As examples of the modern geometry may be cited the descriptive geometry (*Géométrie Descriptive*, *Darstellende Geometrie*) of Monge; the projective geometry (*Géométrie Projective*, *Geometrie der Lage*) of Poncelet, Steiner, and Von Staudt; and the geometry of transformation in general, of which projective geometry is but a particular case. There is one other highly interesting form of modern geometry, which, although analytic in some of its developments, and often exhibited in close alliance with other analytical methods, is nevertheless synoptic as to its fundamental principle, viz., arithmic geometry (*Abzählende Geometrie*) or theory of characteristics, which originated in the characteristic equations of Plücker, and was developed into a powerful special method by Chasles and others. See GEOMETRY and CURVE.

Geometry, however, is not the only field for the synoptic treatment of manifoldness. This is obvious if we reflect that any magnitude whatever may be represented by a line; so that any function of not more than two elements may be represented by a geometrical construction and treated by any method applicable in geometry. Since the famous dissertation of Riemann, *On the Hypotheses that form the Basis of Geometry*, mathematicians have been familiar with the fact that the methods of geometry suitably generalized can be applied to the treatment of an n-fold manifoldness; and in point of fact the synoptic treatment of manifoldness under the name of n-dimensional geometry has been usefully employed by Cayley and others as an adjunct to the analytic method.

The fundamental characteristic of the analytical treatment of an n-fold manifoldness is the specification of an element by means of n continuously varying quantities or variables (see MEASUREMENT). For dealing with continuous as distinguished from discrete quantity we have the special analytical method of the INFINITESIMAL CALCULUS (*q.v.*), built upon the notion of a limit, with its various branches, viz., the differential calculus, the integral calculus including differential equations, the calculus of functions, and the theory of functions in general (see FUNCTION). But, whether we make use of the algorithm of the infinitesimal calculus or not, we find upon examination that all analytical operations with continuous quantity fall under the three laws of commutation, association, and distribution, so that they are fundamentally identical with the operations with discrete quantity; the difference so far as there is any consists simply in the greater generality of the operand. The same fact may be looked at instructively in another light. Whether we consider analytical processes in concrete applications or look at them abstractly, we are equally led to the notion of a unit, by the multiplication or subdivision of which all the other quantities that enter into our calculus are derived. The exigencies of continuity are met by allowing that the multiplication or subdivision of the unit can be carried on to an unlimited extent; but in any case where analytical formulæ have to be reduced to arithmetical calculation (in which of course only a finite number of figures or arithmetical symbols can be used) the subdivision (or multiplication) of the unit actually stops short at a certain point; in other words, all our methods are, in practice at least, discrete. Here therefore we have the meeting point of discrete and continuous quantity, and on this ground alone we might infer the fundamental identity of their laws of operation.

The abstract science of quantity which we have just seen to be the essential part of the analytic treatment of manifoldness receives the name of ALGEBRA (*q.v.*). It was found very early in the history of that science that the full development of which it is capable could not be attained without great extension of the idea of quantity. This necessity first arose in connexion with the inverse operations, such as subtraction, the extraction of roots, and the numerical solution of algebraical equations (see EQUATION), of which root extraction is merely a particular case. In this way arose essentially negative quantities, and the so-called impossible or imaginary quantities. The former may be said to depend on a new abstract unit -1, and the latter upon new units $\pm\sqrt{-1}$. The numbers having ± 1 for abstract unit are usually classed as real numbers, and in that case we may regard the ordinary imaginaries of algebra as depending on the new unit $+\sqrt{-1}$, or ι, defined by the equation $\iota^2 + 1 = 0$. But the extension was soon carried farther by the classical researches of Hamilton and Grassmann.[1] The theory of sets and the QUATERNIONS (*q.v.*) of the former and the *Ausdehnungslehre* of the latter opened up a boundless field for algebra, and led to a total revolution in our ideas of quantity.

In view of the great extension thus effected in the meaning of quantity, it becomes an interesting if somewhat difficult undertaking to define the word. The following may be taken as a provisional definition:—*Quantity is that which is operated with according to fixed mutually consistent laws.* Both operator and operand must derive their meaning from the laws of operation. In the case of ordinary algebra these are the three laws already indicated, in the algebra of quaternions the same save the law of commutation for multiplication and division, and so on. It may be questioned whether this definition is sufficient, and it may be objected that it is vague; but the reader will do well to reflect that any definition must include the linear algebras of Peirce, the algebras of logic, and others that may be easily imagined, although they have not yet been developed. This general definition of quantity enables us to see how operators may be treated as quantities, and thus to understand the rationale of the so-called symbolical methods. In combining operations, it is often observed that the combinations of operators fall under a few simple laws, in some cases in fact under the three laws of ordinary algebra; these operators are therefore quantities according to the general definition, and can be treated as such.

From the historical development of the analytic method there is little danger of the error arising that its application is peculiar to any special kind of manifoldness. As examples of its use in deducing the properties of tridimensional space we may cite the Cartesian geometry, the *Géométrie de Position* of Carnot, and the line geometry of Plücker (see GEOMETRY). Its use in the various branches of applied mathematics, of which geometry is merely one of the simplest, is far more common than that of the

[1] In this connexion should be mentioned the great services of De Morgan, whose bold speculations on the fundamental principles of mathematical science have perhaps met with less than their due share of appreciation.

synoptic method, although most branches of applied mathematics are mixtures using the one or the other, as happens to be convenient. In addition to those already mentioned, we may enumerate the following as among the more important departments of applied mathematics:—Kinematics; Abstract Dynamics, including Statics and Kinetics whether of a Particle, of a Rigid Solid, of an Elastic Solid, of a Fluid, or of a Chain; Statistical Mathematics, as exemplified in the Theory of Annuities, and the Kinetic Theory of Gases; the Mathematical Theory of Diffusion whether of Heat or of Matter; the Theory of Potential; and so on. See MECHANICS, HYDROMECHANICS, ANNUITIES, HEAT, ELECTRICITY, MAGNETISM, &c.

The two great methods employed in the investigation of manifoldness must of course be, at bottom, identical; and every conclusion arrived at by the one must be reachable by the other. The exact nature of the connexion between them will be well seen by studying two instances. One of these is the treatment of areas by Euclid and the treatment by the analytical method, which are carefully compared in the article GEOMETRY, vol. x. p. 379. The other is the connexion between the descriptive and the metrical properties of loci. The former include all properties such as intersection, tangency, &c., depending on position merely, and are obviously the natural product of the synoptic method. The latter include all relations involving the lengths of lines and the magnitudes of angles, they depend therefore on expression in terms of a unit, and are the natural product of the analytic method. Nevertheless the analytic method furnishes descriptive properties of loci, and by the introduction of "the absolute" descriptive theorems are made to furnish metrical relations, as has been fully shown by Cayley, Clifford, and Klein (see MEASUREMENT). (G. CH.)

MATHER, COTTON (1663–1728), was the most learned and widely known of a family which through four generations enjoyed singular consideration, and exercised commanding influence upon New England in its first century. Richard, son of Thomas Mather of Lowton (Winwick), Lancashire, England, after studying for a time at Brasenose, Oxford, and teaching and subsequently preaching at Toxteth Park, went to New England, for nonconformity's sake, in the summer of 1635, where, till his death in 1669, at seventy-three, he was pastor of the Congregational church in Dorchester (now a part of Boston),—acquiring large repute, writing three or four instructive and constructive treatises upon polity, and being much trusted as to the foundations of both church and state. His youngest son Increase took his first degree at Harvard College in 1656, at seventeen,—returning, after a visit to the old country, in which he served several pulpits, to take at twenty-five the pastorate of the second (or North) church in Boston, which place he held till his death in 1723 at eighty-five, while, in addition, he had been acting, or actual, president of the college most of the time from 1681 to 1701, the author of one hundred and sixty books or tracts, and for four of its most perilous years the choice of all its citizens to represent the Massachusetts colony before the English Government. His wife Maria was daughter of the famous John Cotton, and their first-born received both family names, and when he took his B.A. degree at less than sixteen, at Harvard, in 1678, his promise tempted President Oakes to say in his presence, referring to his two distinguished grandfathers: "Cottonus atque Matherus tam re quam nomine coalescant et reviviscant." After a short time spent as tutor, and a period of diligent toil ending in the conquest of an impediment of speech which endangered success in the family profession, he became assistant to his father, in two years being ordained co-pastor, and holding the pulpit for nearly three and forty years, till his death at sixty-five. As a private Christian, from his frank diaries, it is clear that he laboured much with himself, in a single year devoting more than sixty days to fasting and twenty nights to vigil. As a preacher he was conscientious and successful,—always diligently studying his discourses, in one year delivering more than seventy public sermons, with nearly half as many in private houses, sometimes thus "pressing a glorious Christ" through eleven successive days, and, with six competitors by his side, maintaining to the last his hold upon the largest congregation in New England, having about four hundred gifted communicants. As a pastor he was exceptionally laborious,—systematically exhorting and praying with his people at their homes, making conscience of spiritualizing every casual interview, and now and then spending days upon his knees with the names of his flock before him to prompt his intercessions for them, and for himself that he might better reach their peculiar need. As a philanthropist, while abundant in personal benefactions, he originated more than twenty societies for public charity, bore the cost of a school for Christianizing the negroes, and, at the risk of life, in the face of popular opposition medically led, advocated and vindicated the introduction of inoculation as a protection against the then terrible ravages of the small-pox. As an author he was learned—publishing in French, Spanish, and Algonkin as well as English—and voluminous, three hundred and eighty-two of his printed works having been catalogued, several of which are elaborate books, and one a folio of 800 pages; while his *Biblia Americana*, by him considered the great work of his life, remains in six huge volumes of manuscript to this day. As a scholar he was better known across the sea than any other American of his time, once contemporaneously corresponding with more than fifty learned Europeans, in his forty-seventh year being made doctor of divinity at Glasgow, and receiving election as a Fellow of the Royal Society—in those days eminent distinctions for a colonist. With all this it must be confessed that he had some grave defects. His common sense was not uniformly equal to his need. Always ambitious and self-opinioned, he was occasionally irritable and conceited. He lacked good taste, and it was his unconcealed grief that he was never elected to preside over Harvard College. His enormous knowledge did not digest well, and his use of learning tended to be crude. He was superstitious, and it was his misfortune that, as to witchcraft, he was not, as with vaccination, in advance of his generation, any more than such men as Richard Baxter and Sir Matthew Hale. Of his works, the *Magnalia* and *Ratio Disciplinæ* are indispensable to the student of New England history.

MATHEW, THEOBALD (1790–1856), popularly known as Father Mathew, the "Apostle of Temperance," was descended from an illegitimate branch of the Llandaff family, and was born at Thomastown, Tipperary, on October 10, 1790. He received his school education at Kilkenny, whence he passed for a short time to Maynooth; from 1808 to 1814 he studied at Dublin, where in the latter year he was ordained to the priesthood. Having entered the Capuchin order, he, after a brief time of service at Kilkenny, joined the mission in Cork, which was the scene of his religious and benevolent labours for many years. The movement with which his name is most intimately associated began in 1838 with the establishment of a total abstinence association, which in less than nine months, thanks to his moral influence and eloquence, enrolled no fewer than 150,000 names. It rapidly spread to Limerick and elsewhere, and some idea of its popularity may be formed from the fact that at Nenagh 20,000 persons are said to have taken the pledge in one day, 100,000 at Galway in two days, and 70,000 in Dublin in five days.

In 1844 he visited Liverpool, Manchester, and London with almost equal success. Meanwhile the expenses of his enterprise had involved him in heavy liabilities, and led on one occasion to his arrest for debt; from this embarrassment he was only partially relieved by a pension of £300 granted by the queen in 1847. In 1849 he paid a visit to the United States, returning in 1851. He died at Queenstown on December 8, 1856. See *Father Mathew, a Biography*, by J. F. Maguire, M.P. (1863).

MATHEWS, CHARLES (1776–1835), comedian, was born in London, 28th June 1776. His father was what he called "a serious bookseller," and also officiated as minister in one of Lady Huntingdon's chapels. Mathews was educated at Merchant Taylors' School. His love for the stage was formed in his boyhood, partly from admiration of Elliston, with whom he had taken part in private theatricals. According to his own statement, it ripened into an "overpowering, all-absorbing passion," unfitting him for business when he became apprentice to his father, who at length, in 1794, unwillingly permitted him to enter on a theatrical engagement in Dublin. For several years Mathews had not only to content himself with the most thankless parts at an almost nominal salary, but his figure, at this period of life thin and ungainly, and the peculiar twist in his countenance generally awakened the unconcealed ridicule of the audience. In 1798 he obtained a conditional engagement from Tate Wilkinson at York. In 1802 Mathews began to play in London at the Haymarket, and from this time his professional career was an uninterrupted triumph. His special excellence as an actor consisted in his wonderful gift of mimicry, enabling him to grasp the minutest and most individual features of the character he represented. His sense of the purely ludicrous in all its varied phases was perhaps unequalled, and by his marvellous command of facial expression and of different tones and accents of voice he could, when he so willed, completely disguise his personality without even the smallest change of dress. The versatility and originality of his powers were, in public, best seen in his "At Homes," begun in the Lyceum Theatre in 1818, "which," according to Leigh Hunt, "for the richness and variety of his humour, were as good as half a dozen plays distilled." But it was in the social circle that he displayed the finest and rarest traits of genius, while his simple and truly kind-hearted disposition won him an affection and esteem which mere genius could not have purchased. From his infancy the health of Mathews had been uncertain, and the toils of his profession gradually undermined it. He died at Plymouth, of heart disease, 28th June 1835. See *Memoirs*, by Mrs Mathews, 4 vols., 1838–39.

MATHEWS, CHARLES JAMES (1803–1878), comedian, son of the above, was born at Liverpool, 26th December 1803. After attending Merchant Taylors' School he was articled as pupil to an architect, and he continued nominally to follow this business till 1835. His first appearance on the stage was made at the Adelphi, London. In 1838 he married Madame Vestris, then lessee of the Olympic, but neither his management of this theatre, nor subsequently of Covent Garden, nor of the Lyceum, resulted in pecuniary advantage. As an actor, however, he held from the first an unrivalled place in his peculiar vein of light eccentric comedy. The inimitable easy grace of his manner, and the imperturbable solemnity with which he perpetrated his absurdities, never failed to charm and amuse; his humour was never broad, but always measured and restrained. His range of characters was exceptionally narrow, and he was wholly incapable of representing any form of strong passion. It was as the leading character in such plays as the *Game of Speculation*, *My Awful Dad*, *Cool as a Cucumber*, *Patter versus Clatter*, and *Little Toodlekins*, that he specially excelled. Mathews was one of the few English actors who have played in French successfully—his appearance at Paris in 1863 in a French version of *Cool as a Cucumber*, written by himself, being received with the utmost approbation. After reaching his sixty-sixth year, Mathews set out on a tour round the world, and on his return in 1872 he continued to prosecute his professional duties without interruption till within a few weeks of his death, on July 26, 1878. See *Life of Charles James Mathews*, edited by Charles Dickens, 2 vols., 1879.

MATILDA, countess of Tuscany (1046–1114), popularly known as the Great Countess, was born in 1046, of a race of nobles of Lombard descent. By the death of her father Boniface the Rich, duke and marquis of Tuscany, she was left, at eight years old, under the guardianship of her mother, Beatrice of Lorraine, heiress to a powerful state, including Tuscany, Liguria, part of Lombardy, Modena, and Ferrara. Her life was a protracted struggle against the schism which rent the church, under a series of antipopes, supported by a large section of the clergy and people of Italy and Germany, as well as by the whole strength of the empire. Against this formidable combination she maintained the cause of the holy see, often single-handed, for years, with varying fortune but undaunted resolution. The champion of several successive pontiffs, she is best known as the ally of Gregory VII., and her hereditary fief of Canossa was, in 1077, the scene of the celebrated penance of Henry IV. in presence of this pope. On the same occasion she made the donation, subsequently renewed in 1102, of her possessions to the holy see, in right of which the church owned the greater part of its temporal dominions. Matilda was twice married, first to Godfrey of Lorraine, surnamed the Humpbacked, son of her mother's second husband, and secondly to Guelph of Bavaria,—both marriages of policy, which counted for little in her life. She died of gout in 1114, in her sixty-ninth year, and was buried first at San Benedetto, and finally in the Vatican. Her steadfastness of purpose, strength of character, and loftiness of aim, made her one of the most striking figures even of the age which produced Robert Guiscard, William the Conqueror, Pope Hildebrand, and Godfrey of Bouillon, her nephew by marriage. The contemporary record of her life in rude Latin verse, by her chaplain Donnizone, is preserved in the Vatican Library.

An Italian biography was published in Lucca by Francesco Fiorentini in 1642 (new edition by Mansi, 1756), and one in French by Amédée Renée, *La Grande Italienne*, in 1859.

MATLOCK, a town of Derbyshire, England, is situated on the river Derwent and on the Midland Railway, 149 miles north-west of London and 17 north-west of Derby. It possesses cotton, corn, and paper mills, and in the vicinity there are lead-mines. About 1½ miles south-east, also on the Derwent, is Matlock Bath, possessing hot medicinal springs. There are in all three springs, the first of which was discovered in 1692. Their mean temperature is 68° Fahr., and applied both externally and internally the water is efficacious in glandular affections, rheumatism, biliary obstructions, and relaxation of the muscular fibres. The fine scenery of the vale of Matlock, and its proximity to the thickly peopled districts of Lancashire and Yorkshire, cause the village to be much frequented in summer not only by invalids but by holiday visitors. There are several large stalactite caverns. Matlock Bank, a mile to the north-east, in a finely sheltered situation, contains several well-known hydropathic establishments. The population of the urban sanitary district of Matlock (4513 acres) in 1871 was 3834, and in 1881 it was 4396; that of Matlock Bath and Scarthin Nick in the same years was 1386 and 1698. These two districts are conterminous with the civil parish of Matlock.

MATSYS, QUINTIN. See MASSYS.

MATTER, PROPERTIES OF. If we knew thoroughly the nature of any piece of matter, the deduction of its properties would be a question of mere reasoning, just as (for instance) the definition of a circle really involves all the properties which mathematical methods have deduced from it. But, as we do not even know what matter is, in the abstract, the converse operation is (at least for the present) the natural and necessary one. We must endeavour from the experimentally ascertained properties of matter to discover what it is. The reader will find the limits of our present knowledge in the article ATOM. The properties of matter may be arranged in several classes, thus:—

1. Properties of matter in itself; such as Inertia, Hardness, Brittleness, ELASTICITY (*q.v.*), Density, Compressibility, Viscosity, &c. These depend upon its ultimate structure and upon the law and intensity of the so-called molecular forces. See ATOM, CONSTITUTION OF BODIES, ATTRACTION.

2. Relative properties of different kinds of matter, chemical, catalytic, &c. See CAPILLARY ACTION, CHEMISTRY, DIFFUSION, &c.

3. Properties relative to different forms of energy:—Conductivity (Thermal and Electric), Specific Gravity, Specific and Latent Heat, Transparency, Colour, Specific Inductive Capacity, Radiating and Absorbing Power, Magnetic Retentiveness, &c., Thermo-electric Position, Refractive Index, Reflective Power, Double Refraction, Rotatory Polarization, &c. These will be found mainly under the heads ELECTRICITY, HEAT, LIGHT, MAGNETISM, &c.

MATTEUCCI, CARLO (1811–1868), an Italian physicist, was born at Forlì, June 20, 1811. In 1832, after completing his studies at L'École Polytechnique, Paris, he became professor of physics at Bologna, where he had passed his earlier student days. In 1837 he removed to Ravenna, and in 1840 settled as professor of physics at Pisa. From 1847 he took an active part in politics, and in 1860 was chosen an Italian senator. At the same time he became general telegraph director, and later the superintendent of the meteorological bureaus. He died at Leghorn, June 25, 1868.

He is the author of four scientific treatises:—*Lezioni di fisica* (2 vols., Pisa, 1841; second edition 1851), *Lezioni sui fenomeni fisico-chimici dei corpi viventi* (Pisa, 1844; second edition 1846), *Manuale di telegrafia elettrica* (Pisa, 1850; and several later editions), and *Cours spécial sur l'induction, le magnétisme de rotation*, &c. (Paris, 1854). His numerous papers were published in the *Annales de Chimie et de Physique* (1829–58); and most of them also appeared at the time in the Italian scientific journals. They relate almost entirely to electrical phenomena, such as the magnetic rotation of light, the action of gas batteries, the effects of torsion on magnetism, the polarization of electrodes, &c., sufficiently complete accounts of which are given in Wiedemann's *Galvanismus*. Nine memoirs, entitled "Electro-Physiological Researches," were published in the *Philosophical Transactions*, 1845–60. See Bianchi's *Carlo Matteucci e l'Italia del suo tempo* (Rome, 1874).

MATTHEW (Μαθθαῖος or Ματθαῖος, *i.e.*, מתי, a shortened form of Mattaniah or Mattithiah, equivalent to Theodorus; comp. vol. xi. p. 370), one of the twelve apostles of Jesus Christ, and, according to tradition, the author of the First Gospel. In its full Hebrew form the name occurs several times in the Old Testament, being borne by more than one person of priestly or Levitical family. Matthew, in the Gospel which bears his name, is described as having been a tax gatherer (τελώνης, Matt. x. 3), and the circumstances of his call to become a follower of Jesus, which he received as he sat at the "receipt of custom" or "tax office" in one of the towns by the Sea of Galilee, are briefly related in chap. ix. 9. It has sometimes been doubted, but without any good reason, whether the precisely parallel narrative relating to "Levi the son of Alphæus" (Mark. ii. 14; Luke v. 27, 28) has reference to the same person (compare the double names Simon and Peter, Joses and Barnabas, and others). In the lists of the names of the apostles given in the synoptical Gospels and in the Acts, Matthew ranks third or fourth in the second group of four. Little is recorded of him except the feast which he gave in his house at the beginning of his discipleship; the way in which this is related seems to indicate that he was (comparatively at least) a wealthy man. He was also present in "the upper room" at Jerusalem after the ascension, when Matthias was elected to be the successor of Judas. Tradition has nothing trustworthy to tell about his subsequent career, but there is nothing inherently improbable in the allegation of Eusebius (*H. E.*, iii. 24) that he spent several years in Jerusalem preaching to the Hebrews (and writing the Gospel which bears his name), or that he afterwards extended his missionary activities in other directions. Socrates (*H. E.*, i. 19) speaks of him as having carried the gospel to Ethiopia; the earlier legends, however, embodied in the apocryphal *Acta Andreæ et Matthæi* and *Acta et Martyrium Matthæi*, unanimously point to the regions bordering on the Black Sea ("Pontus" and the land of the Anthropophagi) as having been the scene of his labours (see the article of Lipsius on the "Apocryphal Acts of the Apostles" in Smith's *Dict. of Christ. Biog.*; also his *Apokr. Apostelgesch.*, 1883). According to the Gnostic Heracleon, whose statement is quoted and apparently homologated by Clement of Alexandria (*Strom.* iv. 9), Matthew died a natural death. He is commemorated as a martyr by the Greek Church on November 16, and by the Roman on September 21, the scene of his martyrdom being placed by the Breviary in "Ethiopia"; the same authority affirms that his body was afterwards translated to Salerno, where it now lies in the church built by Robert Guiscard. In Christian art (following Jerome) he is generally regarded as symbolized by the "man" in Ezek. i. 10, Rev. iv. 7.

MATTHEW, GOSPEL OF. See GOSPELS, vol. x. p. 789 *sqq.*

MATTHEW OF PARIS, one of our most important writers in connexion with English mediæval history, was born about the year 1200, or possibly somewhat earlier. His surname was probably derived either from his having been born in Paris or having studied in the university there; but his English origin is proved by the tone in which he uniformly speaks of foreigners, especially the French, while his knowledge of the French language is attested by the fact of his having written in that language, and also by the introduction of many French words in his Latin writings.

We have it on his own authority, as recorded in an autograph marginal note (MS. Cott., Nero, D. 1, fol. 165*b*), that he assumed the monastic habit at the abbey of St Alban's on the 21st of January 1217. In 1236 he accompanied the newly-elected prior of his abbey, John of Hertford, to London, to attend the ceremony of the nuptials of Henry III. and Eleanor of Provence; and in October 1247 he was at Westminster, in order to be present at the celebration of the feast of St Edward the Confessor, when he was desired by the king himself to write an account of the proceedings. The most important event in his tranquil and uneventful life (which was passed chiefly within the walls of his monastery) occurred in the year 1248, when he was sent on a mission to the Benedictine monastery of Holm (Throndhjem), which had become involved in difficulties owing to the maladministration of one of its abbots. He returned to England after more than a year's absence, and we can trace him as attending the royal court at Winchester in July 1251, and as present at York on the occasion of the marriage of Henry's daughter with Alexander II. of Scotland, some six months later. In March 1257 Henry himself visited St Alban's, and remained at the monastery for a whole week. During this time he not only admitted Matthew to his table and to conversations in his private chamber, but also communicated to him facts and details of an historical character derived from his own personal knowledge and experience. Among other information, Matthew tells us that Henry repeated to him from memory the titles of the English baronies to the number of two hundred and fifty. The last incident recorded by the historian himself with respect to his own career is the fact that he exerted his influence with Henry on behalf of the university of Oxford, when that body found its privileges endangered by the encroachments of the bishop of Lincoln. In his latter years, Matthew's growing infirmities compelled him to have recourse to the aid of a fellow-monk in order to complete his works; this assistance is to be traced in the *Historia Anglorum* from 1252 to the end of the work (1253); in the *Abbreviatio Chronicorum* for the years 1253, 1254, and 1255; and in the *Chronica Majora* for the years 1258 and 1259. Matthew died after the month of May 1259, and his portrait, as he lay on his couch when dead, was drawn by his fellow-monk.

Works.—Matthew Paris's chief work, the *Historia Major*,—often styled the *Chronica Majora*,—is a narrative professing to record the outlines of human history from the creation, and terminating with the year 1259. It was long supposed that Roger of Wendover was the author of a much larger proportion of the work than was really the case; but the question may be regarded as finally set at rest by the decisive investigations and conclusions of Dr Luard, as stated at length in his prefaces to the volumes of his edition of the work in the Rolls Series. He concludes that the *Historia Major* down to the year 1189 was the work of John de Cella, abbot of St Alban's from the year 1195 to 1214; that it was then continued by Roger of Wendover on the same plan and from the same sources to the year 1235, the whole work down to this date passing for a long time as the production of the latter writer exclusively, and being known as the *Flores Historiarum*; that it was then transcribed by Matthew Paris, who, however, made numerous corrections and additions, but, in the opinion of Professor Stubbs, "interpreted" rather than "interpolated"; that it was then continued by the same writer, and is, from 1235 to the year 1259, exclusively his work. In style, in vividness of narration, and in descriptive power Matthew far excels his two predecessors. He is also entitled to the praise of having been a warm advocate of English rights and liberties, and a sturdy opponent alike of regal and papal tyranny; in fact, the national sentiment may be said first to receive adequate expression in his pages. The work, moreover, is not only the best source of information with respect to events in England during the reign of Henry III. down to the commencement of the Barons' Wars, but is also an authority with respect to Continental affairs, especially those of France and the empire.

The *Historia Anglorum* of Matthew is mainly an abridgment of his larger work,—the chief feature of difference being the omission of almost everything relating to foreign events. Sometimes, however, details and more particularly personal anecdotes are introduced, with many minute facts and circumstances which would be sought for in vain elsewhere, and largely illustrate contemporary usages and the general condition of society. Besides the above, Matthew wrote an *Abbreviatio Chronicorum*, extending from the year 1100 to 1255. Of this only one manuscript exists,—that in the author's own handwriting, preserved in the Cottonian collection in the British Museum, and printed in the third volume of the *Historia Anglorum*, edited by Sir Francis Madden. Matthew also compiled a *Liber Additamentorum* or *Supplementorum*, containing documents illustrative of the Greater Chronicle. This is contained in the folio edition of Matthew's writings edited by Wats, and published in 1640.

The *Vitæ viginti trium Abbatum S. Albani*, or *Lives of the Abbots of St Alban's*, does not bear Matthew's name, but is unquestionably the production of his pen. The biographies which belong to the period preceding the Norman Conquest contain valuable and interesting notices, but also include much of what is evidently fabulous. The *Vitæ duorum Offarum*, or *Lives of the two Offas*,—the one a mythical character, the other the historic monarch of Mercia,—is a composition of little value, and some doubt attaches to the authorship. Both the foregoing, however, are included in the edition by Wats.

Editions.—The best edition of the *Historia Major* is that by Dr Luard, published in five volumes in the Rolls Series, 1872–80. Of the *Historia Minor* an edition in three volumes in the same series was edited by Sir Frederic Madden, 1866–69. (J. B. M.)

MATTHIAS (1557–1619), holy Roman emperor, the fourth son of the emperor Maximilian II., was born on the 24th of February 1557. He was educated in Germany by the diplomatist Busbecq, while his brother, afterwards the emperor Rudolph II., was trained at the court of Philip II. of Spain. In 1577 Matthias went secretly to the Netherlands, the sovereignty of which he unlawfully assumed; but in 1580 he was compelled to withdraw into private life. He was vain, restless, and ambitious, and intrigued incessantly against the emperor Rudolph, a man of weak character, with a constitutional tendency to insanity. Rudolph passed wholly under the dominion of the Jesuits, and this rendered it easy for Matthias to stir up his Protestant subjects against him. In 1595 Matthias was made regent in Austria, and in 1606 the archdukes recognized him as head of the house of Hapsburg. Rudolph had to relax his hold over one country after another, and in 1611 Matthias was ruler of Hungary, Moravia, Silesia, Lusatia, and even Bohemia, whose loyalty the emperor had tried to secure by many concessions, especially by the letter of majesty granting religious freedom to Protestant sects. In 1612, after the death of Rudolph, Matthias was elected emperor; and his reign was not less disturbed than that of his predecessor. The intervention of Turkey in Transylvania led to war, and in 1615 Matthias, being unsupported by the empire and by his own estates, found that he had no alternative but to conclude peace for twenty years on humiliating terms. Protestants and Catholics, bitterly hating each other, formed respectively the Union and the League; and the rising power of the archduke Ferdinand, afterwards emperor, a bigoted prince who became king of Bohemia in 1617 and king of Hungary in 1618, indicated that even more serious troubles were approaching than those with which Rudolph had contended. In the last two years of the reign of Matthias, the Bohemians having rebelled, the first blows in the Thirty Years' War were struck. He died on the 20th of March 1619.

MATTHIAS CORVINUS (1443–1490), king of Hungary, was born at Klausenburg in Transylvania on March 27, 1443, and died at Vienna on April 6, 1490. He was the younger son of John Hunyady (Corvinus) who died in 1456 after having been "governor of Hungary" from 1446 to 1453. On the death of John, the elder of his two sons (Ladislaus) was executed by command of Ladislaus Posthumus, while Matthias was imprisoned at Prague; but shortly after the king's own death without issue in 1457, Matthias Hunyady (Corvinus) was elected by the Hungarian magnates to the vacant throne (January 24, 1458). The leading events of his reign are summarized in the article HUNGARY (vol. xii. p. 368, 369).

MATTING. Under this name are embraced many coarse woven or plaited fibrous materials used for covering floors or furniture, for hanging as screens, for wrapping up heavy merchandise, and for other miscellaneous purposes. In the United Kingdom, under the name of "coir" matting a large amount of a coarse kind of carpet is made from cocoa-nut fibre; and the same material, as well as strips of cane, Manila hemp, various grasses and rushes, is largely employed in various forms for making door mats. Perforated and otherwise prepared india-rubber is also largely utilized for door and floor mats. Matting of various kinds is very extensively employed throughout India for floor coverings, the bottoms of bedsteads, fans and fly-flaps, &c.; and a considerable export trade in such manufactures is carried on. The materials used are numerous; but the principal substances are straw, the bulrushes *Typha elephantina* and *T. angustifolia*, leaves of the date palm (*Phœnix sylvestris*), of the dwarf palm (*Chamærops Ritchiana*), of the Palmyra palm (*Borassus flabelliformis*), of the cocoa-nut palm (*Cocos nucifera*), and of the screw pine (*Pandanus odoratissimus*), the munja or munj grass (*Saccharum Munja*) and allied grasses, and the mat grasses *Cyperus textilis* and *C. Pangorei*, from the last of which the well-known Palghat mats of the Madras Presidency are made. Many of these Indian grass mats are admirable examples of elegant design, and the colours in which they are woven are rich, harmonious, and effective in the highest degree. Vast quantities of coarse matting used for packing furniture, heavy and coarse goods, and plants, &c., are made in Russia from the bast or inner bark of the lime tree. This industry centres in the great forest governments of Viatka, Nijni-Novgorod, Kostroma, Kazan, Perm, and Simbirsk.

MATTOON, a city of the United States, in Coles county, Illinois, 172 miles south-south-west of Chicago, on the Central Illinois Railroad, which at that point intersects the Indianapolis and St Louis and the Peoria, Decatur, and Evansville Railroads. It had 5742 inhabitants in 1880, has railway carriage works and repair shops, and is rising rapidly in commercial importance.

MATURIN, Charles Robert (1782–1824), novelist and dramatist, perplexed the serious and served as a butt for the more light-minded critics of the first quarter of the 19th century. The bombastic extravagance of his language, the incoherence of his plots, the wild improbability of many of his incidents, the inconsistency of his characters, were obvious and undeniable; but there were so many passages of extraordinary eloquence in his novels, especially in his descriptions of turbulent passion, that, though some pronounced him evidently mad, all admitted that it was a madness allied to genius. At first he published only sermons in his own name, being curate of St Peter's, Dublin. His first novels, *The Fatal Revenge* (1804), *The Wild Irish Boy* (1808), *The Milesian Chief* (1811), were issued under the pseudonym of Dennis Jasper Murphy. All these were mercilessly ridiculed by the press and neglected by the public, but the irregular power displayed in them attracted the notice of some social and literary magnates; and through the influence of Byron and Scott Maturin's tragedy of *Bertram* was produced at Drury Lane in 1816, with a prologue by Hobhouse, an epilogue by the Hon. George Lamb, and with Kean and Miss Kelly in the leading parts. The magnificent scenic situations, and the character of Bertram (like one of Byron's sombre heroes), make this an effective stage play. It was the first and only success of the author; he returned to "the baffled efforts and the blighted hopes" of which Hobhouse speaks in his prologue. Two more tragedies, *Manuel* (1817) and *Fredolpho* (1819), were failures. A poem, *The Universe* (1821), fell flat. Three novels, *Women* (1818), *Melmoth* (1820), and *The Albigenses* (1824), produced a considerable impression. In the preface to *Women* he admitted that his previous novels had been justly condemned, being an impossible attempt to revive the exploded style of Mrs Radcliffe, and promised that he would enter on a new vein. But he could not alter his character. The new vein was as wild, fantastic, incoherent, interspersed with passages of really splendid eloquence, as the old. The *Albigenses* was to be the first of a series of historical romances, illustrating periods of European history, and it was noticed in the *Westminster Review* as giving, with all its faults, promise of better things; but the author died in the year of its publication.

MAUBEUGE, a fortified place of northern France, situated on both banks of the Sambre, 142 miles by rail north-east from Paris, and about 2 miles from the Belgian frontier. Its fortifications were planned by Vauban; the enceinte is pierced by two gateways, that of France and that of Mons. Maubeuge, besides containing an arsenal and several old convents, is an industrial town, manufacturing swords, files, axles, tools, hardware, machinery, porcelain tiles, and paper; in the neighbourhood there are numerous forges. The population in 1876 was 14,400.

Maubeuge owes its origin to a double monastery for men and women founded in the 7th century by St Aldegonde. It was burnt by the Normans, by Louis XI., by Francis I., and by Henry II., and was finally assigned to France by the treaty of Nimeguen. It was fortified by Vauban at the command of Louis XIV., who first saw military service there, under Turenne. Besieged in 1793 by the prince of Coburg, it was relieved by the victory of Wattignies. It was unsuccessfully besieged by the duke of Saxe-Weimar in 1814, but was compelled to capitulate, after a vigorous resistance, in the following year.

MAULMAIN, or Moulmein, a town in Amherst district, British Burmah, situated on the left bank of the Salwín river, in 16° 30′ N. lat. and 97° 38′ E. long. At the time of the cession of this part of the province to the British in 1826, Maulmain was a mere waste. It has now developed into a thriving commercial town, ranking next to Rangoon in importance, with a rapidly increasing population and trade. The population, which in 1857 was 23,683, had increased in 1872 to 46,472, and in 1881 to 53,107 (32,895 males and 20,212 females). The principal buildings are Salwín House, originally a private residence, but now the property of the municipality, the hospital, the jail, Protestant and Roman Catholic churches, the custom-house, and other public offices, and the barracks for the garrison of Madras native infantry. For many years timber formed the only export, but with the gradual settlement of the country and increase in agriculture rice and cotton began to be also exported; besides these, the other staple exports are hides, horns, lead, copper, yellow orpiment, and stick-lac. The principal imports are cotton twist and cloth, woollen piece-goods, wines and spirits, sugar, and betel-nuts. In 1880–81 573 vessels (266,010 tons) entered the port, and 536 (265,147 tons) cleared. The value of merchandise imported was £666,810, of treasure £312,190, of merchandise exported £1,389,763, and of treasure £92,817. Shipbuilding forms an important industry of the town.

MAUNDY THURSDAY, the day preceding Good Friday. The word "maundy" (Middle-English, *maundee* or *maunde*, a command) is identical with the "mandatum" of the rubric and anthem of the Missal for the fifth day in Holy Week, sometimes called "Dies Mandati" (see this shown at length by Skeat in *Etym. Dict.*, and in note to *Piers Plowman*, xvi. 140). The "mandatum" or "maund" referred to is the "new commandment" of John xiii. 34, but more particularly the precept given to the disciples in the same chapter "to wash one another's feet." The practice by prelates and others of literally and formally carrying out this injunction in a public manner on a given day has long been established both in the East and in the West. Perhaps an indication of it may be discerned as early as the 4th century in a custom, current in Spain, northern Italy, and elsewhere, of washing the feet of the catechumens towards the end of Lent before their baptism; it was not, however, universal, and in the 48th canon of the synod of Elvira (306 A.D.) it is expressly prohibited (comp. *Corp. Jur. Can.*, c. 104, caus. i. qu. 1). Be this as it may, the "pedilavium," or ceremony of washing the feet of twelve beggars on this day, has now for centuries been observed by the prelates of the Church of Rome, including the pope himself, according to a ritual minutely prescribed in the Missal; it is also practised by the Austrian emperor, the king of Bavaria, and other European sovereigns in the Latin obedience, as well as by the emperor of Russia and others at the head of the Greek Church. In England it was continued by the sovereign even after the Reformation; the last recorded instance of its full performance is in the case of James II., but a distribution of royal alms, consisting of money and clothing, is still continued. It is on Maundy Thursday also that in the Church of Rome the sacred oil is blessed, and the chrism prepared, according to an elaborate ritual which is given in the *Pontificale*.

MAUPERTUIS, Peter Louis Moreau de (1698–1759), a mathematician and astronomer of considerable reputation in his day, was born at St Malo, July 17, 1698. When twenty years of age he entered the army, becoming lieutenant in a regiment of cavalry, and employing his leisure on mathematical studies. After five years he quitted the army and was admitted in 1723 a member of the academy of sciences. In 1728 he visited London, and was elected a fellow of the Royal Society. In 1736 he acted as chief of the expedition sent by Louis XV. into Lapland to measure the length of a degree of the meridian within the polar circle, in order to settle the then much disputed question of the oblate figure of the earth, and, on his return home, he became a member of almost all the scientific societies of Europe. In 1740 Maupertuis went to Berlin on the invitation of the king of Prussia, and took part in the battle of Mollwitz, where he was taken prisoner by the Austrians. On his release he returned to Berlin, and thence to Paris, where he was elected director of the academy of sciences in 1742, and in the following year was admitted into the Academy. Returning to Berlin in 1744, Maupertuis married a lady of rank and great beauty, and in 1746 was chosen president of the royal academy of sciences. Finding his health declining, he repaired in 1757 to the south of France, but went in 1758 to Basel, where he died July 27, 1759. Maupertuis was unquestionably a man of considerable ability as a mathematician, but his restless, gloomy disposition involved him in constant quarrels, of which his controversies with König and Voltaire during the latter part of his life furnish examples.

The following are his most important works:—*Essay on Cosmology*; *Discourse on the Different Figures of the Stars*; *Essay on Moral Philosophy*; *Philosophical Reflexions*, &c.; *Animal Physics*; *System of Nature*; *Elements of Geography*; *Account of the Expedition to the Polar Circle*, &c.; *Laws of Motion*; *Laws of Rest*; *Parallax of the Moon*; *The Comet of* 1742; *On the Progress of the Sciences*. He also contributed a large number of interesting papers to the *Memoirs* of the academies of Paris and Berlin.

MAU RÁNÍPUR, a town in Jhánsí district, in the North-Western Provinces of India, in 25° 15′ N. lat., 79° 11′ E. long. The population in 1872 was 16,428. Although now a large trading centre, the town is of quite modern commercial importance, having risen from the position of a small agricultural village through the influx of merchants seeking relief from extortionate demands made by the rájá of a neighbouring native state. It contains a large community of wealthy merchants and bankers. A special variety of cloth, known as *kharua*, is manufactured and exported to all parts of India. The principal imports are sugar, English piece-goods, silk, metals, and coffee. Trees line many of the streets, and handsome temples ornament the town.

MAURER, Georg Ludwig von (1790–1872), a distinguished German jurist and statesman, was born at Erpolsheim in the Bavarian Palatinate, November 2, 1790. He was the son of a Protestant pastor. He received his education at the university of Heidelberg, and afterwards followed for some time the profession of an advocate. In 1812 he went to reside in Paris, where, with the aid of the great libraries of that city, he entered on a systematic study of the ancient legal institutions of Germany. On his return to Bavaria he was appointed substitute for the attorney-general in the district of Spires and Landau. In 1824 he published at Heidelberg his first work, *Geschichte des alt-germanischen und namentlich alt-bairischen öffentlich-mündlichen Gerichtsverfahren*, which obtained the first prize of the academy of Munich. In 1826 he was made one of the professors of law in the university of Munich. In 1832, Otho, son of King Louis of Bavaria, having been chosen to fill the throne of Greece, a council of regency was nominated to conduct the government of that country during his minority. Of this council Von Maurer was appointed a member, the others being the Count von Armansperg, who was president, Major-General K. W. von Heideck, and K. von Abel. They applied themselves energetically, and at first apparently in a spirit of concord, to the task of creating for the new kingdom institutions adapted to the requirements of a modern civilized community. But grave differences soon made themselves felt, Maurer being at variance with the president on important administrative questions. These being referred to King Louis, he decided in favour of the president, and Maurer and Abel were suddenly recalled in 1834. The loss of Maurer was a serious one for Greece; he was the ablest, most energetic, and most liberal-minded member of the regency, and had already done important work in the juridical and educational organization of the kingdom. It was through his enlightened efforts that Greece had obtained a revised penal code, regular tribunals, and an improved system of civil procedure. Soon after his recall, he published his work entitled *Das griechische Volk in öffentlicher, kirchlicher, und privatrechtlicher Beziehung vor und nach dem Freiheitskampfe bis zum* 31 *Juli* 1834 (3 vols., Heidelberg, 1835–36). This book is a valuable source of information on the history of Greece during the preceding years, its condition before the call of Otho to the throne, and the labours of the council of regency down to the time of the author's recall. Notwithstanding his removal from office, he does not appear to have forfeited the esteem or goodwill of King Louis. After the fall of the ultramontane ministry of Abel in 1847, he became minister of foreign affairs and of justice, but on attempting to carry out reforms he was overthrown; retiring then from political life, he devoted himself altogether to historical and juristic studies, the fruits of which he gave to the world in successive publications. He died at Munich, May 9, 1872.

The following is believed to be a complete list of such of his writings as have not been already mentioned:—*Grundriss des deutschen Privatrechts*, 1828; *Ueber die bairischen Städte und ihre Verfassung unter der römischen und fränkischen Herrschaft*, 1829; *Ueber die deutsche Reichsterritorial- und Rechtsgeschichte*, 1830; *Das Stadt- und das Landrechtsbuch Ruprechts von Freising nach 5 münchener Handschriften, ein Beitrag zur Geschichte des Schwabenspiegels*, 1839; *Ueber die Freipflege* (plegium liberale), *und die Entstehung der grossen und kleinen Jury in England*, 1848; *Einleitung zur Geschichte der Mark-, Hof-, Dorf-, und Stadt-Verfassung und der öffentlichen Gewalt*, 1854; *Geschichte der Marken-Verfassung in Deutschland*, 1856; *Rede bei der 100-jährigen Stiftungsfeier der K. Akademie der Wissenschaften am* 28 *März*, 1859; *Geschichte der Dorf-Verfassung in Deutschland*, 2 vols., 1865–66; *Geschichte der Fronhöfe, der Bauernhöfe, und der Hofverfassung in Deutschland*, 4 vols., 1862–63; *Geschichte der Städteverfassung in Deutschland*, 4 vols., 1869–71. He also superintended the preparation of a part of the continuation of Jacob Grimm's *Weisthümer*, published under the auspices of the academy of Munich, 1866. His researches on the ancient village communities of Germany are of special interest and importance.

MAURETANIA, or Mauritania (the former is the more correct form of the name, according to coins and inscriptions), was the name given in ancient geography to the district which constituted the north-western angle of the African continent. It comprised a considerable part of the modern empire of Morocco, together with the western portion of Algeria. But its limits varied much at different times. When it first appears in history the river Mulucha constituted its eastern limit, which separated it from the Numidian tribe of the Massyli, who held all the country from that river to the Ampsaga; but at a later period the kingdom of Mauretania was extended to the latter river so as to include the whole territory from the Ampsaga to the Atlantic Ocean. Towards the south it was bounded by the great range of Mount Atlas, and it appears to have been regarded by geographers as extending along the coast of the Atlantic as far as the point where that chain descends to the sea, in about 30° N. lat., though the Roman province of the name extended but a little beyond Sala (Sallee), and it is probable that there were no towns or permanent settlements farther south. The magnificent plain, or rather plateau, in which the city of Morocco is situated seems to have been unknown to ancient geographers, and was certainly never included in the Roman empire. On the other hand the Gætulians, who inhabited the narrow strip of fertile date-producing territory on the southern slopes of the Atlas, though not included under the name of Mauretania, seem to have always owned a precarious subjection to the kings of that country, and in after days to its Roman governors.

The physical geography of the country will be described under the heading MOROCCO, though it must be observed that the term Mauretania, as used by the Romans, comprised also the greater portion of the French colony of Algeria, including the provinces of Oran and Algiers, and even a part of that of Constantine. The range of Mount Atlas forms throughout the backbone of the country, from which the streams descend to the Mediterranean and the ocean. The most important of those on the north coast is the Mulucha or Molochath, which in the earliest times constituted the eastern limit of the country; it is still called Muluya. Farther east are the Chinala, the Usar, and the Ampsaga. Of those that flow westward towards the Atlantic, the most considerable were the Lixus, Subur, and Sala. But from the proximity of the mountain ranges to the sea none of these streams were of any importance, or navigable beyond a short distance from the sea.

A large part of the country is of great natural fertility, and was in ancient times extensively cultivated, and produced large quantities of corn, while the slopes of Mount Atlas were clothed with vast forests, which, besides other kinds of timber, supplied the celebrated ornamental wood called *Citrus*, for tables of which the Romans gave such fabulous prices.

Mauretania, or Maurusia, as it was called by Greek writers, unquestionably signified the land of the Mauri, a term still retained in the modern name of Moors, and probably meaning originally nothing but "black men." The origin and ethnical affinities of the race are unknown; but it is probable that the inhabitants of all this northern tract of Africa along the coast of the Mediterranean were kindred races belonging to the family which is represented at the present day by the Berbers of the mountain districts and the Tuaricks of the tract south of the Atlas. They first appear in history at the time of the Jugurthine War (110–106 B.C.), when Mauretania west of the Mulucha was under the government of a king called Bocchus, and appears to have constituted a regular and organized state. It retained its independence till the time of Augustus, who in 25 B.C. bestowed the sovereignty of the previously existing kingdom upon Juba II., king of Numidia, at the same time uniting with it the western portion of Numidia, from the Mulucha to the Ampsaga, which now received the name of Mauretania Cæsariensis, while the province that had previously constituted the kingdom, or Mauretania Proper, came to be known as Mauretania Tingitana. This distinction continued to subsist after the incorporation of the two provinces in the Roman empire under Claudius in 42 A.D., and remained unchanged till the time of Constantine.

In the time of Pliny and Ptolemy, Mauretania contained a number of flourishing cities and towns, several of which enjoyed the privileges of Roman colonies, having been founded no doubt in great part with a view of keeping in check the wild barbarians who still occupied the greater part of the country. The most important of these places were—Tingis, on the site of the modern Tangier, the capital of the province to which it gave its name; Lixus and Sala, on the coast of the Atlantic, at the mouths of the rivers of the same name; and three towns in the interior of the same province, Zilis, Babba, and Banasa, all of them bearing the title of Roman colonies. On the coast of the Mediterranean stood Rusaddir (now Melilla), within the limits of Tingitana; and beyond the Mulucha Cartenna (now Tenes); Iol, surnamed Cæsarea, which was made his capital by Juba II., and continued to be that of Mauretania Cæsariensis under the Romans (its site is now called Cherchell); Icosium (the modern Algiers); Saldæ (Bujeyah); Igilgili (Jijeli) near the eastern limit of the province; and Sitifis (Setif) at no great distance in the interior, a town of considerable importance, which after the time of Constantine gave the name of Mauretania Sitifensis to this eastern portion of the province. The prosperity of this part of Africa under the Roman empire, previous to the irruption of the Vandals in 429 A.D., is shown by the fact that no less than one hundred and seventy towns which were episcopal sees are enumerated in the Notitia in the two provinces of Mauretania.

MAURICE (MAURICIUS), ST, and his companions are commemorated as martyrs by the Roman Church on September 22. The earliest extant form of the legend relating to them is that of Eucherius, bishop of Lyons about the middle of the 5th century, who tells us that Maurice was in command of the Theban legion (so called because raised in the Thebais) when it was sent into the West and attached to the army of Maximian. Themselves Christians to a man, its members refused to persecute their coreligionists, and for this, after having twice been decimated, the legion was utterly destroyed by command of the emperor at Octodurum (Martigny) near Geneva. A later form of the legend connects it with the expedition of Maximian against the Bagaudæ, who are taken to have been Christians; the martyrdom of the legion arises out of its refusal to take part in a great sacrifice which had been ordered at Octodurum; and another name—that of Exsuperius—is associated with Maurice's. Later still, Gregory of Tours knows of a company of the same legion which suffered at Cologne (their leader subsequently became known as Gereon). The date usually assigned to the martyrdom of the Theban legion is 286 A.D.; but it is matter of history that at that period the Christians were everywhere unmolested in the exercise of their religion throughout the Roman empire. On the other hand, at no later date have we any evidence of the presence of Maximian in the Valais; and, apart from the great *a priori* improbability of the extirpation of a whole legion under any circumstances on account of its Christian profession, it is practically impossible to get over the fact that such writers as Eusebius, Lactantius, Orosius, and Sulpicius Severus know nothing of such a noteworthy and startling event having taken place. But in the long and voluminous controversy as to the historical character of this legend it has of course never been attempted to deny that isolated cases of officers being put to death on account of their religion occurred during the reign of Maximian. The cultus of St Maurice and other members of the Theban legion occurs chiefly in Switzerland, the region of the Rhine, and northern Italy; the foundation of the abbey of St Maurice (Agaunum) in the Valais is usually ascribed to Sigismund of Burgundy (515).

MAURICE (MAURICIUS FLAVIUS TIBERIUS), emperor of the East from 582 to 602, was of Roman descent but a native of Arabissus in Cappadocia, where he was born about 539. He spent his youth at the court of Justin II., and, having joined the army, fought with distinction in the Persian war (578–581). At the age of forty-three he was declared Cæsar by the dying emperor Tiberius II., who bestowed upon him the hand of his daughter Constantina. In the meagre annals of the reign of Maurice the most conspicuous events are the termination of the long struggle in the East with the restoration to the Persian throne of Chosroes II. by the Roman general Narses (not the conqueror of Italy) in 591, and the successes of Priscus in the protracted war against the Avars. Some inopportune attempts at army reform, and an ill-judged refusal to provide a ransom which might have prevented the massacre of twelve thousand prisoners in the hands of the enemy, led to a rebellion among the legions on the Danube, who declared Maurice unworthy to reign, and, commanded by Phocas, then a simple centurion, but destined to become emperor, marched upon Constantinople. The capital having declared against him, Maurice abdicated and withdrew to Chalcedon, but was pursued and put to death there after having witnessed the murder of five of his sons (November 27, 602). He was the author of a work on military art (στρατηγικά) in twelve books, of which there is an edition by Scheffer, published at Upsala in 1664. There is a *Vita Mauricii* by Theophylact Simocatta.

MAURICE OF NASSAU, prince of Orange, the younger son of William the Silent, was born at Dillenburg in 1567, and was made governor of the United Provinces after the assassination of his father in 1584. He succeeded his brother as prince of Orange in 1618, and died at the Hague on April 23, 1625. For the leading features of his character and events of his life see HOLLAND, vol. xii. pp. 77, 78.

MAURICE (1521-1553), duke and elector of Saxony, the son of Duke Henry the Pious, was born on the 21st of March 1521. He received a learned education, and at an early age gave evidence of an energetic and ambitious temper. In 1541 he married Agnes, daughter of the landgrave Philip of Hesse, and succeeded his father as duke of Saxony, of the Albertine line. Although a Protestant, he held cautiously aloof from the League of Smalkald; and in 1542 and 1543 he received imperial favour by supporting Charles V. against the Turks and the French. In 1546, when Charles V. attacked the League of Smalkald, Maurice sided with the emperor, the result being that he was made elector of Saxony in place of his cousin John Frederick (of the Ernestine line), who was taken prisoner and deposed. At this time Maurice was detested by the German Protestants, who considered him a traitor to his religion; but the tide soon turned. Fearing that the emperor's ultimate aim was to strike at the authority of the princes, he began silently to make preparations for war; and Charles V. was imprudent enough to provide him with a pretext for opposition by detaining the landgrave Philip of Hesse, whose freedom Maurice had guaranteed. In 1551 Maurice concluded a secret treaty with Henry II. of France against the emperor, and an alliance was also formed with several German princes. Charles V. refused to believe in the reality of the danger; but in March 1552 he was startled by the intelligence that Henry II. had entered Germany as an invader, and that Maurice was hastening southward at the head of a powerful army. John Frederick and Philip were at once released, and the emperor, after an ignominious flight, was compelled to sign the treaty of Passau. After the re-establishment of peace Maurice fought for some time against the Turks in Hungary; he then returned to Saxony, and associated himself with the alliance against Margrave Albert of Brandenburg, by whom the treaty of Passau had not been recognized. At Sievershausen, on the 9th of July 1553, the margrave was defeated; but during the battle Maurice was wounded, and two days afterwards he died in his tent. He was not only a great diplomatist and general, but one of the most enlightened rulers of his age, and his early death was sincerely deplored by his subjects. In his last years he was content "with small diet and little sleep." "Therefore," says Roger Ascham, who had seen him, "he had a waking and working head, and became so witty and secret, so hardy and ware, so skilful of ways, both to do harm to others and to keep hurt from himself, as he never took enterprise in hand wherein he put not his adversary always to the worse."

See Roger Ascham, *A Report and Discourse of the Affairs and State of Germany*; Langenn, *Moritz, Herzog und Kurfürst von Sachsen*, 1841; G. Voigt, *Moritz von Sachsen* 1541-47, 1876.

MAURICE, JOHN FREDERIC DENISON (1805-1872), better known without his first name, an English clergyman and theologian, was born in the year 1805. He was the son of a Unitarian minister, and educated in his father's faith, entering Trinity College, Cambridge, as a Nonconformist, for the sake of the university course, at a time when it was impossible for any but members of the Established Church to obtain a degree. Together with John Sterling, Maurice migrated to the smaller college of Trinity Hall, whence he obtained a first class in civil law in 1827; he then came to London, and gave himself to literary work, editing for a short time the *Athenæum* newspaper. During this period of his life he came under the influence of S. T. Coleridge,—an influence which drew Maurice into conformity, and issued through him in what was known as the Broad-Church school of thought.

When Maurice joined the Church of England, he might no doubt have returned to Cambridge for his degree, or, when he chose Oxford, his terms at Cambridge would have been allowed him, but with characteristic thoroughness he elected to go through the whole Oxford course. He entered Exeter College, and obtained a second class in classics in 1831.

The intellectual stir of Oxford life, and the vehement controversies in the clash of which sparks of truth seemed struck out, were probably among the causes which attracted Maurice to Oxford, and he afterwards took his full share in them, always in a liberal, tolerant, yet strongly Protestant spirit. He was ordained in 1834, and after a short interval spent in parish work in the country was appointed chaplain of Guy's Hospital, and became thenceforward a sensible factor in the intellectual and social life of London. Carlyle has told us how "going to Guy's" Sunday after Sunday was a part of Sterling's routine, and an appreciable number of persons far above the average were attracted to the hospital chapel. In 1840 Maurice was appointed professor of history and literature in King's College, to which in 1846 was added the chair of divinity. These chairs he held till 1853. In that year he published *Theological Essays*, wherein were stated opinions which savoured, to the principal, Dr Jelf, and to the council, of unsound theology in regard to eternal punishment. Maurice maintained with great warmth of conviction that his views were in close accordance with Scripture and the Anglican standards, but the council ruled otherwise, and he was deprived of his professorships. He held at the same time the chaplaincy of Lincoln's Inn (1846-60), but no attempt was made to deprive him of this. Neither was he assailed in the incumbency of St Peter's, Vere Street, which he held for nine years (1860-69), and where, though his congregation was never large, partly perhaps because no parish or district was apportioned to his church, he drew round him a circle of thoughtful persons, attached in no common degree to himself and to his teaching.

During his residence in London Maurice was specially identified with two important movements for education, the Working Men's College, and Queen's College for the education of women, while he threw himself with great energy into all that affected the social life of the people. Certain abortive efforts at a true co-operation among working men, and the movement known as Christian Socialism, were the immediate outcome of his teaching, and directly fostered by himself. In 1866 Maurice was appointed professor of moral philosophy in the university of Cambridge. He died on the 1st of April 1872.

Maurice was before all things a preacher. The actual message he had to proclaim was apparently simple; his two great convictions, which he strove to impress on all other men, were the fatherhood of God, and that all religious systems which had any stability lasted because of a portion of truth which had to be disentangled from the error differentiating them from the doctrines of the Church of England as understood by himself. His love to God as his Father was a passionate adoration which filled his whole heart. No one who ever heard Maurice read the Lord's Prayer can possibly forget it; the intensity of his convictions in the pulpit made his message seem as luminous and clear as it was brief and concentrated, though his teaching apart from the living voice had by no means the same character.

It was the peculiarity of his congregation that those who wanted his advice sought him; having no parish, he had no definite sphere of work beyond the church. Thus his preaching took the forms now of exposition and now of the resolution of metaphysical difficulties, rather than of direct dealing with the facts, the sins, and the temptations of human life common to all. Feeling this defect, he took for a time a district for parochial visitation, but was perplexed and distressed at the experience to which he was unequal. With all his affectionateness and desire to give sympathy he was unable even to conceive intellectual difficulties which were not his own. To those who did not demand of him all they needed, but took thankfully what he had to give, he was altogether a stimulating and helpful teacher. He opened new views, and encouraged men to think for themselves, and see what their words meant. He was even morbidly fearful of founding a party, and was deeply distressed at the name Broad-Church. Those who surrounded him, and were kept together by his personal charm and influence, were learning to think for themselves, and have dispersed in many directions. There are probably not half a dozen persons who, even nominally, reflect the precise shades of Mauricean teaching.

As a writer it is extremely doubtful if his work will have a great and permanent place in the future. His one novel, *Eustace Conway*, is even now unread; his theological works, though abounding in passages of great beauty, full now and then of a fiery eloquence, are as a whole somewhat obscure. He published too much, and a large number of his works are sermons recast. We miss the human voice, and we find a class of writing which only the highest excellence can make tolerable out of the pulpit.

Maurice's greatest effect on his time is in his educational work. The Working Men's College, which owes more to him than to any one else, for which he rendered great sacrifices, and which was and is more full of his spirit than are most institutions of that of their founders, was a totally new departure in education. It was intended to give, and it has largely succeeded in giving, not what is called a popular education, but "higher education" to working men, and in combining teachers and taught in a college with its social life, and a bond of common interests. Queen's College, in like manner for the higher education of girls, is scarcely less identified with his life, though its influence is not so great, nor can its work be so widely known.

Both at King's College and at Cambridge Maurice gathered round him a band of earnest students, to whom he directly taught much that was valuable drawn from wide stores of his own reading, wide rather than deep, for he never was, strictly speaking, a learned man. Still more did he encourage the habit of inquiry and research, more valuable than his direct teaching. In his power, which has been truly called Socratic, of convincing his pupils of their ignorance he did more than perhaps any other man of our time to awaken in those who came under his sway the desire for knowledge and the process of independent thought.

If, as a social reformer, Maurice's name be forgotten in the future, it will be because in much he was before his time, and gave his eager support to schemes for which the world was not ready. From a very early period of his life in London the condition of the poor pressed upon him with consuming force; the enormous magnitude of the social questions involved was a burthen which he could hardly bear. He threw himself with characteristic energy into schemes for a true co-operative system, in which some ardent young men were then engaged, and in spite of his dislike for systems and party names did not shrink from being known as a Christian Socialist, and taking a keen interest in the paper which bore that name, and was the organ of the movement. That and the *Politics for the People*, much the same paper under a different name, received his sanction and aid; many strifes between masters and workmen were appeased, if not directly by himself, by those who were aided by his counsel, and were in constant intercourse with him. For many years he was the clergyman whom working men of all opinions seemed to trust even if their faith in other religious men and all religious systems had faded, and his power of attracting the zealot and the outcast resembled that of the Master whom he followed.

Maurice was twice married, first to a sister of John Sterling, secondly to a sister of his friend Archdeacon Hare. By his family ties and his closest friendships he came in contact with few but intellectual people. Thus while he wrote and spoke and worked for the average man he set that average somewhat high. Those who were privileged to know him did not know a more beautiful soul.

The following are Maurice's more important works. Some of them were re-written and in a measure recast, and the date given is not necessarily that of the first appearance of the book, but of its more complete and abiding form. *Eustace Conway, or the Brother and Sister*, a novel, 1834; *The Kingdom of Christ*, 1842; *Christmas Day and other Sermons*, 1843; *The Unity of the New Testament*, 1844; *The Epistle to the Hebrews*, 1846; *The Religions of the World*, 1847; *Moral and Metaphysical Philosophy* (at first an article in the *Encyclopædia Metropolitana*), 1848; *The Church a Family*, 1850; *The Old Testament*, 1851; *Theological Essays*, 1853; *The Prophets and Kings of the Old Testament*, 1853; *Lectures on Ecclesiastical History*, 1854; *The Doctrine of Sacrifice*, 1854; *The Patriarchs and Lawgivers of the Old Testament*, 1855; *The Epistles of St John*, 1857; *The Commandments as Instruments of National Reformation*, 1866; *On the Gospel of St Luke*, 1868; *The Conscience: Lectures on Casuistry*, 1868; *The Lord's Prayer, a Manual*, 1870. The greater part of these works were, as has been already noticed, first delivered as sermons or lectures. Besides this more formal work, Maurice contributed many prefaces and introductions to the works of friends, as to Archdeacon Hare's *Charges*, Kingsley's *Saint's Tragedy*, &c. His occasional sermons, speeches, periodical writings, and letters to various newspapers need not be here noticed, though they were at the time evidence of his interest in all the life of his time, and his eager and abounding energy.

MAURITIUS, formerly called the ISLE OF FRANCE, an island in the south-western portion of the Indian Ocean, between 57° 18′ and 57° 48′ E. long., and 19° 58′ and 20° 31′ S. lat., 550 miles east of Madagascar, and 115 miles north-east of the island of Réunion, 940 miles south-east of the Seychelles, 2300 miles from the Cape of Good Hope, and 9500 miles from England *via* Aden and Suez. The island is irregularly elliptical—somewhat triangular—in shape, and is 36 miles long from north-north-east to south-south-west, and about 23 miles broad. It is 130 miles in circumference, and its total area is about 713 square miles. The island is surrounded by coral reefs, so that the ports are difficult of access.

Map of Mauritius.

From its mountainous character Mauritius is a most picturesque island, and its scenery is very varied and beautiful. The most level portions of the coast districts are the north and north-east, all the rest being broken by hills, which vary from 500 to 2700 feet in height. There are three principal masses of mountain: the north-western or Pouce range, in the district of Port Louis; the south-western, in the districts of Rivière Noire and Savanne; and the south-eastern range, in the Grand Port district. In the first of these, which consists of one principal ridge with several lateral spurs, overlooking Port Louis, are the singular peaks of the Pouce (2650 feet), so called from its supposed resemblance to the human thumb; and the still loftier Pieter Botte (2676 feet), a tall obelisk of bare rock, crowned with a globular mass of stone. The highest summit in the island is in the south-western mass of hills, the Montagne de la Rivière Noire, which is 2711 feet above the sea. The principal ranges in this mountain mass are three in number, arranged in a triangular form, and are called respectively the mountains of La Pierre Rouge, La Rivière Noire, and Savanne. The south-eastern group of hills consists of one chief range, the Montagne du Bambou, with several spurs running down to the sea. In the interior are extensive fertile plains, some 1200 feet in height, and forming the districts of Moka, Vacois, and Plaines Wilhelms; and from nearly the centre of the island rises an abrupt peak, the Piton du Milieu de l'Île, to a height of 1932 feet above the sea-level. Other prominent summits are the Trois Mamelles, the Montagne du Corps de Garde, the Signal Mountain, near Port Louis, and the Morne Brabant, at the south-west corner of the island.

The rivers are of course small, and none of them are navigable beyond a few hundred yards from the sea. In the dry season most of them are little more than brooks, although they soon become raging torrents when swollen by the heavy rains of the wet period of the year. The principal stream is the Grande Rivière, with a course of about 10 miles. A remarkable and very deep lake, called Grand Bassin, is found in the south of the island, and is probably the extinct crater of an ancient volcano; other similar lakes are the Mare aux Vacois and the Mare aux Jones, and there are some other deep hollows which have a like origin.

The geological structure of Mauritius is undoubtedly a result of volcanic action, all the rocks being of basalt and greyish-tinted lavas, excepting some beds of upraised coral. Columnar basalt is seen in several places. There are many caverns and steep ravines, and from the character of the rocks the ascents are rugged and precipitous. The island has few mineral productions, although iron, lead, and copper in very small quantities have in former times been obtained.

The climate is pleasant during the cool season of the year, but oppressively hot in summer (December to April), except in the interior plains, where the thermometer ranges from 70° to 80°, while in Port Louis and the coast generally it ranges from 90° to 96°. The mean temperature for the year at Port Louis is 78°·6. During the last thirty years the island has been subject to severe epidemics, which have been extremely fatal. In 1854 a visitation of Asiatic cholera swept off 17,000 people; and in 1867 a still more destructive inroad of malarial fever, of an unusually fatal type, almost paralysed the whole community for many weeks, carrying off 30,000 people, and greatly affecting the finances of the colony. The seasons are divisible into two, the cool and comparatively dry season, from April to November, and the hotter season, during the rest of the year. From the month of January to the middle of April, Mauritius, in common with the neighbouring islands and the surrounding ocean from 8° to 30° of S. lat., is subject to severe and destructive cyclones, accompanied by torrents of rain, which often cause great destruction to houses and plantations. These hurricanes generally last about eight hours, but they appear to be now less frequent and violent than in former times, owing, it is thought, to the destruction of the ancient forests and the consequent drier condition of the atmosphere.

The soil of the island is of considerable fertility; it is a ferruginous red clay, but so largely mingled with stones of all sizes that no plough can be used, and the hoe has to be employed to prepare the ground for cultivation. The woods with which the island was largely clothed when first discovered have been to a great extent cut down, and the greater portion of the plains is now a vast sugar plantation. The bright green of the sugar fields is a striking feature in a view of Mauritius from the sea, and gives a peculiar beauty and freshness to the prospect. The soil is suitable for the cultivation of almost all kinds of tropical produce, and it is to be regretted that the prosperity of the colony depends entirely on one article of production, for the consequences are serious when there happens to be a failure, more or less, of the sugar crop. Guano is extensively imported as a manure, and by its use the natural fertility of the soil has been increased to a wonderful extent.

For purposes of law and government Mauritius is divided into nine districts, named respectively Port Louis, Pamplemousses, Rivière du Rempart, Flacq, Grand Port, Savanne, Moka, Plaines Wilhelms, and Rivière Noire. The capital and seat of government, the city of Port Louis, is situated on the north-western side of the island, at the head of an excellent harbour, a deep inlet about a mile long. This is protected by two forts,—Fort William and Fort George,—as well as by the citadel in the city, and its value is further increased by three graving docks connected with the inner harbour. Lighthouses have been erected on Flat Island and at Cannonier's Point. Port Louis has a population of about 70,000, but from the lofty mountains by which it is enclosed its situation is hot, and from the small amount of tide in the harbour effectual drainage is difficult, so that it is not a very healthy town. The public buildings are of no great architectural beauty, the government house being a three-storied structure with broad verandas, of no particular style of architecture, while the Protestant cathedral was formerly a powder magazine, to which a tower and spire has been added. The Roman Catholic cathedral is more pretentious in style, but is tawdry in its interior. In the city are large barracks and military stores. A maximum contribution of £45,000 is paid to the imperial government by the colony towards the expenses of the troops stationed in the island, but this sum is reduced when the garrison is below a certain standard. In 1880 the amount paid was £29,972. The governor and chief officers of government reside out of Port Louis in the cooler uplands of the interior, as do also a large number of the principal inhabitants, especially since the completion of the railways has made access easy to many portions of the island. The most favourite place of residence is at Curepipe, a place situated about 1800 feet above the sea; here the climate resembles that of the south of France, and it has been so much resorted to of late years that it is rapidly becoming a large town. The construction of the Mauritian railways has given a great impetus to the trade of the colony; the system embraces two lines, of a total length of 87 miles. The main roads of the island are kept in good order, but much yet remains to be done before the road system can be said to be complete throughout all the districts.

The prosperity of Mauritius, as already mentioned, depends almost entirely upon its sugar-crop, and the export trade of the island has greatly increased during the last twenty years, as will be seen by the following statistics:—

	1864.	1868.	1873.	1877.	1880.
Imports ...	£2,582,980	£2,200,098	£2,454,101	£2,359,449	£2,169,672
Exports ...	2,249,740	2,339,342	3,375,401	4,201,286	3,634,788

Of the imports the principal items are rice (about a fifth of the whole), wheat, and other grains, plain and coloured cottons, and haberdashery. Madagascar supplies cattle to the colony, and also rice, although the greater portion of the latter import comes from India. Horses are imported from the Cape, ponies from Burmah and Pegu, mules from Spain, and sheep from Bombay and the Cape. Of the exports, sugar forms of course the great item, amounting, on an average, to nearly nineteen-twentieths of the whole; the increase in its production is shown by the following figures, giving values of the sugar exported:—

1864.	1871.	1877.	1878.
£2,126,511	£2,841,829	£3,783,291	£3,408,020

In 1877 the quantity of sugar exported was 189,164 tons; while in 1854 the quantity was 102,000 tons. The next item is rum, which was exported to the value of £45,386 in 1878; and the production of cocoa-nut oil has increased from 7569 gallons in 1864 to 253,263 gallons in 1878, the latter quantity being worth £37,263. The value of the coffee exported in 1879 was £25,064. The currency consists of rupees and cents; and on the 1st of May 1878, the metric system of weights and measures came into use in the island.

Mauritius being an oceanic island of small size, its present fauna is very limited in extent, and does not contain much that is interesting. When first seen by Europeans it contained no mammals except a large fruit-eating bat (*Pteropus vulgaris*), which is plentiful in the woods; but several animals of this class have been introduced, and are now numerous in the uncultivated region. Among these are two monkeys of the genera *Macacus* and *Cercopithecus*, a stag (*Cervus hippelaphus*), a small hare, a shrew-mouse, and the ubiquitous rat. A lemur and one of the curious hedgehog-like *Insectivora* of Madagascar (*Centetes ecaudatus*) have probably both been brought from the larger island. The avifauna resembles that of Madagascar; there are species of a peculiar genus of caterpillar shrikes (*Campephagidæ*), as well as of the genera *Pratincola*, *Hypsipetes*, *Phedina*, *Tchitrea*, *Zosterops*, *Foudia*, *Collocalia*, and *Coracopsis*, and peculiar forms of doves and parroquets. The living reptiles are small and few in number, but in the surrounding seas are great numbers of fish; the coral reefs abound with a great variety of molluscs; and there are numerous land-shells. The extinct fauna of Mauritius has considerable interest. In common with the other Mascarene islands, it was the home of the Dodo (*Didus ineptus*), one of a group of birds incapable of flight; there were also *Aphanapteryx*, a species of rail, and a short-winged heron (*Ardea megacephala*), which probably seldom flew. The defenceless condition of these birds has led to their extinction since the island was colonized. Several species of large fossil tortoises have been discovered; but, strange to say, they are quite different from the living ones of Aldabra, in the same zoological region.

Owing to the extensive destruction of the primeval forests of the island for the formation of sugar plantations, the indigenous flora of Mauritius is only seen in parts of the interior plains, in the river valleys, and on the hills; and it is so much mingled with trees and plants introduced from other parts of the world that it is not very easy to distinguish between what is native and what has come from abroad. The principal timber tree is the ebony (*Diospyros ebeneum*), which grows to a considerable size. Besides this there are bois de cannelle, olive-tree, benzoin (*Croton Benzoe*), colophane (*Colophonia*), and iron-wood, all of which are useful in carpentry; the cocoa-nut palm, an importation, but a tree which has been so extensively planted during the last hundred years that it is extremely plentiful; the palmiste (*Palma dactylifera latifolia*), the latanier (*Corypha umbraculifera*), and the date-palm. The vacoa or vacois, a species of *Pandanus*, is largely grown, the long tough leaves being manufactured into bags for the export of sugar, and the roots being also made of use; and in the few remnants of the original forests the tree which is such a prominent one in the coast flora of Madagascar, the traveller's tree (*Urania speciosa*), grows abundantly. A species of bamboo is very plentiful in the river valleys and in marshy situations. A large variety of fruit is produced, including the tamarind, mango, banana, pine-apple, guava, shaddock, fig, avocado-pear, litchi, custard-apple, and the mabolo (*Diospyros discolor*), a fruit of exquisite flavour, but very disagreeable odour. Many of the roots and vegetables of Europe have been introduced, as well as some of those peculiar to the tropics, including maize, millet, yams, manioc, dhol, gram, &c. Small quantities of tea, rice, and sago have been grown, as well as many of the spices (cloves, nutmeg, ginger, pepper, and allspice), and also cotton, indigo, betel, camphor, turmeric, and vanilla.

Mauritius appears to have been unknown to European nations, if not to all other peoples, until the year 1507, when it was discovered by the Portuguese. It had then no inhabitants, and there seem to be no traces of its previous occupation by any people, either savage or civilized. The island was retained for most of the 16th century by its discoverers, but they made no colonies in it. In 1598 the Dutch took possession, and named the island "Mauritius," in honour of their prince Maurice. It had been previously called by the Portuguese "Ilha do Cerné," from the belief that it was the island so named by Pliny. But, although the Dutch built a fort at Grand Port, they made no permanent settlement in Mauritius, finally abandoning the island in 1710. Five years afterwards the French, in their turn, took possession of what had seemed so worthless to two European powers, but it was half a century before the Government of France appreciated the value of their colony, since from 1715 to 1767 it was held by agents of the French East India Company, by whom its name was again changed to "Ile de France." The Company was fortunate in having several able men as governors of its colony, especially the celebrated Mahé de Labourdonnais (1735–46), "a man of eminent talents and virtue," who introduced the culture of the sugar-cane, and thus laid a firm foundation for the future prosperity of the island. Under his direction roads were made, forts built, and considerable portions of the forest were cleared, and the present capital, Port Louis, was founded. Labourdonnais also promoted the planting of cotton and indigo, and is justly remembered as the most enlightened and best of all the French governors. The colony continued to rise in value during the time it was held by the French crown, and to one of the later governors, De Poivre, was due the introduction of the clove, nutmeg, and other spices. Another governor was D'Entrecasteaux, whose name is kept in remembrance by a group of islands east of New Guinea.

During the long war between France and England, at the commencement of this century, Mauritius was a continual source of much mischief to English Indiamen and other merchant vessels; and at length the British Government determined upon an expedition for its capture. This was effected in 1810; and upon the restoration of peace in 1814 the possession of the island was confirmed to England by one of the provisions of the treaty of Paris. By the eighth article of capitulation it was agreed that the inhabitants should retain their own laws, customs, and religion; and so it happens that, although a British colony, the island is still largely French in language, habits, and predilections; but its name has again been changed to that given by the Dutch. Perhaps the most distinguished of the English governors of the island was Sir Robert Farquhar (1810–23), who did so much to abolish the Malagasy slave trade and to establish friendly relations with the rising power of the Hova sovereign of Madagascar.

Mauritius is one of the crown colonies of Great Britain, and at the head of its administration is a governor, who is assisted by an executive council of seven members, holding the most important Government posts. There is also a legislative council, which consists of the same members as the foregoing, with three others, together with eight of the chief landed proprietors of the island, who are nominated by the crown. The average annual revenue of the colony for the ten years from 1871 to 1880 was £723,876, the average annual expenditure during the same period being £710,261. Up to 1854 there was a surplus in hand, but since that time expenditure has exceeded income, and the public debt is now about £700,000.

The island has largely retained the old French laws, the Codes Civile, de Procédure, du Commerce, and d'Instruction Criminelle being still in force, except so far as altered by the later laws for the administration of justice of April 13, 1831. By these the court of appeal was reconstituted, and a supreme court of civil and criminal justice was established, under a chief judge and three puisne judges. The police force in 1880 included 689 men.

During the last few years great improvements have been effected in the educational system of the colony. The department of public instruction has two branches, the Royal College, for higher education, and the school department, for primary instruction. In 1880 the number of Government schools was 38, with 5077 scholars, and of schools aided by grants 54, with 4316 scholars, the total teaching staff numbering 178. The annual education vote is about £13,000; and of the scholars 73 per cent. are Roman Catholic, 14 per cent. Hindu, 8 per cent. Protestant, and 5 per cent. Mohammedan. It will be seen from the above figures that the Roman Catholic religion is that professed by the large majority of the white population of Mauritius. The clergy supported by the state include the Protestant bishop of Mauritius, with an archdeacon and seven clergymen of the Church of England, and three clergymen of the Church of Scotland; and the Roman Catholic bishop of Port Louis, with a vicar-general and thirty-four priests.

The population of the island is a very varied one, and consists of two great divisions:—those of European blood, chiefly French and English, as well as numerous half-caste people; and a large coloured population, chiefly Hindu coolies, but with representatives from various African and Asiatic regions, Negroes, Malagasy, Parsees, Singhalese, Chinamen, Malays, &c. The Hindu immigrants now form more than two-thirds of the inhabitants of Mauritius, as will be seen from the following figures for the year 1881:—

General.........111,783		Indian.........249,064		Total.........360,847	
Male.	Female.	Male.	Female.	Male.	Female.
58,137	53,646	151,423	97,641	209,560	151,287

The increase of population during the last thirty years is shown by the following figures:—

1851.	1861.	1871.	1881.
183,506	313,469	317,069	360,847

The system of coolie immigration has been of great value to the colony; and the arrangements for shipping these Hindu people are under Government control. But many of the laws have been so unjust to the coloured people, and so much to the advantage of the planters, that gross evils and abuses have arisen. And, unjust as the laws are, their administration has often been still more unfair. The evil grew at length so glaring that in 1871 a royal commission was appointed, which sat for a long time investigating the subject. Various reforms were recommended, and since then some improvements have been effected. But many of the creole planters are not remarkable for their respect for the rights of coloured people, and the system is liable to gross abuse unless under vigilant control by higher authority. Much yet remains to be done for the moral and religious instruction of the labourers; and the presence of a large heathen population, and the prevalence of crime, has been at times a very serious consideration for the colony. The number of coolies arriving in and leaving the island varies very largely, from a few hundreds annually to several thousands.

The dependencies of Mauritius are the Seychelles group, the islands of Rodriguez and Diego Garcia, the Chagos group, and seventy other smaller islands scattered over a large extent of the Indian Ocean, and having a total population of about 16,000 souls. Rodriguez is situated 300 miles east of Mauritius and is cultivated chiefly by colonists from that island.

Literature.—The following works supply fuller details than can be given in this article:—Ch. Grant, *History of Mauritius, or the Isle of France and Neighbouring Islands*, 1801; J. Milbert, *Voyage pittoresque à l'Ile-de-France*, &c., 4 vols., 1812; Aug. Billiard, *Voyage aux Colonies orientales*, 1822; D'Unienville, *Statistique de l'île Maurice*, &c., 1838; J. Backhouse, *Narrative of a Visit to the Mauritius and South Africa*, 1844; P. Beaton, *Creoles and Coolies, or Five Years in Mauritius*, 1859; Paul Chasteau, *Histoire et Description de l'île Maurice*, 1860; F. P. Flemyng, *Mauritius, or the Isle of France*, 1862; James Morris, "Mauritius, Its Commercial and Social Bearings," *Soc. Arts Jour.*, 1862; A. Erny, "Séjour à l'île Maurice," in vol. vii. of *Tour du Monde*, 1863; Ch. J. Boyle, *Far Away, or Sketches of Scenery and Society in Mauritius*, 1867; L. Simonin, *Les Pays lointains, Notes de Voyage (Maurice, &c.)*, 1867; N. Pike, *Sub-Tropical Rambles in the Land of the Aphanapteryx*, 1873; A. R. Wallace, "The Mascarene Islands," in chap. xi. vol. i. of *The Geographical Distribution of Animals*, 1876; K. Möbius, F. Richter, and E. von Martens, *Beiträge zur Meeresfauna der Insel Mauritius und der Seychellen*, Berlin, 1880; G. Clark, *A Brief Notice of the Fauna of Mauritius*, 1881. (J. S., jr.)

MAURUS, St, according to the Roman Breviary (January 15), was a Roman of noble birth, and while still a child was placed by his father Eutychius under the discipline of St Benedict, where he soon became a model of all the virtues and endowed with the gift of miracles. Sent by his master into Gaul, he founded a monastery over which he presided for forty years. When he died in 565 he was over seventy. The monastery referred to is that of Glanfeuil or St Maur-sur-Loire. In point of fact it may be said that everything relating to the introduction of the Benedictine order into France, unless the name of him who introduced it be made an exception, is purely legendary. The famous "Congregation of St Maur" dates from the 17th century, having received papal sanction in 1621 and 1627; it arose out of an earlier "congregation" of reformed Benedictines, which took its name from St Vannes near Verdun, and was sanctioned by Clement VIII.

MAURY, Jean Siffrein (1746-1817), cardinal and archbishop of Paris, the great opponent of Mirabeau in the constituent assembly, and esteemed his rival in eloquence, was the son of a poor cobbler, and was born at Valréas in the Venaissin, the district in France which belonged to the pope. His quickness was soon observed by the priests of Avignon, where he was educated and took orders, and he determined to get what he could by it. He tried his fortune by writing *éloges* of famous persons, then a favourite practice; and in 1771 his *éloge* on Fénelon was pronounced next best to Laharpe's by the Academy. The real foundation of his fortunes was the success of a sermon he preached on St Louis before the Academy in 1772, which caused him to be recommended to the king for an abbacy on the spot. In 1772 he published his *Essai sur l'éloquence de la chaire*, which, as well as his *Principes d'éloquence*, contains much good criticism, and remains a French classic. He became a favourite preacher in Paris, and was Lent preacher at court in 1781, when King Louis XVI. said of his sermon, "If the abbé had only said a few words on religion he would have discussed every possible subject." In 1781 he obtained the rich abbey of Lions, worth 20,000 livres a year, and in 1785 he was elected to the Academy. His morals were as loose as those of his great rival Mirabeau, but he was famed in Paris for his wit and gaiety as well as for his eloquence and his immorality. In 1789 he was elected a member of the states-general by the clergy of Péronne, and from the first proved to be the most able and persevering defender of the *ancien régime*. It is said that he attempted to emigrate both in July and in October 1789; but, whether he did or not, he after that time held firmly to his place, when almost universally deserted by his friends. His life was often in danger among the people, but his ready wit always saved it, and it was said that one *bon mot* would preserve him for a month. At last, in 1792, he found it necessary to fly from Paris; the Revolution had gone too far. When he did emigrate he found himself regarded as a kind of martyr to the church and the king, and was at once named cardinal, archbishop *in partibus*, and extra nuncio to the diet at Frankfort. He was finally made bishop of Montefiascone, and settled down in that little Italian town,—but not for long, for in 1796 the French drove him from his retreat, and he became ambassador, but with hardly any pay, of the exiled king Louis XVIII. to the pope. Such a life soon wearied a man who had been accustomed to wealth and reputation, and in 1804 he began to prepare his return to France by a well-turned letter to Napoleon, congratulating him on restoring religion to France once more. In 1806 he did return; in 1807 he was again received into the Academy; and in 1810, on the refusal of Cardinal Fesch, was made archbishop of Paris. On the restoration of the Bourbons he was summarily turned out of the Academy, and sent to Rome to answer for his disobedience to the pope. There he was imprisoned in the castle of St Angelo for six months, and died in 1817, a year or two after his release, of disease contracted in prison, and of chagrin.

There are two sides to Maury's character to be discussed. As a critic he was a very able writer, and Sainte-Beuve gives him the credit of discovering Bridaine, and giving Bossuet his rightful place as a preacher above Massillon; as a politician, his wit and eloquence make him a worthy rival of Mirabeau, and an interesting character in the early years of the Revolution. If in later years he forsook his old tenets, and joined Napoleon, his punishment was terribly severe, and it would have been a graceful act if Louis XVIII. had remembered the courageous supporter of Louis XVI., and the pope the one intrepid defender of the church in the states-general.

The *Œuvres choisis du Cardinal Maury* (5 vols., 1842) contain what is worth preserving. For his life and character see *Vie du Cardinal Maury par son neveu*, 1827; Poujoulat, *Cardinal Maury, sa vie et ses œuvres*, 1855; Sainte-Beuve, *Causeries du Lundi*, vol. iv.

MAURY, Matthew Fontaine (1806-1873), American naval officer and hydrographer, was born in Spottsylvania county, Virginia, January 14, 1806. In 1825 he entered the American navy as midshipman, circumnavigating the globe in the "Vincennes," during a cruise of four years. In 1836 he was made lieutenant, and gazetted astronomer to an exploring expedition. In 1839 he met with an accident which resulted in permanent lameness, and unfitted him for active service. Maury was placed in charge of the Depôt of Charts and Instruments, out of which have grown the United States Naval Observatory and the Hydrographic Office. He laboured assiduously and with complete success to place the depôt in a state of efficiency. While in the "Vincennes," and in subsequent cruises, Maury made many observations as to the winds and currents, and when in charge of the Hydrographic Office he set himself to collect further data by distributing to captains of vessels specially prepared log-books. So successful was he in this enterprise that in the course of nine years he had collected a sufficient number of logs to make two hundred manuscript volumes, each with about two thousand five hundred days' observations. One result was to show the necessity for combined action on the part of maritime nations in regard to ocean meteorology. This led to an international conference at Brussels in 1853, which produced the greatest benefit to navigation as well as indirectly to meteorology. One result was the establishment of the meteorological department of the English Board of Trade, now known as the Meteorological Office, which adopted Maury's model log-books. In 1853 he published his *Letters on the Amazon and Atlantic Slopes of South America*, and in 1855 he was promoted to the rank of commander. On the outbreak of the American civil war in 1861, Maury threw in his lot with the South, and, having lost nearly his all, retired to England, where he was presented with a handsome testimonial raised by public subscription. Afterwards he became imperial commissioner of emigration to Maximilian of Mexico, on whose death he took up his residence in Virginia, where he died on February 1, 1873.

In 1848 Maury published a *Treatise on Navigation*, which was long used as a text-book in the United States navy. The work, however, by which he is best known is his *Physical Geography of the Sea*, the first edition of which was published in London in 1855, and in New York in 1856; it was translated into several European languages. The theories which it contains are now generally admitted to be quite erroneous. Maury's reputation rests on the eminent services he rendered to navigation and meteorology, he having been the first to show how the latter could be raised to the certainty of a science. He was essentially a practical man; his great aim was to render navigation more secure and economical, and in this he was eminently successful. Other works published by Maury are the papers contributed by him to the *Astronomical Observations* of the United States Observatory, *Letters concerning Lines for Steamers crossing the Atlantic* (1854), *Physical Geography* (1864), and *Manual of Geography* (1871). In 1859 he began the publication of a series of nautical monographs.

MAUSOLUS, or according to his coins *Maussolus* (Μαύσσωλος), a king of Caria, whose reign probably began in 377 and terminated with his death in 353 B.C. The part he took in the revolt against Artaxerxes Memnon, his conquest of Lydia, Ionia, and several of the Greek islands along the coast, his co-operation with the Rhodians and their allies in the war against Athens, and the removal of his capital from Mylasa, the ancient seat of the Carian kings, to the city of Halicarnassus are the leading facts of his history. He is best known, however, from the tomb erected for him by his widow Artemisia with such cultured magnificence that the name of mausoleum has become the generic title of all similar monuments. One of the most curious of the inscriptions discovered at Mylasa details the punishment of certain conspirators who had attempted the life of Mausolus when he was attending a festival in a temple at Labranda. See HALICARNASSUS.

MAXENTIUS, MARCUS AURELIUS VALERIUS, Roman emperor from 306 to 312, was the son of Maximianus Herculius, and the son-in-law of Galerius, but on account of his vices and incapacity was left out of account in the division of the empire which took place in 305. A variety of causes, however, had produced strong dissatisfaction at Rome with many of the arrangements established by Diocletian, and the public discontent on October 28, 306, found expression in the massacre of those magistrates who maintained their loyalty to Severus and in the election of Maxentius to the imperial dignity,—an election in which the rest of Italy, as well as Africa, concurred. With the help of his father, Maxentius was enabled to put Severus to death and to repel the invasion of Galerius; his next steps were first to banish Maximian, and then, after achieving a military success in Africa against one Alexander, to declare war against Constantine for the conduct towards the old emperor of which he in turn had been guilty at Marseilles. The contest resulted in the defeat of Maxentius at Saxa Rubra, and his death by drowning in the Tiber at the Milvian Bridge on October 28, 312. (See CONSTANTINE.) The general testimony to the worthlessness and brutality of his character is unambiguous and unanimous; less apparent are the grounds for the particular statement of Gibbon that he was "just, humane, and even partial towards the afflicted Christians."

MAXIMA AND MINIMA. The consideration of the greatest or the least value of a variable quantity, that is restricted by certain conditions, is a problem of which several simple cases were investigated by the early Greek geometers. Thus in Euclid iii. 7, 8 we find the determination of the greatest and least right lines that can be drawn from a point to the circumference of a circle. But the most characteristic problem of the kind in Euclid is that contained in vi. 27, 28, 29. Thus prop. 27, when reduced to its simplest form, is equivalent to the statement that if a right line be bisected the rectangle under the segments is greater than that under those made by any other point of division. Props. 29 and 30 are, when considered algebraically, reducible to the solution of the equations $x(a-x)=b^2$ and $x(a+x)=b^2$, coupled with the determination of the maximum value of b for which the solution of the former is possible (see Matthiessen, *Grundzüge der antiken und modernen Algebra*, Leipsic, 1878). Apollonius extended the investigation of Euclid, bk. iii., to the problem of the greatest and least distances of a point from an ellipse, showing that it depended on drawing normals from the point to the curve; and he reduced the latter problem to finding the points of intersection of the ellipse with a certain hyperbola.

The next remarkable problems on maxima and minima are said to have been investigated by Zenodorus,[1] and were preserved by Pappus and Theon of Alexandria. Of these we may mention the following:—(1) among regular polygons of equal perimeter that of the greatest number of sides contains the greatest area; (2) of polygons of the same perimeter and the same number of sides the regular polygon contains the greatest area; (3) the circle contains a greater area than any other curve or polygon of the same perimeter; (4) the sphere contains the greatest volume for a given superficial area.

In the progress of mathematics the terms maxima and minima have come to be used to imply, not the absolutely greatest and least values of a variable magnitude, but the value which it has at the moment it ceases to increase and begins to decrease, or *vice versa*. For example, if it be said that the height of the barometer is a maximum at any instant it means that up to that time the barometer was rising and then began to fall. In this way it is possible that there should be several maxima and minima in the course of one day, and that one of the minima should be greater than one of the maxima.

The theory of maxima and minima, in the differential calculus point of view, is very simple. Thus, if u be a given function of a variable x, the values of x for which u has a maximum or a minimum value are, in general, determined by the equation $\frac{du}{dx}=0$. Again, if u be a function of two variables x and y, then the maximum or minimum values of u must satisfy the equations $\frac{du}{dx}=0$ and $\frac{du}{dy}=0$. There is, however, no real maximum or minimum solution if $\left(\frac{d^2u}{dxdy}\right)^2$ is greater than $\frac{d^2u}{dx^2}\frac{d^2u}{dy^2}$. A short account of this method, illustrated by examples, is given in vol. xiii. pp. 23, 24.

John Bernoulli's problem (*Acta Eruditorum*, June 1696) of the "brachystochrone," *i.e.*, of the curve of quickest descent under the action of gravity, differed essentially

[1] Montucla (*Hist. de Math.*, tom. i. p. 113) erroneously attributed these theorems on isoperimetry to Pythagoras, but his statement is based on a misinterpretation of a passage in Diogenes Laertius. See Bretschneider, *Die Geometrie vor Euklides*, pp. 89, 90.

from all problems on maxima and minima which had been previously solved. In this he introduced into mathematics the conception of a new and most important class of problems. James Bernoulli, also, in his solution of this problem of his brother, proposed a more general question, which may be stated as follows:—"Of all curves of the same length described on a given base to determine one such that the area of a second curve, each of whose ordinates is a given function of the corresponding ordinate, or arc, of the first, may be a maximum, or a mininum." Such problems were styled "isoperimetrical," and come under a class now called *relative* maxima and minima, in which the maximum or minimum curve is to be determined, not from all possible curves, but from among those which possess a given property. The investigations of the Bernoullis were extended and generalized by other eminent mathematicians, but more especially by Euler, and culminated in the invention of the calculus of variations, with an appropriate notation, by Lagrange.

MAXIMIANUS, MARCUS AURELIUS VALERIUS, surnamed HERCULIUS, Roman emperor from 286 to 305, and again in a doubtful manner for some time prior to 308, was by birth a Pannonian peasant, but achieved great distinction in the course of long service in the army in almost every quarter of the empire, and, having been made Cæsar by Diocletian in 285, received the title of Augustus in the following year (April 1, 286) with the honorary appellation of Herculius. In 287 he suppressed the rising of the peasants (Bagaudæ) in Gaul, but in 289, after a three years' struggle, his colleague and he were compelled to acquiesce in the assumption by his lieutenant Carausius of the title of Augustus in Britain. After 292, Maximian left the care of the Rhine frontier to Constantius Chlorus, who had been designated Cæsar in that year, but in 297 his arms achieved a rapid and decisive victory over the barbarians of Mauretania, and in November 303 he shared at Rome the triumph of Diocletian, the last pageant of the kind ever witnessed by that city. On May 1, 305, the day of Diocletian's abdication, he also, but without his colleague's sincerity, divested himself of the imperial dignity at Milan, which had been his capital, and retired to a villa in Lucania; in the following year, however, he was induced by his son Maxentius to reassume the purple. In 307 he brought the emperor Severus a captive to Rome, and also compelled the retreat of Galerius, but in 308 he was himself driven by Maxentius from Italy into Illyricum, whence again he was compelled to seek refuge at Arles, the court of his son-in-law Constantine. Here a false report was received, or invented, of the death of Constantine, at that time absent on the Rhine, and Maximian at once grasped at the succession, but was soon driven to Marseilles, where, having been delivered up to his pursuers, he strangled himself in 310 (February).

MAXIMIANUS, GALERIUS VALERIUS, usually referred to by his name GALERIUS, Roman emperor from 305 to 311, was born near Sardica in Dacia, and originally followed his father's occupation, that of a herdsman, whence his surname of Armentarius. He served with distinction as a soldier under Aurelian and Probus, and in 292 was designated Cæsar along with Constantius, receiving in marriage Diocletian's daughter Valeria, and at the same time having assigned to him as his special charge the care of the Illyrian provinces. In 296, at the beginning of the Persian war, he was removed from the Danube to the Euphrates; his first campaign ended in a crushing defeat on the same field as that which had proved fatal to Crassus, but in 297, advancing through the mountains of Armenia, and taking the enemy by surprise, he gained a victory over Narses by which his military reputation was more than restored. In 305, on the abdication of Diocletian and Maximian, he at once assumed the title of Augustus, along with Constantius his former colleague, and, having procured the promotion to the rank of Cæsar of Severus, a faithful servant, and Daza (Maximinus), his nephew, he hoped on the death of Constantius to become sole master of the Roman world. This scheme, however, was defeated by the sudden elevation of Constantine at York on the death of his father, and by the action of Maximian and Maxentius in Italy. After an unsuccessful invasion of Italy in 307 he elevated his friend Licinius to the rank of Augustus, and, moderating his ambition, devoted the few remaining years of his life "to the enjoyment of pleasure and to the execution of some works of public utility." He died—of the *morbus pedicularis*, it is said—in May 311. It was at the instance of Galerius that the first of the celebrated edicts of persecution against the Christians was published, on February 24, 303, and this policy of repression was maintained by him until the appearance of the general edict of toleration, running in his own name and in those of Licinius and Constantine.

MAXIMILIAN I. (1459-1519), holy Roman emperor, the son of the emperor Frederick III., was born on the 22d of March 1459. In 1477 he married Mary, daughter of Charles the Bold of Burgundy, thus securing for his family the possessions of the house of Burgundy; and by the marriage of his son Philip with the infanta Joanna in 1496 he prepared the way for the association of Spain with the empire under his grandson, Charles V. In 1486 Maximilian was chosen king of the Romans, and in 1493, after the death of his father, he succeeded to the imperial throne. During the reign of Frederick III. the system of private war created profound discontent, and there were urgent demands for the reform of imperial institutions. Maximilian was never thoroughly in sympathy with this movement, but at his first diet, in 1495, he declared a perpetual public peace; and he did something for the restoration of order by the establishment, in the same year, of the imperial chamber (*Reichskammergericht*), and, in 1501, of the imperial Aulic council (*Reichshofrath*). Another important change was the division of Germany into six, afterwards (in 1512) into ten, circles (*Kreise*), over each of which was placed a captain with a force for the punishment of disturbers of the peace. Standing troops, called Landsknechte, were for the first time organized by Maximilian, who also improved the artillery then in use, and issued good police regulations. He encouraged science, art, and literature, devoted much attention to the universities, especially those of Vienna and Ingolstadt, collected mediæval poems, and caused copies to be made of ancient chronicles and other important manuscripts. Through the influence of his second wife, Blanca Sforza, daughter of Duke Galeazzo Sforza of Milan, he was induced to contend for supremacy in Milan and Naples; but his resources were inadequate for war on equal terms with the kings of France, Charles VIII. and Louis XII. In 1499 he carried on an unsuccessful war with the Swiss confederates, the result of which was that, by the peace of Basel, the confederates became practically independent of the empire. On the other hand, he was singularly fortunate in increasing the power of the house of Austria. By the death of his cousin, the archduke Sigismund, he inherited Tyrol; he also received Görz, Gradisca, the Pusterthal, and a part of Bavaria; and by the marriage of two of his grandchildren with children of the king of Hungary and Bohemia he took the first step towards the ultimate incorporation of these countries with the Austrian hereditary territories. He wrote several books, and planned the "Weiss-Kunig," a kind of poetical autobiography, completed by his private secretary, Treizsaurwein von Erentreiz. Maximilian had some part also in the preparation of *Theuerdank*, an allegory setting forth adventures in connexion with his marriage with Mary of Burgundy. At Wels, in Upper Austria, on the 12th of January 1519, he died.

See Klüpfel, *Kaiser Maximilian I.*, 1864.

MAXIMILIAN II. (1527-1576), holy Roman emperor, son and successor of Ferdinand I., was born at Vienna on the 1st of August 1527. He was of a mild and tolerant disposition, and in youth received a favourable impression of Protestantism from his tutor, Wolfgang Severus,—an impression which was not effaced by a residence of three years at the Spanish court. In 1562 he became king of Bohemia and king of the Romans, in 1563 king of Hungary, and in 1564 emperor. At the time of his accession to the imperial throne Hungary was at war with Turkey. The sultan Soliman II. was conciliated by the cession of all the territories he had conquered in Hungary, and by the promise of a yearly tribute of 300,000 florins. Soon afterwards Soliman renewed the war on behalf of the prince of Transylvania; but after his death in 1566 his successor, Selim, concluded with Maximilian an armistice of eight years. Maximilian's brothers, Ferdinand and Charles, fought incessantly against Protestantism in their respective lands; but it was tolerated by Maximilian in Austria, Bohemia, and Hungary. His authority, however, was greatly limited by the influence of the Jesuits. He died on the 12th of October 1576. Of his eight children (six sons and two daughters) two—Rudolph II. and Matthias—became emperors.

See Koch, *Quellen zur Geschichte des Kaisers Maximilian II.*, 1857-61; and Wertheimer, *Zur Geschichte des Türkenkriegs Maximilians II.*, 1875.

MAXIMILIAN (1832-1867), archduke of Austria (Ferdinand Maximilian Joseph) and emperor of Mexico, was the second son of the archduke Francis Charles, and was born in Vienna on July 6, 1832. He was trained for the navy, and ultimately attained a high command in that branch of his country's service. In February 1857 he was appointed governor of the Lombardo-Venetian kingdom, and in the same year he married the Princess Charlotte, daughter of Leopold I., king of the Belgians. On the outbreak of the war of 1859, he retired into private life, chiefly at Trieste, until 1863, when at the instance of Napoleon III. he accepted the crown which had been offered to him by the notables of Mexico. He landed at Vera Cruz on May 28, 1864, but from the commencement of his reign found himself involved in difficulties of the most serious kind, which in 1866 made apparent to almost every one outside of Mexico the necessity for his abdicating. This, however, he declined to do. Withdrawing, in February 1867, to Querétaro, he there sustained a siege for several weeks, but on May 15 resolved to attempt an escape through the enemy's lines. He was, however, arrested before he could carry out this resolution, and, after trial by court martial, was condemned to death. The sentence was carried out on June 19, 1867. His remains were conveyed to Vienna, where they were buried in the imperial vault early in the following year. See MEXICO. Maximilian's papers were published in 1867 in seven volumes, under the title *Aus meinem Leben, Reiseskizzen, Aphorismen*, &c.

MAXIMINUS, CAIUS JULIUS VERUS, Roman emperor from 235 to 238, was of barbarian parentage, his father being a Goth and his mother an Alan, and was born in a village on the confines of Thrace, where his immense stature and enormous feats of strength first drew the attention of the emperor Septimius Severus. From being a shepherd he became a soldier, and under Caracalla rose to the rank of centurion. He carefully absented himself from court during the reign of Elagabalus, but rose to the first military command under his successor Alexander Severus. On March 19, 235, the troops saluted him emperor, and shortly afterwards Alexander was put to death. The three years of his reign, which were spent wholly in the camp, were marked by great cruelty and oppression; the widespread discontent thus produced culminated in a revolt in Africa and the assumption of the purple by GORDIANUS (*q.v.*). Maximin, who was in Pannonia at the time, marched against Rome, and passing over the Julian Alps descended on Aquileia; while detained before that city he and his son were murdered in their tent by a body of prætorians. Their heads were cut off and despatched to Rome, where they were burnt on the Campus Martius by the exultant crowd (May 238).

MAXIMINUS, GALERIUS VALERIUS, Roman emperor from 308 to 314, was originally an Illyrian shepherd, and bore the name of Daza. His mother was a sister of him who afterwards became the emperor Galerius. He rose to high distinction after he had joined the army, and in 305 he was raised by his uncle to the rank of Cæsar, with the honorary appellation of Jovius, Syria and Egypt being the government assigned to him. In 308, after the elevation of Licinius, he insisted on receiving the title of Augustus; on the death of Galerius in 311 he succeeded to the supreme command of the provinces of Asia, and, when Licinius and Constantine began to make common cause with one another, Maximin entered into a secret alliance with Maxentius. He came to an open rupture with Licinius in 313, sustained a crushing defeat in the neighbourhood of Heraclea on April 30th, and, having fled with extraordinary celerity first to Nicomedia and afterwards to Tarsus, perished at the latter city in August following. His death was variously ascribed "to despair, to poison, and to the Divine justice." Maximin, in every respect a worthless character, has a bad eminence in the annals of the Christian church as having renewed persecution after the publication of the toleration edict of Galerius.

MAXIMUS, the name of four Roman emperors. In chronological order the first was M. Clodius Pupienus Maximus, who was associated with Balbinus in the imperial dignity by the senate for a short time in 238, before and after the death of the hated Maximin. The second was Magnus Clemens Maximus, a native of Spain, who shared the imperial dignity with Valentinian and Theodosius from 383 to 388. He had accompanied Theodosius on several expeditions, and from 368 held high military rank in Britain. The disaffection of the Roman troops towards the emperor Gratian found expression in 383 in the proclamation of Maximus as emperor,—whether with or without his complicity in the act is uncertain. Voluntarily or under compulsion Maximus forthwith attacked Gratian in Gaul, and drove him from Paris to Lyons, where the fugitive was murdered. Circumstances made it difficult for Theodosius at the time to avenge the death of his colleague by war, and an agreement was therefore come to by which Maximus was recognized as Augustus and sole emperor in Gaul, Spain, and Britain, while Valentinian was to remain unmolested in Italy and Illyricum, Theodosius retaining his sovereignty in the East. A prosperous reign of four years having tempted Maximus, in 387, to pass the Alps, Valentinian was speedily put to flight, while the invader established himself in Milan, and for the time became master of Italy. Theodosius now took vigorous measures: advancing a powerful army by land, he utterly defeated the western troops at Siscia (Sciszek) in Pannonia, and, passing the Julian Alps with great rapidity, came upon Maximus, who had fled to Aquileia, seized him, and caused him to be beheaded (August 388). The third, Maximus Tyrannus, was made emperor in Spain by the Roman general Gerontius, who had rebelled against Constantine in 408. After the defeat of Gerontius at Arles, and his subsequent death in 411, Maximus renounced the imperial title and was permitted by Constantine to retire into private life. About 418 he rebelled again, but, failing in his attempt, was seized, carried into Italy, and put to death at Ravenna in 422. Lastly, Petronius Maximus was a member of the higher Roman nobility, and had held a large number of public offices, including those of præfectus Romæ (420) and of præfectus Italiæ (439–441 and 445). He was one of the intimate associates of Valentinian, who received his assistance in the palace intrigues which led to the death of Aetius in 454; but a brutal outrage committed on the wife of Maximus by the emperor turned his friendship into the bitterest hatred. Maximus was proclaimed emperor immediately after Valentinian's murder in March 455, but reigned for less than three months, having been murdered by some Burgundian mercenaries as he was flying before the Vandals, who, invited by Eudoxia, the widow of Valentinian, had landed at the mouth of the Tiber (May or June 455).

MAXIMUS, St, abbot of Chrysopolis, known as "the Confessor" from his orthodox zeal in the Monothelite controversy, or as "the monk," was born of noble parentage at Constantinople about the year 580. Educated with great care, he early became distinguished by his talents and acquirements, and some time after the accession of the emperor Heraclius in 610 was made his private secretary. In 630 he abandoned the secular life and entered the monastery of Chrysopolis (Scutari), actuated, it was believed, less by any longing for the life of a recluse than by the dissatisfaction he felt with the Monothelite leanings of his master. The date of his promotion to the abbacy is uncertain. In 633 he was one of the party of Sophronius at the council of Alexandria; and in 645 he was again in Africa, when he held in presence of the governor and a number of bishops the disputation with Pyrrhus, the deposed and banished patriarch of Constantinople, which resulted in the (temporary) conversion of his interlocutor to the Dyothelite view. In the following year several African synods, held under the influence of Maximus, declared for orthodoxy. In 649, after the accession of Martin I., he went to Rome, and did much to fan the zeal of the new pope, who in October of that year held the (first) Lateran synod, by which not only the Monothelite doctrine but also the moderating *ecthesis* of Heraclius and *typus* of Constans II. were anathematized. About 653 Maximus, for the part he had taken against the latter document especially, was apprehended by order of Constans and carried a prisoner to Constantinople, and in 655, after repeated examinations, in which he maintained his theological opinions with memorable constancy, was banished to Byzia in Thrace, and afterwards to Perberis. In 662 he was again brought to Constantinople and was condemned by a synod there to be scourged, to have his tongue cut out by the root, and to have his right hand chopped off. After this sentence had been carried out he was again banished to Lazica, where he died on August 13, 662. He is venerated as a saint both in the Greek and in the Latin Church,—in the former on January and on August 12th and 13th, in the latter on August 13th.

A collection of his works, which are of importance for the history of the Monothelite controversy, was undertaken by Combefis, who published two volumes in 1675 (*S. Maximi Confessoris, Græcorum Theologi, eximiique Philosophi Opera*), but did not live to complete his labours. A list of the more important of the writings of Maximus, with bibliographical details, will be found in Smith's *Dictionary of Biography and Mythology*; an exhaustive "Catalogue raisonné," by Wagenmann, occurs in vol. ix. (1881) of the new edition of Herzog's *Real-Encyklopädie*. The details of the disputation with Pyrrhus and of the martyrdom are given very fully and clearly in Hefele's *Conc.-gesch.*, vol. iii.

MAXWELL, James Clerk (1831–1879), was the last representative of a younger branch of the well-known Scottish family of Clerk of Penicuik. He was educated at the Edinburgh Academy (1840–47) and the university of Edinburgh (1847–50). Entering at Cambridge in 1850, he spent a term or two in Peterhouse, but afterwards migrated to Trinity. He took his degree in 1854 as second wrangler, and was declared equal with the senior wrangler of his year in the higher ordeal of the Smith's prize examination. He held the chair of natural philosophy in Marischal College, Aberdeen, from 1856 till the fusion of the two colleges there in 1860. For eight years subsequently he held the chair of physics and astronomy in King's College, London, but resigned in 1868 and retired to his estate of Glenlair in Kirkcudbrightshire. He was summoned from his seclusion in 1871 to become the first holder of the newly-founded professorship of experimental physics in Cambridge; and it was under his direction that the plans of the Cavendish laboratory were prepared. He superintended every step of the progress of the building and of the purchase of the very valuable collection of apparatus with which it was equipped at the expense of its munificent founder the duke of Devonshire (chancellor of the university, and one of its most distinguished alumni). So far for the outline of Maxwell's career, as regards dates, official work, &c. The rest belongs almost exclusively to mathematical and physical science. For more than half of his brief life he held a prominent position in the very foremost rank of natural philosophers. His contributions to scientific societies began in his fifteenth year, when Professor J. D. Forbes communicated to the Royal Society of Edinburgh a short paper of his on a mechanical method of tracing Cartesian ovals. In his eighteenth year, while still a student in Edinburgh, he contributed two valuable papers to the *Transactions* of the same society—one of which, "On the Equilibrium of Elastic Solids," is remarkable, not only on account of its intrinsic power and the youth of its author, but also because in it he laid the foundation of one of the most singular discoveries of his later life, the temporary double refraction produced in viscous liquids by shearing stress. Immediately after taking his degree, he read to the Cambridge Philosophical Society a very novel memoir *On the Transformation of Surfaces by Bending*. This is one of the few purely mathematical papers he published, and it exhibited at once to experts the full genius of its author. About the same time appeared his elaborate memoir *On Faraday's Lines of Force*, in which he gave the first indication of some of those extraordinary electrical investigations which culminated in the greatest work of his life. He obtained in 1859 the Adams prize in Cambridge for a very original and powerful essay *On the Stability of Saturn's Rings*. From 1855 to 1872 he published at intervals a series of valuable investigations connected with the *Perception of Colour* and *Colour-Blindness*. For the earlier of these he received the Rumford medal in 1860. The instruments which he devised for these investigations were simple and convenient, but could not have been thought of for the purpose except by a man whose knowledge was co-extensive with his ingenuity. One of his greatest investigations bore on the *Kinetic Theory of Gases*. Originating with D. Bernoulli, this theory was advanced by the successive labours of Herapath, Joule, and particularly of Clausius, to such an extent as to put its general accuracy beyond a doubt. But by far the greatest developments it has received are due to Maxwell, part of whose mathematical work has recently been still further extended in some directions by Bolzmann. In this field Maxwell appears as an experimenter (on the laws of gaseous friction) as well as a mathematician. His two latest papers deal with this branch of physics; one is an extension and simplification of some of Bolzmann's chief results, the other treats of the kinetic theory as applied to the motion of the radiometer. He has written an admirable text-book of the *Theory of Heat*, which has already (1882) gone through several editions, and a very excellent elementary treatise on *Matter and Motion*. Even this, like his other and larger works, is full of valuable matter, worthy of the most attentive perusal not of students alone but of the very foremost scientific men.

But the great work of his life was devoted to electricity. He began by reading with the most profound admiration and attention the whole of Faraday's extraordinary self-revelations, and proceeded to translate the ideas of that master into the succinct and expressive notation of the mathematicians. A considerable part of this translation was accomplished during his career as an undergraduate in Cambridge. The writer had the opportunity of perusing the MS. on *Faraday's Lines of Force*, in a form little different from the final one, a year before Maxwell took his degree. His great object, as it was also the great object of Faraday, was to overturn the idea of action at a distance. The splendid researches of Poisson and Gauss had shown how to reduce all the phenomena of statical electricity to mere attractions and repulsions exerted at a distance by particles of an imponderable on one another. Sir W. Thomson had, in 1846, shown that a totally different assumption, based upon other analogies, led (by its own special mathematical methods) to precisely the same results. He treated the resultant electric force at any point as analogous to the *flux of heat* from sources distributed in the same manner as the supposed electric particles. This paper of Thomson's, whose ideas Maxwell afterwards developed in an extraordinary manner, seems to have given the first hint that there are at least two perfectly distinct methods of arriving at the known formulæ of statical electricity. The step to magnetic phenomena was comparatively simple; but it was otherwise as regards electro-magnetic phenomena, where current electricity is essentially involved. An exceedingly ingenious, but highly artificial, theory had been devised by Weber, which was found capable of explaining all the phenomena investigated by Ampère, as well as the induction currents of Faraday. But this was based upon the assumption of a distance-action between electric particles, whose intensity depended on their relative motion as well as on their position. This was, of course, even more repugnant to Maxwell's mind than the statical distance-action developed by Poisson. The first paper of Maxwell's in which an attempt at an admissible physical theory of electromagnetism was made was communicated to the Royal Society in 1867. But the theory, in a fully developed form, first appeared in his great treatise on *Electricity and Magnetism* (1873). This work, already in a second edition, is one of the most splendid monuments ever raised by the genius of a single individual. Availing himself of the admirable generalized coordinate system of Lagrange, Maxwell has shown how to reduce all electric and magnetic phenomena to stresses and motions of a material medium, and, as one preliminary, but excessively severe, test of the truth of his theory, has shown that (if the electromagnetic medium be that which is required for the explanation of the phenomena of light) the velocity of light in vacuo should be numerically the same as the ratio of the electromagnetic and electrostatic units. We do not as yet certainly know either of these quantities very exactly, but the means of the best determinations of each separately agree with one another more closely than do the various values of either. There seems to be no longer any possibility of doubt that Maxwell has taken the first grand step towards the discovery of the true nature of electrical phenomena. Had he done nothing but this, his fame would have been secured for all time. But, striking as it is, this forms only one small part of the contents of his truly marvellous work.

One of his last great contributions to science was his editing (with copious original notes) the *Electrical Researches of the Hon. Henry Cavendish*, which had been altogether unappreciated by the witlings to whom they had previously been confided. It now appears that Cavendish, already famous by many other researches (such as the mean density of the earth, the composition of water, &c.), must be looked on as, in his day, a man of Maxwell's own stamp as a theorist, and an experimenter of the very first rank.

This encyclopædia has been, in its scientific aspects, greatly indebted to Clerk Maxwell. The articles ATOM, ATTRACTION, CAPILLARITY, DIFFUSION, ETHER, &c., were intended as parts merely of one comprehensive system, in which a general résumé of all that is known of the properties of matter should be given in simple yet profound completeness. The reader of these articles cannot but feel how much has been lost when this splendid series cannot be completed by its initiator.

In private life Clerk Maxwell was one of the most lovable of men, a sincere and unostentatious Christian. Though perfectly free from any trace of envy or ill-will, he yet showed on fit occasion his contempt for that pseudo-science which seeks for the applause of the ignorant by professing to reduce the whole system of the universe to a fortuitous sequence of uncaused events.

His collected works will shortly be issued from the Pitt press; and an extended biography, by his former school-fellow and lifelong friend Professor Campbell, has just been published (1882). (P. G. T.)

MAXWELL, SIR WILLIAM STIRLING-, BART. (1818–1878), man of letters, the only son of Mr Archibald Stirling of Keir, Perthshire, and of Elizabeth, second daughter of Sir John Maxwell, seventh baronet of Pollok, Renfrewshire, was born at Kenmure, near Glasgow, in 1818. William Stirling was educated at Trinity College, Cambridge, where he graduated in 1839, and afterwards he spent some years on the Continent chiefly in France and Spain. Having succeeded his father as proprietor of Keir in 1846 (when he was made vice-lieutenant of Perthshire), he in 1852 entered parliament as member for that county; and he was several times re-elected. On the death of his uncle in 1865 he succeeded to the baronetcy and estates of Pollok, in respect of which he assumed the additional name of Maxwell. In the same year he became deputy-lieutenant of Lanarkshire, and a like office was conferred on him in Renfrewshire in 1870. The services which his talent, energy, and wealth enabled him to render to literature were recognized in a great variety of ways by numerous universities; in 1863 he was chosen lord rector of St Andrews, in 1871 the same honour was conferred by Edinburgh, and in 1875 he became chancellor of Glasgow. In the following year he was created a Knight of the Thistle, being the only commoner of the order. He died at Venice on January 15, 1878.

Sir W. Stirling-Maxwell's works, which are invariably characterized by thoroughness of workmanship and refinement of literary taste, were in some cases issued for private circulation only, and almost all of them are now exceedingly rare. They include an early volume of verse (*Songs of the Holy Land*, 1847), and several volumes containing costly reproductions of old engravings, along with valuable explanatory matter. His best-known publications are *Annals of the Artists of Spain* (1848; 2d ed., 1853), *The Cloister Life of Charles V.* (1852; 3d ed., 1853), and *Velazquez and his Works* (1855). A life of *Don John of Austria*, from his posthumous papers, is now (1882) in the press.

MAY, the fifth month of our modern year, was the third of the old Roman calendar. The name is of doubtful origin. Ovid (*Fasti*, v. 483–90) suggests the three derivations of *majestas*, *majores* (the *patres* of the old Roman city), and *Maia*, the mother of Mercury, to whom the Romans were accustomed to sacrifice on the first day of the month. It was considered unlucky among the Romans to contract marriages during this month, on account of the celebration of the Lemuria,—a superstition of which traces are still to be found among ourselves. In the Roman Catholic Church May is known as "the month of Mary."

May-day is the name given to the first day of the month in England, when, according to ancient custom, all ranks of the people rose at early dawn and went out "a-Maying" to welcome the advent of spring. The customs of the day chiefly took their rise with the Romans. In the southern counties of England they differ materially from those of the northern and western. That of gathering branches of trees and flowers, to deck the person, is still observed in many places.

The May-Pole was once general throughout the country. The assemblage of the people, sanctioned by the presence of the priests, marching on May morning in procession to some neighbouring wood, returned in triumph with the pole, round which were suspended flowers, boughs, and other tokens of the spring season. On one of these festive occasions, Henry VIII. assembled his court at Shooter's Hill; and Queen Elizabeth also used to keep "May Games" at Greenwich. The May-pole, once fixed, often remained until nearly the end of the year; and there were some specially made of durable wood, which remained for many years, and were from time to time resorted to at other seasons of festivity. The last May-pole erected in London, 100 feet in height, was on the spot where the church in the Strand now stands, near Somerset House. Being taken down in 1717–18 it was conveyed to Wanstead Park in Essex, where it was fixed as part of the support of a large telescope set up by Sir Isaac Newton. The May Lady, Maulkin, Jack in the Green, and Morris Dancing are merely variations in the mode of representing the goddess Flora. The chimney sweepers, who are now the principal performers, are probably more interested than any other class in May sports. For, as the commencement of summer deprives them in a considerable degree of their business occupation, they naturally seek to avail themselves of the customary liberality of festive meetings.

The other principal fixed days observed and noted in the month are May 9, Half-Quarter-Day, and May 15, Whitsunday term,—not to be confounded with Whit Sunday, which is a movable feast.

MAYA. See Mexico.

MAYBOLE, a burgh of barony and market-town of Scotland, in the county of Ayr, 9 miles south of Ayr on the railway to Stranraer, is built on the face of a hill gently sloping to the south. The characteristic features of the place are the old family mansions in the main street, the castle of the earls of Cassilis, and the old church ruins with the Cassilis burial-place. It has recently increased considerably in size, and it is now busy with various manufacturing industries in addition to its staple trade of shoemaking. The population was 3797 in 1871 and 4474 in 1881. New waterworks to supply 60,000 gallons daily were commenced in 1882; the site of the reservoir, about 3 miles south-east of the town, is almost that of the remarkable Lochspouts crannog (see *Ayr and Wigton Arch. and Hist. Collections*, vol. iii.; and Munro, *Ancient Scottish Lake Dwellings*, 1882).

A charter was granted to the town by Duncan in 1193; and the church was bestowed in 1213 on the Cistercian nunnery at North Berwick. In 1516 Maybole became a burgh of regality, and in 1639 the seat of the head courts of Carrick; but the independence of its local government was long contested by the superiors, the earls of Cassilis. Cotton weaving was introduced in the 18th century.

See J. Paterson, *History of Ayr and Wigton*, vol. ii., 1864.

MAYENCE. See Mainz.

MAYENNE, a department of north-western France, three-fourths of which formerly belonged to Lower Maine and the remainder to Anjou, lies between 47° 45′ 10″ and 48° 34′ 30″ N. lat., and 0° 2′ E. and 1° 14′ W. long., and is bounded on the N. by Manche and Orne, on the E. by Sarthe, on the S. by Maine-et-Loire, and on the W. by Ille-et-Vilaine, having a maximum length from north to south of 51 miles, a breadth of 39 miles, and an area of 1996 square miles. Its ancient geological formations connect it with Brittany. The surface is agreeably undulated; forests are numerous, and the beauty of the cultivated portions is enhanced by the hedgerows and lines of trees by which the farms are divided. The highest point of the department, and indeed of the whole north-west of France, is the Mont des Avaloirs (1368 feet). Hydrographically Mayenne belongs to the basins of the Loire, the Vilaine, and the Sélune; the first-mentioned has the larger part of the entire area. The principal stream is the Mayenne, which passes successively from north to south through the three most important towns—Mayenne, Laval, and Château-Gontier; by means of weirs and sluices it is navigable below Mayenne, but steamers do not ascend past Château-Gontier. The chief affluents are the Jouanne on the left, and on the right the Colmont, the Ernée, and the Oudon. A small area in the east of the department drains by the Erve into the Sarthe; the Vilaine rises in the west, and in the north-west the Sélune flows into the English Channel. The climate of Mayenne, which is that of the Sequanian region, is generally healthy except in the neighbourhood of the numerous marshes. The temperature is lower and the moisture of the atmosphere greater than in the neighbouring departments; the rainfall is above the average for France.

Of the entire area two-thirds are arable, and a twentieth is under wood. A large number of horned cattle are reared (98,000 oxen, 150,000 cows), and in no other French department are so many horses (92,500) found within the same area; the breed, that of Craon, is famed for its strength. Craon has also given its name to the most prized breed of pigs in western France. There are 83,000 pigs in the department, 80,000 sheep, and 5000 goats. Mayenne produces excellent butter, poultry, and game, and a large quantity of honey. The cultivation of the vine is very limited, and the most common beverage is cider, of which nearly 9,000,000 gallons are annually made. Agriculture is in a flourishing condition; in 1878 were produced upwards of 3½ million bushels of wheat, ¾ million of meslin, nearly an equal amount of rye, 1½ million of barley, 2 million of oats, and nearly 3 million bushels of potatoes, besides a large quantity of flax and hemp. The timber grown is chiefly beech, oak, birch, elm, and chestnut. The department produces a little iron-ore and manganese; it is rich in anthracite and coal, of which, however, the annual production has recently decreased from 80,000 tons to 60,000. Marble and granite, limestone, slate, and porphyry are quarried; the last-named material is capable of a fine polish, and is also used for paving the streets of Paris. There are several chalybeate springs. The industries include iron and brass founding, brick and tile making, brewing, the manufacture of candles, cotton, linen, and woollen thread, and the production of various textile fabrics (that of ticking being the specialty of the department), agricultural implement making, wood and marble sawing, tanning, dyeing, and the like. The population in 1881 was 343,167. The arrondissements are those of Laval, Château-Gontier, and Mayenne.

Mayenne, capital of an arrondissement in the above department of France, is an old feudal town irregularly built on two hillocks which overlook the river Mayenne, at the point where the railway from Caen to Laval is joined by that from Fougères to Alençon. The old castle still has towards the river five towers, one of which has retained its conical roof; the vaulted chambers and chapel are ornamented in the style of the 13th century; the building is now used as a prison. The church of Notre Dame, dating partly from the 12th century, is the only other building of any special interest. In the Place de Cheverus is a statue, by David of Angers, to the cardinal of that name, who was born in Mayenne. The chief industry of the place is the cloth manufacture, which occupies 8000 persons in the town and neighbourhood. The population in 1876 was 10,098.

Mayenne had its origin in the castle built here by Juhel, the son of Geoffroy of Maine, in the beginning of the 11th century. It was besieged by William the Conqueror, and afterwards by the earl of Salisbury; and the possession of it was disputed by the Royalists and the Leaguers, as also by the Republicans and the Vendeans.

MAYER, JOHANN TOBIAS (1723–1762), one of the greatest of last century's astronomers, was born at Marbach in Würtemberg, February 17, 1723. He was brought up at Esslingen in comparatively poor circumstances, and as a mathematician was mainly self-taught. He had already published several original geometrical tracts when, in 1746, he entered Homann's cartographic establishment at Nuremberg. Here he introduced many improvements in map-making, and gained a scientific reputation which led (in 1751) to his election to the chair of economy and mathematics in the university of Göttingen. In 1754 he became superintendent of the observatory, where he laboured with great zeal and success till his death, February 20, 1762. His first important astronomical work was a careful investigation of the libration of the moon (*Kosmographische Nachrichten*, Nuremberg, 1750), the elements of which and the position of the moon's axis of rotation he determined with much greater accuracy than had previously been done. His great fame rests on his lunar tables, which were published in 1753 along with new solar tables, and transmitted to England in 1755. These tables, which were compared by Bradley with the Greenwich observations, and found to be sufficiently accurate to determine the longitude at sea to within half a degree, solved the problem of practically determining longitude anywhere on the earth's surface. An improved set was afterwards published in London (1770), as also the theory (*Theoria Lunæ juxta Systema Newtonianum*, 1767) upon which the tables are based. They were sent to England by his widow, who in consideration received from the British Government a grant of £3000. Appended to the London edition of the solar and lunar tables are two short tracts,—the one on determining longitude by lunar distances, together with a description of the repeating circle (invented by Mayer in 1760), the other on a formula for atmospheric refraction, which applies a remarkably accurate correction for temperature.

Mayer left behind him a considerable quantity of manuscript, part of which was collected by Lichtenberg and published in one volume (*Opera Inedita*, Göttingen, 1775). It contains, amongst other papers, an easy and accurate method for calculating eclipses; an essay on colour, in which three primary colours are recognized; a catalogue of nine hundred and ninety-eight zodiacal stars; and a memoir, the earliest of any real value, on the proper motion of fixed stars, which was originally communicated to the Göttingen Royal Society in 1760. The other part still remains in manuscript, and includes papers on atmospheric refraction (dated 1755), on the motion of Mars as affected by the perturbations of Jupiter and the Earth (1756), and on terrestrial magnetism (1760 and 1762). In these last Mayer seeks to explain the magnetic action of the earth by a simple hypothesis. He supposes a small bar-magnet to be placed with its centre at the earth's centre, and calculates the position of equilibrium of a second small magnet at any given point on the earth's surface, assuming the law of magnetic attraction and repulsion to be that of the inverse square. Though the values of the declination and dip calculated according to this theory do not agree with the observed values, Mayer must be credited with the first really definite attempt to establish a mathematical theory of magnetic action, and as the first who gave any experimental evidence in favour of the inverse square of the distance as the law of force. See Hansteen's *Magnetismus der Erde*.

MAYER, JULIUS ROBERT (1814–1878), was born at Heilbronn, Nov. 25, 1814, studied medicine at Tübingen, Munich, and Paris, and, after a journey to Java in 1840 as surgeon of a Dutch vessel, obtained a medical post in his native town. He claims recognition as an independent *a priori* propounder of the "First Law of Thermodynamics," but more especially as having early and ably applied that law to the explanation of many remarkable phenomena, both cosmical and terrestrial. His first little paper on the subject, "Bemerkungen über die Kräfte der unbelebten Natur," appeared in 1842 in Liebig's *Annalen*, five years subsequent to the republication, in the same journal, of an extract from the great memoir of MOHR (*q.v.*). Mayer's statements as to the "indestructibility of force" (as he calls it) were based almost entirely upon scholastic dicta, such as *causa æquat effectum*, &c. The main experimental fact which he adduces in support of his reasoning as to the convertibility of work and heat is a mere repetition, in a very inadequate form, of a curious experiment made by Dr Reade of Cork, who found (*Nicholson's Journal*, xx., 1808, p. 113) that water was sensibly heated after being violently shaken in a phial. But Dr Reade states explicitly the precautions he had taken to protect the phial and its contents from heating by the hand of the operator,—an important detail which is unnoticed by Mayer.

It has been repeatedly claimed for Mayer that he calculated the value of the dynamical equivalent of heat, indirectly no doubt, but in a manner altogether free from error, and with a result according almost exactly with that obtained by Joule after years of patient labour in direct experimenting. Mayer assumed that the heat developed by compression of air is the equivalent of the work spent in the compression. If we had independent proof of this the result would undoubtedly follow.[1] And it has been urged that the man who, by a single burst of genius, reached at once the goal which others had been painfully seeking, merits an amount of fame commensurate with that due to discoverers like Newton or Galileo. This claim on Mayer's behalf was first shown to be baseless by Thomson and Tait ("Energy," *Good Words*, 1862). This article gave rise to a long but lively discussion. A calm and judicial annihilation of the claim is to be found in a brief article by Stokes, *Proc. Roy. Soc.*, 1871, p. 54. See also Maxwell's *Theory of Heat*, chap. xiii. Mayer entirely ignored the grand fundamental principle laid down by Sadi Carnot, a principle which has done even more for physics than has the conservation of energy itself, viz., that nothing can be concluded as to the relation between heat and work from an experiment in which the working substance is left at the end of an operation in a different physical state from that in which it was at the commencement. Mayer has also been styled the discoverer of the fact that heat consists in (the energy of) motion, a matter settled at the very end of the 18th century by Rumford and Davy. In the teeth of this statement we have Mayer's own words, "We might much rather assume the contrary,—that in order to become heat, motion must cease to be motion."

Mayer's real merit consists in the fact that, having for himself made out, on inadequate and even questionable grounds, the conservation of energy, and having obtained (though by inaccurate reasoning) a numerical result correct so far as his data permitted, he applied the principle with great power and insight to the explanation of numerous physical phenomena. His papers, which have been republished in a single volume with the title *Die Mechanik der Wärme* (2d ed., Stuttgart, 1874), are of extremely unequal merit. But some, especially those on *Celestial Dynamics* and *Organic Motion*, are admirable examples of what really valuable work may be effected by a man of high intellectual powers, in spite of imperfect information and defective logic.

Different, and, it would appear, exaggerated, estimates of Mayer are given in Dr Tyndall's papers in the *Phil. Mag.*, 1863–64 (whose avowed object was "to raise a noble and a suffering man to the position which his labours entitled him to occupy"), and in the extraordinary treatise by Dühring, *Robert Mayer, der Galilei des neunzehnten Jahrhunderts*, Chemnitz, 1880. Some of the simpler facts of the case are summarized by Tait in the *Phil. Mag.*, 1864, ii. p. 289.

MAYHEM (MAIM), an old term of the law signifying an assault whereby the injured person is deprived of a member proper for his defence in fight, *e.g.*, an arm, a leg, a fore tooth, &c. The loss of an ear, jaw tooth, &c., was not mayhem. The most ancient punishment in English law was retaliative—*membrum pro membro*, but ultimately at common law fine and imprisonment. Various statutes were passed aimed at the offence of maiming and dis-

[1] Séguin, three years before, had assumed that the work done by steam or any other expanding substance is the equivalent of the heat which disappears during the expansion. A similar idea, but more accurately expressed, is to be found in Mohr's paper, above referred to.

figuring, which is now dealt with by section 18 of 24 & 25 Vict. c. 100. Mayhem may also be the ground of a civil action, which had this peculiarity that the court on sight of the wound might increase the damages awarded by the jury.

MAYKOP, a town of the Caucasus, Russia, in the province of Kuban, on the Byelaya, a tributary of the Kuban, 93 miles to the south-east of Yekaterinodar, the capital of the province. Formerly it was merely a fortified "stanitsa" (village of Cossacks) and the centre for military operations against western Caucasus. But, owing to its position in a very fertile country where settlers from Russia found plenty of rich soil which had been abandoned by the natives, Maykop has become a wealthy town, and its population has rapidly increased to 22,550. Most of them are still agriculturists, but others are engaged in a brisk trade in the produce obtained from the large and wealthy stanitsas of the surrounding district.

MAYNOOTH, a village in the county of Kildare, province of Leinster, Ireland, is situated on the Royal Canal and on the Midland Great Western Railway, 15 miles north-west of Dublin. The Royal Catholic College of Maynooth, instituted by the Irish parliament in 1765, is the chief seminary for the education of the Roman Catholic clergy of Ireland. It was supported by a parliamentary grant of £26,000 a year, which at the disestablishment of the Irish Church in 1869 was commuted by the payment of a capital sum fourteen times its amount. The building is a fine Gothic structure by Pugin, erected by a parliamentary grant obtained in 1846. Near the college stand the ruins of Maynooth Castle, built in 1426, and formerly the residence of the Fitzgerald family. It was besieged in the reign of Henry VIII., in that of Edward VI., and during the Cromwellian wars, when it was demolished. The beautiful mansion of the duke of Leinster is about a mile from the town.

MAYO, a maritime county on the west coast of Ireland, province of Connaught, is bounded N. and W. by the Atlantic Ocean, N.E. by Sligo, E. by Roscommon, S.E. and S. by Galway. Its greatest length from north to south is about 75 miles, and its greatest breadth about 65 miles. The total area is 1,318,129 acres, or 2060 square miles.

About two-thirds of the boundary of Mayo is formed by sea, and the coast is very much indented, and abounds in picturesque scenery. The principal inlets are Killary Harbour between Mayo and Galway; Clew Bay, in which are the harbours of Westport and Newport; Blacksod Bay and Broad Haven, which form the peninsula of the Mullet; and Killala Bay between Mayo and Sligo. The islands are very numerous, the principal being Inishturk (area 1445 acres, and population 132 in 1881), near Killary Harbour; Clare Island (area 3949 acres, population 62) at the mouth of Clew Bay, where there are many islets all formed of drift; and Achil (area 35,838 acres, population 5070), the largest island in Ireland. In the eastern half of the county, where Carboniferous rocks prevail, the surface is comparatively level, with occasional hills consisting chiefly of granite and slate. The western half is very mountainous, but there are a few valleys adjoining the sea-shore. A great portion of the coast extending from Killala to Clew Bay consists of Old Red and Yellow Sandstone. The remainder of the mountainous region consists chiefly of quartzite or alternating beds of quartzite and granite or gneiss schist. Muilrea (2688 feet) is included in a mountain range, lying between Killary Harbour and Lough Mask, which belongs to the Upper Silurian formation. The next highest summits are Nephin (2530 feet), to the west of Lough Conn, and Croagh Patrick (2370 feet), to the south of Clew Bay. The river Moy flows northwards, forming the boundary of the county with Sligo, and falls into Killala Bay. The courses of the other streams are short, and except when swollen by rains their volume is small. The principal lakes are Lough Mask and Lough Corrib, on the borders of the county with Galway, and Loughs Conn, Carrah, Castlebar, Cullin, and Carrowmore. Limestone is abundant, and also iron ore, which, however, is not smelted, from want of fuel. There are several valuable slate quarries; and ochres, granite, and manganese are found.

Agriculture.—There are some very fertile regions in the level portions of the county, but in the mountainous districts the soil is poor, the holdings are subdivided beyond the possibility of affording proper sustenance to their occupiers, and, except where fishing is combined with agricultural operations, the circumstances of the peasantry are among the most wretched of any district of Ireland.

In 1881 there were 179,343 acres, or less than one-eighth of the whole area, under crops, while 545,040 were pasture, 10,702 woods, and 521,673 waste. The total number of holdings in 1881 was 37,693, of which 22,914 were less than 15 acres in extent, and 9386 between 15 and 30 acres. The following table shows the areas under the principal crops in 1855 and 1882:—

	Wheat.	Oats.	Other Cereals.	Potatoes.	Turnips.	Other Green Crops.	Flax.	Meadow and Clover.	Total.
1855	4,638	83,543	5,396	59,037	9,556	2,193	745	18,229	183,337
1882	1,083	61,125	3,016	54,594	7,960	3,964	286	43,363	175,391

Horses between 1855 and 1882 increased from 17,531 to 18,050, of which 12,150 were used solely for agricultural purposes. The number of cattle in 1855 was 153,583, and in 1882 it was 162,331, of which 53,153 were milch cows. Sheep in 1855 numbered 265,448, and in 1882 only 225,509, although in 1880 there were as many as 271,282. Pigs in 1882 numbered 62,227, goats 5987, and poultry 632,432. According to the latest return the land was divided among 1483 proprietors, who possessed 1,308,367 acres, at an annual rateable value of £310,140, the rateable value per acre being 4s. 8d. The average size of the properties was 882 acres. No fewer than 21 proprietors, possessed upwards of 10,000 acres, and of these 8 possessed upwards of 20,000, viz., Marquis of Sligo, 114,881 acres; Viscount Dillon, 83,749; Sir R. W. H. Palmer, Bart., 80,990; Earl of Lucan, 60,570; T. S. Carter, 37,773; G. Clive, 35,229; Earl of Arran, 29,644; C. H. Knox, 24,374.

Manufactures and Trade.—Coarse linen and woollen cloths are manufactured to a small extent. There are very productive fishing banks on the coast, especially in the neighbourhood of the islands, and the Moy is a fine river for salmon.

Railways.—The Great Northern and Western Railway crosses the county from near Ballyhaunis to Westport, and a branch from it runs north to Ardnaree near Killala Bay.

Administration and Population.—The county includes nine baronies and seventy-three parishes. It is in the Connaught circuit. Assizes are held at Castlebar, and quarter sessions at Ballina, Ballinrobe, Bellmullet, Castlebar, Claremorris, Swineford, and Westport. There are twenty-two petty sessions districts within the county, and portions of two other districts. It includes the seven poor-law unions of Bellmullet, Castlebar, Claremorris, Killala, Newport, Swineford, and Westport, and part of the unions of Ballina, Ballinrobe, and Castlerea. It is in the Dublin military district, subdistrict of Galway; and there are barrack stations at Castlebar, Ballinrobe, Westport, Foxford, and Ballaghaderreen. In the Irish parliament two members were returned for the county, and two for the borough of Castlebar, but at the Union Castlebar was disfranchised.

From 77,508 in 1760 the population gradually increased till in 1841 it was 388,887, but in 1851 it had diminished to 274,499, in 1871 to 246,030, and in 1881 to 245,212, of whom 119,421 were males and 125,791 females. The county contains a portion (with 4318 inhabitants) of the township of Ballina, the townships of Castlebar, 3855, and Westport, 4469, and the town of Ballinrobe, 2286. The number of emigrants from 1st May 1851 to 31st December 1881 was 85,431. The number of emigrants in 1881 was 4469, or a proportion of 18·4 to every 1000 of the population. The death-rate to every 1000 of the population for 10 years ending 31st March 1881 was 13·8, the birth-rate 27·1, and the marriage-rate 3·9. Roman Catholics in 1881 numbered 238,262, Episcopalians 5575, Presbyterians 925, and Methodists 275. In 1881 as many as 8808 persons could speak Irish only, and 138,930 Irish and English.

History and Antiquities.—The name given by Ptolemy to the inhabitants of this district of Ireland was Nagnatæ. Erris in Mayo was the scene of the landing of the chief colony of the Firbolgs, and the battle which is said to have resulted in the overthrow and almost annihilation of this tribe took place also in this county, at Moytura near Cong. Along with the greater part of Connaught it was granted by King John to Hubert de Burgo, but after the rebellion against William de Burgo, third earl, headed by Mac William Oughter, the whole province of Connaught remained nearly independent of British rule till the time of Elizabeth. In the eleventh year of her reign Mayo was made shire ground, taking its name from the monastery of Maio or Mageo, which was the see of a bishop. Even, however, after this period the Mac Williams continued to exercise very great authority. Large confiscations of the estates in the county were made in 1586, on the termination of the wars of 1641, and after the restoration of the Stuarts. Killala was the scene of the landing of a French squadron in connexion with the rebellion of 1798.

There are four round towers in the county,—at Killala, Turlogh, Meelick, and Bal or Ballagh. The monasteries were numerous, and many of them of considerable importance—the principal being those at Mayo, Ballyhaunis, Cong, Ballinrobe, Ballintober, Burrishoole, Cross or Holycross in the peninsula of Mullet, Moyne, Rosserick, and Strade. Of the old castles the most notable are Downpatrick, on a cliff 300 feet in height projecting into the sea, Rockfleet near Newport, said to have been built by the celebrated Grace O'Malley, Ballylahan Castle near Foxford, and Deel Castle near Ballina, at one time the residence of the earls of Arran.

MAYOR. See MUNICIPALITY.

MAYOTTA. See COMORES, vol. vi. p. 220.

MAYSVILLE, a city of the United States, the capital of Mason county, Kentucky, lies on the south bank of the Ohio, 69 miles north-east of Lexington by rail. Settled in 1784 and incorporated in 1833, it has grown into a busy place of 5220 inhabitants (1880), with several good public buildings, flour-mills, plough-factories, &c., and is one of the principal hemp-markets in the States.

MAZAMET, an industrial town in the department of Tarn, France, stands on the northern slope of the Montagnes Noires (part of the Cevennes), and on the Arnette, a tributary of the Tarn by the Agout. In last century it was an insignificant village, but at present it has 14,000 inhabitants, an increase of prosperity due to the introduction by M. Houlès (whose statue stands in the public square) of the manufacture of a particular kind of woollen fabric sold almost exclusively in France. The factories, driven by water-power, have a total of 45,000 spindles, and an annual turnover of from 15 to 18 millions of francs. Mazamet is connected by a branch line of railway with the town of Castres.

MAZANDARÁN, a province of northern Persia, lying between the Caspian Sea and the Elbúrz range, and bounded E. and W. by the provinces of Astrábád and Gílán respectively, is 220 miles in length and 60 miles in (mean) breadth, with an area of about 10,000 square miles and a population estimated at from 150,000 to 200,000. Mazandarán comprises two distinct natural regions presenting the sharpest contrasts in their relief, climate, and products. In the north the Caspian is encircled by the level and swampy lowlands, varying in breadth from 10 to 30 miles, partly under impenetrable jungle, partly under rice, cotton, sugar, and other crops. This section is fringed northwards by the sandy beach of the Caspian, here almost destitute of natural harbours, and rises somewhat abruptly inland to the second section, comprising the northern slopes and spurs of the Elbúrz, which approach at some points within 1 or 2 miles of the sea, and which are almost everywhere covered with dense forest. The lowlands, rising but a few feet above the Caspian, and subject to frequent floodings, are extremely malarious, while the highlands, culminating with the magnificent Damávand (18,600 feet), enjoy a tolerably salubrious climate. But the climate, generally hot and moist in summer, is everywhere capricious and liable to sudden changes of temperature, whence the prevalence of rheumatism, dropsy, and especially ophthalmia, noticed by all travellers. Snow falls heavily on the uplands, where it often lies for weeks on the ground. The direction of the long sandbanks at the river mouths, which project with remarkable uniformity from west to east, shows that the prevailing winds blow from the west and north-west. The rivers themselves, of which there are as many as fifty, are little more than mountain torrents, all rising on the northern slopes of Elbúrz, flowing mostly in independent channels to the Caspian, and subject to sudden freshets and inundations along their lower course. The chief are the Safed-rúd on the Gílán frontier, the Lár, Hari-rúd, Alam-rúd, Rústam-rúd, and Hárez, and all are well stocked with trout, mullet (safed máhí), carp, sturgeon, and other fish, which with rice form the staple food of the inhabitants, and supply large quantities of caviare for the Russian market. Near their mouths the rivers, running counter to the prevailing winds and waves of the Caspian, form long sand-hills 20 to 30 feet high and about 200 yards broad, behind which are developed the so-called *múrd-áb*, or "dead waters," stagnant pools and swamps characteristic of this coast, and a chief cause of its unhealthiness.

The province abounds in iron ores and in mineral pitch in every state of transition from pure petroleum to the finest naphtha. The chief cultivated plants are rice, cotton, sugar, a little silk, and fruits in great variety, including several kinds of the orange, lemon, and citron. Some of the slopes are covered with extensive thickets of the pomegranate, and the wild vine climbs to a great height round the trunks of the forest trees. These woodlands are haunted by the tiger, panther, bear, wolf, and wild boar in considerable numbers. Of the domestic animals, all remarkable for their small size, the chief are the black, humped cattle somewhat resembling the Indian variety, the yabu (a sturdy breed of horses), and sheep and goats.

Kinneir, Frazer, and other observers speak unfavourably of the Mazandaráni people, whom they describe as very ignorant and bigoted, arrogant, rudely inquisitive, and almost insolent towards strangers. The peasantry, however, although called the "Bœotians of Persia," are far from dull, and betray much shrewdness where their interests are concerned. In the healthy districts they are stout and well made, and are the most warlike race in Persia, furnishing 5000 cavalry and 12,000 foot to the Government. Of the latter 2000 are always in attendance on the shah at Tehrán. They speak a marked and somewhat rude Persian dialect; but a Túrki idiom closely akin to the Turkoman is still current amongst the foreign tribes, although they have mostly already passed from the nomad to the settled state. Of these intruders the most numerous are the Modaunlú, Khojehvand, and Abdul Maleki, originally of Lek or Kurd stock, besides branches of the royal Afshár and Kájár tribes of Túrki descent. All these are exempt from taxes in consideration of their military service.

The export trade is chiefly with Russia through Bákú, where broadcloths, flour, saffron, and bar iron are taken in exchange for the white and coloured calicoes, caviare, rice, and raw cotton of Mazandarán. Owing to the almost impenetrable character of the country, there are scarcely any roads accessible to wheeled carriages, and the great causeway of Shah Abbas has in many places even disappeared under the jungle. Two routes, however, lead to Tehrán, one by Firoz Koh, 180 miles long, the other by Lariján, 144 miles long, both in tolerably good repair. Except where crossed by these routes the Elbúrz forms an almost impassable barrier to the south.

The administration is in the hands of the prince governor, who appoints most of the beglerbegs and governors of the nine districts of Amól, Bárfarósh, Mashhad-i-Sar, Sárí, Ashraf, Farah-ábád, Tennacorben, Kellauristak, and Kújúr into which the province is divided. There is fair security for life and property; and, although otherwise indifferently administered, the country is quite free from marauders or local disturbances. The revenue is about 105,000 tománs, of which nothing goes to the state treasury, all being required for the governors, troops, pensions, and police. The capital is Sárí, the other chief towns being Bárfarósh, Mashhad-i-Sar, Ashraf, and Farah-ábád.

MAZARIN, JULES (1602-1661), cardinal, the successor of Richelieu, and forerunner of Louis XIV., was the elder son of Pietro Mazarini, the intendant of the household of Philip Colonna, and of his wife Ortensia Buffalini, a connexion of the Colonnas, and was born at Piscina in the Abruzzi on July 14, 1602. He was educated by the Jesuits at Rome till his seventeenth year, when he accompanied Jerome Colonna as chamberlain to the university of Alcala in Spain. There he distinguished himself more by his love of gambling and his gallant adventures than by study, but made himself a thorough master, not only of the Spanish language and character, but also of that romantic fashion of Spanish love-making which was to help him greatly in after life, when he became the servant of a Spanish queen. On his return to Rome he took his degree as Doctor Utriusque Juris, and then became captain of infantry in the regiment of Colonna, which took part in the war in the Valtelline. During this war he gave proofs of much diplomatic ability, and Pope Urban VIII. entrusted him, in 1629, with the difficult task of putting an end to the war of the Mantuan succession. His success marked him out for further distinction. He was presented to two canonries in the churches of St John Lateran and Sta Maria Maggiore, although he had only taken the minor orders, and had never been consecrated priest; he negotiated the treaty of Turin between France and Savoy in 1632, became vice-legate at Avignon in 1634, and nuncio at the court of France from 1634-36. But he began to wish for a wider sphere than papal negotiations, and, seeing that he had no chance of becoming a cardinal except by the aid of some great power, he accepted Richelieu's offer of entering the service of the king of France, and in 1639 became a naturalized Frenchman. In 1640 Richelieu sent him to Savoy, where the regency of Christine, the duchess of Savoy, and sister of Louis XIII., was disputed by her brothers-in-law, the princes Maurice and Thomas of Savoy, and he succeeded not only in firmly establishing Christine but in winning over the princes to France. This great service was rewarded by his promotion to the rank of cardinal on the presentation of the king of France in December 1641. On the 4th December 1642 Cardinal Richelieu died, and on the very next day the king sent a circular letter to all officials ordering them to send in their reports to Cardinal Mazarin, as they had formerly done to Cardinal Richelieu. Mazarin was thus acknowledged supreme minister, but he still had a difficult part to play. The king evidently could not live long, and to preserve power he must make himself necessary to the queen, who would then be regent, and do this without arousing the suspicions of the king or the distrust of the queen. His measures were ably taken, and when the king died on May 14, 1643, to every one's surprise her husband's minister remained the queen's. The king had by a royal edict cumbered the queen-regent with a council and other restrictions, and it was necessary to get the parlement of Paris to overrule the edict, and make the queen absolute regent, which was done with the greatest complaisance. Now that the queen was all-powerful, it was expected she would at once dismiss Mazarin and summon her own friends to power. One of them, Potier, bishop of Beauvais, already gave himself airs as prime minister, but Mazarin had had the address to touch both the queen's heart by his Spanish gallantry and her desire for her son's glory by his skilful policy abroad, and he found himself able easily to overthrow the clique of Importants, as they were called. That skilful policy was shown in every arena on which the great Thirty Years' War was being fought out. Mazarin had inherited the policy of France during the Thirty Years' War from Richelieu. He had inherited his desire for the humiliation of the house of Austria in both its branches, his desire to push the French frontier to the Rhine and maintain a counterpoise of German states against Austria, his alliances with the Netherlands and with Sweden, and his four theatres of war—on the Rhine, in Flanders, in Italy, and in Catalonia. This is not the place to examine the campaigns of the last five years of the great war (see CONDÉ, TURENNE), but it was Mazarin alone who directed the French diplomacy of the period. He it was who made the peace of Brömsebro between the Danes and the Swedes, and turned the latter once again against the empire; he it was who sent Lionne to make the peace of Castro, and combine the princes of North Italy against the Spaniards, and who made the peace of Ulm between France and Bavaria, thus detaching the emperor's best ally. He made one fatal mistake,—he dreamt of the French frontier being the Rhine and the Scheldt, and that a Spanish princess might bring the Spanish Netherlands as dowry to Louis XIV. This roused the jealousy of the United Provinces, and they made a separate peace with Spain in January 1648; but the valour of the French generals made the skill of the Spanish diplomatists of no avail, for Turenne's victory at Zusmarshausen, and Condé's at Lens, caused the peace of Westphalia to be definitely signed in October 1648. This celebrated treaty belongs rather to the history of Germany than to a life of Mazarin; but two questions have been often asked, whether Mazarin did not delay the peace as long as possible in order to more completely ruin Germany, and whether Richelieu would have made a similar peace. To the first question Mazarin's letters, published by M. Cheruel, prove a complete negative, for in them appears the zeal of Mazarin for the peace. On the second point, Richelieu's letters in many places indicate that his treatment of the great question of frontier would have been more thorough, but then he would not have been hampered in France itself.

We must now notice that strange period of the Fronde which has always been variously treated, for modern historians have written its history from many different standpoints, all of which can be categorically supported from the varying mémoires of the principal actors. Now, however, thanks to the labours of M. Cousin on the *carnets* of Mazarin, which contain the substance of his inmost thoughts, and of M. Cheruel on the letters written to and by Mazarin, it is possible to construct a more accurate and trustworthy history of the Fronde than has ever yet been attempted. It is not, however, intended here to trace the whole history of the Fronde, interesting as that would be, but merely to trace the policy of Mazarin throughout the epoch. The origin of both the Frondes was partly Mazarin's fault. In 1645 the parlement of Paris had protested against certain taxes, and had been checked by a *lit de justice*; and when, in 1648, it united its members in the Chambre de Saint Louis for the general reform of the kingdom, Mazarin and the queen, instead of holding another *lit de justice*, calling the states-general, or transferring the parlement out of Paris, any of which measures would have broken its power, foolishly believed in the influence of the victory of Lens, and threw the people of Paris on the side of the parlement by the arrest of Broussel. The Fronde of the princes and the nobles, on the other hand, was largely due to Mazarin's absorption of political power. These Frondeurs were not, like their ancestors, moved by great religious and political sympathies, but by merely selfish aims for restoring the old licence of duel and intrigue, and were only united in one sentiment, hatred to Mazarin. That this was so was greatly Mazarin's own fault; he had tried consistently to play off Gaston of Orleans against Condé, and their respective followers against each other, and had also, as his *carnets* prove, jealously kept any courtier from getting into the good graces of the queen-regent except by his means, so that it was not unnatural that the nobility should hate him, while the queen found herself surrounded by his creatures alone. Events followed each other quickly; the day of the barricades was followed by the peace of Ruel, the peace of Ruel by the arrest of the princes, by the battle of Rethel, and Mazarin's exile to Brühl before the union of the two

Frondes. It was while in exile at Brühl that Mazarin saw the mistake he had made in isolating himself and the queen, and that his policy of balancing every party in the state against each other had made every party distrust him. So by his counsel the queen, while nominally in league with De Retz and the parliamentary Fronde, laboured to form a purely royal party, wearied by civil dissensions, who should act for her and her son's interest alone, under the leadership of Mathieu Molé, the famous premier president of the parlement of Paris. The new party grew in strength, and in January 1652, after exactly a year's absence, Mazarin returned to the court. Turenne had now become the royal general, and out-manœuvred Condé, while the royal party at last grew to such strength in Paris that Condé had to leave the capital and France. In order to promote a reconciliation with the parlement of Paris, Mazarin had again retired from court, this time to Sedan, in August 1652, but he returned finally in February 1653. Long had been the trial, and greatly had Mazarin been to blame in allowing the Frondes to come into existence, but he had retrieved his position by founding that great royal party which steadily grew until Louis XIV. could fairly have said "L'État, c'est moi." As the war had progressed, Mazarin had steadily followed Richelieu's policy of weakening the nobles on their country estates. Whenever he had an opportunity he destroyed a feudal castle, and by destroying the towers which commanded nearly every town in France, he freed such towns as Bourges, for instance, from their long practical subjection to the neighbouring great lord.

The Fronde over, Mazarin had to build up afresh the power of France at home and abroad. It is to his shame that he did so little at home. Beyond destroying the brick and mortar remains of feudalism, he did nothing for the people. But abroad his policy was everywhere successful, and opened the way for the policy of Louis XIV. He at first, by means of an alliance with Cromwell, recovered the north-western cities of France, though at the price of yielding Dunkirk to the Protector. On the Baltic, France guaranteed the treaty of Oliva between her old allies Sweden, Poland, and Brandenburg, which preserved her influence in that quarter. In Germany he, through Lionne, formed the league of the Rhine, by which the states along the Rhine bound themselves under the headship of France to be on their guard against the house of Austria. By such measures Spain was induced to sue for peace, which was finally signed in the Isle of Pheasants on the Bidassoa, and which is known as the treaty of the Pyrenees. By it Spain recovered Franche Comté, but ceded to France Roussillon, and much of French Flanders; and, what was of greater ultimate importance to Europe, Louis XIV. was to marry a Spanish princess, who was to renounce her claims to the Spanish succession if her dowry was paid, which Mazarin knew could not happen at present from the emptiness of the Spanish exchequer. He returned to Paris in declining health, and did not long survive the unhealthy sojourn on the Bidassoa; after some political instruction to his young master, he passed away at Vincennes on March 9, 1661, leaving a fortune estimated at from 18 to 40 million livres behind him, and his nieces married into the greatest families of France and Italy.

The man who could have had such success, who could have made the treaties of Westphalia and the Pyrenees, who could have weathered the storm of the Fronde, and left France at peace with itself and with Europe to Louis XIV., must have been a great man; and historians, relying too much on the brilliant memoirs of his adversaries, like De Retz, are apt to rank him too low. That he had many a petty fault there can be no doubt; that he was avaricious and double-dealing was also undoubted; and his *carnets* show to what unworthy means he had recourse to maintain his influence over the queen. What that influence was will be always debated, but both his *carnets* and the Brühl letters show that a real personal affection, amounting to passion on the queen's part, existed. Whether they were ever married may be doubted; but that hypothesis is made more possible by M. Cheruel's having been able to prove from Mazarin's letters that the cardinal himself had never taken more than the minor orders, which could always be thrown off. With regard to France he played a more patriotic part than Condé or Turenne, for he never treated with the Spaniards, and his letters show that in the midst of his difficulties he followed with intense eagerness every movement on the frontiers. It is that immense mass of letters, now in course of publication, that prove the real greatness of the statesman, and disprove De Retz's portrait, which is carefully arranged to show off his enemy against the might of Richelieu. To concede that the master was the greater man and the greater statesman does not imply that Mazarin was but a foil to his predecessor. It is true that we find none of those deep plans for the internal prosperity of France which shine through Richelieu's policy. Mazarin was not a Frenchman, but a citizen of the world, and always paid most attention to foreign affairs; in his letters all that could teach a diplomatist is to be found, broad general views of policy, minute details carefully elaborated, keen insight into men's characters, cunning directions when to dissimulate or when to be frank. From first to last the diplomatist peeps forth, and gives the key to his character, and to the causes of his success. Italian though he was by birth, education, and nature, France owed him a great debt for his skilful management during the early years of Louis XIV., and the king owed him yet more, for he had not only transmitted to him a nation at peace, but had educated for him his great servants Le Tellier, Lionne, and Colbert. Literary men owed him also much; not only did he throw his famous library open to them, but he pensioned all their leaders, including Descartes, Voiture, Balzac, and Pierre Corneille. The last-named, the greatest of them all, did not care for Mazarin as a paymaster only, but as a statesman; he was a profound royalist, believing that absolutism alone could save France from the horrors of religious wars, or the selfish turbulence of a Fronde, and to Mazarin he applied, with an adroit allusion to his birthplace, in the dedication of his *Pompée*, the line of Virgil—

"Tu regere imperio populos, Romane, memento."

All the earlier works on Mazarin, and early accounts of his administration, of which the best were Bazin's *Histoire de France sous Louis XIII. et sous le Cardinal Mazarin*, 4 vols., 1846, and Saint-Aulaire's *Histoire de la Fronde*, have been superseded by M. Cheruel's admirable *Histoire de France pendant la minorité de Louis XIV.*, 4 vols., 1879–80, which covers from 1643–51, and its sequel *Histoire de France sous le Ministère de Cardinal Mazarin*, 2 vols., 1881–82, which is the first account of the period written by one able to sift the statements of De Retz and the memoir writers, and rest upon such documents as Mazarin's letters and *carnets*. To M. Cheruel the Government of France has entrusted the task of editing Mazarin's *Letters*, of which two volumes have at present appeared, which must be carefully studied by any student of the history of France. For his "*carnets*" reference must be made to M. Cousin's articles in the *Journal des Savants*; for his early life to Cousin's *Jeunesse de Mazarin*, 1865, and for the careers of his nieces to Renée's *Les Nieces de Mazarin*, 1856. For the Mazarinades or squibs written against him in Paris during the Fronde, see Moreau's *Bibliographie des Mazarinades*, 1850, containing an account of 4082 Mazarinades. On the Fronde, also, consult Gaillardin's *Histoire de Louis XIV.*, 6 vols., 1876–78, and Feillet's interesting *Misère au temps de la Fronde*. For his foreign policy, besides his *Letters*, see Valfrey's *Hugues de Lionne*, and Mignet's *Histoire des Négociations relatives à la Succession d'Espagne*. (H. M. S.)

MAZATLAN, a city and seaport of Mexico, in the state of Cinaloa, on the coast of the Pacific, near the mouth of the Gulf of California, in 23° 18′ N. lat. and 106° 56′ W. long. It occupies an attractive situation, but, as the houses are for the most part low, has not an imposing appearance. The port is often visited by English and American vessels, and is consequently the seat of several consular agents. A large smuggling trade was formerly carried on in much the same lines as the present legitimate traffic—export of bullion, dye-stuffs, and pearls, and import of manufactured goods from Europe and fruits and vegetables from San Francisco. In 1878 the value of the imports was about £600,000, that of the exports about £500,000. The population, which contains a large floating element, was stated at 12,706 in 1871.

MAZEPPA, Ivan Stephanovitch (1644–1709), a Cossack chief, best known as the hero of one of Lord Byron's poems, was born in 1644, of a poor but noble family, at Mazepintzui in the palatinate of Podolia. At an early age he became a page at the court of John Casimir, king of Poland. After some time he returned to his native province; but, engaging in an intrigue with a Polish matron of high rank, he was detected by the injured husband, and was sentenced to be bound naked on the back of an untamed horse. The animal on being let loose galloped off to its native wilds of the Ukraine. Mazeppa, half-dead and insensible, was released from his fearful position, and restored to animation by some poor peasants. In a short time his agility, courage, and sagacity rendered him popular among the Cossacks. He was appointed secretary and adjutant to Samoilovitch, their hetman or chief, and succeeded that functionary in 1687. The title of prince was afterwards conferred upon him by his friend and patron, Peter the Great, who long believed confidingly in his good faith, and banished or executed as calumnious traitors all who, like Palei, Kotchubey, and Iskra, ventured to accuse him of conspiring with the enemies of Russia. Bent, however, upon casting off the Russian yoke, Mazeppa became, in his seventieth year, and after much hesitation and inconstancy of purpose, an ally of the Swedish monarch, Charles XII. After the disastrous battle of Pultowa, fought, it is said, by his advice, Baturin, his capital, was taken and sacked by Menshikoff, and his name anathematized throughout the churches of Russia, and his effigy suspended from the gallows. A wretched fugitive, he escaped to Bender, but only to end his life by poison in 1709. Pushkin made Mazeppa the hero of his drama "Pultowa."

MAZZARA DEL VALLO, a city of Italy, on the coast of Sicily, in the province Trapani, 13 miles by rail south-east of Marsala. It is surrounded by a wall 37 feet in height, strengthened by towers rising at intervals; and it possesses a castle and a cathedral, both founded by Count Roger in the 11th century. The harbour is spacious but badly sheltered from the south winds. The population of the city was 11,756 in 1871; that of the commune was 10,999 in 1861 and 13,505 in 1881.

Mazara or Mazaris appears from Diodorus Siculus (xiii. 54) to have been a trading establishment of Selinus, and it was captured by the Carthaginian general in 409 B.C. on his march against that city. It was in this neighbourhood that the Saracens landed in 827 A.D.; and the name of Val di Mazzara long indicated one of the three divisions of Sicily.

MAZZINI, GIUSEPPE (1805–1872), Italian patriot, was born on June 22, 1805, at Genoa, where his father, Giacomo Mazzini, was a physician in good practice, and a professor in the university. His mother is described as having been a woman of great personal beauty, as well as of active intellect and strong affections. During infancy and childhood his health was extremely delicate, and it appears that he was nearly six years of age before he was quite able to walk; long before this, however, he had learned to read, and otherwise begun to show great intellectual precocity. His first tutor was an old priest who taught him Latin, but his omnivorous reading was not directed by any master. At the age of thirteen he began to attend classes in the faculty of arts at the university; he afterwards studied anatomy with a view to following his father's profession, but finally (1826) graduated in laws. Apart from his professional studies, he took lessons in music, English, and fencing. Of his student days little more is recorded than that his exceptional abilities as well as the remarkable generosity and benevolence of his impulses and aims were quickly recognized by his comrades,—his professors, however, having frequent occasion to complain of his disregard for conventional rules. As to his inner life during this period, we have only one brief but significant sentence; "for a short time," he says, "my mind was somewhat tainted by the doctrines of the foreign materialistic school; but the study of history and the intuitions of conscience—the only tests of truth—soon led me back to the spiritualism of our Italian fathers." For some time after his admission as an advocate Mazzini was occupied in the Ufficio dei Poveri; but, although he seems to have discharged the duties arising from this with zeal and success, he never really overcame his repugnance to the dry and technical details of legal practice. The natural bent of his genius was towards literature, and, in the course of the four years of his nominal connexion with the legal profession, he wrote a considerable number of essays and reviews, some of which have been wholly or partially reproduced in the critical and literary volumes of his *Life and Writings*. His first essay, characteristically enough on "Dante's Love of Country," was sent to the editor of the *Antologia Fiorentina* in 1826, but did not appear until some years afterwards in the *Subalpino*. He was an ardent supporter of romanticism as against what he called "literary servitude under the name of classicism"; and in this interest all his critiques (as, for example, that of Giannoni's *Exile* in the *Indicatore Livornese*, 1829) were penned. But in the meantime the "republican instincts" which he tells us he had inherited from his mother had been developing, and his sense of the evils under which Italy was groaning had been intensified; and at the same time he became possessed with the idea that Italians, and he himself in particular, "*could* and therefore *ought* to struggle for liberty of country." His literary articles accordingly became more and more suggestive of advanced liberalism in politics, and led to the suppression by Government of the *Indicatore Genovese* and the *Indicatore Livornese* successively. Having joined the Carbonari, he soon rose to one of the higher grades in their hierarchy, and was entrusted with a special secret mission into Tuscany; but, as his acquaintance grew, his dissatisfaction with the organization of the society increased, and he was already meditating the formation of a new association having closer bonds of union and more definite aims when shortly after the French revolution of 1830 he was betrayed, while initiating a new member, to the authorities of Piedmont. He was imprisoned in the fortress of Savona on the western Riviera for about six months, when, a conviction having been found impracticable through deficiency of evidence, he was released, but upon conditions involving so many restrictions of his liberty that he preferred the alternative of leaving the country. He withdrew accordingly into France, living chiefly in Marseilles. While in his lonely cell at Savona, in presence of "those symbols of the infinite, the sky and the sea," with a greenfinch for his sole companion, and having access to no books but "a Tacitus, a Byron, and a Bible," he had finally become aware of the great mission or "apostolate" (as he himself called it) of his life; and soon after his release his prison meditations took shape in the programme of the organization which was destined soon to become so famous throughout Europe, that of *La Giovine Italia*, or Young Italy. Its publicly avowed aims were to be the liberation of Italy both from foreign and domestic tyranny, and its unification under a republican form of government; the means to be used were education, and, where advisable, insurrection by guerrilla bands; the motto was to be "God and the people," and the banner was to bear on one side the words "Unity" and "Independence" and on the other "Liberty," "Equality," and "Humanity," to describe respectively the national and the international aims. In April 1831 Charles Albert, "the ex-Carbonaro conspirator of 1821," succeeded Charles Felix on the Sardinian throne, and towards the close of that year Mazzini, making himself, as he afterwards confessed, "the interpreter of a hope which he did not share," wrote the new king a letter, published at Marseilles, urging him to take the lead in the impending struggle for Italian independence. Clandestinely reprinted, and rapidly circulated all over Italy, its bold and outspoken words produced a great sensation, but so deep was the offence it gave to the Sardinian Government that orders were issued for the immediate arrest and imprisonment of the author should he attempt to cross the frontier. Towards the end of the same year appeared the important Young Italy "Manifesto," the substance of which is given in the first volume of the *Life and Writings* of Mazzini; and this was followed soon afterwards by the society's *Journal*, which, smuggled across the Italian frontier, had great success in the objects for which it was written, numerous "congregations" being formed at Genoa, Leghorn, and elsewhere. Representations were consequently made by the Sardinian to the French Government, which issued in an order for Mazzini's withdrawal from Marseilles (August 1832); he lingered for a few months in concealment, but ultimately found it necessary to retire into Switzerland. From this point it is somewhat difficult to follow the career of the mysterious and terrible conspirator who for twenty years out of the next thirty led a life of voluntary imprisonment (as he himself tells us) "within the four walls of a room," and "kept no record of dates, made no biographical notes, and preserved no copies of letters." In 1833, however, he is known to have been concerned in an abortive revolutionary movement which took place in the Sardinian army; several executions took place, and he himself was laid under sentence of death. Before the close of the same year a similar movement in Genoa had been planned, but failed through the youth and inexperience of the leaders. At Geneva, also in 1833, Mazzini set on foot *L'Europe Centrale*, a journal of which one of the main objects was the emancipation of Savoy; but he did not confine himself to a merely literary agitation for this end. Chiefly through his agency a considerable body of German, Polish, and Italian exiles was organized, and an armed invasion of the duchy planned. The frontier was actually crossed on February 1, 1834, but the attack ignominiously broke down without a shot having been fired. Mazzini, who personally accompanied the expedition, is no doubt correct in attributing the failure to dissensions with the Carbonari leaders in Paris, and to want of a cordial understanding between himself and the Savoyard Ramorino, who had been chosen as military leader. In April 1834 the "Young Europe" association "of men believing in a future of liberty, equality, and fraternity for all mankind, and desirous of consecrating their thoughts and actions to the realization of that future" was formed, also under the influence of Mazzini's enthusiasm; it was followed soon afterwards by a "Young Switzerland" society, having for its leading idea the formation of an Alpine confederation, to include Switzerland, Tyrol, Savoy, and the rest of the Alpine chain as well. But *La Jeune Suisse* newspaper was compelled to stop within a year, and in other respects the affairs of the struggling patriot became embarrassed. He was permitted to remain at Grenchen in Solothurn for a while, but at last the Swiss diet, yielding to strong and persistent pressure from abroad, exiled him about the end of 1836. In January 1837 he arrived in London, where for many months he had to carry on a hard fight with poverty and the sense of spiritual loneliness so touchingly described by himself in the first volume of the *Life and Writings*. Ultimately, as he gained command of the English language, he began to earn a livelihood by writing review articles, some of which have since been reprinted, and are of a high order of literary merit; they include papers on "Italian Literature since 1830" and "Paolo Sarpi" in the *Westminster Review*, articles on "Lamennais," "George Sand," "Byron and Goethe" in the *Monthly Chronicle*, and on "Lamartine," "Carlyle," and "The Minor Works of Dante" in the *British and Foreign Review*. In 1839 he entered into relations with the revolutionary committees sitting in Malta and Paris, and in 1840 he originated a working men's association, and the weekly journal entitled *Apostolato Popolare*, in which the admirable popular treatise "On the Duties of Man" was commenced. Among the patriotic and philanthropic labours undertaken by Mazzini during this period of retirement in London may be mentioned a free evening school conducted by himself and a few others for some years, at which several hundreds of Italian children received at least the rudiments of secular and religious education. The most memorable episode in his life during the same period was perhaps that which arose out of the conduct of Sir James Graham, the home secretary, in systematically, for some months, opening Mazzini's letters as they passed through the British post-office, and communicating their contents to the Neapolitan Government—a proceeding which brought about the arrest and execution of the brothers Bandiera, Austrian subjects, who had been planning an expedition against Naples. The prolonged discussions in parliament, and the report of the committee appointed to inquire into the matter, did not, however, lead to any practical result, unless indeed the incidental vindication of Mazzini's character, which had been recklessly assailed in the course of debate. Mazzini did not share the enthusiastic hopes everywhere raised in the ranks of the Liberal party throughout Europe by the first acts of Pius IX., in 1846, but at the same time he availed himself, towards the end of 1847, of the opportunity to publish a letter addressed to the new pope, indicating the nature of the religious and national mission which the Liberals expected him to undertake. The leaders of the revolutionary outbreaks in Milan and Messina in the beginning of 1848 had long been in secret correspondence with Mazzini; and their action, along with the revolution in Paris, brought him early in the same year to Italy, where he took a great and active interest in the events which dragged Charles Albert into an unprofitable war with Austria; he actually for a short time bore arms under Garibaldi immediately before the re-occupation of Milan, but ultimately, after vain attempts to maintain the insurrection in the mountain districts, found it necessary to retire to Lugano. In the beginning of the following year he was nominated a member of the short-lived provisional government of Tuscany formed after the flight of the grand-duke, and almost simultaneously, when Rome had, in consequence of the withdrawal of Pius IX., been proclaimed a republic, he was declared a member of the constituent assembly there. A month afterwards, the battle of Novara having again decided against Charles Albert in the brief struggle with Austria, into which he had once more been drawn, Mazzini was appointed a member of the triumvirate, with supreme executive power. The opportunity he now had for showing the administrative and political ability which he was believed to possess was more apparent than real, for the approach of the professedly friendly French troops soon led to hostilities, and resulted in a siege which terminated, towards the end of June, with the assembly's resolution to discontinue the defence, and Mazzini's indignant resignation. That he succeeded, however, for so long a time, and in circumstances so adverse, in maintaining a high degree of order within the turbulent city is a fact that speaks for itself. His diplomacy, backed as it was by no adequate physical force, naturally showed at the time to very great disadvantage, but his official correspondence and proclamations can still be read with admiration and intellectual pleasure, as well as his eloquent vindication of the revolution in his published "Letter to MM. de Tocqueville and De Falloux."

The surrender of the city on June 30 was followed by Mazzini's not too precipitate flight by way of Marseilles into Switzerland, whence he once more found his way to London. Here in 1850 he became president of the National Italian Committee, and at the same time entered into close relations with Ledru-Rollin and Kossuth. He had a hand in the abortive rising at Mantua in 1852, and again, in February 1853, a considerable share in the formidable insurrection which broke out at Milan; once more, in 1854, he had gone far with preparations for renewed action when his plans were completely disconcerted by the withdrawal of professed supporters, and by the action of the French and English Governments in sending ships of war to Naples. The year 1857 found him yet once more in Italy, where, for complicity in short-lived emeutes which took place at Genoa, Leghorn, and Naples, he was again laid under sentence of death. Undiscouraged in the pursuit of the one great aim of his life by any such incidents as these, he returned to London, where he edited his new journal *Pensiere ed Azione*, in which the constant burden of his message to the overcautious practical politicians of Italy was—"I am but a voice crying *Action*; but the state of Italy cries for it also. So do the best men and people of her cities. Do you wish to destroy my influence? *Act.*" The same tone was at a somewhat later date assumed in the letter he wrote to Victor Emmanuel, urging him to put himself at the head of the movement for Italian unity, and promising republican support. As regards the events of 1859–60, however, it may be questioned whether, through his characteristic inability to distinguish between the ideally perfect and the practically possible, he did not actually hinder more than he helped the course of events by which the realization of so much of the great dream of his life was at last brought about. As has been said elsewhere (vol. xiii. p. 487), if Mazzini was the prophet of Italian unity, and Garibaldi its knight errant, to Cavour alone belongs the honour of having been the statesman by whom it was finally accomplished. After the irresistible pressure of the popular movement had led to the establishment not of an Italian republic but of an Italian kingdom, Mazzini could honestly enough write, "I too have striven to realize unity under a monarchical flag," but candour compelled him to add, "The Italian people are led astray by a delusion at the present day, a delusion which has induced them to substitute material for moral unity and their own reorganization. Not so I. I bow my head sorrowfully to the sovereignty of the national will; but monarchy will never number me amongst its servants or followers." In 1865, by way of protest against the still uncancelled sentence of death under which he lay, Mazzini was elected by Messina as delegate to the Italian parliament, but, feeling himself unable to take the oath of allegiance to the monarchy, he never took his seat. In the following year, when a general amnesty was granted after the cession of Venice to Italy, the sentence of death was at last removed, but he declined to accept such an "offer of oblivion and pardon for having loved Italy above all earthly things." In May 1869 he was again expelled from Switzerland at the instance of the Italian Government for having conspired with Garibaldi; after a few months spent in England he set out (1870) for Sicily, but was promptly arrested at sea and carried to Gaeta, where he was imprisoned for two months. Events soon made it evident that there was little danger to fear from the contemplated rising, and the occasion of the birth of a prince was seized for restoring him to liberty. The remainder of his life, spent partly in London and partly at Lugano, presents no noteworthy incidents. For some time his health had been far from satisfactory, but the immediate cause of his death was an attack of pleurisy with which he was seized at Pisa, and which terminated fatally on March 10, 1872. The Italian parliament by a unanimous vote expressed the national sorrow with which the tidings of his death had been received, the president pronouncing an eloquent eulogy on the departed patriot as a model of disinterestedness and self-denial, and one who had dedicated his whole life ungrudgingly to the cause of his country's freedom. A public funeral took place at Pisa on March 14, and the remains were afterwards conveyed to Genoa.

The published writings of Mazzini, mostly occasional, are very voluminous, and have nowhere been exhaustively collected. The fullest edition of them is that begun by himself and continued by Satti (*Scritti editi e inediti di Giuseppe Mazzini*, 10 vols., 1861–80); many of the most important are found in the partially autobiographical work already referred to (*Life and Writings of Joseph Mazzini*, 6 vols., 1864–70), and the two most systematic—"Thoughts upon Democracy in Europe," a remarkable series of criticisms on Benthamism, St-Simonianism, Fourierism, and other economic and socialistic schools of the day, and the treatise "On the Duties of Man," an admirable primer of ethics, dedicated to the Italian working class—will be found in a volume entitled *Joseph Mazzini, a Memoir*, by Mrs E. A. Venturi (London, 1875). Mazzini's "first great sacrifice," he tells us, was "the renunciation of the career of literature for the more direct path of political action," and as late as 1861 we find him still recurring to the long-cherished hope of being able to leave the stormy arena of politics and consecrate the last years of his life to the dream of his youth. He had specially contemplated three considerable literary undertakings,—a volume of *Thoughts on Religion*, a popular *History of Italy*, to enable the working classes to apprehend what he conceived to be the "mission" of Italy in God's providential ordering of the world, and a comprehensive collection of translations of ancient and modern classics into Italian. None of these was actually achieved. No one, however, can read even the briefest and most occasional writing of Mazzini without gaining some impression of the simple grandeur of the man, the lofty elevation of his moral tone, his unwavering faith in the living God, who is ever revealing Himself in the progressive development of humanity. His last public utterance is to be found in a highly characteristic article on Renan's *Réforme Morale et Intellectuelle*, finished on March 3, 1872, and published in the *Fortnightly Review* for February 1874. (J. S. BL.)

MAZZOLA. See PARMIGIANO.

MEAD, RICHARD (1673–1754), physician, was born on August 11, 1673, at Stepney (near London), where his father, at one time minister of the parish, had been ejected for nonconformity in 1662. He was sent to Utrecht, where he studied for three years under Grævius; having decided to follow the medical profession, he then went to Leyden and attended the lectures of Hermann and Pitcairn. In 1695 he graduated in philosophy and physic at Padua, and in the following year he returned to his native place, entering at once on a successful practice. His *Mechanical Account of Poisons* appeared in 1702, and in 1703 he was admitted to the Royal Society, to whose *Transactions* he contributed in that year a paper on the parasitic nature of scabies. In the same year he was also elected physician to St Thomas's Hospital, and appointed to read anatomical lectures at the Surgeons' Hall. On the death of Radcliffe in 1714 Mead became the recognized head of his profession; he attended Queen Anne on her death-bed, and in 1727 was appointed physician to George II., having previously served him in that capacity when he was prince of Wales. He died on February 16, 1754. For his place in the annals of medical science see MEDICINE, p. 811 of the present volume.

Besides the *Mechanical Account of Poisons*, of which a second edition appeared in 1708, Mead published a treatise *De Imperio Solis et Lunæ in Corpora Humana et Morbis inde Oriundis* (1704), *A Short Discourse concerning Pestilential Contagion, and the Method to be used to prevent it* (1720), *De Variolis et Morbillis Dissertatio* (1747), *Medica Sacra, sive de Morbis insignioribus qui in Bibliis memorantur Commentarius* (1748), *On the Scurvy* (1749), and *Monita et Præcepta Medica* (1751). A *Life* of Mead by Dr Maty appeared in 1755.

MEADVILLE, a city of the United States, county seat of Crawford county, Pennsylvania, on the left bank of French Creek, a tributary of the Alleghany river, and at the junction of the Franklin branch with the main line of the New York, Pennsylvania, and Ohio Railroad, 102 miles from Salamanca. It is a well-built town, maintains a large trade with the oil regions, and has railway and other machine works, glass works, woollen mills, and paper mills. The Meadville theological school was established by the Unitarians in 1844; and Allegheny College, opened in 1816 as a Presbyterian Church institution, has been carried on since 1833 by the Methodist Episcopal Church. Meadville was founded by General David Mead as a fortified post in 1789. In 1816 it had only 400 inhabitants; but the number was 3702 in 1860, 7103 in 1870, and 8860 in 1880.

MEASLES (*Morbilli*, *Rubeola*; German, *Masern*; French, *Rougeole*), an acute infectious disease occurring mostly in children. It appears to have been known from an early period in the history of medicine, mention being made of it in the writings of Rhazes and others of the Arabian physicians in the 10th century. For long, however, its specific nature was not recognized, and it was held to be a variety of small-pox. After the non-identity of these two diseases had been established, measles and scarlet fever continued to be confounded with each other; and in the account given by Sydenham of epidemics of measles in London in 1670 and 1674 it is evident that even that accurate observer had not as yet clearly perceived their pathological distinction, although it would seem to have been made a century earlier by Ingrassias, a physician of Palermo. It is only within a comparatively recent period that measles has come to be universally regarded as a distinct and independent malady.

Like the other eruptive fevers (exanthemata), to which class of diseases measles belongs, its progress is marked by several stages more or less sharply defined.

After the reception of the contagion into the system a period of incubation or latency precedes the development of the disease, during which scarcely any disturbance of the health is perceptible. This period appears to vary in duration, but it may be stated as generally lasting for from ten to fourteen days, when it is followed by the invasion of the symptoms specially characteristic of measles. These consist in the somewhat sudden onset of acute catarrh of the mucous membranes. Sneezing, accompanied with a watery discharge, sometimes bleeding, from the nose, redness and watering of the eyes, cough of a short, frequent, and noisy character, with little or no expectoration, hoarseness of the voice, and occasionally sickness and diarrhœa, are the chief local phenomena of this stage. But along with these there is well-marked febrile disturbance, the temperature being elevated (102°–104° F.), and the pulse rapid, while headache, thirst, and restlessness are usually present to a greater or less degree. In some instances, however, these initial symptoms are so slight that they almost escape notice, and the child is allowed to associate with others at a time when, as will be afterwards seen, the contagion of the disease is most active. In rare cases, especially in young children, convulsions usher in, or occur in the course of, this stage of invasion, which lasts as a rule for four or five days, the febrile symptoms, however, showing some tendency to undergo abatement after the second day. On the fourth or fifth day after the invasion, sometimes later, rarely earlier, the characteristic eruption appears on the skin, being first noticed on the brow, cheeks, chin, also behind the ears, and on the neck. It consists of small spots of a dusky red or crimson colour, slightly elevated above the surface, at first isolated, but tending to become grouped together into patches of irregular, occasionally crescentic, outline, with portions of skin free from the eruption intervening. The face acquires a swollen and bloated appearance, which, taken along with the catarrh of the nostrils and eyes, is almost characteristic, and renders the diagnosis at this stage a matter of no difficulty. The eruption spreads downwards over the body and limbs, which are soon thickly studded with the red spots or patches. Sometimes these become confluent over a considerable surface, giving rise to a larger area of uniform redness. The rash continues to come out for two or three days, and then begins to fade in the order in which it first showed itself, namely, from above downwards. By the end of about a week after its first appearance scarcely any trace of the eruption remains beyond a faint staining of the skin. Occasionally during convalescence slight peeling of the epidermis takes place, but much less frequently and distinctly than is the case in scarlet fever. At the commencement of the eruptive stage the fever, catarrh, and other constitutional disturbance, which were present from the beginning, become aggravated, the temperature often rising to 105° or more, and there is headache, thirst, furred tongue, and soreness of the throat, upon which red patches similar to those on the surface of the body may be observed. These symptoms usually decline as soon as the rash has attained its maximum, and often there occurs a sudden and extensive fall of temperature, indicating that the crisis of the disease has been reached. In favourable cases convalescence proceeds rapidly, the patient feeling perfectly well even before the rash has faded from the skin.

Measles may, however, occur in a very severe or malignant form, in which the symptoms throughout are of urgent character, the rash but feebly developed, and of dark purple hue, while there is great prostration of strength, accompanied with intense catarrh of the respiratory or gastro-intestinal mucous membrane. Such cases, always of serious import, are happily rare, occurring mostly in circumstances of bad hygiene, both as regards the individual and his surroundings. On the other hand, cases of measles are often met with of so mild a form throughout that the patient can scarcely be persuaded to submit to treatment.

Measles as a disease derives its chief importance in the view of medical men from the risk, by no means slight, of certain complications which are apt to arise during its course, more especially inflammatory affections of the respiratory organs. These are most liable to occur in the colder seasons of the year and in very young and delicate children. It has been already stated that irritation of the respiratory passages is one of the symptoms characteristic of measles, but that this subsides with the decline of the eruption. Not unfrequently, however, these symptoms, instead of abating, become aggravated, and bronchitis of the capillary form (see BRONCHITIS), or pneumonia, generally of the diffuse or lobular variety (see PNEUMONIA), impart a gravity to the case which it did not originally possess. By far the greater proportion of the mortality in measles is due to its complications, of which those just mentioned are the most common, but which also include inflammatory affections of the larynx, with attacks resembling croup, and also diarrhœa assuming a dysenteric character. Or there may remain as direct results of the disease chronic ophthalmia, or discharge from the ears, with deafness, and occasionally a form of gangrene affecting the tissues of the mouth or cheeks and other parts of the body, leading to disfigurement and even endangering life.

Apart, however, from those immediate risks, it deserves to be borne in mind that in measles there appears to be a tendency in many cases for the disease to leave behind a weakened and vulnerable condition of the general health, which may render children, previously robust, delicate and liable to chest complaints, and is in not a few instances the precursor of some of those tubercular affections to which the period of childhood and youth is liable.

These various effects or sequelæ of measles plainly indicate that although in itself a comparatively mild ailment, it cannot safely be regarded with indifference. Indeed it is doubtful whether any other disease of early life demands more careful watching as to its influence on the health. Happily many of those attending evils now alluded to may by proper management be averted.

Measles is a disease of the earlier years of childhood. Like other infectious maladies, it is admittedly rare, though not unknown, in nurslings or infants under six months old. It is comparatively seldom met with in adults, but this is simply due to the fact that most persons have undergone an attack in early life, since, where this has not been the case, the old suffer equally with the young. All races of men appear liable to this disease, provided that which constitutes the essential factor in its origin and spread exists, namely, contagion. Some countries enjoy long immunity from outbreaks of measles, but it has frequently been found in such cases that when the contagion has once been introduced the disease extends with great rapidity and virulence. This was shown in two well-known instances in recent times,—namely, the epidemic in the Faroe Islands in 1846, where, within six months after the arrival of a single case of measles, more than three-fourths of the entire population were attacked and many perished; and the similarly produced and still more destructive outbreak in Fiji in 1875, in which it was estimated that about one-fourth of the inhabitants were cut off by the disease within a period of about three months (see FIJI). In both these cases the great mortality has been ascribed to the complications of the malady, specially induced by over-crowding, by insanitary surroundings, the absence of proper nourishment and nursing for the sick, and the utter prostration and terror of the people, rather than to any marked malignancy in the type of the disease.[1] Not a few authorities, however, while fully recognizing the baneful effect of these unfavourable conditions, are yet disposed to hold that epidemics of this kind, when occurring in what might be termed a virgin soil, are apt to possess an innate severity. In many lands, such as the United Kingdom, measles is rarely absent, especially from large centres of population, where sporadic cases are found in greater or less number at all seasons. Every now and then epidemics arise from the extension of the disease among those members of a community who have not been in some measure protected by a previous attack. There are few diseases so contagious as measles, and its rapid spread in epidemic outbreaks is no doubt due to the well-ascertained fact that contagion is most potent in the earlier stages, even before its real nature has been evinced by the characteristic appearances on the skin. Hence the difficulty of timely isolation, and the readiness with which the disease is spread in schools and families. There is little doubt too that the contagion may be carried from one place to another by persons themselves unaffected, as well as by clothing, &c., although its tenacity and activity in this respect is apparently much less marked than that of small-pox or scarlet fever. Of the nature of the infecting agent nothing certain is known. Recent investigations into the mode of origin of others of the acute infectious diseases, and the discovery in the blood and tissues in the case of some of them of lower forms of organic life (bacilli), which can be isolated and can by inoculation be made to communicate the particular malady to which they are related, give countenance to the opinion, now widely entertained, that the infecting principle of the exanthemata is of this nature. The subject, however, is still under investigation, and more information is wanting before definite statements can be made. Second attacks of measles are occasionally observed, but they are rare.

[1] *Transactions of the Epidemiological Society.* London, 1877.

Treatment.—The treatment of measles embraces the preventive measures to be adopted in the case of an outbreak by the isolation of the sick at as early a period as possible. Epidemics have often, especially in limited localities, been curtailed by such a precaution. In families with little house accommodation this measure is frequently, for the reason already referred to regarding the communicable period of the disease, ineffectual; nevertheless where practicable it ought to be tried, for it is a grave error needlessly to expose the healthy children in a family to the risk of infection under the idea that they must necessarily take the disease at some time or other. The unaffected children should likewise be kept from school for a time (probably about three weeks from the outbreak in the family would suffice if no other case occur in the interval), and all clothing in contact with the patient should be subjected to disinfection or thorough washing. In extensive epidemics it is often desirable to close the schools of a locality for a time. As regards special treatment, in an ordinary case of measles little is required beyond what is necessary in febrile conditions generally. Confinement to bed in a somewhat darkened room, into which, however, air is freely admitted in such a manner as to avoid the risk of draughts, light nourishing liquid diet (soups, milk, &c.), and mild diaphoretic remedies such as the acetate of ammonia or ipecacuanha, are all that is necessary in the febrile stage. When the catarrhal symptoms are very severe, the hot bath or warm packing to the body generally or to the chest and throat afford relief, and the same measures may with advantage be adopted should the eruption be but feebly developed or tend to recede, and especially should convulsions set in. The serious chest complications of measles are to be dealt with by those measures applicable for the relief of the particular symptoms (see BRONCHITIS, PNEUMONIA). The inhalation of vapour and the use of the preparations of ammonia are of special efficacy. Diarrhœa is treated by the usual remedies, including carefully administered doses of Dover's powder, chalk, &c. During convalescence the patient must be guarded from exposure to cold, and for a time after recovery the state of the health ought to be watched with the view of averting the evils, both local and constitutional, which but too often follow this disease.

German Measles (*Rötheln*, or *Epidemic Roseola*) is a term applied to a contagious eruptive disorder having certain points of resemblance to measles, and, according to some observers, also to scarlet fever, but exhibiting its distinct individuality in the fact that it protects from neither of these diseases. It occurs most commonly in children, and is occasionally seen in extensive epidemics. Beyond confinement to the house in the eruptive stage, which, from the slight symptoms experienced, is often difficult of accomplishment, no special treatment is called for. There is little doubt that the disease is often mistaken for true measles, and many of the alleged second attacks of the latter malady are probably cases of rötheln. The chief points of difference are the following:—

1. The absence of distinct premonitory symptoms, the stage of invasion, which in measles is usually of four days' duration, and accompanied with well-marked fever and catarrh, being in rötheln either wholly absent or exceedingly slight, enduring only for one day.

2. The eruption of rötheln, which, although as regards its locality and manner of progress similar to measles, differs somewhat in its appearance, the spots being of smaller size, paler colour, and with less tendency to grouping in crescentic patches. The rash attains its maximum in about one day, and quickly disappears. There is no accompanying increase of temperature in this stage as in measles.

3. The milder character of the symptoms of rötheln throughout its whole course, and the absence of complications and of liability to subsequent impairment of health such as have been seen to appertain to measles. (J. O. A.)

MEASUREMENT. We propose in the first place to enter into some detail on the fundamental principles of the theory of measurement, and in doing so it will be necessary to sketch the very remarkable theory established by Riemann and other mathematicians as to the foundations of our geometrical knowledge.

Every system of geometrical measurement, as indeed the whole science of geometry itself, is founded on the possibility of transferring a fixed figure from one part of space to another with unchanged form. We are so familiar with this process that we are apt not to realize its importance until very special attention has been directed to the subject. We therefore propose to make a logical examination of the nature of the assumptions involved in the possibility of moving a figure in space so that it shall undergo no alteration. We shall find that we require to postulate certain suppositions with regard to the nature of space and to the measurement of distances.

It will facilitate the conception of this somewhat difficult subject to consider the case of hypothetical reasoning beings which Sylvester described as being infinitely attenuated bookworms confined to infinitely thin sheets of paper. We suppose such two-dimensional beings to be absolutely limited to a certain surface. They could have no conception of space except as of two dimensions. The movement of a point would for them form a line, the movement of a line would form a surface. They could conduct their measurements and form their geometrical theories. They would be able to draw the shortest lines between two points, these lines being what we would call geodesics. To these two-dimensioned geometers geodesics would possess many of the attributes of straight lines in ordinary space. If the surface to which the beings were confined were actually a plane, then the geometry would be the same as our geometry. They would find that only one straight line could be drawn between two points, that through a point only one parallel to a given line could be drawn, and that the ends of a line would never meet even though the line be prolonged to infinity.

We might also suppose that intelligent beings could exist on the surface of a sphere. Their straightest line between two points would be the arc of the great circle joining those two points. They would also find that a second geodesic could be drawn joining the two points, this being of course the remaining part of the great circle. A curious exception would, however, be presented by two points diametrically opposite. An infinite number of geodesics can be drawn between these points and all those geodesics are of equal length. The axiom that there is one shortest line between two given points would thus not hold without exception. There would be no parallel lines known to the dwellers on the sphere. It would be found by them that every two geodesics must intersect, not only in one, but even in two points. The sum of the three angles of a triangle would for them not be constant. It would always be greater than two right angles, and would increase with the area of the triangle. They would thus have no conception of similarity between two geometrical figures of different sizes. If two triangles be constructed which have their sides proportional, the angles of the larger triangle would be greater than the corresponding angles of the smaller triangle.

It is thus plain that the geometrical axioms of the sphere-dwellers must be very different from those of the plane-dwellers. The different axioms depend upon the different kinds of space which they respectively inhabit, while their logical powers are identical. In one sense, however, the dwellers on the sphere and on the plane have an axiom in common. In each case it will be *possible for a figure to be moved about without alteration of its dimensions.* A spherical triangle can be moved on the surface of a sphere without distortion just as a plane triangle may be moved in a plane. The sphere-dwellers and the plane-dwellers would be equally able to apply the test of congruence. It is, however, possible to suppose reasoning beings confined to a space in which the translation of a rigid figure is impossible. Take, for instance, the surface of an ellipsoid or even a spheroid such as the surface of the earth itself. A triangle drawn on the earth at the equator could not be transferred to the surface of the earth near the pole and still preserve all its sides and all its angles intact.

If a surface admits of a figure being moved about thereon so as still to retain all its sides and all its angles unaltered, then that surface must possess certain special properties. It can be shown that, if a surface is to possess this property, a certain function known as the "measure of curvature" is to be constant. The measure of curvature is the reciprocal of the product of the greatest and least radii of curvature. We do not now enter into the proof, but it is sufficiently obvious that a sphere of which the radius is the geometric mean between the greatest and least radii of curvature at each point will to a large extent osculate the surface, so that a portion of the surface in the neighbourhood of the point will, generally speaking, have the same curvature as the sphere. If the sphere thus determined be the same at all the different points of the surface, then the curvature of the different parts of the surface will on the whole resemble that of the sphere, and therefore we cannot be surprised that the surface possessing this property will admit the displacement of a rigid figure thereon without derangement of its form.

We are thus conducted to a kind of surface the geometry of which is similar to that of the plane, but in which the axiom of parallels does not hold good. In this surface the radii of curvature at every point have opposite signs, so that the measure of curvature which is zero for the plane and positive for the sphere is negative for the surface now under consideration. This surface has been called the "pseudosphere," and its nature has been investigated by Beltrami.[1] In the geometry of two dimensions we can thus have either a plane or a sphere or a pseudosphere which are characterized by the property that a surface may be moved about in all directions without any change either in the lengths of its lines or in the magnitudes of its angles. The axiom which assumes that there is only one geodesic connecting two points marks off the plane and the pseudosphere from the sphere. The axiom that only one parallel can be drawn through a given point to a given line marks off the plane from the pseudosphere. The geometry of Euclid is thus specially characterized among all conceivable geometries of two dimensions by the following three axioms—(1) the mobility of rigid figures, (2) the single geodesic between two points, (3) the existence of parallels.

A very interesting account of this theory will be found in Clifford's *Lectures and Essays*, vol. i. p. 317. We shall follow to some extent the method employed by him in order to obtain an idea of the important conception which is called the "curvature of space." Suppose a geodesic be drawn on a surface of constant curvature. Then a piece of the surface adjoining this geodesic can be slid along the curve so as all the time to fit in close contact therewith. If the piece of surface be turned to the other side of the geodesic it will still fit along this side. A

[1] *Saggio di Interpretazione della Geometria non-Euclidea*, Naples, 1868; "Teoria fondamentale degli sparii di curvatura constante," *Annali di Matematica*, ser. ii. tom. ii. pp. 232–55. Both papers have been translated into French by J. Houël (*Annales Scientifiques de l'École Normale*, tom. v., 1869). An exceedingly interesting account of the whole subject will be found in Helmholtz, *Popular Lectures on Scientific Subjects*, translated by Atkinson, second series, London, 1881, pp. 27–71.

line possessing this property is called by Leibnitz a straight line. It can be easily shown that a geodesic drawn on a figure will also be a geodesic when the figure is transferred to any other position. Suppose that the figure be divided into two parts A and B by the geodesic; then the part B can be moved round so as to lie upon A, and the boundary lines of the two portions will be coincident. Now let the two parts while superposed be translated to any other position, then the piece B may be slid off and back to its original position with regard to A. It must still fit, because the whole figure might have been translated before the subdivision took place. It follows that the division between A and B having been a geodesic in its original position will continue to be a geodesic however the figure may be translated.

In a similar way we obtain the conception of a plane. According to Leibnitz's definition a plane is a surface such that if a portion of the space contiguous thereto be slid along the surface it will continuously fit, and if the portion of space be transferred to the other side of the surface it will fit also. This definition has no meaning except we assume that the bodies may be translated in space without derangement of their dimensions. From any point we can imagine a doubly infinite number of geodesics radiating in all directions; if a plane be drawn through the point, then all the geodesics touching the plane at that point form what may be called a "geodesic surface." It is shown that geodesic surfaces of this description can alone fulfil the conditions by which planes are to be defined. A doubly infinite number of geodesic surfaces can be drawn through every point. If a rigid body be divided into two parts by a geodesic plane, then no matter how the body be displaced the plane of section will still be geodesic. The plane of section may be made to pass through any point, and the body may then be given such an aspect as shall cause the section to coincide with any geodesic surface through the point, but this necessarily involves that the section shall fit each geodesic surface, in other words, that *all the geodesic surfaces shall have a constant curvature.*

The point which we have now gained is one of very great importance. In our ordinary conceptions of space the geodesic surfaces are of course our ordinary planes, and the common curvature they possess is zero, but the condition that rigid bodies shall be capable of translation with unaltered features does not require that the curvatures shall be zero, it merely requires that the curvatures shall be constant. If we add, however, the postulate of similarity, then the curvatures must be zero. The postulate of similarity requires that it shall be possible to construct a figure on any scale and anywhere similar to a given figure. This practically includes the ordinary doctrine of parallels. Lobatchewsky developed the system of geometry on the supposition that the space had a constant curvature different from zero. In this geometry the parallels can be drawn through a given point to a given line, and, to quote Clifford—

> "The sum of the three angles of a triangle is less than two right angles by a quantity proportional to the area of the triangle. The whole of this geometry is worked out in the style of Euclid, and the most interesting conclusions are arrived at, particularly in the theory of solid space, in which a surface turns up which is not plane relatively to that space but which for the purpose of drawing figures upon it is identical with the Euclidean plane."

The most comprehensive mode of viewing the whole theory is that adopted by Riemann in his celebrated memoir "Ueber die Hypothesen welche der Geometrie zu Grunde liegen," 1854 (*Abhandl. der königl. Gesellsch. zu Göttingen*, vol. xiii.).[1] The analytical treatment of this subject possesses one obvious advantage. The use of symbols only admits of deductions on purely logical principles. There is not therefore the risk of tacitly introducing other axioms in addition to those with which we started.

Magnitudes which have only one dimension present the theory of measurement in its simplest form. The length of a straight line may be taken as an illustration of a one-dimensioned magnitude. The velocity of a moving particle, the temperature of a heated body, the electric resistance of a metal, all these and many others are instances of one-dimensioned magnitude, the measure of which is to be expressed by a single quantity. But there may be magnitudes which require more than a single measurement for their complete specification. Take, for instance, a four-sided field which has been duly surveyed. Of what is the measurement of this field to consist? If the number of acres in the field be all that is required then the area is expressed by a simple reference to a number of standard acres. If, however, the entire circumstances of the field are to be brought into view, then a simple statement of the area is not sufficient. It can be easily shown that the surveyor must ascertain five independent quantities before the details of the shape of the field can be adequately defined. Four of these quantities may naturally be the lengths of the four sides of the field, the fifth may be one of the angles, or the area, or the length of one of the diagonals. Speaking generally, we may say that five distinct measurements will be necessary to define the field adequately. The actual choice of the particular measurements to be made is to a great extent arbitrary. The only condition absolutely necessary is that they shall be all independent and free from ambiguity. Once these five quantities are ascertained then all the other features of the figure are absolutely determined. For instance, the four sides and the diagonal being ascertained by measurement, then the other diagonal, the four angles, and the area can all be computed by calculation. The five quantities would determine everything about the field except its actual position on the surface of the earth. If we further desired to have the field exactly localized certain other quantities must be added. The latitude and the longitude of one specified corner of the field would completely indicate that corner, while the azimuth of one side from that corner would complete the definition of its position. We are thus led to see that for the complete delineation of every circumstance relating to the shape of the field and its locality eight different measurements have been required. Two sets of eight measurements differing in any particular can never indicate the same field. It is very important to notice that the *number* of quantities required is quite independent of the particular nature of the measurements adopted. We might for instance have simply measured the latitude and the longitude of each of the four corners of the field. Once these quantities are known, then the shape of the field, its area, its angles, and its diagonals have all been implicitly determined. Here again we see that as two quantities are required to localize each of the four corners, so eight quantities will be required to fully determine the whole field.

In the operations of analytical geometry we are accustomed to specify the position of a point by the relation which it bears to certain fixed axes. By means of certain quantities, either altogether linear or partly linear and partly angular, we are enabled to specify the position of the point with absolute definiteness. These quantities

[1] A translation of this paper was published by Clifford in *Nature* (vol. viii. Nos. 183, 184, pp. 14–17, 36, 37), and has been reprinted in the collected edition of Clifford's *Works*, 1882, pp. 55–69. For a bibliography of higher-space and non-Euclidean geometry, see articles by George Bruce Halsted in the *American Journal of Mathematics Pure and Applied*, i. 261–276, 384, 385; ii. 65–70.

are called the coordinates of the point. In a similar though more extended sense we may use the word "coordinates" to express the group of eight magnitudes which we have found to be adequate to the complete specification of the field. By the measurement of the field in the most complete sense of the term we mean the measurement of its eight coordinates.

Suppose that an object is completely specified by n coordinates, then every different group of n coordinates will specify a different object. The entire group of such objects will form what is called a continuously extended manifoldness. The singly extended manifoldness may be most conveniently illustrated by the conception of time, the various epochs of which are the elements in the manifoldness. Space is a triply extended manifoldness whereof the elements are points. All conceivable spheres form a quadruply extended manifoldness. All conceivable triangles in space form a manifoldness of nine dimensions. The number of coordinates required to specify the position of an element in a manifoldness is thus equal to the order of the manifoldness itself. It is important to observe that the elements of the manifoldness may be themselves objects of no little complexity. Thus, for instance, the conics forming a confocal group constitute the elements of a singly extended manifoldness.

The essential feature of a singly extended manifoldness is that a continuous progress of an element can take place only in two directions, either forwards or backwards. But a singly extended manifoldness may be regarded as itself an element in a manifoldness of a higher order. Thus the points on a circle form a singly extended manifoldness, while the circle itself is one element of the manifoldness which consists of a series of concentric circles. The system of concentric circles may in like manner be regarded as an element in the manifoldness which embraces all systems of concentric circles whose centres lie along a given line. We are thus led to conceive of a multiply extended manifoldness as made up by the successive composition of singly extended manifoldnesses.

It follows from the conception of a manifoldness that in the case of a singly extended manifoldness the position of every element must be capable of being completely specified by a single quantity. It becomes natural to associate with each element of the manifoldness a special numerical magnitude. These magnitudes may vary from $-\infty$ to $+\infty$; to each magnitude will correspond one element of the manifoldness, and conversely each element of the manifoldness is completely specified whenever the appropriate number has been assigned. It is quite possible to have this association of numerical magnitude with the actual position of an element independent of any ordinary metrical relations of the system; it will, however, most usually be found that the numerical magnitudes chosen are such as admit of direct interpretations for the particular manifoldness under consideration. Thus, for instance, in the case of the system of concentric circles it will be natural to associate with each circle its radius, and the position of each circle in the manifoldness will thus be completely defined by the radius. So also in the case of that singly extended manifoldness which consists of colours, it will be natural to employ as the number which specifies each particular colour the wave-length to which that particular colour corresponds.

If the elements of such a manifoldness can receive a simultaneous displacement, then it is plain that to each element in the original position will correspond an element in the second position. Let x and y be the numerical magnitudes correlated to these two elements. Then, since the relation must be of the one-to-one type, it is necessary that the magnitudes x and y must be connected by an equation of the type

$$axy + bx + cy + d = 0.$$

It follows from this that there are a pair of elements which are common to both systems, for if $x = y$ we have the equation

$$ax^2 + (b+c)x + d = 0.$$

The original equation may be written in the form

$$axy + (b-\omega)x + (c+\omega)y + d = 0,$$

and whatever value ω may have this equation will lead to the same quadratic for the two common elements. We thus have a singly infinite number of displacements which are compatible with the condition that the two fundamental elements shall remain unaltered, and it is displacements of this kind which express the movements of a rigid system.

The position of a point is to be defined by three coordinates. In our ordinary conception of coordinates the position of the point is defined by certain measurements, and thus it would seem that the very mention of coordinates had already presupposed the idea of distance. This, however, need not be the case. We can assume a point in space to be completely defined by three purely numerical quantities. It will be supposed that to each group of three coordinates corresponds one point, and that conversely to one point will correspond three coordinates and no ambiguity is to be present. This latter consideration will exclude from our present view such cases as those where the position of a point is defined by a line and two angles, because angles are subject to a well-known ambiguity amounting to any even multiple of π. In this case it would not be true that to one point corresponds one set of coordinates, although the converse may be correct.

It is necessary to understand clearly the nature of the suppositions which are made with regard to space by this assumption. Let x, y, z and x', y', z' be the coordinates of two points a and a'. Now x, y, z can change continuously by any law into x', y', z'. Each intermediate stage will give the coordinates of a point. It must thus be possible to pass continuously in an infinite number of ways from the point a to the point a'. We thus assume that space is continuous when we have assumed that its points are represented by coordinates. It must be observed that we predicate nothing as to space which is not involved in the fact that to each point corresponds one group of three coordinates. To some extent the considerations now before us will apply to any other continuous manifoldness which requires three coordinates for the complete specification of its elements. Take, for instance, a musical note. It can be specified accurately by its pitch, intensity, and timbre. These three quantities may be regarded as the three coordinates which will discriminate one sound from the rest. The manifoldness comprising all musical notes is, however, very different from the manifoldness which embraces all the points of space. Each of these manifoldnesses is no doubt continuous, and each of them is of three dimensions, but the conception of distance can have no place in the musical manifoldness. This is due to the absence from the musical manifoldness of anything parallel with the conception of rigidity in the space manifoldness. These remarks will show that the conception of "distance" is something of a special type even in a three-dimensioned continuous manifoldness.

There are also other three-dimensioned and continuous manifoldnesses from which the conception of distance is also absent. Take, for instance, the manifoldness which embraces all the circles that can lie in a given plane. The points of such a manifoldness are the circles. It is three-dimensioned, for two coordinates will be required for the centre of each circle and one for its radius. It is obviously a continuous manifoldness, for one circle may by infinitely graduated modifications pass into any other. Yet from this manifoldness also the conception of distance is absent. There is no intelligible relation of one circle to another which is analogous to the distance which we require to determine.

We shall now give the investigation of Helmholtz, by which the analytical form of the function expressing the distance is to be ascertained (*Göttingen Nachrichten*, 1868, pp. 193 *sq.*).

It must be remembered that our definition of a point will be purely analytical. Suppose three different scales of pure quantity each extending from $-\infty$ to $+\infty$. Each of these scales is perfectly continuous, so that, no matter how close any two elements in the scale may be, it is always possible to conceive the insertion of an infinite number of intermediate elements. A point is to be defined for our present purpose as a group of three numerical magnitudes taken one from each of the three scales. This conception may be stated more generally. We can conceive n different numerical scales. Then a group of n numbers, one from each scale, will define an element of a continuous n-fold manifoldness.

It will be obvious that unless the theory of distance possess a special character it will not be possible for a rigid body to exist. Take, for instance, five points in a rigid body ABCDE. There are ten different pairs of points and ten corresponding distances; all these ten distances must remain unchanged when the body is displaced. We may assume the position of A arbitrarily. Then after the dislpacement B must be placed at the right distance from A, but will only be limited by this condition to a certain surface, C must be placed at the right distance from A and from B, thus C will be limited to a certain curve. D must be placed at the proper distances from A, from B, and from C. These conditions will be sufficient to define D with complete definiteness. In the same way E will be completely defined by its distances from A, B, and C, but as D and E are thus fully defined we have no guarantee that the distance DE shall retain, after the translation, the same value which it had before. This then indicates that the function which is to express the distance must have a very special form. Any arbitrary function of the six coordinates of the two points would in general not fulfil the condition that the distance DE after the transformation will retain the same value as it had before. If a greater number of points than five be taken, the conditions which a rigid system must fulfil become still more numerous.

Let x, y, z be the coordinates of a point in a rigid body free to rotate around a point. We shall assume that x, y, z is in the vicinity of the fixed point, and that the displacement of the body is such that a second point remains unaltered. In other words, the displacement is to be a rotation around a line joining the two points, and we shall also assume that when this rotation has been completed every point will be restored to its original position. Let η be the angle of rotation around the axis, then x, y, z will all be functions of η, and we may assume that the following equations will hold—

$$\frac{dx}{d\eta}=a_0x+b_0y+c_0z$$

$$\frac{dy}{d\eta}=a_1x+b_1y+c_1z$$

$$\frac{dz}{d\eta}=a_2x+b_2y+c_2z\,.$$

In the first place it is plain that these differential coefficients must be functions of x, y, z, and, these functions being expanded in ascending powers, we may omit all powers above the first. It will also be obvious that the absolute terms must be zero as the origin is by hypothesis to be a fixed point. As the displacement is a rotation, it follows that the differential coefficients must be zero for certain values of x, y, z different from zero, but this involves the condition

$$\begin{vmatrix} a_0, & b_0, & c_0 \\ a_1, & b_1, & c_1 \\ a_2, & b_2, & c_2 \end{vmatrix}=0\,.$$

We now proceed to solve the three linear differential equations by the well-known process. If we multiply the three equations by l, m, n respectively, and if we determine l, m, n so that

$$lh=la_0+ma_1+na_2$$

$$mh=lb_0+mb_1+nb_2$$

$$nh=lc_0+mc_1+nc_2,$$

where h is another constant determined by the equation

$$\begin{vmatrix} a_0-h, & a_1, & a_2 \\ b_0, & b_1-h, & b_2 \\ c_0, & c_1, & c_2-h \end{vmatrix}=0\,,$$

the differential equations then give

$$\frac{d}{d\eta}(lx+my+nz)=h(lx+my+nz),$$

whence $$lx+my+nz=Ce^{h\eta}.$$

We have already seen that one of the values of h must be zero, whence if the other values be h_1 and h_2 we have the three equations

$$l_0x+m_0y+n_0z=A$$

$$l_1x+m_1y+n_1z=Be^{h_1\eta}$$

$$l_2x+m_2y+n_2z=Ce^{h_2\eta}.$$

It is plain that h_1 and h_2 cannot be real quantities, for then the quantities $l_1x+m_1y+n_1z$ and $l_2x+m_2y+n_2z$ could attain any values from $-\infty$ to $+\infty$ according to the variations in η. If h_1 and h_2 are imaginary then will also the corresponding values of l, m, n be imaginary. We therefore write

$$h_1=\theta+\omega i \qquad h_2=\theta-\omega i$$

$$l_1=\lambda_0+\lambda_1 i \qquad l_2=\lambda_0-\lambda_1 i$$

$$m_1=\mu_0+\mu_1 i \qquad m_2=\mu_0-\mu_1 i$$

$$n_1=\nu_0+\nu_1 i \qquad n_2=\nu_0-\nu_1 i$$

so that $$\lambda_0x+\mu_0y+\nu_0z=Ae^{\theta\eta}\cos(\omega y+c)$$

$$\lambda_1x+\mu_1y+\nu_1z=Ae^{\theta\eta}\sin(\omega y+c);$$

in which case we have

$$(\lambda_0x+\mu_0y+\nu_0z)^2+(\lambda_1x+\mu_1y+\nu_1z)^2=Ae^{2\theta\eta}.$$

But it is plain that unless θ be zero the left-hand side of this equation will be susceptible of indefinite increase, which is contrary to our hypothesis. We are therefore entitled to assume that $\theta=0$. The two roots of the cubic for h must, therefore, be pure imaginaries, and thus we have the condition

$$a_0+b_1+c_2=0\,.$$

Finally we have for the determination of x, y, z the following three equations :—

$$l_0x+m_0y+n_0z=\text{const.}$$

$$\lambda_0x+\mu_0y+\nu_0z=A\cos(\omega y+c)$$

$$\lambda_1x+\mu_1y+\nu_1z=A\sin(\omega y+c)\,.$$

It will simplify the subsequent calculations if we now make such a transformation of the coordinates as will enable us to write

$$X=l_0x+m_0y+n_0z$$

$$Y=\lambda_0x+\mu_0y+\nu_0z$$

$$Z=\lambda_1x+\mu_1y+\nu_1z\,.$$

We shall then have from the results just obtained

$$\frac{dX}{d\eta}=0$$

$$\frac{dY}{d\eta}=-\omega Z$$

$$\frac{dZ}{d\eta}=+\omega Y\,.$$

The movement corresponding to η is such as leaves unaltered all points of which the Y and the Z are equal to zero.

Let us now suppose another displacement to be given to the system by a rotation η' about another axis so chosen that all the points for which $X=0$ and $Z=0$ shall remain unaltered. For this condition to be fulfilled we must have the equation

$$\frac{dX}{d\eta'}=\alpha_0X+0+\nu_0Z$$

$$\frac{dY}{d\eta'}=\alpha_1X+0+\nu_1Z$$

$$\frac{dZ}{d\eta'}=\alpha_2X+0+\nu_2Z\,,$$

for then each side of these equations will be equal to zero for points which make X and Z zero. The condition that the roots of h shall be purely imaginary gives us

$$\alpha_0+\nu_2=0\,.$$

If the body receives both the rotation η and the rotation η' then the joint effect of these two rotations must be equal to that of a single rotation ϕ, so that

$$\frac{dX}{d\phi}=\frac{dX}{d\eta}+\frac{dX}{d\eta'}$$
$$\frac{dY}{d\phi}=\frac{dY}{d\eta}+\frac{dY}{d\eta'}$$
$$\frac{dZ}{d\phi}=\frac{dZ}{d\eta}+\frac{dZ}{d\eta'};$$

or uniting the two sets of equations we have

$$\frac{dX}{d\phi}=\alpha_0X+0\ \ +\nu_0Z$$
$$\frac{dY}{d\phi}=\alpha_1X+0\ \ +(\nu_1-\omega)Z$$
$$\frac{dZ}{d\phi}=\alpha_2X+\omega Y+\nu_2Z\,.$$

As this movement must also be a rotation, the three right-hand members must be capable of being rendered zero for certain values of X, Y, Z, and therefore we have (remembering that $\alpha_0+\nu_2=0$)

$$\begin{vmatrix}\alpha_0, & 0, & \nu_0\\ \alpha_1, & 0, & \nu_1-\omega\\ \alpha_2, & \omega, & -\alpha_0\end{vmatrix}=0\,.$$

This condition reduces to

$$\omega\alpha_0(\nu_1-\omega)-\omega\alpha_1\nu_0=0\,,$$

or

$$\alpha_0\omega^2+\omega(\alpha_1\nu_0-\alpha_0\nu_1)=0\,.$$

This equation must be satisfied for every value of ω; for, whatever be the amplitudes of the two rotations, they must when compounded be equal to a single rotation. We therefore have the conditions

$$\alpha_0=0$$
$$\alpha_1\nu_0=0\,.$$

To satisfy the latter condition either α_1 or ν_0 must be equal to zero. We must examine which of these two conditions is required by the problem. Since α_0 is equal to zero we have

$$\frac{dX}{d\eta'}=\nu_0Z$$
$$\frac{dY}{d\eta'}=\alpha_1X+\nu_1Z$$
$$\frac{dZ}{d\eta'}=\alpha_2X\,.$$

If ν_0 were zero then the first equation would show X to be constant; and the result would be that

$$Y=\alpha_1X\eta+\tfrac{1}{2}\alpha_2\nu_1X\eta^2+\text{const.};$$

or, in other words, Y would be susceptible of indefinite increase with the increase of η. The supposition $\nu_0=0$ is therefore precluded, and we are forced to admit that $\alpha_1=0$. The three equations then reduce to

$$\frac{dX}{d\eta'}=\nu_0Z$$
$$\frac{dY}{d\eta'}=\nu_1Z$$
$$\frac{dZ}{d\eta'}=\alpha_2X\,.$$

If the body receives a rotation η'' about an axis which leaves X and Y unaltered, we then have

$$\frac{dX}{d\eta''}=f_0X+g_0Y+0$$
$$\frac{dY}{d\eta''}=f_1X+g_1Y+0$$
$$\frac{dZ}{d\eta''}=f_2X+g_2Y+0\,.$$

The condition that the two roots of h shall be purely imaginary gives us

$$f_0+g_1=0\,.$$

Let this rotation and the first rotation be communicated together. The resulting rotation could have been produced by a rotation χ, and thus we have

$$\frac{dX}{d\chi}=\frac{dX}{d\eta}+\frac{dX}{d\eta''}$$
$$\frac{dY}{d\chi}=\frac{dY}{d\eta}+\frac{dY}{d\eta''}$$
$$\frac{dZ}{d\chi}=\frac{dZ}{d\eta}+\frac{dZ}{d\eta''}\,.$$

Substituting, we obtain as before

$$\frac{dX}{d\chi}=f_0X+g_0Y+0$$
$$\frac{dY}{d\chi}=f_1X+g_1Y-\omega Z$$
$$\frac{dZ}{d\chi}=f_2X+(g_2+\omega)Y+0\,;$$

and as before the condition must be fulfilled

$$\begin{vmatrix}f_0, & g_0, & 0\\ f_1, & g_1, & -\omega\\ f_2, & g_2+\omega, & 0\end{vmatrix}=0\,;$$

or, expanding,

$$\omega f_0(g_2+\omega)-\omega f_2g_0=0\,.$$

This can only be satisfied for all values of ω if $f_0=0$ and if

$$f_2g_0=0\,.$$

To determine whether g_0 can be zero, we have the equations

$$\frac{dX}{d\eta''}=g_0Y$$
$$\frac{dY}{d\eta''}=f_1X$$
$$\frac{dZ}{d\eta''}=f_2X+g_2Y\,.$$

It can be shown that if g_0 were zero then we should have Z capable of indefinite increase; and hence we see that f_2 must be zero, so that the three equations have the form

$$\frac{dX}{d\eta''}=g_0Y$$
$$\frac{dY}{d\eta''}=f_1X$$
$$\frac{dZ}{d\eta''}=g_2Y\,.$$

Let us now see whether these equations will fulfil the necessary condition for a rotation ψ. If

$$\frac{dX}{d\psi}=\frac{dX}{d\eta'}+\frac{dX}{d\eta''}$$
$$\frac{dY}{d\psi}=\frac{dY}{d\eta'}+\frac{dY}{d\eta''}$$
$$\frac{dZ}{d\psi}=\frac{dZ}{d\eta'}+\frac{dZ}{d\eta''}\,,$$

we shall then have by substitution

$$\frac{dX}{d\psi}=0+g_0Y+\nu_0Z$$
$$\frac{dY}{d\psi}=f_1X+0+\nu_1Z$$
$$\frac{dZ}{d\psi}=\alpha_2X+g_2Y+0\,.$$

But, if this is to represent a rotation,

$$f_1g_2\nu_0+\alpha_2g_0\nu_1=0\,.$$

As this is always to be true, even suppose g_0, f_1, and g_2 for instance were multiplied by a common factor, it is plain that we must have

$$f_1g_2\nu_0=0$$

and

$$\alpha_2g_0\nu_1=0\,.$$

The first condition is to be satisfied by making g_2 zero; for neither of the other possible solutions is admissible if the coordinates are to be presented from indefinite increase. In a similar way the second condition requires that ν_1 must be zero.

Resuming now the three groups of equations, they are as follows:—

$$\frac{dX}{d\eta}=0\ ,\quad \frac{dX}{d\eta'}=\nu_0Z\ ,\quad \frac{dX}{d\eta''}=g_0Y$$
$$\frac{dY}{d\eta}=-\omega Z\ ,\quad \frac{dY}{d\eta'}=0\ ,\quad \frac{dY}{d\eta''}=f_1X$$
$$\frac{dZ}{d\eta}=+\omega Y\ ,\quad \frac{dZ}{d\eta'}=\alpha_2X\ ,\quad \frac{dZ}{d'\eta''}=0\,.$$

Finally let us suppose that the body receives all three motions simultaneously. The resulting motion must still be a rotation, and thus we have the condition

$$\begin{vmatrix}0, & g_0, & \nu_0\\ f_1, & 0, & -\omega\\ \alpha_2, & +\omega, & 0\end{vmatrix}=0\,,$$

which when expanded gives

$$\omega(f_1\nu_0 - \alpha_2 g_0).$$

It is therefore necessary that

$$f_1\nu_0 - \alpha_2 g_0 = 0.$$

But, as this is homogeneous in the two component rotations involved, it does not follow that the separate terms of this equation must necessarily be zero. We satisfy this condition by writing

$$kf_1 = -g_0$$

and $$k\alpha_2 = -\nu_0.$$

Let the body next receive *any* displacement, $\delta\eta$, $\delta\eta'$, and $\delta\eta''$, then we have in general

$$\delta X = \frac{dX}{d\eta}\delta\eta + \frac{dX}{d\eta'}\delta\eta' + \frac{dX}{d\eta''}\delta\eta'',$$

with similar equations for δY and δZ.

By substitution these equations become

$$\delta X = -\alpha_2 kZ\delta\eta' - kf_1 Y\delta\eta''$$

$$\delta Y = -\omega Z\delta\eta + f_1 X\delta\eta''$$

$$\delta Z = +\omega Y\delta\eta + \alpha_2 X\delta\eta'.$$

If we multiply the first of these equations by X, the second by kY, and the third by kZ, and add, we find

$$X\delta X + kY\delta Y + kZ\delta Z = 0$$

or $$X^2 + kY^2 + kZ^2 = \text{const.}$$

Here we have attained the fundamental property which the coordinates must satisfy. If k be equal to unity then we have the well-known condition of ordinary space and ordinary rectangular coordinates, but it will be seen that there is nothing in the preceding investigation to make it necessary that k should be unity. There are therefore a singly infinite variety of spaces in which it is possible for a rigid body to be displaced. The different values of k thus correspond to the different "curvatures" which a space might have while it still retained the fundamental property which is necessary for measurement by congruence.

It will now be proper to study the special characteristics of the space with which we are familiar. It has been called flat space or homaloidal space to distinguish it from other spaces in which the curvature is not zero. It is manifest that the characteristic features of our space are not necessarily implied in the general notion of an extended quantity of three dimensions and of the mobility of rigid figures therein. The characteristic features of our space are not necessities of thought, and the truth of Euclid's axioms, in so far as they specially differentiate our space from other conceivable spaces, must be established by experience and by experience only.

The special feature of our space, by which it is distinguished from spherical space on the one hand and pseudospherical space on the other hand, depends upon what Riemann calls the measure of curvature. If the sum of the three angles of a triangle is to be two right angles, and if the geometrical similarity of large figures and small figures is to be possible, then the measure of curvature must be zero. Now all measurements that can be made seem to confirm the axiom of parallels and seem to show the measure of curvature of our space to be indistinguishable from zero.

It can be proved that the amount by which the three angles of a triangle would differ from two right angles in curved space depends upon the area of the triangle. The greater the area of the triangle the greater is the difference. To test the famous proposition, Euclid i. 32, it will therefore not be sufficient to measure small triangles. It might be contended that in small triangles the difference between the sum of the three angles and two right angles was so small as to be inextricably mixed up with the unavoidable errors of measurement. Seeing therefore that small triangles obey the law, it is necessary to measure large triangles, and the largest triangles to which we have access are, of course, the triangles which the astronomers have found means of measuring. The largest available triangles are those which have the diameter of the earth's orbit as a base and a fixed star at the vertex. It is a very curious circumstance that the investigations of annual parallax of the stars are precisely the investigations which would be necessary to test whether one of these mighty triangles had the sum of its three angles equal to two right angles. It must be admitted that the parallax-seeking astronomers have never yet found any reason to think that there is any measurable difference. If there were such a difference it would probably be inextricably mixed up with the annual parallax itself. Were space really pseudospherical, then stars would exhibit a real parallax even if they were infinitely distant. Astronomers have sometimes been puzzled by obtaining a negative parallax as the result of their labours. No doubt this has generally or indeed always arisen from the errors which are inevitable in inquiries of this nature, but if space were really curved then a negative parallax might result from observations which possessed mathematical perfection.

It must, however, be remembered that even the triangles of the parallax investigations are utterly insignificant when compared with the dimensions of space itself. Even the whole visible universe must be only an unconceivably small atom when viewed in its true relation to infinite space. It may well be that even with the parallax triangles our opportunities of testing the proposition are utterly inadequate to pronounce on the presence or absence of curvature in space. It must remain an open question whether if we had large enough triangles the sum of the three angles would still be two right angles.

Helmholtz illustrates the subject by considering the representation of space which is obtained in a spherical mirror. A mirror of this kind represents the objects in front of it in apparently fixed positions behind the mirror. The images of the sun and of other distant objects will lie behind the mirror at a distance equal to its focal length, or, to quote the description of Helmholtz—

"The image of a man measuring with a rule a straight line from the mirror would contract more and more the farther he went, but with his shrunken rule the man in the image would count out exactly the same number of centimetres as the real man. And in general all geometrical measurements of lines or angles made with regularly varying images of real instruments would yield exactly the same results as in the outer world. All congruent bodies would coincide on being applied to one another in the mirror as in the outer world. All lines of sight in the outer world would be represented by straight lines of sight in the mirror. In short I do not see how men in the mirror are to discover that their bodies are not rigid solids and their experiences good examples of the correctness of Euclid's axioms. But if they could look out upon our world as we can look into theirs, without overstepping the boundary, they must declare it to be a picture in a spherical mirror, and would speak of us just as we speak of them; and if two inhabitants of the different worlds could communicate with one another, neither so far as I can see would be able to convince the other that he had the true, the other the distorted relations. Indeed I cannot see that such a question would have any meaning at all so long as mechanical considerations are not mixed up with it."

A very important contribution to this subject has been made by Professor Simon Newcomb, entitled "Elementary Theorems Relating to the Geometry of a Space of Three Dimensions and of Uniform Positive Curvature in the Fourth Dimension," see *Jour. f. d. reine und angewandte Math.*, vol. lxxxiii., Berlin, 1877.

He commences by assuming the three following postulates:—

1 "That space is triply extended, unbounded, without properties dependent either upon position or direction, and possessing such planeness in its smallest parts that both the postulates of the Euclidean geometry and our common conceptions of the relations of the parts of space are true for every indefinitely small region in space."

2. "That this space is affected with such curvature that a right line shall always return into itself at the end of a finite and real distance 2D without losing in any part of its course that symmetry with respect to space on all sides of it which constitutes the fundamental property of our conception of it."

3. "That if two right lines emanate from the same point making the indefinitely small angle α with each other, their distance apart

at the distance r from the point of intersection will be given by the equation

$$s=\frac{2aD}{\pi}\sin\frac{r\pi}{2D}."$$

Newcomb also assumes that two straight lines intersect only in a single point. He defines a "complete right line" as one returning into itself, as supposed in postulate 2. Any small portion of it is to be conceived as a Euclidean right line. The locus of all complete right lines passing through the same point and touching a Euclidean plane through that point will be called a "complete plane."

A "region" will mean any indefinitely small portion of space in which we are to conceive of the Euclidean geometry as holding true.

Newcomb then proceeds to demonstrate the following propositions.

I. All complete right lines are of the same length 2D. Hence D is the greatest possible distance at which the points can be situated, it being supposed that the distance is measured on the line of least absolute length.

II. The complete plane is a Euclidean plane in every region of its extent.

III. Every system of right lines passing through a common point A and making an indefinitely small angle with each other are parallel to each other in the region A′ at distance D.

IV. If a system of right lines pass in the same plane through A the locus of their most distant points will be a complete right line.

V. The locus of all the points at distance D from a fixed point A is a complete plane, and indeed a double plane if we consider as distinct the coincident surfaces in which the two opposite lines meet.

VI. Conversely, all right lines perpendicular to the same complete plane meet in a point at the distance D on each side of the plane.

VII. For every complete right line there is a conjugate complete right line such that every point of the one is at distance D from every point of the other.

VIII. Any two planes in space have as a common perpendicular the right line joining their poles, and intersect each other in the conjugate to that right line.

IX. If a system of right lines pass through a point, their conjugates will be in the polar plane of that point. If they also be in the same plane the conjugates will all pass through the pole of that plane.

X. The relation between the sides a, b, c of a plane triangle in curved space and their opposite angles A, B, C will be the same as in a Euclidean spherical triangle of which the corresponding sides are $\frac{a\pi}{2D}, \frac{b\pi}{2D}, \frac{c\pi}{2D}$.

XI. Space is finite, and its total volume admits of being definitely expressed by a number of Euclidean solid units which is a function of D.

XII. The total volume of space is $\frac{8D^3}{\pi}$.

XIII. The two sides of a complete plane are not distinct, as in a Euclidean surface.

XIV. If moving along a right line we erect an indefinite series of perpendiculars each in the same Euclidean plane with the one which precedes it, then on completing the line and returning to our starting point, the perpendiculars will be found pointing in a direction the opposite of that with which we started.

Newcomb concludes thus: "It may be also remarked that there is nothing within our experience which will justify a denial of the possibility that the space in which we find ourselves may be curved in the manner here supposed. It might be claimed that the distance of the farthest visible star is but a small fraction of the greatest distance D, but nothing more. The subjective impossibility of conceiving of the relation of the most distant points in such a space does not render its existence incredible. In fact our difficulty is not unlike that which must have been felt by the first man to whom the idea of the sphericity of the earth was suggested in conceiving how by travelling in a constant direction he could return to the point from which he started without during his journey feeling any sensible change in the direction of gravity."

A sketch of the non-Euclidean geometry is given by Professor G. Chrystal in the *Proc. Roy. Soc. Edin.*, vol. x., session 1879-80. The study of this paper is recommended to all who desire to study the elements of what has been called "pangeometry." A more extensive work, which contains the theories of Riemann and Helmholtz, is J. Frischauf's *Elemente der absoluten Geometrie*, Leipsic, 1876.

A fundamental step in the abstract theory of measurement was taken by Professor Cayley in his "Sixth Memoir upon Quantics," *Philosophical Transactions*, vol. cxlix. (1859). The theory thus originated by Cayley has been more fully developed by Klein in his memoir "Ueber die nicht-Euclidische geometrie," *Mathematische Annalen*, vol. iv. p. 573. We shall here enter into this theory in some detail, for in it lies the true foundation of geometrical measurement. A sketch of the theory was given by the author of the present article in *Hermathena*, No. vi. pp. 500-541, Dublin, 1879.

This theory may be regarded merely as a more generalized method of measuring distances and angles in ordinary space, but the results to which it leads are in many respects identical with those to which we are conducted by the theory just discussed. For instance, Newcomb's principle as to the length of the shortest distance between two points never exceeding a certain magnitude is common to his theory and to Cayley's. The theory of Cayley has, however, claims on our attention of a special kind. We here deal with the space with which Euclid has made us familiar, only observing that it is the *measurements* in that space which are to be conducted on a more general principle.

We commence by assuming the existence of a certain surface called the "fundamental quadric," often called "the absolute." By the aid of this quadric and an arbitrary constant c we determine the generalized distance between the points in accordance with the following definition:—*The distance between two points is equal to* c *times the logarithm of the anharmonic ratio in which the line joining the two points is divided by the fundamental quadric.*

Let us first test this theory by a very obvious principle which any theory of distance ought to fulfil. It is plain that, if P, Q, R be three collinear points, then in ordinary measurement we ought to have

$$PQ+QR=PR;$$

but it is easy to see that this condition is fulfilled in the generalized measurement. Let the line PQ cut the fundamental quadric in the two points X, Y, then we have

$$PQ=c\log(PX\div PY)-c\log(QX\div QY)$$
$$QR=c\log(QX\div QY)-c\log(RX\div RY)$$
$$PR=c\log(PX\div PY)-c\log(RX\div RY);$$

whence, as in the ordinary measures,

$$PQ+QR=PR.$$

It is also obvious that in the generalized as in the ordinary measures

$$(PQ)=-(QP),$$

and that the distance between the coincident points is equal to zero.

From an obvious property of logarithms we also learn the important fact that the generalized distance between the points is indeterminate to the extent of any integral number of the periods $2ci\pi$.

The distance from any point to its harmonic conjugate with respect to the two fundamental points is equal to $ci\pi$. We thus see that the distance between any two harmonic conjugates is constant. It is usual to make the arbitrary constant c equal to $-i\div 2$, in which case we see that the distance between the two harmonic conjugates is equal to $\pi\div 2$. It can also be shown that, if the two absolute points on a right line coalesce, then the generalized system of measurement degrades to the ordinary system. The two absolute points are at an infinite distance from every other point, so that in the generalized system of measurement every right line has two points at infinity, and in general all the points in space which lie at infinity are situated on the fundamental quadric.

In ordinary geometry we define a circle to be the locus of a point which is at a constant distance from a given point. In the more generalized geometry we retain the same definition of the circle, only observing that the distance to be constant must be expressed in the generalized manner. The plane of course cuts the absolute in a conic section, so that the determination of the circle whose centre is C is the following problem in conic sections:—Through a fixed point O a straight line OP is drawn which cuts a given conic in the points X, Y; determine the locus of P so that the anharmonic ratio (O, P, X, Y) shall remain constant.

This problem is most readily solved by projecting the conic into a circle the centre of which is the projection of O. The problem then assumes the very simple form. On the diameter of a fixed circle a point P′ is taken so that the anharmonic ratio of the four points consisting of P′, the centre O′, and the two points in which the line O′P′ cuts the circle remains constant. It is required to find the locus of P′. The solution is obvious, and hence we learn that a conic which has double contact with the fundamental conic is a *circle* in the generalized sense, and the centre of that circle is the pole of the chord of contact.

A system of conics which have double contact with the fundamental conic in the same two points form a system of concentric circles, and the centre of the system is the pole of the chord of contact. We are accustomed in ordinary geometry to admit that every circle passes through the two imaginary circular points at infinity. This is the specialized form of the general theorem which asserts that every circle has double contact with the fundamental conic. The two theorems indeed coincide if the fundamental conic degrades to the infinity of ordinary measurement.

A critical case is presented when the chord through O coincides with either of the two tangents which may be drawn from O to the fundamental conic. The two fundamental points then coincide, and hence the distance between any two points on a tangent to the fundamental conic is equal to zero. We have thus the curious result that in every system of concentric circles, including even the fundamental conic itself, the two points common to the system of circles are at the distance zero from the centre of the system. In fact the pair of tangents from the centre may be regarded as a conic having double contact with the fundamental conic, and therefore forming one of the circles of the concentric system of which the radius is zero.

The reader will at once perceive the analogy to a well-known phenomenon in ordinary geometry. The equation in rectangular coordinates

$$x^2+y^2=0$$

denotes *either* a circle of which the radius is zero *or* the pair of lines

$$x\pm\sqrt{-1}y=0;$$

in the latter case we are obliged to admit that the distance of any point on either of these lines from their intersection is equal to zero.

We have now to consider the displacement of a rigid figure, and we shall for the present speak only of a plane movement. We shall first show that it is possible for a plane figure to receive such a displacement that the distance between every two points in the figure after the displacement is equal to what it was before.

Let x, y, z be the trilinear coordinates of a point in a plane, and suppose that x', y', z' are the coordinates of the position to which this point is transferred in accordance with the linear transformation

$$x'=ax+by+cz$$
$$y'=a'x+b'y+c'z$$
$$z'=a''x+b''y+c''z.$$

There are in general three points in the plane which are not altered by this transformation; for, if we assume

$$x'=\rho x, \qquad y'=\rho y, \qquad z'=\rho z,$$

we have for ρ the cubic equation

$$\begin{vmatrix} a-\rho, & b, & c \\ a', & b'-\rho, & c' \\ a'', & b'', & c''-\rho \end{vmatrix}=0.$$

The three values of ρ which satisfy this equation determine the coordinates of the three points. It is natural to take the sides of the triangle formed by these three points as the three lines of reference, in which case, if α, β, γ be constants, the system of equations assume the simple form

$$x'=\alpha x, \qquad y'=\beta y, \qquad z'=\gamma z.$$

It is easily shown that four collinear points before the transformation are collinear after the transformation, and that their anharmonic ratio is unaltered.

This general form of linear transformation must be specialized in order to represent the movement. As no finite movement can either bring a point to infinity or from infinity, it is obvious that the displacement must be such as to leave the fundamental conic unaltered. It is easily seen that the specification of the transformation in its general form requires eight constants; viz., the ratios of the nine quantities a, b, c, a', b', c', a'', b'', c''. We may imagine five of these constants to be disposed of by the provision that the conic shall remain unaltered. There will still remain three disposable constants to give variety to the possible displacements.

Although the fundamental conic will coincide with itself after the transformation, yet it *generally* happens that each point thereon will slide along the conic during the transformation. It is, however, very important to observe that there are two exceptions to this statement.

Let O, A, B, C be four points upon the fundamental conic which by transformation move into the positions O′, A′, B′, C′. If OX be one of the double rays of the systems OA, OB, OC and OA′, OB′, OC′, and if we use the ordinary notation for anharmonic pencils, then we have

$$O(A, B, C, X)=O(A', B', C', X).$$

But the anharmonic ratio subtended by four points on a conic at any fifth point is constant, whence

$$O(A', B', C', X)=O'(A', B', C', X),$$

and therefore

$$O(A, B, C, X)=O'(A', B', C', X).$$

Suppose the transformation moved X to X′, then since the anharmonic ratio of a pencil is unaltered by transformation we have

$$O(A, B, C, X)=O'(A', B', C', X');$$

whence

$$O'(A', B', C', X)=O'(A'B'C'X');$$

but this can only be true if the rays O′X and O′X′ are coincident, in which case X and X′ are coincident, whence it follows that the point X has remained unaltered notwithstanding the transformation. Similar reasoning applies to the point Y defined by the other double ray, and hence we have the following theorem:—

In that linear transformation of the points in a plane which constitutes a generalized movement, there are two points upon the fundamental conic which remain unchanged.

It also follows that the tangents to the fundamental conic at the points X and Y, as well as the chord of contact, must remain unaltered. These two tangents and their chord of contact must therefore form the triangle of reference to which we were previously conducted by the general theory of this transformation.

It will now easily appear how a transformation of this kind is really a displacement of a rigid plane. The distance between each pair of points is expressed by an anharmonic ratio; such ratios are unchanged by the transformation, and the two points which lay on the absolute originally are also there after the transformation. It therefore appears that the distance in the generalized sense between every pair of points is unchanged by the transformation. In other words, a rigid system will admit of a displacement of the kind now under consideration.

If we denote the two tangents at the unaltered points on the conic by $x=0$, $y=0$, and the chord of contact by $z=0$, then the equation to the absolute is

$$xy-k^2z^2=0.$$

Transforming this equation by the substitution

$$x'=\alpha x, \qquad y'=\beta y, \qquad z'=\gamma^2,$$

we see that the condition $\alpha\beta=\gamma^2$ must be fulfilled.

It is very remarkable that the fundamental conic is only one of a family of conics, each of which remains unaltered by the transformation. In fact every generalized circle of which the intersection of the two tangents is the centre has for its equation $xy-h^2z^2$; and, whatever h may be, this circle remains unaltered by the transformation. Hence we have the following remarkable theorem:—

When a plane rigid system is displaced upon itself there is one point O of the system which remains unaltered, and all the circles which have O as their centre remain unaltered also.

It is quite natural to speak of this motion as a "rotation," and thus we may assert the truth in generalized measurement of the well-known theorem in ordinary geometry that

Every displacement of a plane upon itself could have been produced by a rotation of the plane around a certain point in the plane.

Notwithstanding the rotation of the plane round O, the two tangents from O to the fundamental conic and also their chord of intersection, or the polar of O, remain unaltered; each point on the polar of O is displaced along the polar, and we would in ordinary geometry call this motion a translation parallel to the polar. It thus appears that, in the sense now attributed to the words rotation and translation, a rotation round a point is identical with a translation along the polar of the point.

Another point on which the present theory throws light on the ordinary geometry must be here alluded to. We have seen that the two tangents from O to the fundamental conic remain unchanged during the rotation of the plane round O. It certainly does seem paradoxical to assert that a plane, and all it contains are rotated around a point, and that nevertheless this operation does not alter the position of a certain pair of lines in the plane which pass through the point. But have we not precisely the same difficulty in ordinary geometry? Let us suppose that a plane pencil of rays is rotated through an angle θ about the origin. Then a line through the origin whose equation before the rotation was

$$x+hy=0$$

becomes after the rotation

$$x\cos\theta+y\sin\theta+h(y\cos\theta-x\sin\theta)=0.$$

The lines thus represented are of course in general different, but they will be the same if

$$1+h^2=0.$$

It follows that even in ordinary geometry the two lines $x\pm iy=0$ remain unaltered notwithstanding the rotation of the plane which contains them around their intersection. The two lines here referred to are of course those which are drawn through the two circular points at infinity. This paradox is therefore only a degraded form of the property of the tangents to the fundamental conic.

It can also be readily shown that, *if a plane receive two small rotations round two points, then the total rotation produced could have been produced by a single rotation about a certain point on the line joining the two points.*

Let A, B be the two points and P the pole of the line AB, then a rotation round A will displace B along the line PB to an adjacent point B′. The rotation around B will displace A to A′ along the line PA; but, if A′B′ intersects AB in O, then a single rotation about O would have effected the required displacement of A and B, and therefore of the whole line. For, as the point O in the line AB could only move by displacement into the line A′B′, while it can also only move in the direction OP, it must obviously remain unaltered.

We are now in a position to inquire how the magnitude of an angle is to be expressed in the present system of measurement. Our definition of the magnitude of an angle must be made consistent with the supposition that when the angle is carried round by rotation about the vertex the magnitude shall remain unaltered. As anharmonic ratios are unaltered by the rotation, it follows that the anharmonic ratio of the pencil formed by the two legs of the angle and the two tangents to the fundamental conic must remain unaltered. Remembering that the tangents do not move by the rotation, it is natural to choose a function of this anharmonic ratio as the appropriate measure of an angle. The question still remains as to what function should be chosen. The student of ordinary geometry is doubtless aware that the angle between two lines multiplied into $2i$ is equal to the logarithm of the anharmonic ratio of the pencil formed by joining the intersection of the two lines to the two imaginary circular points at infinity. This consideration suggests that the angle between the straight lines in the generalized sense may be appropriately measured by the logarithm of the anharmonic ratio of the pencil formed by the two legs of the angle and the two tangents drawn from their point of intersection to the fundamental conic. There is also a convenience in assuming the angle to be actually *equal* to c times the logarithm of the anharmonic ratio, where c is the same constant as is employed in the expression of the distance. In this case the angle between two lines is by a well-known theorem equal to the distance between their poles. There is here an analogy to a well-known theorem in spherical geometry.

It will now be obvious that, however the angle be situated, its magnitude is unchanged by any displacement of the plane; for, as we have already seen that the displacement does not alter the distance between the poles of the two lines forming the angle, it follows that the magnitude of the angle itself is unaltered.

Just as in the measurement of distance we find a pair of fundamental points on each straight line, so in the measurement of angles we find a pair of fundamental rays in each plane pencil. These rays are the two tangents from the vertex of the pencil to the fundamental conic. In ordinary geometry the two fundamental points on each straight line coalesce into the single point at infinity; but it is exceedingly interesting to observe that even in ordinary geometry the two fundamental rays on each pencil do not coincide. It should also be observed that in the degraded circumstances of ordinary geometry it would be impracticable to employ the *same* constant c for the purpose of both linear and angular measurement.

It is easy to see that the definition of a right angle in the generalized sense is embodied in the statement that "if two corresponding legs of an harmonic pencil touch the fundamental conic then the two other legs are at right angles." We also see that all the perpendiculars to a given line pass through a point, *i.e.*, the pole of the given line; and from a given point a perpendicular can be drawn to a given line by joining the point to the pole of the line. The common perpendicular to two lines is obtained by joining their poles.

The student of modern geometry is already accustomed to think of parallel lines as lines which intersect at infinity, or as lines whose inclination is zero. In speaking of the generalized geometry *in a plane*, we may define that *two straight lines which intersect upon the fundamental conic are parallel.* It thus follows that through any point two distinct parallels can be drawn to a given straight line. The only exception will arise in the case where the given line touches the fundamental conic. This is precisely the case in which the generalized system of measurement degrades to the ordinary system. It will follow that in the present theory of measurement the three angles of a triangle are together not equal to two right angles. In fact, to take an extreme case, we may suppose the three vertices of the triangle to lie upon the fundamental conic. In this case each of the three angles, and therefore their sum, is equal to zero.

A sphere in the generalized system of measurement is the locus of a point which moves at a constant distance from a fixed point. It can therefore be easily shown that a sphere is a quadric which touches the fundamental quadric along its intersection with the polar plane of the centre of the sphere.

In discussing the general case of the displacement of a rigid system it will simplify matters to suppose that the fundamental quadric has real rectilinear generators. It must, however, be understood that the results are not on that account less general. A displacement must not alter the quadric, and must not deform a straight line. Hence it follows that the only effect of a displacement upon a generator of the fundamental quadric will be to convey it to a position previously occupied by a different generator. We shall further suppose that the displacement is such that the two generators to which we have referred belong to the same system. Let A, B, C, D be four generators of the first system which by displacement are brought to coincide with four other generators A′, B′, C′, D′. Let X be one generator of the second system which the displacement brings to X′. Since the anharmonic ratio of the four points in which four fixed generators of the one system are cut by any generator of the other system is constant, we must have, using an obvious notation for anharmonic ratio,

$$X(ABCD) = X'(ABCD);$$

but, since anharmonic ratios are unaltered by displacement, we have

$$X(ABCD) = X'(A'B'C'D'),$$

whence

$$X'(ABCD) = X'(A'B'C'D').$$

It therefore follows that the anharmonic ratio in which four generators cut a fixed generator X′ is equal to the anharmonic ratio in which the four generators after displacement cut the same generator X′.

If P be a generator which passes through one of the double points on X′ determined by the two systems of points in which X′ is cut by the four generators before and after displacement, we must have

$$X(A, B, C, P) = X'(A', B', C', P);$$

hence we see that the generator P will be unaltered by displacement. Similar reasoning applies to the generator which passes through the other double point, and of course to a pair of generators of the second system, and hence we have the following remarkable theorem :—

In the most general displacement of a rigid system two generators of each of the systems on the fundamental quadric remain unaltered.

These four fixed generators are the edges of a tetrahedron. Denoting the four faces of this tetrahedron by the equations

$$x=0,\ y=0,\ z=0,\ w=0,$$

the equation of the fundamental quadric is

$$xz + h^2yw = 0.$$

If the quadric be unaltered by the transformation

$$x' = \alpha x,\ y' = \beta y,\ z' = \gamma z,\ w' = \delta w,$$

then we must have

$$\alpha\gamma = \beta\delta.$$

When this condition is satisfied, then, whatever h may be, every quadric of the family

$$xz + hyw = 0$$

will remain unaltered.

The family of quadrics here indicated are analogous to the right circular cylinders which have for a common axis the screw along which any displacement of a rigid body in ordinary space may be effected.

The two lines

$$x=0,\ z=0$$

and

$$y=0,\ w=0$$

are conjugate polars with respect to the fundamental quadric, and both these lines are unaltered by the displacement. Hence we see that *in any displacement of a rigid system there are two right lines which remain unaltered, and these lines are conjugate polars with respect to the fundamental quadric.*

Since the pole of a plane through one of these lines lies on the other line, it appears that *a rotation of a rigid system about a straight line is identical with a translation of the system along its conjugate polar.*

Clifford has pointed out the real nature of the lines which are to be called parallel in the generalized system of measurement. We have explained that in the plane two parallel lines intersect upon the fundamental conic; in a certain sense also we may consider two lines in space of three dimensions to be parallel whenever they intersect upon the fundamental quadric. This is the view of parallel lines to which we are conducted by simply generalizing the property that two parallel lines intersect at infinity. But we can take a different definition of two parallel lines. Let us, for example, call two lines parallel when they admit of an indefinitely large number of common perpendiculars. It is exceedingly interesting to observe that when this condition is fulfilled in the generalized system of measurement the parallel lines so obtained enjoy many of the properties of ordinary parallel lines. The perpendicular distance between such a pair of parallels is constant, and the angles which they make with any common transversal are equal.

It will be shown in a moment that any pair of straight lines which intersect the same two generators of the same system on the fundamental quadric are parallel in this new sense. The fact is that in the degraded circumstances of ordinary geometry two quite different conceptions have become confused. A pair of lines which intersect on the fundamental quadric and a pair of lines which intersect the same pair of generators of the same kind on the fundamental quadric are quite different conceptions; but when the fundamental quadric degrades to the ordinary infinity then the conceptions coalesce, and each of them is merely a pair of parallel lines in the ordinary sense of the word. The ordinary properties of parallel lines have all their analogues in the generalized geometry, but these analogues are distributed between the two original sources of parallels. Clifford proposes to retain the word "parallel" in non-Euclidean space for that conception which exhibits the more remarkable properties of ordinary space, and defines as follows:—

Straight lines which intersect the same two generators of the same system on the fundamental quadric are parallel.

Let X and Y be two rectilinear generators of the fundamental quadric belonging to the same system, and let A and B be two straight lines which intersect both X and Y. Since AX and AY are tangent planes their poles must lie on X and Y respectively, and therefore A′ (and B′), the polar of A (and B), must intersect both X and Y. The anharmonic ratio of the four points in which X intersects AB, A′B′ respectively is equal to that of the tangent planes drawn at the points where X intersects A′B′, AB respectively; and, as all these tangent planes contain X, their anharmonic ratio must be equal to that in which they are cut by the line Y. It hence follows that the lines X and Y are divided equianharmonically by the four rays A, B, A′, B′, and therefore the four rays A, B, A′, B′ must be all generators of the same system on an hyperboloid. An infinite number of transversals can therefore be drawn to intersect these four rays, that is to say, an infinite number of common perpendiculars can be drawn to the two rays A and B, and it is easy to show that the lengths of all these perpendiculars are equal.

Clifford has proved the very remarkable theorem that rotations of equal amplitude about two conjugate polars have simply the effect of translating every point operated on through equal distances along parallel lines. This property leads to most important consequences, but it would lead us too far to enter into the subject at present.

A memoir by the present writer on the extension of the theory of screws to space of this description will be found in the *Transactions of the Royal Irish Academy*, vol. xxvii. pp. 157–184.

Units of Measurement.—A most excellent account of the units employed in scientific measurements will be found in Professor J. D. Everett's *Units and Physical Constants*, London, 1879. We shall here only give a very brief outline of this branch of the general theory of measurement, referring inquirers to Everett's volume for further details.

Most of the quantities for which measurements are needed can be ultimately expressed by means of (1) a definite length, (2) a definite mass, or (3) a definite interval of time.

It is very important that the units thus referred to should be chosen judiciously, and it must be admitted that the units ordinarily used do not fulfil the conditions which a well-chosen system of units should fulfil. The most scientific system is beyond doubt that which has been suggested by the units committee of the British Association. In this system the unit of length is the *centimetre*, the unit of mass is the *gramme*, and the unit of time is the *second*, and the system is therefore often referred to for brevity as the C.G.S. system. The unit of force is termed the *dyne*, and it is defined to be the force which, acting upon a gramme of matter for a second, generates a velocity of a centimetre per second. The unit of work is the work done by this force working through a centimetre, and this unit is termed the *erg*. The unit of power is the power of doing work at the rate of one erg per second, and the power of an engine can be specified in ergs per second. By the prefixes deca, hecto, kilo, mega, we can express a magnitude equal to the unit multiplied by 10, 100, 1000, or 1,000,000 respectively. On the other hand the prefixes deci, centi, milli, micro, signify the units divided by 10, 100, 1000, or 1,000,000 respectively.

For comparison with the ordinary units the following statements will be useful. The weight of a gramme at any part of the earth's surface is about 980 dynes, or rather less than a kilodyne. The weight of a kilogramme is rather less than a megadyne, being about 980,000 dynes.

The application of these units to electrical and many other measurements will be found in Professor Everett's book already referred to. On the general principles of appliances for measurement, see a paper by Clifford in the *Handbook to the Special Loan Collection of Scientific Apparatus*, 1876, pp. 55–59, reprinted in Clifford's *Mathematical Papers*, pp. 419–23. (R. S. B.)

MEATH, a maritime county of Ireland, in the province of Leinster, is bounded E. by the Irish Sea, S.E. by Dublin, S. by Kildare and King's county, W. by Westmeath, N.W. by Cavan and Monaghan, and N.E. by Louth. Its greatest length north and south is about 40 miles, and its breadth east and west about 45 miles. The total area comprises 578,247 acres, or 904 square miles.

The county forms part of the great limestone plain that occupies the central portion of Ireland. In some districts the surface is variegated by hills and swells, which to the west reach a considerable elevation, although the general features of a fine champaign country are never lost. The coast, which is low and shelving, extends to about 10 miles, but there is no harbour of importance. The Boyne, whose banks are specially beautiful, enters the county at its south-west extremity, and flowing north-east to Drogheda divides it into two almost equal parts. At Navan it receives the Blackwater, which flows south-west from Cavan. The Boyne is navigable for barges as far as Navan, where a canal is carried to Trim. The Royal Canal passes along the southern boundary of the county to Dublin. There are no lakes of importance.

Climate and Agriculture.—The climate is genial and favourable for all kinds of crops, there being less rain than even in the neighbouring counties. The principal substratum is limestone, but there are some districts of clay slate. Except a small portion occupied by the Bog of Allen, the county is very verdant and fertile. The soil is principally a rich deep loam resting on limestone gravel, but varies from a strong clayey loam to a light sandy gravel.

The total number of holdings in 1881 was 11,867, of which 1632 were less than 1 acre in extent, and 4300 between 5 and 15 acres. Only 93 were above 500 acres. According to the agricultural statistics for 1881, the area of arable land was 532,708 acres, or 92·4 per cent. of the whole area of the county, while 9599 acres were under plantations, 11,260 bog and marsh, and 201 barren mountain land. Of the arable land, 60,411 were under tillage, 85,893 meadow and clover, and 386,374 pasture. The following table shows the area under the different crops in 1855 and 1882:—

	Wheat.	Oats.	Other Cereals.	Potatoes.	Turnips.	Other Green Crops.	Flax.	Meadow and Clover.	Total.
1855	18,764	86,831	4,876	19,235	9,904	4,005	266	64,646	208,527
1882	2,783	31,202	1,577	12,071	6,724	3,109	59	82,572	140,097

Horses between 1855 and 1882 have diminished from 23,310 to 15,316, an average of 2·9 to every 100 acres under cultivation, the average for Ireland being 3·2. Cattle in 1855 numbered 135,485, and in 1882 had increased to 176,121, an average of 33 to every 100 acres under cultivation, the average for Ireland being 26·2. Sheep in 1855 numbered 170,582, and in 1882 only 146,749, although in 1880 they were 174,573. Pigs in 1882 numbered 19,709, goats 6398, and poultry 318,968.

According to the latest return the land was divided among 1322 proprietors, who possessed 577,846 acres, with a total annual value of £544,550. The average size of the properties was 436 acres, and the average annual value per acre was 18s. 10d. The following four proprietors possessed more than 10,000 acres each: viz., Earl of Darnley, 21,858 acres; J. L. Naper, 18,863; Marquis of Lansdowne, 12,995; and Lord Athlumney, 10,213.

Manufactures.—Almost the sole industry of the county is agriculture, but coarse linen is woven by hand-looms, and there are a few woollen manufactories.

Railways.—The Dublin and Meath line intersects the county in a north-westerly direction, and separates into several branches, while the Great Western line skirts the southern boundary.

Administration and Population.—The county includes 18 baronies, 146 parishes, and 1626 townlands. Assizes are held at Trim, and quarter sessions at Dunshauglin, Duleek, Kells, Navan, and Trim. Two poor-law unions, Navan and Trim, are wholly within the county, and parts of Ardee, Celbridge, Drogheda, Dunshauglin, Edenderry, Kells, and Old Castle. It is in the Dublin military district, subdistrict of Birr, with barrack stations at Navan and Trim. Ecclesiastically it is in the Meath diocese, with portions in Armagh and Kilmore. Previous to the Union it sent fourteen members to parliament, but now only the two members for the county are returned.

From 81,516 in 1760 the population in 1821 had increased to 159,183, and in 1841 to 183,828, but by 1851 had diminished to 140,768, in 1871 to 95,558, and in 1881 to 87,469, of whom 44,315 were males and 43,154 females. The principal towns are Navan, 3873; Kells, 2822; and Trim, 1586. A portion of the parliamentary borough of Drogheda, including 933 of the inhabitants, is also within the county. The number of births in the county during the ten years ending 3d March 1881 was 21,293, an average of 23·3 to every 1000 of the population; of deaths 16,878, an average of 18·4; of marriages 3165, an average of 3·5; and of emigrants 10,521, an average of 12·1. From 1st May 1851 to 3d March 1881 the total number of emigrants was 49,375. Of the population five years old and upwards in 1881, 22·7 per cent. were illiterate, the percentage in 1871 being 29·9. In 1881 there were 3531 persons able to speak Irish, but none were unable to speak English.

History and Antiquities.—According to Ptolemy, Meath was originally inhabited by the Eblani, whose territory extended from the Boyne to the Liffey. A district known as Meath, and including the present county of Meath as well as Westmeath and Longford, with parts of Cavan, Kildare, and King's county, was in the 2d century formed by Tuathal into a kingdom to serve as mensal land of the Ard Ré or over-king. Afterwards it was divided into Oireamhain, now known as Meath, and Eireamhain, which included the remainder of the old kingdom. The district was frequently subject to invasions from the Danes; they were totally defeated at Tara in 980. About 800,000 acres, including all the present county of Meath, was granted by Henry II. to Hugh de Lacy.

The most remarkable antiquarian remains are two round towers, the one at Kells, and the other in the churchyard of Donoughmore, near Navan. At New Grange, near Slane, there is an artificial cavern of a very peculiar construction. A large rath on Tara hill was the meeting-place of the princes before the Danish invasion, and the seat of a royal palace referred to in the well-known lines of Moore. A stone on the top of the rath is supposed by some to be the stone of destiny where the ancient monarchs of Ireland were crowned. Monastic buildings were very numerous, among the more important ruins being those of Duleek, which is said to have been the first ecclesiastical edifice in Ireland built of stone and mortar; the extensive remains of Bective; and those of Clonard, where also were a cathedral and a very famous college. Of the old fortresses, Trim Castle on the Boyne still presents an imposing appearance. There are also many fine old mansions.

MEAUX, capital of an arrondissement, and an episcopal see, in the department of Seine-et-Marne, France, and formerly chief town of Haute Brie, is situated 28 miles east of Paris, on the Marne, which runs through the town, and on the Paris and Strasburg Railway. The cathedral, dedicated to St Stephen, dates from the 12th century; its restoration was begun thirty years ago. From the top of its western tower (250 feet high), in fine weather, the heights of Montmartre and Mont Valérien, near Paris, can be seen. The building, which is 275 feet long and 105 feet high, consists of a nave, two aisles, a fine transept, a choir, and a sanctuary. The choir contains the statue and the tomb of Bossuet, and the pulpit of the cathedral has been reconstructed with the panels of that from which the "Eagle of Meaux" used to preach. The great window of the south transept contains some magnificent stained glass. The episcopal palace, behind the cathedral, has several very curious old rooms; the buildings of the choir school, which also adjoins the cathedral, are likewise of some architectural and archæological interest.

Meaux is the centre of a considerable trade in corn, cheese, eggs, and poultry; and its mills, on the Marne, provide a great part of the meal with which Paris is supplied. The Canal de l'Ourcq, which surrounds the town, and the Marne, furnish the means of transport. A starch manufactory, a copper and iron foundry, and manufactories of food-pastes, of preserved vegetables, and of agricultural implements are the other principal industrial establishments. About a mile from the town is the sugar factory of Villenoy, which is one of the largest in France. The population of Meaux is 11,740.

In the Roman period Meaux was the capital of the Meldi, a small Gallic tribe. It formed part of the kingdom of Austrasia, and afterwards belonged to the counts of Vermandois and Champagne. Its communal charter dates as far back as 1179. Meaux suffered much from the disorders of the Jacquerie, from the Hundred Years' War, and from the religious wars, during which it was an important Protestant centre. After the League, it was the first town which opened its gates to Henry IV., in 1594. Placed as it is on the highroad of invaders marching on Paris from the east of France, Meaux saw its environs ravaged by the army of Lorraine in 1652, and was laid under heavy requisitions in 1814, 1815, and 1870.

MECCA (مكة, *Makka*), the chief town of the Ḥijáz in Arabia,[1] and the great holy city of Islám, is situated two camel marches (the resting-place being Baḥra or Ḥadda in the Baṭn Marr), or about 45 miles, almost due east, from Jidda, on the Red Sea.[2] Thus on a rough estimate Mecca lies in 21° 30′ N. lat. and 40° E. long.

It is said in the Koran (*sur.* xiv. 40) that Mecca lies in a sterile valley, and the old geographers observe that the whole Ḥaram or sacred territory round the city is almost absolutely without cultivation or date palms, while fruit trees, springs, wells, gardens, and green valleys are found immediately beyond. Mecca in fact lies in the heart of a mass of rough hills, intersected by a labyrinth of narrow valleys and passes, and projecting into the Tiháma or low country on the Red Sea, in front of the great mountain wall that divides the coast lands from the central plateau, though in turn they are themselves separated from the sea by a second curtain of hills forming the western wall of the great Wády Marr. The inner mountain wall is pierced by two and only two great passes, and the valleys descending from these embrace on both sides the Mecca hills. The north-western pass, through which the Nejd traffic descends to the coast, and which also affords the easiest though longest route from Jidda and Mecca to Ṭáif and thence through the true Ḥijáz to Yemen, is the Derb el-Seil or torrent path down the well-watered Wády Marr.[3] This Wády skirts the complex of Mecca hills on the north-west from Zeima by Wády Fáṭima (where it is joined by the great coast road from Medina and Syria) to Ḥadda on the Mecca and Jidda road, a distance of perhaps 50 miles. Main roads converge to Mecca from the three points of the Wády just named, the distance of the city from the last two being about 20 miles. From this side the most prominent of the Mecca hills is the northern "Mountain of Light" (J. Núr). The other pass, which affords a shorter mule road to Ṭáif and the southern highlands, but is not practicable for ordinary baggage camels, descends from the summit of J. Kara, and leads through the great W. Naʿmán, the Wády of the Hodheil, to the plain beneath ʿArafa, the most

---

[1] Ḥijáz is here taken in the usual political sense of the word. The Turkish Wály of the Ḥijáz has his winter residence at Mecca and his summer quarters at Ṭáif. In a narrower sense the Ḥijáz is the lofty mountainous country between the central plateau of Nejd (or Negd, as it is called by the natives) and the lowlands of the coast (Tiháma). In this sense El-Asmaʿí reckons Mecca to the Tiháma, and well-informed Arabs still follow him.

[2] A variant of the name Makka is Bakka (*sur.* iii. 90; Bekrí, 155 *sq.*). For other names and honorific epithets of the city see Bekrí, *ut supra*, Azraḳí, p. 197, Yáḳút, iv. 617 *sq.* The lists are in part corrupt, and some of the names (Kúthá and ʿArsh or ʿUrsh, "the huts") are not properly names of the town as a whole.

[3] The upper part of this wády has two branches, W. Leimún and W. Nakhla. In the latter lie the gardens of Sóla and the village of Zeima with its great hot spring (comp. Yáḳút, iii. 197). Above Zeima the path is desert.

easterly of the holy sites connected with Mecca. From this point a tolerably level route skirts the Mecca hills on the south, passing very close to Mecca under the opposite side of J. el-Thaur, is joined or crossed by several roads from the south, including the great lowland Yemen road, and ultimately falls into the road from Mecca to Hadda, a little beyond the pillars that define the Haram. The broad valleys through which this southern road leads are not so well watered as W. Marr, but have several fertile spots and a good deal of land cultivable after rain.[1] From this description the importance of the situation of Mecca will be easily understood. It commands both the great routes connecting the lowlands with central Arabia, and thus has the advantage over Țáif, its former commercial rival, which lies indeed on the inland mountain road from Yemen to Nejd behind Mount Kara, but has no ready connexion with the Tihâma. Mecca, on the contrary, though apparently secluded in its hills from the main valleys—it is in fact not visible from any point till one is quite close to the town—lies in the focus of all the great roads from north to south or from the coast inland, with the single exception of the mountain road behind Kara; and the low passes that intersect the Mecca hills form a series of practicable short cuts connecting all the chief points of the circle of valleys already described.[2]

Holding this position, and situated in a narrow and barren valley quite incapable of supporting an urban population, Mecca must have been from the first a commercial town.[3] In the palmy days of South Arabia it was probably a station on the great incense route, and thus Ptolemy may have learned the name, which he writes Makoraba. At all events, long before Mohammed we find Mecca established in the twofold quality of a commercial centre and a privileged holy place, surrounded by an inviolable territory (the Haram), which was not the sanctuary of a single tribe but a place of pilgrimage, where religious observances were associated with a series of annual fairs at different points in the vicinity.[4] The combination of commerce with religion was no unusual thing in Arabia. Of old the incense trade had its religious features, and indeed in the unsettled state of the country commerce was possible only under the sanctions of religion, and through the provisions of the sacred truce which prohibited war for four months of the year, three of these being the month of pilgrimage, with those immediately preceding and following. The first of the series of fairs in which the Meccans had an interest was at 'Okáz on the easier road between Mecca and Țáif, where there was also a sanctuary, and from it the visiters, drawn from tribes far and near, moved on to points still nearer Mecca (Majanna, and finally Dhu'l-Majáz, on the flank of J. Kabkab behind 'Arafa) where further fairs were held,[5] culminating in the special religious ceremonies of the great feast at 'Arafa, Kuzah (Mozdalifa), and Mecca itself. The system of intercalation in the lunar calendar of the heathen Arabs was designed to secure that the feast should always fall at the time when the hides, fruits, and other merchandise were ready for market,[6] and the Meccans, who knew how to attract the Bedouins by profuse and systematic hospitality, bought up these wares in exchange for imported goods, and so became the leaders of the international trade of Arabia. Their caravans traversed the length and breadth of the peninsula. Syria, and especially Gaza, was their chief goal, and we read that the Syrian caravan intercepted, on its return, at Bedr represented capital to the value of £20,000, an enormous sum for those days.[7]

The victory of Mohammedanism made a vast change in the position of Mecca. The merchant aristocracy became satraps or pensioners of a great empire; but the seat of dominion was removed beyond the desert, and though Mecca and the Hijáz strove for a time to maintain political as well as religious predominance, as will be related under MOHAMMEDAN EMPIRE, the struggle was vain, and terminated on the death of Ibn Zubeyr, the Meccan pretendant to the caliphate, when the city was taken by Hajjáj (692 A.D.). On the other hand, the sanctuary and feast of Mecca received a new prestige from the victory of Islám. Purged of elements obviously heathenish, the Ka'ba (Caaba) became the holiest site, and the pilgrimage the most sacred ritual observance of Mohammedanism, drawing worshippers from so wide a circle that the confluence of the petty traders of the desert was no longer the main feature of the holy season. The pilgrimage retained its importance for the commercial wellbeing of Mecca; to this day the Meccans live by the Hajj—letting rooms, acting as guides and directors in the sacred ceremonies, as contractors and touts for land and sea transport, as well as exploiting for their own advantage the many benefactions that flow to the holy city; while the surrounding Bedouins derive a chief part of their support from the camel-transport it demands and from the subsidies and gifts by which they are engaged to protect or abstain from molesting the pilgrim caravans. But the ancient "fairs of heathenism" were given up, and the traffic of the pilgrim season, sanctioned by the Prophet in *sur.* ii. 194, was concentrated at Miná and Mecca, where most of the pilgrims still have something to buy or sell, so that Miná, after the sacrifice of the feast day, presents the aspect of a huge international fancy fair.[8] In the Middle Ages this trade was much more important than it is now. Ibn Jubair in the 12th century describes the mart of Mecca in the eight days following the feast as full of gems, unguents, precious drugs, and all rare merchandise from India, 'Irák, Khorásán, and every part of the Moslem world.[9]

Mecca, as has been already indicated, lies in a narrow sandy valley running approximately from north to south between the Red Mountain on the west and the loftier chain of J. Abu Kobeys on the east. These ranges, which are partly built on and rise several hundred feet above the valley, so enclose the city that the ancient walls only barred the valley at three points, where three gates led into the town. In the time of Ibn Jubair the gates still stood though the walls were ruined, but now the gates have only left their names to

[1] To this description of the valleys surrounding the Mecca group on three sides, which is mainly drawn from personal observation in 1880, it may be added that there is a direct and easy camel route from Zeima to 'Arafa between the Mecca hills and the mountains of the Hodheil. Taking this fact with the statement of Wákidí (Wellhausen's *Muh. in Med.*, p. 341) that every wády in the sacred territory flows outwards into common ground except that at Tan'im (near the Hudúd on the Medina road, Yákút, i. 879; Ibn Jubair, p. 110) we see that Mecca lies in an isolated group of hills—a sort of outpost of the great mountain wall.

[2] The inland road in ancient times was not so valuable as the coast road to Syria, on account of the scarcity of water (*Muh. in Med.*, p. 100).

[3] Mecca, says one of its citizens, ap. Wákidí (Kremer's ed., p. 196, or *Muh. in Med.*, p. 100), is a settlement formed for trade with Syria in summer and Abyssinia in winter, and cannot continue to exist if the trade is interrupted.

[4] Details as to the inhabitants and constitution of Mecca before Islám will be given under MOHAMMED.

[5] The details are variously related. See Bírúní, p. 328 (E. T., p. 324); Asma'í in Yákút, iii. 705, iv. 416, 421; Azrakí, p. 129 *sq.*; Bekrí, p. 661. Jebel Kabkab is a great mountain occupying the angle between W. Na'mán and the plain of 'Arafa. The peak is due north of Sheddád, the hamlet which Burckhardt (i. 115) calls Shedad. According to Azrakí, p. 80, the last shrine visited was that of the three trees of 'Uzzá in W. Nakhla.

[6] So we are told by Bírúní, p. 62 (E. T., p. 73).

[7] Wákidí, ed. Kremer, pp. 20, 21; *Muh. in Med.*, p. 39.

[8] The older fairs were not entirely deserted till the troubles of the last days of the Omayyads (Azrakí, p. 131).

[9] Ibn Jubair, ed. Wright, p. 118 *sq.*

quarters of the town. At the northern or upper end was the Báb el Ma'lá, or gate of the upper quarter, whence the road continues up the valley towards Miná and 'Arafa as well as towards Zeima and the Nejd. Beyond the gate, in a place called the Ḥajún, is the chief cemetery, said to be the resting-place of many of the companions of Mohammed. Here a cross-road, running over the hill to join the main Medina road from the western gate, turns off to the west by the pass of Kadá, the point from which the troops of the Prophet stormed the city (A.H. 8).[1] Here too the body of Ibn Zubeyr was hung on a cross by Ḥajjáj. The lower or southern gate, at the Masfala quarter, opened on the Yemen road, where the rain-water from Mecca flows off into an open valley. Beyond, there are mountains on both sides; on that to the east, commanding the town, is the great castle, a fortress of considerable strength. The third or western gate, Báb el-'Omra (formerly also Báb el-Záhir, from a village of that name), lay almost opposite the great mosque, and opened on a road leading westwards round the southern spurs of the Red Mountain. This is the way to Wády Fátima and Medína, the Jidda road branching off from it to the left. Considerable suburbs now lie outside the quarter named after this gate; in the Middle Ages a pleasant country road led for some miles through partly cultivated land with good wells, as far as the boundary of the sacred territory and gathering place of the pilgrims at Tan'ím, near the mosque of 'Áisha. This is the spot on the Medína road now called the 'Omra, from a ceremonial connected with it which will be mentioned below.

The length of the sinuous main axis of the city from the furthest suburbs on the Medina road to the suburbs in the extreme north, now frequented by Bedouins, is, according to Burckhardt, 3500 paces.[2] About the middle of this line the longitudinal thoroughfares are pushed aside by the vast courtyard and colonnades composing the great mosque, which, with its spacious arcades surrounding the Ka'ba and other holy places, and its seven minarets, forms the only prominent architectural feature of the city. The mosque is enclosed by houses with windows opening on the arcades and commanding a view of the Ka'ba. Immediately beyond these, on the side facing J. Abu Ḳobeys, a broad street runs south-east and north-west across the valley. This is the Mas'á or sacred course between the eminences of Ṣafá and Merwa, and has been from very early times one of the most lively bazaars and the centre of Meccan life. The other chief bazaars are also near the mosque in smaller streets. The rest of the town presents no points of individual interest, but its general aspect is picturesque; the streets are fairly spacious, though ill-kept and filthy; the houses are all of stone, many of them well-built and four or five stories high, with terraced roofs and large projecting windows as in Jidda—a style of building which has not varied materially since the 10th century (Moḳaddasí, p. 71), and gains in effect from the way in which the dwellings run up the sides and spurs of the mountains. Of public institutions there are baths, ribáṭs or hospices for poor pilgrims from India, Java, &c., a hospital with fifty beds, a public kitchen for the poor, badly administered by the Turkish authorities. A settler from India has recently set up a theological school; but the old colleges around the mosque have long since been converted into lodgings.[3] The minor places of visitation for pilgrims, such as the birth-places of the Prophet and his chief followers, are not notable.[4] Both these and the court of the great mosque are observed to lie beneath the general level of the city, so that it is evident that the site of the town has been gradually raised by accumulated rubbish. The town in fact has little air of antiquity; genuine Arab buildings do not last long, especially in a valley periodically ravaged by tremendous floods when the tropical rains burst on the surrounding hills. The history of Mecca is full of the record of these inundations, unsuccessfully combated by the great dam drawn across the valley by the caliph 'Omar (Ḳuṭb el-Dín, p. 76), and later works of El-Mahdí.[5]

The fixed population of Mecca in 1878 was estimated by Assistant-Surgeon 'Abd el-Razzáḳ at 50,000 to 60,000; but the materials for an estimate are very inadequate where there is so large a floating population—and that not merely at the proper season of pilgrimage, the pilgrims of one season often beginning to arrive before those of the former season have all dispersed. At the height of the season the town is much overcrowded, and the entire want of a drainage system is severely felt. Fortunately good water is tolerably plentiful; for, though the wells are mostly undrinkable, and even the famous Zamzam water very unwholesome and tainted with sewage, the underground conduit from beyond 'Arafa, completed by Sultan Selim II. in 1571, supplies to the public fountains a sweet and light water, containing, according to 'Abd el-Razzáḳ, a large amount of chlorides. The water is said to be free to townsmen, but is sold to the pilgrims at a rather high rate.[6]

Mediæval writers celebrate the copious supplies, especially of fine fruits, brought to the city from Ṭáif and other fertile parts of Arabia. These fruits are still famous; rice and other foreign products are brought by sea to Jidda; mutton is plentifully supplied from the desert.[7] The industries of Mecca all centre in the pilgrimage; the chief object of every Meccan—from the notables and sheikhs, who use their influence to gain custom for the Jidda speculators in the pilgrim traffic, down to the cicerones, pilgrim brokers, lodging-house keepers, and semi-mendicant hangers on at the holy places—being to pillage the visiter in every possible way. Thus the fanaticism of the Meccan is an affair of the purse; the mongrel population (for the town is by no means purely Arab) has exchanged the virtues of the Bedouin for the worst corruptions of Eastern town life, without casting off the ferocity of the desert, and it is hardly possible to find a worse certificate of character than the three parallel gashes on each cheek, called Tashríṭ, which are the customary mark of birth in the holy city. The unspeakable vices of Mecca are a scandal to all Islám, and a constant source of wonder to pious pilgrims.[8] The slave trade, which still

[1] This is the cross-road traversed by Burckhardt (i. 109), and described by him as cut through the rocks with much labour.

[2] Istakhrí gives the length of the city proper from north to south as 2 miles, and the greatest breadth from the Jiyád quarter east of the great mosque across the valley and up the western slopes as two-thirds of the length.

[3] The pious foundations of Mecca have been robbed by their guardians from very early times. See already Ibn Ḥauḳal, p. 25.

[4] For details as to the ancient quarters of Mecca, where the several families or septs lived apart from generation to generation, see Azraḳí, p. 445 *sq.*, and compare Ya'kubí, ed. Juynboll, p. 100. The modern town is best described by Burckhardt, who gives a plan of the city. The minor sacred places are described at length by Azraḳí and Ibn Jubair. They are either connected with genuine memories of the Prophet and his times, or have spurious legends to conceal the fact that they were originally holy stones, wells, or the like, of heathen sanctity.

[5] Beládhorí, in his chapter on the floods of Mecca (p. 53 *sq.*), says that 'Omar built two dams.

[6] The aqueduct is the successor of an older one associated with the names of Zobeyda, wife of Harún el-Rashíd, and other benefactors. But the old aqueduct was frequently out of repair, and seems to have played but a secondary part in the mediæval water supply. Even the new aqueduct gave no adequate supply in Burckhardt's time.

[7] In Ibn Jubair's time (p. 132) large supplies were brought from the Yemen mountains. The revenues of Yemen are still mainly expended on the distribution of grain by the sultan in the Ḥijáz.

[8] The corruption of manners in Mecca is no new thing. See the letter of the caliph Mahdí on the subject; Wüstenfeld, *Chron. Mek.*, iv. 168.

subsists and is very dear to the Arab heart, has connexions with the pilgrimage which are not yet thoroughly cleared up; but there is no doubt that under cover of the pilgrimage a great deal of kidnapping and importation of slaves goes on.

Since the fall of Ibn Zubeyr the political position of Mecca has always been dependent on the movements of the greater Mohammedan world. In the splendid times of the caliphs immense sums were lavished upon the pilgrimage and the holy city; and conversely the decay of the central authority of Islám brought with it a long period of faction, wars, and misery, in which the most notable episode was the sack of Mecca, with circumstances of great barbarity, by the Carmathians at the pilgrimage season of 930 A.D. The victors carried off the "black stone," which was not restored for twenty-two years, and then only for a great ransom, when it was plain that even the loss of the palladium could not destroy the sacred character of the city. Under the Fatimites Egyptian influence began to be strong in Mecca; it was opposed by the sultans of Yemen, while native princes claiming descent from the Prophet—the Háshimite emírs of Mecca, and after them the emírs of the house of Katáda (since 1202)—attained to great authority and aimed at independence; but soon after the final fall of the Abbasids the Egyptian overlordship was definitively established by Sultan Bíbars (1269 A.D.). The Turkish conquest of Egypt transferred the supremacy to the Ottoman sultans (1517), who treated Mecca with much favour, and during the 16th century executed great works in the sanctuary and temple. The Ottoman power, however, became gradually almost nominal, and that of the emírs or sherífs increased in proportion, culminating under Ghálib, whose accession dates from 1786. Then followed the wars of the Wahhábís (see ARABIA, vol. ii. p. 260) and the restoration of Turkish rule by the troops of Mohammed ʿAlí. By him the dignity of sheríf was deprived of much of its weight, and in 1827 a change of dynasty was effected by the appointment of Ibn ʿAun. Since that time the Turkish authority has again decayed, though Mecca is still nominally the capital of a Turkish province, and has a governor-general and a Turkish garrison, while Mohammedan law is administered by a judge sent from Constantinople. But, except within the larger towns, at which troops are stationed, the Turks are practically powerless, and the real sovereign of Mecca and the Ḥijáz is the sheríf, who, as head of a princely family claiming descent from the Prophet, holds a sort of feudal position in the country. The dignity of sheríf (or grand sheríf, as Europeans usually say for the sake of distinction, since all the kin of the princely houses reckoning descent from the Prophet are also named sherífs), is often conceived as a religious pontificate, and anti-Turkish Arabs contend that if the sultan and the sheríf were together in a mosque the latter would lead the prayers as imám; but it is more correct to regard the sheríf as the modern counterpart of the ancient emírs of Mecca already referred to, who were named in the public prayers immediately after the reigning caliph. This dignity long ran in the family of Ḥasan, son of the caliph ʿAlí, with which the present sherífs, in spite of changes of dynasty, still count kindred. The influence of the princes of Mecca has varied from time to time according to the strength of the foreign protectorate in the Ḥijáz or in consequence of feuds among the branches of the house; at present it is for most purposes much greater than that of the Turks. The latter are strong enough to hold the garrisoned towns, and thus the sultan is able within certain limits—playing off one against the other the two rival branches of the aristocracy, viz., the kin of Ghálib and the house of Ibn ʿAun—to assert the right of designating or removing the sheríf, to whom in turn he owes the possibility of maintaining, with the aid of considerable pensions, the semblance of his much-prized lordship over the holy cities. The grand sheríf can muster a considerable force of freedmen and clients, and his kin, holding wells and lands in various places through the Ḥijáz, act as his deputies and administer the old Arabic customary law to the Bedouins. To this influence the Ḥijáz owes what little of law and order it enjoys. After the sherífs the principal family of Mecca is the house of Sheyb, which holds the hereditary custodianship of the Kaʿba.

The Great Mosque and the Kaʿba.—Long before Mohammed the chief sanctuary of Mecca was the Kaʿba, a rude stone building, so named from its resemblance to a monstrous *astragalus* or die, of about 40 feet cube, though the shapeless mass is not really an exact cube or even exactly rectangular.[1] The Kaʿba has been rebuilt more than once since Mohammed purged it of idols and adopted it as the chief sanctuary of Islám, but the old form has been preserved except in secondary details;[2] so that the "Ancient House," as it is titled, is still essentially a heathen temple, adapted to the worship of Islám by the clumsy fiction that it was built by Abraham and Ishmael by divine revelation as a temple of pure monotheism, and that it was only temporarily perverted to idol worship from the time when ʿAmr ibn Lohay introduced the statue of Hobal from Syria[3] till the victory of Islám. This fiction has involved the superinduction of a new mythology about Abraham, Hagar, and Ishmael over the old heathen ritual, which remains practically unchanged. Thus the chief object of veneration is the ancient fetish of the black stone, which is fixed in the external angle facing Ṣafá. The building is not exactly oriented, but this may for convenience be called the south-east corner. Its technical name is the black corner, the others being named the Yemen (south-west), Syrian (north-west), and ʿIráḳ (north-east) corners, from the lands to which they approximately point. The black stone is a small dark mass a span long, with an aspect suggesting volcanic or meteoric origin, fixed at such a height that it can be conveniently kissed by a person of middle size. It was broken by fire in the siege of 683 A.D. (not as many authors relate by the Carmathians), and the pieces are kept together by a silver setting. The history of this heavenly stone, given by Gabriel to Abraham, does not conceal the fact that it was originally a fetish, the most venerated of a multitude of idols and sacred stones which stood all round

[1] The following measurements may be cited:—Ibn ʿAbd Rabbih (10th century), south side 20 cubits, north 21, east and west 25 each (so Azraḳí); Ibn Jubair (12th century), sides 54 and 48 spans, height 29 cubits at the highest or south wall, with a slight fall to the north side where the mízáb or water-spout discharges (Azraḳí, 27 cubits); Burckhardt, sides 18 paces by 14, height 35 to 40 feet. Other modern measures vary considerably. The height was raised by Ibn Zubeyr from 18 to 27 cubits. Compare *Muh. in Med.*, p. 426.

[2] The Kaʿba of Mohammed's time was itself the successor of an older building said to have been destroyed by fire. It was constructed in the still usual rude style of Arabic masonry, with string courses of timber between the stones (like Solomon's temple). The roof rested on six pillars; the door was raised above the ground and approached by a stair (probably on account of the floods which often swept the valley); and worshippers left their shoes under the stair before entering. During the first siege of Mecca (683 A.D.) the building was burned down, and Ibn Zubeyr reconstructed it on an enlarged scale and in better style of solid ashlar work. After his death his most glaring innovations (the introduction of two doors on a level with the ground, and the extension of the building lengthwise to include the Ḥijr) were corrected by Ḥajjáj under orders from the caliph, but the building retained its more solid structure. The roof now rested on three pillars, and the height was raised one-half. The Kaʿba was again entirely rebuilt after the flood of 1626 A.D., but since Ḥajjáj there seem to have been no structural changes.

[3] Hobal was set up within the temple over the pit that contained the sacred treasures. His chief function was connected with the sacred lot to which the Meccans were accustomed to betake themselves in all matters of difficulty.

the sanctuary in the time of Mohammed. The Prophet destroyed the idols, but he left the characteristic form of worship—the *ṭawáf*, or sevenfold circuit of the sanctuary, the worshipper kissing or touching the objects of his veneration—and besides the black stone he recognized the so-called "southern" stone, the same presumably with that which is still touched in the ṭawáf at the Yemen corner (*Muh. in Med.*, pp. 336, 425). The ceremony of the ṭawáf and the worship of stone fetishes was common to Mecca with other ancient Arabian sanctuaries.[1] It was, as it still is, a frequent religious exercise of the Meccans, and the first duty of one who returned to the city or arrived there under a vow of pilgrimage; and thus the outside of the Kaʿba was and is more important than the inside. Islám did away with the worship of idols; what was lost in interest by their suppression has been supplied by the invention of spots consecrated by recollections of Abraham, Ishmael, and Hagar, or held to be acceptable places of prayer. Thus the space of ten spans between the black stone and the door, which is on the east side, between the black and ʿIráḳ corners, and a man's height from the ground, is called the *Multazam*, and here prayer should be offered after the ṭawáf with outstretched arms and breast pressed against the house. On the other side of the door, against the same wall, is a shallow trough which is said to mark the original site of the stone on which Abraham stood to build the Kaʿba. Here the growth of the legend can be traced, for the place is now called the "kneading-place" (Maʿjan) where the cement for the Kaʿba was prepared. This name and story do not appear in the older accounts. Once more, on the north side of the Kaʿba, there projects a low semicircular wall of marble with an opening at each end between it and the walls of the house. The space within is paved with mosaic, and is called the Ḥijr. It is included in the ṭawáf, and two slabs of *verde antico* within it are called the graves of Ishmael and Hagar, and are places of acceptable prayer. Even the golden or gilded *mízáb* (water-spout) that projects into the Ḥijr marks a place where prayer is heard, and another such place is the part of the west wall close to the Yemen corner.

The feeling of religious conservatism which has preserved the structural rudeness of the Kaʿba through so many centuries did not interfere with the adoption of costly surface decoration. In Mohammed's time the outer walls were covered by a vail (or *kiswa*) of striped Yemen cloth. The magnificence of the caliphs substituted a covering of figured brocade, and the sultan still sends with each pilgrim caravan from Cairo a new kiswa of black brocade, adorned with a broad band embroidered with golden inscriptions from the Koran, as well as a richer curtain for the door. The aspect thus given to the Kaʿba is seen in the woodcut; there are openings to show the two sacred stones.[2] The door of two leaves, with its posts and lintel, is of silver gilt.

The interior of the Kaʿba is now opened but a few times every year; there is a great scramble for admission—the portable staircase being seldom brought forward—and a great clamour for backshish; thus the modern descriptions, from observations made under difficulties, are not very complete. Little change, however, seems to have been made since the time of Ibn Jubair, who describes the floor and walls as overlaid with richly variegated marbles, and the upper half of the walls as plated with silver thickly gilt, while the roof was vailed with coloured silk. Modern writers describe the place as windowless, but Ibn Jubair mentions five windows of rich stained glass from ʿIráḳ. Between the three pillars of teak hung thirteen silver lamps. A chest in the corner to the left of one entering contained Korans, and at the ʿIráḳ corner a space was cut off enclosing the stair that leads to the roof. The door to this stair (called the door of mercy—Báb el-Raḥma) was plated with silver by the caliph Mutawakkil. Here, in the time of Ibn Jubair, the Maḳám or standing-stone of Abraham was usually placed for better security, but brought out on great occasions (pp. 131, 161).[3]

The houses of ancient Mecca pressed close upon the Kaʿba, the noblest families, who traced their descent from Ḳoṣay, the reputed founder of the city, having their dwellings immediately round the sanctuary. To the north of the Kaʿba was the Dár el-Nadwa, or place of assembly of the Koreysh, where all matters of public interest were discussed. The multiplication of pilgrims after Islám soon made it necessary to clear away the nearest dwellings and enlarge the place of prayer around the Ancient House. ʿOmar, ʿOthmán, and Ibn Zubeyr had all a share in this work, but the great founder of the mosque in its present form, with its spacious area and deep colonnades, was the caliph El-Mahdí, who spent enormous sums in bringing costly pillars from Egypt and Syria. The work was still incomplete at his death in 785 A.D., and was finished in less sumptuous style by his successor. Subsequent repairs and additions, extending down to Turkish times, have left little of El-Mahdí's work untouched, though a few of the pillars probably date from his days. There are more than five hundred pillars in all, of very various style and workmanship, and the enclosure—250 paces in length and 200 in breadth, according to Burckhardt's measurement—is entered by nineteen archways irregularly disposed.

After the Kaʿba the principal points of interest in the mosque are the well Zamzam and the Maḳám Ibráhím. The former is a deep shaft enclosed in a massive vaulted building paved with marble, and, according to Mohammedan tradition, is the source (corresponding to the Beer-lahai-roi of Gen. xvi. 14) from which Hagar drew water for her son Ishmael. This of course is pure invention, and indeed the legend tells that the well was long covered up and rediscovered by ʿAbd el-Muṭṭalib, the grandfather of the Prophet. Sacred wells are familiar features of Semitic sanctuaries, and Islám, retaining the well, made a quasi-Biblical story for it, and endowed its tepid waters with miraculous curative virtues. They are eagerly drunk by the pilgrims, or when poured over the body are held to give a miraculous refreshment after the fatigues of religious exercise, and the manufacture of bottles or jars for carrying the water to distant countries is quite a trade. Ibn Jubair (p. 139) mentions a curious superstition of the Meccans, who believed that the water rose in the shaft at the full moon of the month Shaʿbán. On this occasion a great crowd, especially of young people, thronged round the well with shouts of religious enthusiasm, while the servants of the well dashed buckets of water over their heads. The Maḳám or standing place of Abraham is also connected with a relic of heathenism, the ancient holy stone which once stood on the Maʿjan, and is said to bear the prints of the patriarch's

[1] See Ibn Hishám, i. 54; Azraḳí, p. 80 (ʿUzzá in Batn Marr); Yáḳút, iii. 705 (Otheydá); Bar Hebræus on Psalm xii. 9. Stones worshipped by circling round them bore the name *dawár* or *duwár* (Krehl, *Rel. d. Araber*, p. 69). The later Arabs not unnaturally viewed such cultus as imitated from that of Mecca (Yáḳút, iv. 622; comp. Dozy, *Israeliten te Mekka*, p. 125, who draws very perverse inferences).

[2] The old *kiswa* is removed on the 25th day of the month before the pilgrimage, and fragments of it are bought by the pilgrims as charms. Till the 10th day of the pilgrimage month the Kaʿba is bare.

[3] Before Islám the Kaʿba was opened every Monday and Thursday; in the time of Ibn Jubair it was opened with considerable ceremony every Monday and Friday, and daily in the month Rajab. But, though prayer within the building is favoured by the example of the Prophet, it is not compulsory on the Moslem, and even in the time of Ibn Batúta the opportunities of entrance were reduced to Friday and the birthday of the Prophet.

feet. The whole legend of this stone, which is full of miraculous incidents, seems to have arisen from a misconception, the Maḳám Ibráhím in the Korán meaning the sanctuary itself; but the stone, which is a block about 3 spans in height and 2 in breadth, and in shape "like a potter's furnace" (Ibn Jubair), is certainly very ancient. It is now covered up, and no one is allowed to see it, though the box in which it lies can be seen or touched through a grating in the little chapel that surrounds it. In the Middle Ages it was sometimes shown, and Ibn Jubair describes the pious enthusiasm with which he drank Zamzam water poured on the footprints. It was covered with inscriptions in an unknown character, one of which was copied by Fákihí in his history of Mecca. To judge by the facsimile in Dozy's *Israeliten te Mekka*, the character is probably essentially one with that of the Syrian Ṣafá inscriptions, which we now know to have extended through the Nejd and into the Ḥijáz.[1]

The general aspect of the great mosque will be best understood by reference to the woodcut, which is taken from a photograph. The photographer has taken his stand on a lofty building facing the black stone corner of the Ka'ba, so that house tops, with high parapets serving to protect the privacy of the women, who spend much of their time on these terraces, form too prominent a feature in the foreground, and obstruct the view of part of the cloistered area. The background is the Red Mountain; the fort which is seen above the town is not the great castle but a building of the sherif Ghálib, dating from about the beginning of this century. It will be observed that at two places there are smaller cloistered courts annexed to the main colonnade. That to the right, with a polygonal minaret, corresponds to the ancient Dár el-Nadwá, which was included in the mosque by the caliph Mo'taḍid. The other minor court is at the Báb Ibráhím. Of the two walls of the Ka'ba concealed from view, that to the right is the one adjoining the Ḥijr. The two-storied pagoda-like building facing this wall is the Maḳám or station for prayer of orthodox Moslems of the Ḥanafí rite, to which the Turks belong. The similar stations of the other orthodox sects have but one story; that of the Málikí rite is seen to the left of the Ka'ba; the roof of the Ḥanbalí station is just visible in the foreground a little to the left of the "black" corner; the Sháfi'í station, which stands on the roof of the Zamzam building, is more prominent a little to the right. Between this and the Maḳám Ḥanafí rises the slender gilt spire of the white marble pulpit from which sermons are preached on Fridays and high days. Between the pulpit and the Zamzam is the small chapel of Abraham's stone. It does not rise high enough to be seen in the cut. The two small and ugly domes to the right of the Zamzam are the dome of 'Abbás and the dome of the Jewess. They are used as storerooms, but the former, which has its name from the uncle of the Prophet, was formerly the drinking-place of the pilgrims. In the time of Ibn Jubair it was still used for cooling the Zamzam water. The oval part of the court next to the Ka'ba within the railing is paved with marble; parts of the area beyond are also paved, part being strewn with gravel. Around the railing a number of glass lamps are lighted at night.

Ṣafá and Merwa.—In religious importance these two points or "hills," connected, as we have seen, by the Mas'á, stand second only to the Ka'ba. Ṣafá is an elevated platform surmounted by a triple arch, and approached by a flight of steps.[2] It lies south-east of the Ka'ba, facing the black corner, and 76 paces from the "Gate of Ṣafá," which is architecturally the chief gate of the mosque. Merwa is a similar platform, formerly covered with a single arch, on the opposite side of the valley. It stands on a spur of the Red Mountain called J. Ḳu'ayḳi'án. The course between these two sacred points is 493 paces long, and the religious ceremony called the "sa'y" consists in traversing it seven times, beginning and ending at Ṣafá. The lowest part of the course, between the so-called green milestones, is done at a run. This ceremony, which, as we shall presently see, is part of the 'omra, is generally said to be performed in memory of Hagar, who ran to and fro between the two eminences vainly seeking water for her son. The observance, however, is certainly of pagan origin; and at one time there were idols on both the so-called hills (see especially Azraḳí, pp. 74, 78).

Mecca—the Great Mosque.

The Ceremonies and the Pilgrimage.—Before Islám the Ka'ba was the local sanctuary of the Meccans, where they prayed and did sacrifice, where oaths were administered and hard cases submitted to divine sentence according to the immemorial custom of Semitic shrines. But besides this, as we have seen, Mecca was already a place of pilgrimage. Pilgrimage with the ancient Arabs was the fulfilment of a vow, which appears to have generally terminated—at least on the part of the well-to-do—in a sacrificial feast. A vow of pilgrimage might be directed to other sanctuaries than Mecca—the technical word for it (ihlál) is applied for example to the pilgrimage to Manát (Bekrí, p. 519). He who was under such a vow was bound by ceremonial observances of abstinence from certain acts (*e.g.*, hunting) and sensual pleasures, and in particular was forbidden to shear or comb his hair till the fulfilment of the vow. This old Semitic usage has its close parallel in the vow of the Nazarite. It was not peculiarly connected with Mecca; at Ṭáif, for example, it was customary on return to the city after an absence to present oneself at the sanctuary, and there shear the hair (*Muh. in Med.*, p. 381). Pilgrimages to Mecca were not tied to a single time, but they were naturally associated with festive occasions, and especially with the great annual feast and market already spoken of, when by extensive hospitality the citizens did all in their power to attract the worshippers who were at the same time their customers. The pilgrimage was so intimately connected with the wellbeing of Mecca, and had already such a hold on the Arabs round about, that the politic Mohammed could not afford to sacrifice it to an abstract purity of religion, and thus the old usages were transplanted into Islám in the double form of the 'omra or vow of pilgrimage to Mecca, which can be discharged at any time, and the ḥajj or pilgrimage at the great annual feast. The latter closes with a visit to the Ka'ba, but its essential ceremonies lie outside Mecca, at the neighbouring shrines where the old Arabs gathered before the Meccan fair.

The 'omra begins at some point outside the Ḥaram or holy territory, generally at Tan'ím described above, both for convenience sake and because 'Áisha began the 'omra there in the year 10 of the Flight. The pilgrim enters the Ḥaram in the antique and scanty pilgrimage dress (iḥrám), consisting of two cloths wound round his person in a way prescribed by ritual. His devotion is expressed in

[1] See De Vogüé, *Syrie Centrale: Inscr. Sem.*; Lady Anne Blunt, *Pilgrimage to Nejd*, vol. ii.; and W. R. Smith, in the *Athenæum*, March 20, 1880.

[2] Ibn Jubair speaks of fourteen steps, Aly Bey of four, Burckhardt of three. The surrounding ground no doubt has risen so that the old name "hill of Ṣafá" is now inapplicable.

shouts of Labbeyka (a word of obscure origin and meaning); he enters the great mosque, performs the ṭawáf and the sa'y[1] with circumstances and prayers which it is unnecessary to detail, and then has his head shaved and resumes his common dress. This ceremony is now generally combined with the ḥajj, or is performed by every stranger or traveller when he enters Mecca, and the iḥrám (which involves the acts of abstinence already referred to) is assumed at a considerable distance from the city. But it is also proper during one's residence in the holy city to perform at least one 'omra from Tan'ím in connexion with a visit to the mosque of 'Áisha there. The absurd triviality of these rites is ill concealed by the legends of the sa'y of Hagar and of the ṭawáf being first performed by Adam in imitation of the circuit of the angels about the throne of God; but in truth the meaning of their ceremonies seems to have been almost a blank to the Arabs before Islám, whose religion had become a mere formal tradition. We do not even know to what deity the worship expressed in the ṭawáf was properly addressed. There is a tradition that the Ka'ba was a temple of Saturn (Shahrastání, p. 431); perhaps the most distinctive feature of the shrine may be sought in the sacred doves which still enjoy the protection of the sanctuary. These recall the sacred doves of Ascalon (Philo, vi. 200 of Richter's ed.), and suggest Venus-worship as at least one element (comp. Herod., i. 131; iii. 8; Ephr. Syr., *Op. Syr.*, ii. 457).

To the ordinary pilgrim the 'omra has become so much an episode of the ḥajj that it is often described as a mere visit to the mosque of 'Áisha; a better conception of its original significance is got from the Meccan feast of the seventh month (Rajab) graphically described by Ibn Jubair from his observations in 1184 A.D. Rajab was one of the ancient sacred months, and the feast, which extended through the whole month, and was a joyful season of hospitality and thanksgiving, no doubt represents the ancient feasts of Mecca more exactly than the ceremonies of the ḥajj, in which old usage has been overlaid by traditions and glosses of Islám. The 'omra was performed by crowds from day to day, especially at new and full moon.[2] The new moon celebration was nocturnal; the road to Tan'ím, the Mas'á, and the mosque were brilliantly illuminated; and the appearing of the moon was greeted with noisy music. A genuine old Arab market was held, for the wild Bedouins of the Yemen mountains came in thousands to barter their cattle and fruits for clothing, and deemed that to absent themselves would bring drought and cattle plague in their homes. Though ignorant of the legal ritual and prayers, they performed the ṭawáf with enthusiasm, throwing themselves against the Ka'ba and clinging to its curtains as a child clings to its mother. They also made a point of entering the Ka'ba. The 29th of the month was the feast day of the Meccan women, when they and their little ones had the Ka'ba to themselves without the presence even of the Sheybís.

The central and essential ceremonies of the ḥajj or greater pilgrimage are those of the day of 'Arafa, the 9th of the "pilgrimage month" (Dhu'l Ḥijja), the last of the Arab year; and every Moslem who is his own master, and can command the necessary means, is bound to join in these once in his life. By them the pilgrim becomes as pure from sin as when he was born, and gains for the rest of his life the honourable title of ḥájj. Neglect of other parts of the pilgrim ceremonial may be compensated by offerings, but to miss the "stand" (wokúf) at 'Arafa is to miss the pilgrimage. 'Arafa or 'Arafát is a space artificially limited, round a small isolated hill called the Hill of Mercy, a little way outside the holy territory, on the road from Mecca to Ṭáif. One leaving Mecca after midday can easily reach the place on foot the same evening. The road is first northwards along the Mecca valley and then turns eastward. It leads through the straggling village of Miná, occupying a long narrow valley (W. Miná), two to three hours from Mecca, and thence by the mosque of Muzdalifa over a narrow pass opening out into the plain of 'Arafa, which is an expansion of the great W. Na'mán, through which the Ṭáif road descends from Mount Kara. The lofty and rugged mountains of the Hodheyl tower over the plain on the north side and overshadow the little Hill of Mercy, which is one of those bosses of weathered granite so common in the Ḥijáz. 'Arafa, as we have already seen, lay quite near Dhu'l-Maják, where, according to Arabian tradition, a great fair was held from the 1st to the 8th of the pilgrimage month; and the ceremonies from which the ḥajj was derived were originally an appendix to this fair. Now on the contrary the pilgrim is expected to follow as closely as may be the movements of the Prophet at his "farewell pilgrimage" in the year 10 of the Flight (632 A.D.). He therefore leaves Mecca in pilgrim garb on the 8th of Dhú'l Ḥijja, called the day of tarwíya (an obscure and pre-Islamic name), and strictly speaking should spend the night at Miná. It is now, however, customary to go right on and encamp at once at 'Arafa. The night should be spent in devotion, but the coffee booths do a lively trade, and songs are as common as prayers. Next forenoon the pilgrim is free to move about, and towards midday he may if he please hear a sermon. In the afternoon the essential ceremony begins; it consists simply in "standing" on 'Arafa shouting Labbeyka and reciting prayers and texts till sunset. After the sun is down the vast assemblage breaks up, and a rush (technically *ifáda*, *daf'*, *nafr*) is made in the utmost confusion to Muzdalifa, where the night prayer is said and the night spent. Before sunrise next morning (the 10th) a second "stand" like that on 'Arafa is made for a short time by torchlight round the mosque of Muzdalifa, but before the sun is fairly up all must be in motion in the second *ifáda* towards Miná. The day thus commenced is the "day of sacrifice," and has four ceremonies—(1) to pelt with seven stones a cairn (*jamrat el 'akaba*) at the eastern end of W. Miná, (2) to slay a victim at Miná and hold a sacrificial meal, part of the flesh being also dried and so preserved, or given to the poor,[3] (3) to be shaved and so terminate the *iḥrám*, (4) to make the third *ifáda*, *i.e.*, go to Mecca and perform the ṭawáf and sa'y (*'omrat el-ifáda*), returning thereafter to Miná. The sacrifice and visit to Mecca may, however, be delayed till the 11th, 12th, or 13th. These are the days of Miná, a fair and a joyous feast, with no special ceremony except that each day the pilgrim is expected to throw seven stones at the *jamrat el 'akaba*, and also at each of two similar cairns in the valley. The stones are thrown in the name of Alláh, and are generally thought to be directed at the devil. This is, however, a custom older than Islám, and a tradition in Azrakí, p. 412, represents it as an act of worship to idols at Miná. As the stones are thrown on the days of the fair, it is not unlikely that they have something to do with the old Arab mode of closing a sale by the purchaser throwing a stone (Bírúní, p. 328).[4] The pilgrims leave Miná on the 12th or 13th, and the ḥajj is then over.

The colourless character of these ceremonies is plainly due to the fact that they are nothing more than expurgated heathen rites. In Islám proper they have no *raison d'être*; the legends about Adam and Eve on 'Arafa, about Abraham's sacrifice of the ram at Thabír by Miná, imitated in the sacrifices of the pilgrimage, are mere clumsy afterthoughts, as appears from their variations and only partial acceptance. It is not so easy to get at the nature of the original rites, which Islám was careful to suppress. But old usages were not quickly eradicated, and we find mention of practices condemned by the orthodox, or forming no part of the Moslem ritual, which may be regarded as traces of an older ceremonial. Such are nocturnal illuminations at Miná (Ibn Baṭúta, i. 396), 'Arafa, and Muzdalifa (Ibn Jubair, p. 179), and ṭawáfs performed by the ignorant at holy spots at 'Arafa not recognized by law (Snouck-Hurgronje, p. 149 *sq.*). We know that the rites at Muzdalifa were originally connected with a holy hill bearing the name of the god Kuzaḥ (the Edomite Kozé) whose bow is the rainbow, and there is reason to think that the *ifádas* from 'Arafa and Kuzaḥ, which were not made as now after sunset and before sunrise, but when the sun rested on the tops of the mountains, were ceremonies of farewell and salutation to the sun-god.

The statistics of the pilgrimage cannot be given with certainty and vary much from year to year. The quarantine office keeps a record of arrivals by sea at Jiddah (30,271 for the year 1878 A.D., or 1295 A.H.); but to these must be added the great overland caravans from Cairo, Damascus, and 'Irak, the pilgrims who reach Medina from Yanbu' and go on to Mecca, and those from all parts of the peninsula. Burckhardt in 1814 estimated the crowd at 'Arafa at 70,000, Burton in 1853 at 50,000, 'Abd el-Razzák in 1858 at 60,000. This great assemblage is always a dangerous centre of infection, and the days of Miná especially, spent under circumstances originally adapted only for a Bedouin fair, with no provisions for proper cleanliness, and with the air full of the smell of putrefying offal and flesh drying in the sun, produce much sickness.

Literature.—Besides the Arabic geographers and cosmographers, many of whom have been already cited, we have Ibn 'Abd Rabbih's description of the mosque, early in the 10th century (*'Iḳd Faríd*, Cairo edition, iii. 362 *sq.*), but above all the admirable record of Ibn Jubair (1184 A.D.), by far the best account extant of Mecca and the pilgrimage. It has been much pillaged by Ibn Baṭúṭa. The Arabic historians are largely occupied with fabulous matter as to Mecca before Islam; for these legends the reader may refer to C. de Perceval's *Essai*. How little confidence can be placed in the pre-Islamic history appears very clearly from the distorted accounts of Abraha's excursion against the Ḥijáz, which fell but a few years before the birth of the Prophet, and is the first event in Meccan history which has confirmation from other sources. See Nöldeke's version of Ṭabarí, p. 204 *sq.* For the period of the Prophet Ibn Hishám and Wáḳidí are valuable sources in topography as well as history. Of the special histories and descriptions of Mecca published by Wüstenfeld (*Chroniken der Stadt Mekka*, 3 vols., 1857–59, with an abstract in German 1861), the most valuable is that of Azraḳí. It has passed through the hands of several editors, but the oldest part goes back to the beginning of the 9th Christian century. Ḳuṭb el-Dín's history (vol. iii. of the *Chroniken*) goes down with the additions of his nephew to 1592 A.D.

Of European descriptions of Mecca from personal observation the best is Burckhardt's *Travels in Arabia* (cited above from the 8vo ed., 1829). *The Travels of Aly Bey* (Badia), London, 1816, describe a visit in 1807; Burton's *Pilgrimage* (3d ed., 1879) often supplements Burckhardt; Von Maltzan's *Wallfahrt nach Mekka*, 1865, is lively but very slight. 'Abd el-Razzák's report to the Government of India on the pilgrimage of 1858 is specially directed to sanitary questions. For the pilgrimage see particularly Snouck-Hurgronje, *Het Mekkaansche Feest*, Leyden, 1880. (W. R. S.)

[1] The latter perhaps was no part of the ancient 'omra; see Snouck-Hurgronje, *Het Mekkaansche Feest*, 1880, p. 115 *sq.*

[2] The 27th was also a great day, but this day was in commemoration of the rebuilding of the Ka'ba by Ibn Zubeyr.

[3] The sacrifice is not indispensable except for those who can afford it and are combining the ḥajj with the 'omra.

[4] On the similar pelting of the supposed graves of Abú Lahab and his wife (Ibn Jubair, p. 110) and of Abú Righál at Mughammas, see Nöldeke's translation of Ṭabarí, p. 208.

MECHANICS

STRICTLY speaking, the derivation of this word should have prevented the use of it as the designation of a pure science. It has been, however, employed for a long period in English speech in the identical sense that the French attach to *Mécanique pure* or the Germans to *Reine Mechanik*. These terms are all employed to denote what we should much prefer to call *Abstract Dynamics*,—the pure science which (as the derivation implies) treats of the action of Force upon Matter, but which is, correctly, the *Science of Matter and Motion*, or *of Matter and Energy*.

With the view of making clear from the outset the reason for the arrangement adopted in this article, we commence by stating in Newton's own words (accompanied by a paraphrase) the *Axiomata, sive Leges Motus*, which form the entire basis of our subject. These laws will at once indicate the order in which the subject may most logically be treated. We defer to the end of the article the more close consideration of the idea introduced by the word "force," as well as general remarks on "energy," &c. For the present we are content to regard force as defined for us by Newton's Laws.

Newton's Laws of Motion.

Newton's first law.

§ 1. Lex I. Corpus omne perseverare in statu suo quiescendi vel movendi uniformiter in directum, nisi quatenus illud a viribus impressis cogitur statum suum mutare.

Every body continues in its state of rest, or of uniform motion in a straight line, except in so far as it is compelled by force to change that state.

Second law.

Lex II. Mutationem motus proportionalem esse vi motrici impressæ, et fieri secundum lineam rectam qua vis illa imprimitur.

Change of (quantity of) motion is proportional to force, and takes place in the straight line in which the force acts.

Third law.

Lex III. Actioni contrariam semper et æqualem esse reactionem; sive corporum duorum actiones in se mutuo semper esse æquales et in partes contrarias dirigi.

To every action there is always an equal and contrary reaction; or the mutual actions of any two bodies are always equal and oppositely directed.

Scholium.

§ 2. In 1863 Thomson and Tait (upon whose *Treatise on Natural Philosophy* much of what follows is based) called attention to the fact that, as regards Lex III., Newton gives in a scholium a second sense in which the words may be interpreted. In the first sense the action and reaction are mere forces, in the second they are *the rates at which forces do work*. Hence, and for another reason which will appear later, the word "activity" has been introduced as the English equivalent of the word *actio* in Newton's second sense. Here is the passage:—

Si æstimetur agentis actio ex ejus vi et velocitate conjunctim; et similiter resistentis reactio æstimetur conjunctim ex ejus partium singularum velocitatibus et viribus resistendi ab earum attritione, cohæsione, pondere, et acceleratione oriundis; erunt actio et reactio, in omni instrumentorum usu, sibi invicem semper æquales.

If the activity of an agent be measured by its amount and its velocity conjointly; and if, similarly, the counter-activity of the resistance be measured by the velocities of its several parts and their several amounts conjointly, whether these arise from friction, molecular forces, weight, or acceleration;—activity and counter-activity, in all combinations of machines, will be equal and opposite.

This may be looked upon as a Fourth Law. But, in strict logic, the First Law is superfluous, because its consequences are all implied (by negation) in the statement of the Second. (See § 8 below.) Hence there are, virtually, only three laws, so far as Newton's system is concerned.

Basis of Newton's laws.

§ 3. These laws are to be considered as deductions from observation and experiment, and in no sense as having an *a priori* foundation. Their proof, so far as rigorous proof is attainable in physical matters, is commonly looked on as being furnished in the most conclusive form by observational astronomy. The *Nautical Almanac*, published usually about four years in advance, contains the predicted places of the sun, moon, and principal planets from day to day, in some cases from hour to hour, throughout the year. The predictions are entirely based upon the laws of motion (along with the law of gravitation), and could not possibly be accurate unless these laws are true. So thoroughly satisfactory has hitherto been the coincidence between prediction and observation that, when a deviation occurs, no one dreams of a defect in the principles of the reasoning. On the contrary, such deviations are utilized for the purpose of correcting our knowledge of the "elements" of the orbits of the moon and planets, or our estimates of the masses of these bodies; and, as in the brilliant investigations of Adams and Leverrier, they sometimes enable us to discover the existence and even assign the position of a planet never before seen.

Newton's predecessors.

§ 4. It is not clear in what order, or by whom, these laws were first discovered. Galileo was undoubtedly acquainted with the first two; and Huygens, Wren, Hooke, and others were acquainted with the Third Law in some of its many applications. But they were first systematized and, as we have seen, extended in a most important manner by Newton. Though they were sadly disfigured in Britain during the fifty years which elapsed after the revival of mathematics in the early part of this century, they have of late been restored to the form in which Newton gave them. This readoption of Newton's simple but comprehensive system has of itself aided in no small degree the recent rapid advance of science.

Anthropomorphisms.

One peculiarity of Newton's language must be noticed here, though very briefly, as we will return to the subject towards the end of the article. A force is said to "compel" a change of state in a body; bodies are said mutually to "act" on one another, &c. Such language is, of course, in its literal acceptation, of an anthropomorphic character; but, if one thinks of the habitual use even in scientific books of such expressions as "the sun rises," "the wind blows," &c., it cannot be construed into an assertion that force has real objective existence.

Comments on the Laws of Motion.

Definition of force.

§ 5. Law I. First of all this law tells us what happens to a piece of matter which is left to itself, *i.e.*, not acted on by forces. It preserves its "state," whether of rest or of uniform motion in a straight line. This property (which, as we shall presently show, § 7, is considerably extended by Newton himself) is commonly called the "inertia" of matter, in virtue of which it is incapable of varying in any way its state of rest or motion. It may be the sport of forces for any length of time, but so soon as they cease to act it remains in the state in which it was left until they recommence their action on it. Hence, whenever we find the state of a piece of matter changing, we conclude that it is under the action of a force or forces. Thus, for the present, we have the definition of "force" as part of this First Law:—

Inertia.

Force is whatever changes the state of rest or uniform motion of a body.

When a body, originally at rest, begins to move, we conclude that force is acting on it. And when a moving body is seen to change *either* the speed *or* the direction of its motion, we conclude that this is due to force.[1]

ıbsolute nd elative.

§ 6. But there is much more than this, even in the First Law. What is "rest"? The answer must be that the term is relative. Absolute rest and absolute motion are terms to which we find it impossible to assign a meaning. Maxwell has well said (in his *Matter and Motion*):—

> "All our knowledge, both of time and place, is essentially relative. When a man has acquired the habit of putting words together, without troubling himself to form the thoughts which ought to correspond to them, it is easy for him to frame an antithesis between this relative knowledge and a so-called absolute knowledge, and to point out our ignorance of the absolute position of a point as an instance of the limitation of our faculties. Any one, however, who will try to imagine the state of a mind conscious of knowing the absolute position of a point will ever after be content with our relative knowledge."

As will be seen later, the First Law gives us also a physical definition of "time," and physical modes of measuring it.

ʼewton's om-ıents on ıe first ıw.

§ 7. Newton's own comment on this law is as follows:—

Projectilia perseverant in motibus suis, nisi quatenus a resistentia aeris retardantur, et vi gravitatis impelluntur deorsum. Trochus, cujus partes cohærendo perpetuo retrahunt sese a motibus rectilineis, non cessat rotari, nisi quatenus ab aere retardatur. Majora autem planetarum et cometarum corpora motus suos et progressivos et circulares, in spatiis minus resistentibus factos, conservant diutius.

It is particularly worthy of notice that we have here the undisturbed rotation of a body about an axis introduced as another of those "states" in which it will continue, in virtue of the First Law, until force acts to compel it to change that state. Also it is to be noticed that Newton adduces a hoop, whose axis is fixed in direction both in the body and in space, as an example of this new form of state maintained in virtue of inertia. Later, it will be seen that the same thing is true of a body free in space and rotating about the principal axis of greatest or of least moment of inertia through its centre of mass.[2]

ʼonse-ıuences f second aw.

§ 8. Law II. What Newton designates by the word *motus* is, as he has clearly pointed out, the same as is expressed by *quantitas motus*, that for which we now usually employ the term "momentum." Its numerical value depends not only on the rate of motion, but also on the amount of matter, or "mass," of the moving body, and is directly proportional to either of these when the other is unaltered. But it is regarded by Newton as having direction as well as magnitude. It is, in fact, what in the language of quaternions is called a "vector." The change of such a quantity may be either in numerical magnitude, or in direction, alone, or simultaneously in both. We now see what this Second Law enables us to do. For

(*a*) Given the mass of a body, the force acting on it, and the time during which it acts, we can calculate the change of motion. This is the *direct* problem of dynamics of a particle.

(*b*) Given the mass, and the change of velocity, we can calculate the magnitude and direction of the force acting. This is the *inverse* problem.

(*c*) We can compare, and so measure, forces by the changes of motion they produce in one and the same body.

(*d*) We can compare the masses of different bodies by finding what changes of velocity one and the same force produces in them.

(*e*) We can find the *one* force which is equivalent, in its action, to any given set of forces. For, however many changes of motion may be produced by the separate forces, they must obviously be capable of being compounded into a single change, and we can calculate what force would produce that.[3]

Necessity for a third law.

§ 9. Hitherto, we have spoken of *the* motion of a body,—thus implying (except, of course, in the case of Newton's hoop or that of the earth) that all its parts are moving in exactly the same way. From this point of view every body, however large, may be treated as if it were a single particle. But when the parts of a body have different velocities, as when a rigid body is rotating, or as when a non-rigid body is suffering a change of form, the question becomes much more complex. We cannot at this stage enter into a full explanation, but will take a couple of very simple cases to show the nature of the new difficulties, and thence the necessity for an additional law.

Suppose a bullet to be thrown in any direction. If we know with what force the earth attracts it, the calculation of the path it will pursue depends on the Second Law, which gives all the necessary preliminary information. But let two bullets be tied together by a string: we know by trial that each moves, in general, in a manner very different from that in which it would move if free. The path of each is now, usually, a tortuous curve, while its free path would be plane. It is no longer subject to gravity alone but also to what is called the "tension" of the string. If we knew the amount of this tension on either of the bullets and its direction, we could calculate, by the help of the Second Law alone, all the circumstances of the motion of that bullet. But how are we to find this tension? Is it even the same for each bullet? This, if answered in the affirmative, would simplify matters considerably, but we should still require to know the amount and direction of the tension. It is clear that, without a further axiom, we cannot advance to a solution of the question.

Consequences of third law.

Rigid constraint.

§ 10. Law III. Furnished with this, in addition to our previous information, we can attack the question with more hope. We see by this law that, whatever force be exerted by the string on one of the bullets, an equal and opposite force, which must therefore be in the direction of the string, is exerted on the other. Still, the magnitude of these equal forces remains to be found. But the string in no way interferes with the motion of either bullet *unless it is tight*, *i.e.*, unless the distance between the bullets is equal to the length of the string. Hence, whenever the unknown force comes into play, at the same time there comes in a geometrical relation of relative position between the two bullets. *This supplies the additional equation necessary for the determination of the new unknown quantity.*

Variable constraint.

§ 11. As an additional illustration, suppose the string to be made of india-rubber. The Third Law tells us that the tensions it exerts on the bullets are still equal and opposite. But we no longer have the geometrical condition we had before. We have, however, what is quite sufficient, a

---

[1] The words we have italicized will be seen to have very important bearings on certain old errors which even now crop up, and which have introduced one of the most inappropriate and apparently ineradicable of terms ("centrifugal force") into the usual vocabulary of our subject.

[2] It is also, in a partial sense, true of a free body of which two principal axes through the centre of mass have equal moments of inertia. In that case, as we will show later, even when couples act upon the body, provided they be in planes passing through the third axis, the rate of rotation about that axis remains unaltered, *though its direction in space changes.* This is approximately the case of the earth. The attractions of the sun and moon on the protuberant parts about the equator produce "precession" and "nutation," but do not influence the length of the day.

[3] It is to be observed here that Newton's silence is as expressive as his speech. When he says "change of motion" we understand that it does not matter what the original motion was; and, when he mentions only one force, he implies that the effect of any one force is the same whether others are also at work or not. In fact, with Newton there can be no balancing of forces, though there may be balancing of the effects of forces, a very different thing.

knowledge of *how the tension of the string depends on its length.* Thus the tension can be calculated from the relative position of the bullets.

Transference of energy.

§ 12. Scholium to Law III. On this we will, for the present, remark only that it furnishes us with the means of studying directly the transference of energy from one body or system to another. Experiment, however, was required to complete the application of this part of Newton's systematic treatment of the subject. What was wanted, and how it has been obtainéd, will be treated of later. The first words of the scholium, however, claim for Newton the discovery of the clause we have extracted from it. For they run thus :—Hactenus principia tradidi a mathematicis recepta, et experientia multiplici confirmata.

Division of the subject.

§ 13. What has now been said enables us to see the order in which the fundamental ideas should be taken up, so that the necessities of each should be provided for before its turn comes. An indispensable preliminary is the study of motion in the abstract, *i.e.*, without any reference to *what is moving.* This is demanded in order that we may be able to apply the Second Law. The science of pure motion, without reference to matter or force, is an extension of geometry by the introduction of the idea of time and the consequent idea of velocity. Ampère suggested for it the term *Cinematique*, or, as we shall write it, *Kinematics.* We include under it all changes of form and grouping which can occur in geometrical figures or in groups of points.

We shall then be prepared to deal with the action of force on a single particle of matter, or on a body which may be treated as if it were a mere particle. Thus we have the Dynamics of a Particle. This, again, splits into two heads, Statics and Kinetics of a Particle. But all this requires the Second Law only. When we have two or more connected particles, or two particles attracting one another or impinging on one another, the Third Law is required. Next in order of simplicity come the Statics and Kinetics of a Rigid Solid. Then we have to deal with bodies whose form, &c., are altered by forces—flexible bodies, elastic solids, fluids, &c. Finally, we must briefly consider the general principles, such as "conservation of energy," "least action," &c., which are deducible by proper mathematical methods from Newton's Laws, and of which some at least, if we could more clearly realize their intrinsic nature, would probably be found to express even more simply than do Newton's Laws the true fundamental principles of abstract dynamics.

We will not restrict ourselves to one uniform course in the application of mathematical methods. Rather, as considerations of space require to be attended to, we will vary our methods from one part of the subject to another, so as to exhibit, each at least once, all the more usual processes. And we will endeavour to make the large-type portions of the article, in which only the most elementary mathematics will be introduced, a self-contained treatise which may be read by students of very moderate mathematical knowledge.

KINEMATICS.

Position and the Means of Assigning it.

Position.

§ 14. Motion (or displacement) consists simply in "change of position." Hence, to describe motion, we must have the means of assigning position. This is, of course, a question of GEOMETRY (*q.v.*). See also QUATERNIONS.

From these articles it appears that the position of one free point with reference to another (all these space relations are relative, as we have already said) depends on *three numbers*, of which one at least must involve the unit of length. In Cartesian rectangular coordinates, we denote these by x, y, z, which indicate respectively the distance of the point from each of three planes at right angles to each other, and all passing through the origin (or reference point). From another point of view they may be called "degrees of freedom." When the value of one is assigned, say by

Degrees of freedom,

$$x=a,$$

the point is said to have lost one degree of freedom, or to have had imposed upon it one "degree of constraint." It must now lie in a plane parallel to the first of the reference planes, and at a distance a from it. When a second degree of constraint is applied, say by

of constraint

$$y=b,$$

another degree of freedom is lost. The point's position is limited to lie in a second plane in a given position at right angles to the first. It must therefore lie somewhere on the straight line which consists of the series of points common to the two planes. A third degree of constraint

$$z=c$$

takes away its one remaining degree of freedom; and its position is now definitely assigned as the single point of intersection of three given planes.

§ 15. But constraint may be applied in other ways. Thus if we assign the condition

$$x^2+y^2+z^2=a^2,$$

we deprive the point of one degree of freedom by compelling it to remain at a distance a from the origin. It is now limited to the surface of a sphere, but its latitude and longitude on that sphere may be any whatever. Here again the imposition of one degree of constraint has taken away one degree of freedom.

Example of constraint.

§ 16 In general, one degree of constraint may be expressed as

$$f(x, y, z)=\xi.$$

This, when ξ has an assigned value, is the equation of a definite surface on which the point must lie. Three such conditions determine the position of the point, and may therefore be looked upon as introducing ξ, η, ζ, another set of coordinates, which may be used in place of x, y, z. The number of such systems is, of course, unlimited; but it is often possible to choose one in which the conditions of a problem are much more simply expressed than they were when expressed in x, y, z. The whole question belongs to what is called "change of variables." To give an elementary instance of its use,—suppose we take the ordinary simple pendulum, a pellet supported by a fine thread or wire, and oscillating in a vertical plane. If the origin be placed at the point of suspension, and the axis of z be vertical, we have two conditions :—

$$x^2+y^2+z^2=a^2,$$

where a is the length of the thread; and

$$y/x=\tan\alpha,$$

where α denotes the azimuth of the plane of oscillation. There is but one degree of freedom left, because two degrees of constraint have been imposed. We may choose for this either x, y, or z; but we should in each case be led to complex expressions. If, however, we consider that all the freedom left to the pendulum is to oscillate in a given plane, we may denote its sole remaining degree of freedom by θ, the angle which the string makes with the vertical; and form our dynamical equation in terms of this. When θ is found by dynamical considerations, we have

$$x=a\sin\theta\cos\alpha\,,\ \ y=a\sin\theta\sin\alpha\,,\ \ z=a\cos\theta\,.$$

Generalized coordinate.

Here θ comes in as what is called a "generalized coordinate."

If the pendulum be not limited to one plane, the azimuth, as well as the angle, of the displacement from the vertical may be any whatever. Hence there are two degrees of freedom, which are indicated by the generalized coordinates α and θ.

§ 17. In general, in any system originally with any number m of degrees of freedom, and subjected to a number n of degrees of constraint, the whole motion can be fully characterized by $m-n$ independent quantities, called generalized coordinates, and corresponding to the degrees of freedom which remain. The elegance and simplicity of a solution often depend in a marked manner upon the choice of these; and the transformation of the general equations from Cartesian to generalized coordinates forms one of the most powerful and elegant contributions to abstract dynamics which Lagrange made in the *Mécanique Analytique.*

eedom a gid stem.

§ 18. A rigid system has only *six* degrees of freedom:—three translations for any one of its points, and three independent rotations about axes passing through that point.

When one point is fixed, it loses the three translations, and has only three degrees of freedom. When a second point is fixed, it loses other two; in fact it can no longer move except by turning round the line joining the fixed points. When a third point, not in line with the other two, is fixed, there is no degree of freedom left; the system is fixed.

inear lations nong nall splace- ents.

§ 19. It may be well to notice here that, in all cases which we shall require to consider, whatever be the relations among two different sets of variables which we employ alternatively to determine the relative positions of the parts of any system, the equations which give the relations between corresponding small increments of these variables are always *linear* so far as these increments are concerned. Thus, for instance, if we have as above a condition of the form

$$f(x,\ y,\ z)=\xi\ ,$$

we deduce from it at once

$$\left(\frac{df}{dx}\right)\delta x+\left(\frac{df}{dy}\right)\delta y+\left(\frac{df}{dz}\right)\delta z=\delta\xi\ .$$

Here the differential coefficients are partial.

In such cases, any homogeneous function of the second order in δx, δy, δz, &c., will be represented by a homogeneous function, also of the second order, in $\delta\xi$, $\delta\eta$, &c., however many be the coordinates in the separate systems. When, however, one or more of the equations of condition involves the element of *time* explicitly, the relations among corresponding small increments of the alternative sets of coordinates, though still linear, will not be *homogeneous.* Thus a homogeneous function of the second order in one set will be a function of the second order in the other set, but not homogeneous, unless the increments are produced instantaneously.

To give a single instance, suppose that the string of a simple pendulum (not necessarily oscillating in one plane) *contracts* uniformly. We shall now have

$$x^2+y^2+z^2=(a-ct)^2$$

instead of the equation in the example § 15, and one of our equations among increments is

$$x\delta x+y\delta y+z\delta z=-c(a-ct)\delta t\ ,$$

which, though still linear, is no longer homogeneous in the increments of *coordinates.*

Kinematics of a Point.

ontinu- y of ath of oint.

§ 20. The one necessary characteristic of the path described by a moving point is its *continuity.* There can be no break or gap in it. But, as we study kinematics, at present, solely for its physical applications, we impose a restriction on such complete generality. The path of a moving *particle* must be one of *continuous curvature*, unless either (1) the motion ceases and commences again in a different direction (in which case we have two separate and successive states of motion to consider), or (2) an infinite force is applied to the particle (a case which we need not consider). A similar remark, we may say in passing, applies to velocity also. So that, for our purpose, we may confine ourselves to the geometrical properties of the motion of a point whose rate and direction of motion change continuously, if at all, and not by fits and starts.

)irec- ion of notion.

§ 21. If the point describe a straight line, that line gives the direction of its motion at every instant. If it describe a curve, the direction of its motion is at every instant that of the corresponding tangent to the curve.

Change of direction.

Let A, B, C, D represent four points on the path taken in close succession, in the order in which the moving point reaches them. From A the point moves to B, so that the line joining A and B (the tangent) is the direction of motion at A. Similarly the line joining B and C gives the direction of motion at B. The points A, B, C of course lie in one plane. This is the plane in which, for two successive elements of its path, the point is moving. It is therefore that in which the change of direction of motion takes place, and is called the "osculating plane." And, just as the straight line through A and B gives the direction of motion at A, so the circle passing through the points A, B, C determines the "curvature" of the path at A. If we apply the same reasoning to the three successive points B, C, D, we see the difference between a "plane" and a "tortuous" curve. For, if D lie in the plane ABC, the osculating plane is the same at A and at B; and if the same holds for other successive points the whole bending takes place in one plane. But if D be not in the plane ABC, BCD is the osculating plane at B, and we thus see that successive positions of the osculating plane of a tortuous curve are produced by its rotation about the tangent BC to the path; for BC is in both planes ABC and BCD. We shall not have space here to deal in detail with cases of tortuosity; but it was necessary to point out their essential nature.

Osculating plane.

Tortuous path.

Curvature.

§ 22. The curvature of ABC obviously depends upon the change of direction from AB to BC, and is directly proportional to it. But it is obviously greater, for the same amount of change of direction, as ABC is less. In a circle the curvature is the same at all points, and, as the radius is everywhere perpendicular to the tangent, the change of its direction is the same as that of the tangent. Hence the curvature, being the change of direction *per unit length of the arc*, is measured simply by the reciprocal of the radius.

Generally, if ϕ be the angle between the tangent at A and any fixed line in the osculating plane, and if s represent the length of the curve measured from any fixed point on it to A, we have, by the fundamental property of infinitesimals,

$$\mathrm{L}\frac{\delta\phi}{\delta s}=\frac{d\phi}{ds}=\text{curvature.}$$

(We will use, as above, the letter L for a limit, in the sense in which that term was introduced by Newton.)

In a circle we have always (a being the radius)

$$s=a\phi\ ,$$

and hence the curvature

$$\frac{d\phi}{ds}=\frac{1}{a}\ ;$$

so that in general the measure of curvature is the reciprocal of the radius of the circle passing through three consecutive points of the path. For other analytical expressions for curvature see vol. xiii. p. 26.

For a curve in space (whether tortuous or not) we have

$$\text{Curvature}=\frac{1}{\rho}=\sqrt{\left(\frac{d^2x}{ds^2}\right)^2+\left(\frac{d^2y}{ds^2}\right)^2+\left(\frac{d^2z}{ds^2}\right)^2}\ ,$$

while the direction cosines of the radius of curvature are

$$\rho\frac{d^2x}{ds^2}\ ,\quad \rho\frac{d^2y}{ds^2}\ ,\quad \rho\frac{d^2z}{ds^2}\ .$$

Evolute and involute.

§ 23. The chief properties connected with the curvature of a plane curve are made very clear by the artifice of regarding it as an "involute." This idea introduces us to the kinematics of a flexible and inextensible line. Suppose such a line, held tight, to be wrapped round a cylinder of any form, in a plane perpendicular to its axis, each point of it, when it is unwound in its own plane, will describe a curve whose form depends upon that of the transverse section of the cylinder. Let $P_0M'M$ (fig. 1) be such a section of the cylinder; MP, M′P′, two positions of the free part of the cord; P, P′, the corresponding positions of

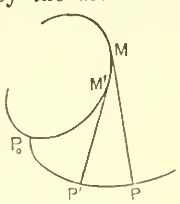

Fig. 1.

a definite point of the cord; $PP'P_0$ the path described by that point. Then $PP'P_0$ is one of the involutes of $MM'P_0$; the others are the curves traced by other points of the string. But, with reference to $PP'P_0$, the curve $MM'P_0$ is *the* "evolute." The evolute of such a curve is, in fact, unique; for it is obvious that the line MP, in any of its positions, is revolving about the point of contact M with the evolute; so that P describes an infinitesimal arc of a circle of which M is the centre. Thus the evolute of a plane curve is the locus of its centre of curvature. And it is clear from the genesis of the involute that

$$PM = P'M' + M'M = P_0M'M.$$

For the analytical discussion of evolutes, see vol. xiii. p. 26.

The subject of evolutes is of importance in various branches of physics, especially in optics. In mechanics its chief use is connected with the theory of the pendulum, as it shows how to cause the bob to move in a cycloid, the only path in which the time of oscillation is the same whatever be the extent of the oscillations.

Speed. § 24. When the line, curved or straight, in which the motion takes place is given, the position of the moving point is at once assigned in terms of a single numerical quantity. In fact it has only one degree of freedom, and its position is known by the length of the arc of the curve from any fixed point to the given position. In such a case as this we are not concerned with the direction of the motion, for that is already assigned at every point of the path. We are concerned only with what we may call the "speed" of the motion. (We purposely avoid the use of the term "velocity" here, because it properly includes direction as well as speed, as will be seen later.)

Average speed. § 25. Suppose an observer to be watching the motion (as, for instance, a traveller by rail notes the telegraph posts which he passes, referring at each to his watch), and to find that at any time t_1 the moving point was at s_1, while at time t_2 it was at s_2.

Then it is clear that the *average* speed during this part of the motion is to be found by dividing the number of units of space passed over by the number of units of time employed. For it must be greater as the former is greater and less as the latter is greater. Hence the average speed is $\frac{s_2 - s_1}{t_2 - t_1}$. If the speed has been *uniform* during the motion observed, this average value has coincided with the actual value all through; and, if the measures of space and time are accurate, we shall get exactly the same value of this ratio whether the interval of time is small or large. Hence, if v be the speed of a uniformly moving point, the space it describes in time t is vt. But if the speed has been *variable*, it must at some parts of the interval have been greater, at others less, than this average. And the shorter we take the interval the less will be the difference between the greatest and least speeds during its lapse, so that the average speed will coincide more and more nearly with the actual speed. In the language of "fluxions" (which was invented for the sake of this subject) the measure of the speed at any time t_1 is

Measurement of uniform and of variable speed.

$$\dot{s} = L\frac{s_2 - s_1}{t_2 - t_1},$$

when the interval $t_2 - t_1$ is shortened indefinitely. The accuracy of the preceding process depends entirely upon the limitations we have introduced for the purpose of confining ourselves to cases which can occur in ordinary physical problems. For the general reasoning on which it is based is obviously inapplicable to cases in which the speed alters by jerks—at least during the interval considered, small as it may be. But we are fortunately not required to discuss here the very delicate questions to which this may give rise. Considerable difficulty is sometimes felt by a student when he is told that at a certain part of its course a point has a speed say of 10 miles an hour, while the whole course may be only a few inches. But this arises from the novelty of the conception. It is not meant, when we speak of a speed of 10 miles per hour, that the motion necessarily lasts for an hour, or even for a second, but only that, *if the then speed were to be maintained constant for an hour, the moving point's path, of whatever form, would be exactly* 10 *miles long*. In actual experience in a railway train we can judge the speed (roughly at least), and we find nothing strange in saying "Now we are going at twenty miles an hour," "Now at six," and so on. And it is clear that, after the steam is put on, the train, however short its run, must go through all rates of speed from zero to its maximum, and then through all of them to zero again, when the steam is cut off and the brake applied.

In the language of the differential calculus this becomes

$$\dot{s} = L\frac{\delta s}{\delta t} = \frac{ds}{dt}.$$

The fluxional notation of Newton, in which the dot over a quantity expresses the rate of its increase, *i.e.*, its differential coefficient with regard to time considered as the independent variable, is still very convenient in abstract dynamics, and is, in fact, indispensable when we come to the higher generalizations. We shall, therefore, freely employ it when it is specially useful.

Dimensions of speed. § 26. Whether uniform or variable, speed depends for its numerical value upon the units chosen for linear space and for time. Its dimensions are $[LT^{-1}]$, and consequently its numerical expression is increased in proportion as the unit of time is increased, and diminished in proportion as that of length is increased. Thus the speed represented by 10 in feet per second becomes

$$\frac{3600}{5280} \cdot 10 = \frac{75}{11}$$

when expressed in miles per hour.

Rate of change of speed. § 27. The rate at which the speed (when not uniform) changes is found by a process precisely similar to that employed for the speed itself. Let the speed

at time t_1 be observed to be v_1,
" t_2 " " v_2;

then the average rate of increase of speed during the interval is

$$\frac{v_2 - v_1}{t_2 - t_1}.$$

The dimensions of this quantity are obviously $[LT^{-2}]$. Thus its numerical value is diminished, like that of speed, in proportion as the unit of length is increased. But it is increased in the duplicate of the proportion in which the unit of time is increased. For instance a rate of increase of speed of 32·2 feet per second per second (the mere *statement* is enough to show the double dependence on the time unit) becomes

$$32{\cdot}2\frac{(3600)^2}{5280} = 79{,}036 \text{ nearly},$$

when expressed in terms of miles and hours.

Uniform change of speed. § 28. When the rate of increase of speed is uniform, the above average value is its actual value throughout the interval. Hence with uniform rate of increase $= a$, a speed V becomes in time t

$$v = V + at.$$

Also, as it increases uniformly, its average value during time t is half way between its values at the beginning and end of that time; *i.e.*, it is

$$V + \tfrac{1}{2}at.$$

The space described during the interval is at once found (§ 25) as the product of the interval and the average speed during its lapse;—*i.e.*, it is

$$s = Vt + \tfrac{1}{2}at^2.$$

And it is easy to see from these expressions that

$$v^2 = V^2 + 2as,$$

which gives the speed acquired in terms of the space traversed.

[Stone moving vertically.] § 29. This is the only case in which the result can be reached without formally using the methods of the integral calculus. These expressions enable us at once to solve a great number of simple questions connected with the motion of a stone or bullet, under the action of gravity, in a vertical line. For it is found by experiment that gravity impresses, in every second, a downward speed of 32·2 feet per second on an unsupported body; and, by the Second Law, this is independent of the body's previous motion.

Hence, if a stone be let fall, its speed after t seconds is $32{\cdot}2t$, and the space fallen through is $16{\cdot}1t^2$. Also, if it fall through s feet, it will acquire a speed whose square is $v^2 = 64{\cdot}4s$.

Again, if a stone be thrown upwards with a speed of 300 feet per second, after t seconds its speed will be $300 - 32{\cdot}2t$, and the height to which it has then ascended is $300t - 16{\cdot}1t^2$. Thus it stops, and turns, after $\frac{300}{32{\cdot}2}$ seconds; and the greatest height it reaches is $\frac{300^2}{64{\cdot}4}$ feet.

From the statement above, putting $\dot{s} = v$, we find

$$\ddot{s} = \dot{v} = L\frac{v_2 - v_1}{t_2 - t_1} = \frac{dv}{dt}.$$

From this expression the preceding results may be at once obtained. Thus, assuming

$$\ddot{s} = a,$$

we have by integration

$$\dot{s} = V + at,$$

and again $$s = s_0 + Vt + \tfrac{1}{2}at^2.$$

As an instance of the indirect problem—*i.e.*, to find the speed, and its rate of increase, when the law of the motion is given:—suppose

$$s = a\cos\omega t.$$

(This equation describes the simplest form of vibratory motion, and will be fully treated later.) We have, by taking the fluxion,

$$\dot{s} = -a\omega\sin\omega t,$$

and again $$\ddot{s} = -a\omega^2\cos\omega t = -\omega^2 s.$$

[Velocity.] § 30. Velocity, as we have already said, involves the ideas of speed and of direction of motion conjointly.[1] To compound two velocities (as is required in the application of Newton's Second Law), we have the following obvious construction. From any fixed point O (fig. 2), draw a line OA representing, in magnitude and direction, one of the two velocities. From its extremity A draw AB representing in the same way, and on the same scale, the other. Complete the triangle OAB. Then OB represents, in magnitude and direction (still on the same scale), the resultant velocity. We have called the construction obvious because one has only to think of *how* a point can be said to have simultaneous velocities, in order to see its truth. Thus, if OA represents the velocity of a railway train, AB that of a passenger walking in a saloon carriage, O may be looked upon as the position of the point of the carriage at which he began his walk, at the moment when he did begin it; while B represents the position of the point of the carriage which he has reached at the end of his walk, just at the moment when he did reach it. Here OA is the velocity of the carriage relative to the earth, AB that of the passenger relative to the carriage. This proposition may be called the triangle of velocities. Another obvious mode of stating it is to complete the parallelogram of which OB is a diagonal (fig. 3); and then we have the same construction in the form:—If the two velocities to be compounded, represented by OA and OC, be taken as contiguous sides of a parallelogram, the conterminous diagonal OB represents their resultant.

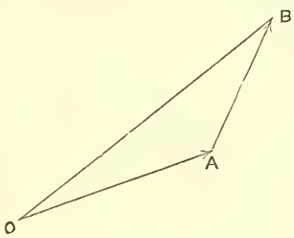

Fig. 2.

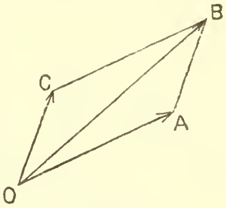

Fig. 3.

[Composition of velocities.] § 31. From the triangle of velocities we may pass at once to the polygon of velocities, which gives us the resultant of any number of simultaneous velocities. Thus, beginning as above at any point O (fig. 4), lay off OA, AB, BC (however many there may be) as successive sides of a polygon *all taken in the same direction round.* The separate velocities may be in one plane or not. When this is done, the final point C is easily seen to be independent of the *order* in which the separate velocities were taken, and is thus a perfectly definite point. OC, completing the polygon, represents the resultant velocity. But it is taken *in the opposite direction round.* If C coincide with O, there is no resultant;—*i.e.*, a point which has, simultaneously, velocities represented by the successive sides of any polygon, all taken the same way round, is at rest.

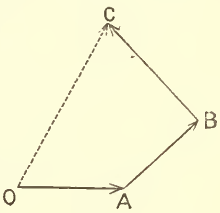

Fig. 4.

In what precedes, we have denoted the position of the moving point in its known path by the single quantity s. But if we think of its Cartesian coordinates x, y, z, we see that in general each of these must vary during the motion. And just as we represented the whole speed by $\dot{s}$ so we may speak of $\dot{x}$ as the speed in the direction of the axis of x, &c. And now we have a hint of a most important character. For, by the ordinary laws of the differential calculus, we have three equations of the form

$$\frac{\dot{x}}{\dot{s}} = \frac{dx}{ds} \text{ or } \dot{x} = \frac{dx}{ds}\dot{s}.$$

Now $\frac{dx}{ds}$ is the cosine of the inclination of the tangent at s to the axis of x. And so with $\dot{y}$ and $\dot{z}$. These give us

$$\dot{x}^2 + \dot{y}^2 + \dot{z}^2 = \dot{s}^2\left(\left(\frac{dx}{ds}\right)^2 + \left(\frac{dy}{ds}\right)^2 + \left(\frac{dz}{ds}\right)^2\right) = \dot{s}^2.$$

Hence we see that a speed in any direction may be resolved into three in any assigned directions at right angles to one another; that the speed in any one of these is determined by multiplying the whole speed by the cosine of the angle between its direction and that of its resolved part; and that the square of the whole speed is the sum of the squares of the speeds in the resolved motions. These results, however, can be obtained more directly, and in a more instructive manner, by the consideration of "velocities," and not of mere "speeds." But, before we take this step, let us take the second fluxions of the coordinates, and see to what they lead us.

From $$\dot{x} = \frac{dx}{ds}\dot{s}$$

we obtain at once $$\ddot{x} = \frac{dx}{ds}\ddot{s} + \frac{d^2x}{ds^2}\dot{s}^2;$$

or, introducing in the last term, both as a multiplier and as a divisor, the radius of curvature of the path,

$$\ddot{x} = \frac{dx}{ds}\ddot{s} + \rho\frac{d^2x}{ds^2}\cdot\frac{\dot{s}^2}{\rho},$$

with similar expressions for $\ddot{y}$ and $\ddot{z}$. These show that the rates of increase of speed, parallel to the three axes respectively, may be considered as made up of the resolved parts of the two directed quantities $\ddot{s}$ and $\dot{s}^2/\rho$. The first is in the direction of the tangent to the path, the second in the direction of the radius of curvature; and the law of resolution is, for each, multiplication by the cosine of the angle between the two directions concerned. We shall presently recognize these as the components of the acceleration.

[1] It is, in fact, in the language of quaternions, a "vector," of which the speed is the "tensor" or length, and of which the "versor" assigns the direction. And the laws of composition of velocities are in all respects the same as those of vectors.

Resolution of velocity.

§ 32 To resolve a velocity is of course a perfectly indefinite problem, unless the number of conditions requisite for definiteness be imposed. For, in general, it may be taken as one side of any complete polygon, whether in one plane or not; and the other sides, all taken in the opposite order round, represent its components.

The only cases which we need consider, in which the conditions are such as to ensure one definite solution, are—(1) when a velocity is to be resolved into components parallel and perpendicular to a given line; and (2) an extension of the same case to components parallel respectively to three lines at right angles to one another. In case (1) the given velocity is to be taken as the hypotenuse of a right-angled triangle of which one of the sides is parallel to the given line. In case (2) it is to be taken as the diagonal of a rectangular parallelepiped of which the edges are parallel to the three lines respectively. In either case the magnitude of each component is found by multiplying the amount of the velocity by the cosine of the angle between its direction and that of the component; and the square of the whole velocity is equal to the sum of the squares of the components. We are now prepared to take up the requisite preliminaries for the application of the Second Law. What, in fact, is "change of velocity"? The preceding statements at once enable us to give the answer. For let OA (fig. 5) be the velocity of a point at one instant, OB at a succeeding instant. To convert OA into OB, we must compound with it a velocity represented by AB. AB represents the change. Hence if, during any motion *whatever* of a point, a line OA be constantly drawn from a fixed point O, so as to represent at every instant the magnitude and direction of the velocity of the moving point, the extremity of OA will describe a curve (plane if the original path be plane, but not otherwise, except in certain special cases) which possesses the following important but obvious properties:—(1) the tangent at A is the direction of the change of velocity in the original path; (2) the rate of motion of A is the rate of change of velocity in the original path. Hence in this auxiliary curve, called the HODOGRAPH (*q.v.*), the velocity represents, in magnitude and direction, what is called "acceleration" in the original path. And, because the acceleration can thus be represented as a velocity, the laws of composition and resolution of velocities hold good for accelerations also.

Change of velocity.

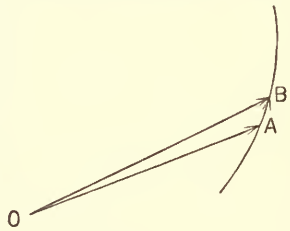

Fig. 5.

Hodograph.

Acceleration.

§ 33. Hence, if we desire to know the whole acceleration in any case of motion of a point, we need only find its components in, and perpendicular to, the tangent to the path. That in the tangent has already been found; it is $\dot{v}$ or $\ddot{s}$ as in § 29. For that perpendicular to the path we may study the simple case of uniform motion in a circle.

Acceleration in uniform circular motion.

§ 34. If a point move with uniform speed V in a circle, the hodograph is evidently a circle of radius V, and is described uniformly in the same time as the orbit (see fig. 6). Hence the speeds in the two circles are as their radii. Let R be the radius of the orbit. Then the magnitude of the acceleration in the orbit (the speed in the hodograph) is found from

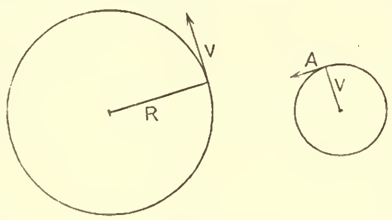

Fig. 6.

$$A : V :: V : R;$$

that is,

$$A = V^2/R.$$

The direction of this acceleration, being that of the tangent to the hodograph, is perpendicular to the corresponding radius of the hodograph, *i.e.*, to the tangent to the orbit. Hence it is *along the radius of the orbit and directed inwards to its centre.*

The so-called centrifugal force.

§ 35. In other words, to *compel* a mass to describe an *unnatural* (because curved) path, it must be acted on by a force directed towards the centre of curvature of the path. We anticipate so far as to introduce here mass and force, although, strictly, we are dealing with kinematics. But the student cannot be too early warned of the dangerous error into which so many have fallen, who have supposed that a mass has a tendency to fly *outwards* from a centre about which it is revolving, and therefore exerts a "centrifugal force," which requires to be balanced by a "centripetal force." The centripetal force is required if the path is to be curved; it is required for the purpose of *producing the curvature*, and not because there is any tendency to fly out from the centre.

Components of acceleration.

§ 36. Thus, in any motion of a point, the whole acceleration is the resultant of two parts—the first in the direction of motion and of magnitude equal to the rate of increase of speed, the second directed towards the centre of curvature and of magnitude as the curvature and the square of the speed conjointly. The sole effect of the first component is to alter the *speed*, of the second to alter the *direction*, of the motion. There is no acceleration perpendicular to the osculating plane, because two successive values of the velocity, and therefore also the corresponding *change of velocity*, are in that plane.

Angular velocity.

§ 37. A very convenient expression for acceleration which changes the direction of motion is furnished in terms of what is called the "angular velocity," *i.e.*, the rate at which direction changes. This also is properly a vector, or directed line, perpendicular to the plane in which the change of direction takes place, and of length proportional to the rate at which the angle assigning the direction changes.

§ 38. In the case of uniform motion in a circle of radius R, with speed V, the time of describing the complete circumference $(2\pi R)$ is $2\pi R/V$. Hence the angular velocity is V/R, usually denoted by ω. Thus the above expression for the acceleration in a direction perpendicular to the path of a point (§ 34) may be written in the form $\rho\omega^2$, where ρ is the radius of curvature of the orbit and ω the angular velocity of that radius. The direction of this acceleration, as we have seen, is always towards the centre of curvature.

§ 39. The general difficulty of any question concerning acceleration is usually a purely mathematical one, involving only such physical considerations as are required for the formation of the differential equations, and for the determination of the so-called arbitrary constants or arbitrary functions involved in the integrals. We will not now discuss the various forms in which the difficulty may present itself, because in the course of the article many of the more important of these will be fully treated in connexion with motions actually observed among terrestrial or cosmical bodies.

Uniform acceleration parallel to a fixed line.

§ 40. We have sufficiently considered (§§ 27–29) uniform acceleration in the line of motion. Let us now consider uniform acceleration in a fixed direction, whether the motion of the point be in that direction or not. This is the most general case of the motion of an *unresisted* projectile, on the supposition that its path is confined to a region throughout which gravity is sensibly constant alike in direction and in intensity. Two well-known properties of the parabola lead to an immediate solution of our problem.

Let fig. 7 represent a parabola, defined completely by its focus S and its directrix MN. We suppose it to be placed with its axis vertical, and vertex upwards. Take any point P, join PS, and draw PM perpendicular to the directrix. Then

(*a*) If PQ bisect the angle SPM, it is the tangent to the parabola at P.

Let Q be any point in the tangent, and let QR, drawn parallel to MP, meet the curve in R. Then we have

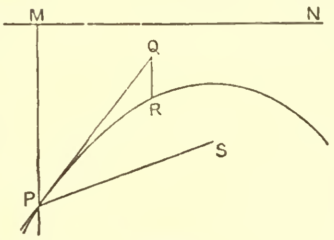

Fig. 7.

(*b*) $$PQ^2 = 4SP.QR.$$

.th of unre- .ted o- tile.

§ 41. Now suppose a point, originally moving along PQ with uniform speed V, to have its motion accelerated in a direction parallel to MP, the acceleration being α, a constant. Then, after t seconds it would have moved along PQ through a space Vt, and parallel to MP through a space $\frac{1}{2}\alpha t^2$. Hence, if R be its position at that time,

$$PQ = Vt, \qquad QR = \tfrac{1}{2}\alpha t^2.$$

From these equations we find at once

$$PQ^2 = \frac{2V^2}{\alpha}QR.$$

This relation is of the same form as that already written for a parabola, and (as it does not involve t) it holds for every point of the path. Hence the point moves in a parabola whose axis is vertical, which touches PQ (the direction of projection) in P, and in which $SP = V^2/2\alpha$. But these three data determine the parabola. For we have only to draw PM vertical, make the angle QPS = QPM, and measure off the lengths PM and PS each equal to $V^2/2\alpha$. M is a point in the (horizontal) directrix, and S is the focus. Hence the path is completely determined.

It is well to notice that, as $V^2 = 2\alpha PM$, M is the point which the projectile would just reach if it were projected vertically upwards (§ 29).

amples motion pro- tile.

§ 42. If the speed of projection be kept constant, while the direction of PQ alters in a vertical plane, S describes a circle about P as centre. This consideration enables us easily to *find the direction of projection that a given object may be struck.* Let O (fig. 8) be the object. Join PO, and let it cut in B the circle MBS (whose centre is P). Draw ON perpendicular to the common directrix, and with radius ON describe a circle about O. This will (in general) cut MBS in two points F and F′. *These are the foci of the two paths by either of which the projectile can reach O.* For by construction FO = ON, so that O lies on the path whose focus is F. Similarly for F′.

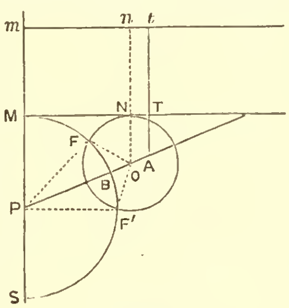

Fig. 8.

To find the most distant point along PO which can be reached, with the given speed of projection from P, we have merely to note that, as O is taken farther and farther from P, F and F′ approach B, and finally coincide with it. If O be then at A, we have AT = AB, where AT is perpendicular to the directrix. Hence, if we produce AT to t so that Tt = BP, we have At = AP. Draw through t a line tm parallel to TM. Then A lies on the parabola whose focus is P and directrix mt. This parabola is the envelop of all the possible paths from P. Any point within it can be reached by two different paths. These become coincident when the point lies on the curve; and no point outside it can be reached.

§ 43. Many of the most important cases of motion of a point involve acceleration whose direction is always towards a definite "centre" as it is called. In such cases the motion is obviously confined to the plane which, at any instant, contains the centre and the line of motion of the point. Acceleration to fixed centre.

Also the "moment" of the point's velocity about the centre remains constant. Here a slight digression is necessary.

Def.—*Given a directed quantity (a velocity, force, &c.) in a line AB* (fig. 9). *If a perpendicular OP be drawn to AB from any point O, the "moment" of the directed quantity about O is the product of its amount by the length of the perpendicular.* Moment.

If the directed quantity be reversed, the *sign* of the moment is changed. The moment is, in fact, properly a directed quantity (or vector) perpendicular to the plane OAB. And its numerical magnitude is double the area of the triangle OAB.

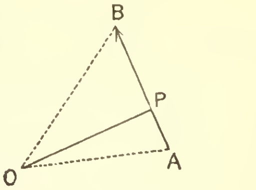

Fig. 9.

[§ 44. The convention usually made as to the sign of rotation about an axis is to regard it as positive when it is in the same sense as that in which the earth turns about its axis, as seen by a spectator above the north pole. This is in the opposite direction to that of the hands of a watch. Hence the plane angle AOP (fig. 10), representing the change of direction of a line originally coincident with OA, is positive, and is looked on as due to rotation about an axis drawn from O *upwards* from the plane of the figure. Thus the rotation of the sun and the orbital motions of the planets take place in the positive direction about axes drawn on the whole northwards from the plane of the ecliptic; or we may put it thus:—seizing an axis by the positive end, we must *un*screw—by the negative end, we must screw—to give positive rotation. And when, later, we consider rotations about three rectangular axes, Ox, Oy, Oz, we shall suppose them so drawn that rotation through a positive right angle Convention as to sign of angle, angular velocity, &c.

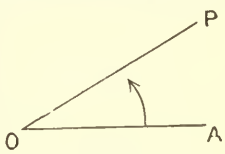

Fig. 10.

about Ox changes Oy into Oz,
,, Oy ,, Oz ,, Ox,
,, Oz ,, Ox ,, Oy,

the three letters being throughout arranged in cyclical order, xyz, yzx, &c.]

§ 45. Here we must introduce a simple geometrical proposition:— Geometrical proposition.

If any point be taken in the plane of a parallelogram, and triangles be formed with the point as vertex and with contiguous sides and the conterminous diagonal as their respective bases, the sum of the areas of the first two triangles is equal to the area of the third.

Thus, in areas (fig. 11),

$$OAB + OAC = OAD.$$

If O lie within the angle BAC, as in fig. 12, the proposition becomes

$$OAC - OAB = OAD.$$

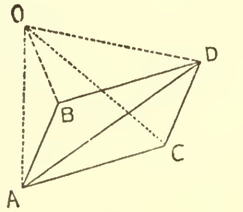

Fig. 11.

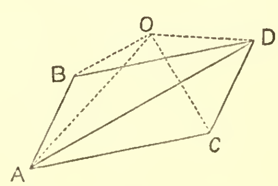

Fig. 12.

§ 46. Remembering that these areas represent half the moments of the bases of the respective triangles about the point O (that of OAB being *negative* in the second case above), we see that

The moment of a diagonal of a parallelogram about any point in the plane of the figure is the (algebraic) sum of the moments of two conterminous sides.

Now, suppose the sides of the parallelogram to represent a velocity and its change. If the direction of the change pass through O, its moment is *nil*. Hence, *for acceleration directed towards a fixed point the moment of the velocity about that point is constant.*

Equable description of areas.

This is commonly expressed by saying that *the radius-vector describes equal areas in equal times about the point to which the acceleration is directed.* For the moment of the velocity is double the area so traced in unit of time.

Another way of expressing the same thing is to say that the angular velocity of the radius-vector is inversely as the square of its length. For the product of the square of the radius-vector and its angular velocity is double the area described by it in unit of time.

The converse of this proposition is also evidently true; *i.e., when a point moves so that the moment of the velocity about a point in the plane of its motion is constant, its acceleration relative to that point (if any) is directed towards or from that point.*

Analytical treatment of central acceleration.

§ 47. Analytically: if P be the acceleration, directed towards a fixed point which we choose as origin, we have

$$\ddot{x} = -P\cos\theta = -Px/r,$$
$$\ddot{y} = -P\sin\theta = -Py/r,$$

(r and θ being the polar coordinates of the moving point; we have already seen that the path is necessarily plane). Eliminating P, we have

$$0 = x\ddot{y} - y\ddot{x} = \frac{d}{dt}(r^2\dot{\theta}).$$

Thus $$x\dot{y} - y\dot{x} = r^2\dot{\theta} = \text{const.} = h.$$

This may be transformed, at once, by the methods of the differential calculus, into

$$p\dot{s} = pv = h,$$

where p is the length of the perpendicular from the origin to the tangent to the path. Conversely, if equal areas be described by the radius-vector in equal times, we have

$$r^2\dot{\theta} = x\dot{y} - y\dot{x} = h.$$

Whence $$x\ddot{y} - y\ddot{x} = 0,$$

or $$\ddot{x} = Qx,\ \ \ddot{y} = Qy.$$

Hence the whole acceleration is Qr, and is directed towards or from the origin.

Polar coordinates.

While we are dealing with these formulæ we may investigate the general expressions for velocity and acceleration in terms of polar coordinates for a point moving in a plane.

We have $$x = r\cos\theta,\ \ y = r\sin\theta.$$

From these

$$\dot{x} = \dot{r}\cos\theta - r\dot{\theta}\sin\theta,$$
$$\dot{y} = \dot{r}\sin\theta + r\dot{\theta}\cos\theta.$$

Hence the speed along the radius-vector is

$$\dot{x}\cos\theta + \dot{y}\sin\theta = \dot{r};$$

and that perpendicular to the radius-vector (in the direction in which θ increases) is

$$\dot{y}\cos\theta - \dot{x}\sin\theta = r\dot{\theta}.$$

These expressions might have been written down at once, if we note that δr and $r\delta\theta$ are the resolved parts of δs along, and perpendicular to, r. But we must be careful how we carry this species of reasoning one step further. Taking the second fluxions of x and y, we have

$$\ddot{x} = (\ddot{r} - r\dot{\theta}^2)\cos\theta - (2\dot{r}\dot{\theta} + r\ddot{\theta})\sin\theta,$$
$$\ddot{y} = (\ddot{r} - r\dot{\theta}^2)\sin\theta + (2\dot{r}\dot{\theta} + r\ddot{\theta})\cos\theta.$$

Hence the acceleration along the radius-vector is

$$\ddot{x}\cos\theta + \ddot{y}\sin\theta = \ddot{r} - r\dot{\theta}^2,$$

and that perpendicular to it (positive when in the direction in which θ increases) is

$$\ddot{y}\cos\theta - \ddot{x}\sin\theta = 2\dot{r}\dot{\theta} + r\ddot{\theta} = \frac{1}{r}\frac{d}{dt}(r^2\dot{\theta}).$$

Thus, although $\dot{r}$ represents truly the speed along r, $\ddot{r}$ does not represent the acceleration in that direction. It represents, in fact, only the *acceleration of speed* along r. But we have seen that there is acceleration along r, if its direction changes, even when its length is constant, *i.e.*, when the path is circular; and in that case $r\dot{\theta}^2$ is the quantity which we designated as $\rho\omega^2$ in § 38.

As a verification of these formulæ, let us consider uniform motion in a straight line.

Here $$r\cos\theta = a,$$

the equation of the straight line, and

$$a\tan\theta = Vt,$$

the condition of uniform motion. We have

$$\dot{r} = a\sec\theta\tan\theta.\dot{\theta},$$
$$V = a\sec^2\theta.\dot{\theta} = r^2\dot{\theta}/a;$$
$$\dot{r} = V\sin\theta,$$
$$\ddot{r} = V\cos\theta.\dot{\theta} = \frac{aV}{r}\dot{\theta} = \frac{a^2V^2}{r^3}.$$

Here, although there is no acceleration, $\ddot{r}$ has a definite value. But

$$\ddot{r} - r\dot{\theta}^2 = a^2V^2/r^3 - a^2V^2/r^3 = 0.$$

From the expressions for the acceleration along and perpendicular to the radius-vector we at once obtain the result above (§ 46). For, if there be no acceleration perpendicular to the radius-vector,

we have $$\frac{1}{r}\frac{d}{dt}(r^2\dot{\theta}) = 0,$$

from which $$r^2\dot{\theta} = \text{const.} = h.$$

We have, in addition to this, the expression for the acceleration towards the origin,

$$\ddot{r} - r\dot{\theta}^2 = -P.$$

Eliminating $\dot{\theta}$, we have

$$\ddot{r} - h^2/r^3 = -P.$$

This gives r in terms of t, and thus reduces (if we please) any case of a central orbit to a corresponding case of rectilinear motion. The difference between the accelerations in the revolving radius-vector and in the fixed line is a term depending on the inverse cube of the radius-vector. But the usual mode of proceeding is as follows.

Reduction to case of recti-linear motion.

Multiply by $\dot{r}dt$ and integrate, then

$$\dot{r}^2 + \frac{h^2}{r^2} = C - 2\int P dr;$$

or $$\left(\frac{dr}{d\theta}\right)^2\frac{h^2}{r^4} + \frac{h^2}{r^2} = C - 2\int P dr.$$

The left-hand member obviously represents the square of the velocity, as it is the sum of the squares of $\dot{r}$ and $r\dot{\theta}$. For we have

$$\dot{r} = \frac{dr}{d\theta}\dot{\theta} = \frac{dr}{d\theta}\frac{h}{r^2}.$$

This gives a relation between r and θ, which is therefore the polar equation of the path described. It is usual to employ, instead of r, its reciprocal $1/r = u$. With this the equation becomes

$$h^2\left(\left(\frac{du}{d\theta}\right)^2 + u^2\right) = C + 2\int\frac{P du}{u^2}.$$

Differentiating with regard to θ, and dividing by $2h^2\frac{du}{d\theta}$, we obtain finally

$$\frac{d^2u}{d\theta^2} + u = \frac{P}{h^2u^2},$$

Polar equation of path.

an equation of very great importance.

When there is acceleration T perpendicular to the radius-vector, as well as $-P$ along it, this equation takes the form

$$\frac{d^2u}{d\theta^2} + u = \frac{\dfrac{P}{u^2} - \dfrac{T}{u^3}\dfrac{du}{d\theta}}{h^2 + 2\displaystyle\int\frac{T}{u^3}d\theta}.$$

§ 48. There are two specially important cases of central acceleration. The first is that of the gravitation law, the other that of Hooke's law. We will take these in order, but by very different methods.

Special cases.

§ 49. *Planetary Motion.*—With the gravitation law the acceleration varies inversely as the square of the distance from the point to which it is directed. But, as we have just seen, the angular velocity of the radius-vector, *i.e.*, of the direction of acceleration, varies according to the same law. Hence in the hodograph, the linear velocity (whose *magnitude* is that of the acceleration in the path) is pro-

Planetary motion.

portional to the angular velocity of the tangent (whose direction is parallel to the acceleration).

rcular lo- ph.

Thus, in the hodograph, the angle between successive tangents is proportional to the arc between their points of contact; and therefore the curvature is constant;—*i.e.*, *the hodograph is a circle.*

rm of ne- y bit.

Let A (fig. 13) be the centre of this circle, O the pole of the hodograph, P any position of the tracing point. Then OP is, in magnitude and direction, the velocity in the orbit. But it may be looked on as consisting of two parts, OA and AP. Of these both are constant in magnitude; but OA is constant in direction, while AP is perpendicular to the direction of acceleration in the orbit. Hence the velocity in the orbit is the resultant of two constant parts,—one always in a fixed direction, the other always perpendicular to the radius-vector.

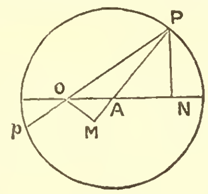

Fig. 13.

This gives the form of the orbit as follows:—

$$\dot{x}=a(e-y/r),\ \dot{y}=ax/r\ ;$$

so that $r\dot{r}=x\dot{x}+y\dot{y}=cr\dot{y}$,

or $r=c\ (y+b)$;

where the meanings of the quantities are obvious.

But if PO cut the circle again in p, Op is proportional to the perpendicular on the tangent to the orbit from the centre of acceleration (because PO.Op is constant) and is at right angles to it (because it is in the direction of the velocity). Hence the path is such that the locus of the foot of the perpendicular from the centre of acceleration on the tangent is a circle. This property belongs exclusively to conic sections, one focus being the point from which the perpendiculars are drawn.

A third and even simpler mode of treating this most important problem is as follows. Draw OM perpendicular to PA (produced if necessary) and PN perpendicular to OA. Then OM is the resolved part of OP parallel to the tangent at P, *i.e.*, it is the speed with which the length of the radius-vector changes. Also PN is the resolved part of OP perpendicular to the fixed line OA, *i.e.*, it is the speed with which the moving point travels in a fixed direction. But by similar triangles OAM, PAN, we have

$$\text{OM} : \text{PN} :: \text{OA} : \text{AP} = \text{a constant ratio}.$$

Hence the increment of the radius-vector bears a constant ratio to the simultaneous increment of the distance of the moving point from a fixed line in the plane of motion. This is only a slightly altered form of statement of the focus and directrix property of conic sections.

When O is within the circle, the constant ratio is less than unity, and the conic is an ellipse; when without, the ratio is greater than unity, and we have an hyperbola. When O is on the circumference of the hodograph, the path is a parabola; for the ratio is unity.

In a subsequent section we will return to this question, and treat it from the point of view of Kepler's Laws of Planetary Motion.

Analy- ical proof.

Simple as are the geometrical methods above, the direct analytical one is still simpler. For we have

$$\text{P}=-\frac{\mu}{r^2}\ ,$$

so that $\ddot{x}=-\frac{\mu}{r^2}\cos\theta\ ,\ \ \ddot{y}=-\frac{\mu}{r^2}\sin\theta\ .$

Hence, as before (§ 47),

$$x\dot{y}-y\dot{x}=r^2\dot{\theta}=h\ ;$$

and therefore, by eliminating r^2, we have

$$\ddot{x}=-\frac{\mu}{h}\cos\theta\ .\ \dot{\theta}\ ,\ \ \ddot{y}=-\frac{\mu}{h}\sin\theta\ .\ \dot{\theta}\ ,$$

so that $\dot{x}-a=-\frac{\mu}{h}\sin\theta\ ,\ \ \dot{y}-\beta=+\frac{\mu}{h}\cos\theta\ .$

These give at once, by squaring and adding,

$$(\dot{x}-a)^2+(\dot{y}-\beta)^2=\mu^2/h^2\ ,$$

the equation of the circular hodograph. Also, by multiplying the first by y, and subtracting it from the second multiplied by x, we have

$$h-\beta x+ay=r\mu/h\ ,$$

the equation of the orbit. This is evidently a conic section of which the origin is a focus. The directrix corresponding is the line

$$ay-\beta x+h=0\ ,$$

and the excentricity is

$$h\sqrt{a^2+\beta^2}/\mu\ .$$

From these the major axis can be calculated.

§ 50. *Elliptic Motion about the Centre.*—When a point moves uniformly in a circle, the motion presents very different appearances according to the spectator's point of view. If we suppose him to be situated at a distance very great compared with the radius of the circle, he sees what is practically an orthographic projection of the orbit on a plane perpendicular to the line of sight. In general, an orthographic projection of a circle is an ellipse—whose centre is the projection of that of the circle. As equal areas are projected orthographically into equal areas, the appearance is therefore elliptic motion, in which the radius-vector from the centre describes equal areas in equal times. Hence (§ 46) the acceleration is directed towards the centre. But accelerations are projected like velocities, and like lines. Hence, as the acceleration in uniform circular motion is constant, and directed towards the centre, so in elliptic motion, with equable description of areas about the centre, the acceleration is towards the centre, and is *proportional to the length of the radius-vector.*[1] But this projected orbit may again be projected orthographically, as often as we please, on different planes. It will always remain elliptical, and with the radius-vector from the centre describing equal areas in equal times. And the acceleration will always be in the same proportion as before to the radius-vector. However different in size and shape these elliptic orbits may be, they have one common property, *the time of describing them is the same.*

Central acceleration proportional to radius-vector.

Thus we see that when the orbit is an ellipse described about its centre of figure the acceleration is central, and proportional to the radius-vector. The time of describing such an ellipse depends only upon the *ratio* of the acceleration to the length of the radius-vector; or, if we choose, upon the magnitude of the acceleration at unit distance. And the converse of this proposition is also evidently true. When we look edgewise at the uniformly-described circular path with which we commenced, it is seen projected into a straight line, in which the moving point appears to *oscillate.* This is the case, for instance, very approximately, with the satellites of Jupiter as seen from the earth. Sun-spots, the red-spot on Jupiter, &c., all appear to move approximately in this way. But the extreme importance of this species of motion is that it is the simplest type of oscillation of a particle of matter displaced from a position of stable equilibrium. The vibrations of the ether when homogeneous plane-polarized light is passing through it, of the air when a pure musical note is sounded, the oscillations of a pendulum (through small arcs), the simplest vibrations of a pianoforte wire or a tuning-fork, the indications of a tide-gauge when the sea is calm,—all are instances of it. Hence the special necessity for studying it in detail.

§ 51. Def.—*Simple harmonic motion is the resolved part, parallel to a diameter, of uniform circular motion.*

Simple harmonic motion.

[1] The elastic force called into play by displacement is, by Hooke's law, proportional to the displacement, and tends to restore the displaced particle to its equilibrium position. We mention this, in passing, to show the importance of the present investigation.

Let a point P (fig. 14) move uniformly in the circle APA′. Then, drawing any diameter AOA′, and PM perpendicular to it, the motion of M is simple harmonic.

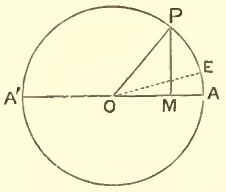

Fig. 14.

The speed and acceleration of M are obviously the resolved parts, along AA′, of the speed and acceleration of P. Hence if V be the speed of P we have

$$\text{speed of } M = \frac{PM}{PO}V,$$

$$\text{acceleration of } M = \frac{MO}{PO} \times \text{acceleration of } P$$

$$= \frac{MO}{PO} \cdot \frac{V^2}{PO} = \frac{V^2}{PO^2} MO.$$

From these expressions we see that, if we call ω the angular velocity of OP, so that $\omega = V/PO$, we have

$$\text{speed of } M = PM.\omega,$$

$$\text{acceleration of } M = MO.\omega^2.$$

Thus the speed of M increases from A to O,—being zero at A, and V at O; then it falls off to zero at A′, and goes through the same numerical values in the opposite order, when the direction of motion is reversed at A′.

The acceleration of M is always directed *towards* O. It has its greatest value at A and again at A′, and is always *proportional to the distance from O*. If T be the *period* of the simple harmonic motion, *i.e.*, the period of rotation of P in the circle, we have

$$T = \frac{2\pi}{\omega} = \frac{2\pi}{V}a,$$

Amplitude.

where a is the radius of the circle, or, as it is also called, the "amplitude" of the simple harmonic motion. We may now write as the characteristic of this species of motion

$$\text{acceleration} = \frac{4\pi^2}{T^2} \times \text{displacement};$$

or

$$T = 2\pi\sqrt{\frac{\text{displacement}}{\text{acceleration}}}.$$

Phase and epoch.

§ 52. In our further remarks about simple harmonic motion the following terms will be found convenient. P is the position at time t of the point moving in the circle. Let E be its position at the zero of reckoning, when $t=0$. Then the angle AOP may be called the "phase" of the simple harmonic motion, and AOE the "epoch." In time units the values of the phase and epoch are found from their circular measure by dividing by ω.

If the position of the point moving with simple harmonic motion be denoted by x, we obviously have

$$x = OM = OP\cos POA,$$
$$= OP\cos(POE + EOA),$$
$$= a\cos(\omega t + \epsilon).$$

This expression is to be found, perhaps more frequently than any other, in all branches of mathematical physics. It is in terms, or series of terms, of this form that *every* periodic phenomenon can be described mathematically, as will be seen later. From the expressions for the longitude and radius-vector of a planet or a satellite to those of the most complex undulations whether in water, in air, or in the luminiferous medium, all are alike dependent upon it.

The results obtained geometrically above are easily reproduced from this form:—

thus $\quad \dot{x} = -a\omega\sin(\omega t + \epsilon);$

and $\quad \ddot{x} = -a\omega^2\cos(\omega t + \epsilon) = -x\omega^2.$

Graphic representation.

§ 53. The simplest graphical method of exhibiting the nature of any kind of rectilineal motion is to compound it with a uniform velocity in a direction perpendicular to the line in which it is executed. This is, in fact, what is done in the majority of *self-registering* instruments, where a slip of paper is drawn by clock-work uniformly past the moving point, in a direction perpendicular to its line of motion, and a record is made by mechanical means, by a pencil, by an electric spark, or (best of all) by photographic processes. When this process is applied to a simple harmonic motion the record is of the general form of the curve in fig. 15. This curve has long been known as

Fig. 15.

the "curve of sines," or the "harmonic" curve. All its forms can be deduced from any one of them by mere extension or foreshortening in the vertical or horizontal directions in the figure. It represents the simplest forms into which a vibrating string can be thrown, as well as the instantaneous form of a section of the surface of water along which a simple series of oscillatory waves or ripples is passing. In this case the *form* of the section remains the same as time goes on, but the whole figure moves steadily onwards in the direction in which the waves are travelling.

Analy- cal ex- pressi for a wave.

This is expressed analytically by the form

$$y = a\cos(nt - mx),$$

where x and y are horizontal and vertical coordinates of a point at the surface of the water, y being measured from the level of the undisturbed surface. When x is constant we study, for all time, the simple harmonic rise and fall at a particular *place*. When t is constant we have the above-figured instantaneous glance of a section of the whole water-surface.

The rate at which the wave travels is obviously n/m; for, if we increase t by any quantity τ, and x by the corresponding quantity $n\tau/m$, the value of y is unaltered.

Comp- sition simple harmo- nic mo- tions i one li

§ 54. We have next to consider the result of superposing or compounding two simple harmonic motions which take place in the same line. The geometrical method amply suffices for this purpose provided the *periods* of the two are equal, however different may be their amplitudes and their phases. For, if we suppose PQ (fig. 16) to turn about P in the same plane and with the same angular velocity as OP about O, the angle OPQ will remain unaltered, and therefore the triangle OPQ will remain of constant size and form while turning about O. Thus Q describes a circle about O in the given period. The resolved parts of OP, PQ, along any diameter OA, together make up the resolved part of OQ along the same line. Hence *two simple harmonic motions, of the same period and in the same line, are equivalent to a single simple harmonic motion of the common period.* The amplitude of the resultant simple harmonic motion is OQ, and depends only upon OP, PQ, and the angle OPQ,—the amplitudes of the two component simple harmonic motions and *the supplement of the difference of their phases.*

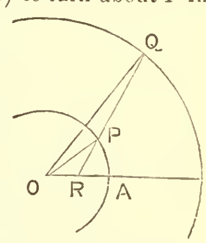

Fig. 16.

Ampli- tude, &c., o result- ant.

§ 55. When the difference of phase is *nil*, or any whole number of circumferences, the resultant amplitude is the sum of the amplitudes of the components, which is its greatest value. When the difference of phase is an odd number of semi-circumferences, the amplitude of the resultant is the difference of those of the components.

If we produce QP to meet OA in R, we see that QOA, the phase of the resultant simple harmonic motion, is intermediate in value to the phases of the components, which are POA and QRA respectively. Its excess over the one, and its defect from the other, are the angles at O and Q in the triangle OPQ; and their sines are to one another as the separate amplitudes QP, PO. Hence, when these amplitudes differ, the phase of the resultant coincides more nearly with that of the component whose amplitude is the greater.

ıalyti- ıl treat- ıent.

Analytically the resultant motion is expressed by

$$x = a\cos(\omega t+\epsilon) + a'\cos(\omega t+\epsilon'),$$
$$= (a\cos\epsilon + a'\cos\epsilon')\cos\omega t - (a\sin\epsilon + a'\sin\epsilon')\sin\omega t,$$
$$= \mathrm{P}\cos(\omega t + \mathrm{Q}),$$

provided that

$$\mathrm{P}\cos\mathrm{Q} = a\cos\epsilon + a'\cos\epsilon',$$

and

$$\mathrm{P}\sin\mathrm{Q} = a\sin\epsilon + a'\sin\epsilon'.$$

These expressions give for the amplitude of the resultant

$$\mathrm{P} = \sqrt{(a\cos\epsilon + a'\cos\epsilon')^2 + (a\sin\epsilon + a'\sin\epsilon')^2},$$
$$= \sqrt{a^2 + 2aa'\cos(\epsilon - \epsilon') + a'^2}.$$

This may be put in either of the forms

$$\sqrt{(a+a')^2 - 4aa'\sin^2\tfrac{1}{2}(\epsilon-\epsilon')} \text{ or } \sqrt{(a-a')^2 + 4aa'\cos^2\tfrac{1}{2}(\epsilon-\epsilon')},$$

from which the above conclusions follow at once.

Also, for the epoch of the resultant, we have

$$\tan\mathrm{Q} = \frac{a\sin\epsilon + a'\sin\epsilon'}{a\cos\epsilon + a'\cos\epsilon'}.$$

'eriods early ıqual.

When ϵ and ϵ' are both positive and less than $\frac{1}{2}\pi$, this is obviously intermediate in value to $\tan\epsilon$ and $\tan\epsilon'$.

When the periods of the components are not exactly equal, the simple artifice which follows enables us still to apply the same method of composition. We have now

$$x = a\cos(\omega t+\epsilon) + a'\cos(\omega' t+\epsilon'),$$
$$= a\cos(\omega t+\epsilon) + a'\cos(\omega t+\epsilon'+(\omega'-\omega)t).$$

Hence the above values of P and Q will still satisfy the conditions if we write $\epsilon' + (\omega'-\omega)t$ instead of ϵ'. Thus we may treat the two components as being of the same period, but make the epoch of one of them steadily increase with an angular velocity equal to the difference of the angular velocities in the generating circles of the components.

The triangle OPQ will no longer preserve its form; it will pass *continuously* through all the various forms which we have seen would be given to it by various differences of phase in the component simple harmonic motions. The time in which it returns to a former value is evidently $2\pi/(\omega'-\omega)$, which is greater the more nearly equal are the periods of the components.

ˣxam- ıle. ıolar ınd ıunar ides.

§ 56. One of the best examples of the principles we have just discussed is furnished by the tides. If there were but one tide-producing body, we should have (approximately) a simple harmonic rise and fall of the sea-level at any given place twice over in the course of about twenty-four hours, and the phase would depend simply upon the distance of the tide-producing body from the meridian (whether above or below the pole). The joint effect of the sun and moon is practically the resultant of the effects which they would separately produce. Hence, when these bodies are in conjunction or in opposition (*i.e.*, at new or at full moon), the whole rise of the tide is the sum of the solar and lunar tides; and we have what are called "spring tides." When the moon is in quadrature, the amplitude of the tidal rise or fall is the excess of the lunar over the solar tide, for it is low water as regards the sun when it is high water as regards the moon. In intermediate positions the effect lies between these extremes, but the joint high-tide lies nearer to the crest of the lunar than to that of the solar tide. In the first and third quarters of the moon, high tide is *earlier* than the high tide due to the moon alone; in the second and fourth *later*. This is what is called "priming" and "lagging" of the tides, and is seen at once to follow from the construction given above. Had the lunar and solar tides been of equal amplitude, spring tides would have been of double the altitude of either, and there would have been no tide at all at the time of neap.

Spring and neap tides.

Priming and lagging.

The mode in which we have treated this special case is an illustration of the general method (above described) of combining simple harmonic motions in which the periods are slightly different.

Composition of two wave motions generally.

§ 57. What we have said of the tide-waves holds of course of all waves in which the separate disturbances are so small that the joint effect is found by superposing the separate effects. Thus when, at sea, two series of waves of equal length meet at any place, the resultant is still a set of waves of the same length, but the altitudes and phases of the components determine those of the resultant. When crest meets crest, we have waves of the sum of the original amplitudes; when crest meets trough, the difference. In the latter case we have still water when the amplitudes of the components are equal. What is called a "jabble,"—where, for a short time, a portion of a stormy sea is almost calm, and after a little it is violently agitated,—is the result of a number of "cross seas."

Common phenomena.

§ 58. If we now consider the instantaneous form of a section of the surface, instead of the successive displacements of one portion of it, we can easily account for a striking phenomenon which is very frequently observed on a shelving beach. We often notice that every ninth or tenth wave or so is higher than those immediately before or after it. This is the result of superposition of two or more sets of waves in which the distance from crest to crest is different in the different sets. In the joint system we have, represented as in § 53, phenomena akin to the spring and neap tides, and the priming and lagging of the tides.

Fig. 17 shows part of the result when the amplitudes are equal, and the wave-lengths as 15 to 17. It gives also a rough approximation to the whole result when the lengths are as 7 to 8 or as 8 to 9

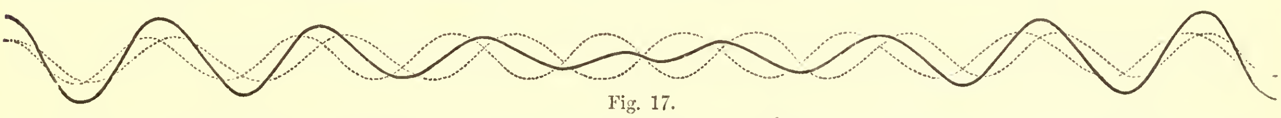

Fig. 17.

Compo- sition of more than two simple harmo- nic mo- tions of one period.

§ 59. To compound any number of simple harmonic motions, of equal periods, in one line, we may obviously take them two by two, and apply the preceding process over and over again till we have as final resultant another simple harmonic motion of the common period.

Or thus:—

$$x = \Sigma a\cos(\omega t+\epsilon) = \cos\omega t\,\Sigma(a\cos\epsilon) - \sin\omega t\,\Sigma(a\sin\epsilon) = \mathrm{P}\cos(\omega t+\mathrm{Q}),$$

where $\mathrm{P}\cos\mathrm{Q} = \Sigma(a\cos\epsilon)$, $\mathrm{P}\sin\mathrm{Q} = \Sigma(a\sin\epsilon)$.

When the separate periods are not equal, and not even *nearly* equal, it is only in special cases that any simplification can be effected by analytical processes. But this is not much to be regretted, because for most purposes a graphic method is sufficiently accurate, and it can always be easily carried out.

Two simple harmo- nic mo- tions at right angles.

§ 60. We must now consider the composition of simple harmonic motions in directions at right angles to each other;—but for the present we confine ourselves to the case in which their periods are equal. In this case we know that the acceleration is in the *same* ratio to the displacement in each of the two rectangular directions. Hence by the general theorem of § 50 the motion is elliptic, with uniform description of areas about the centre.

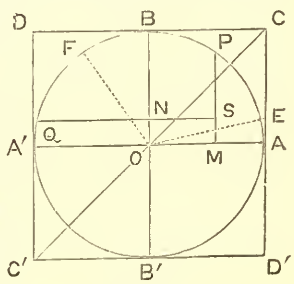

Fig. 18.

To analyse this, suppose, at starting, that their amplitudes also are equal. Let OA, OB (fig. 18) represent the two rectangular directions. With centre O, and radius equal to the common amplitude, describe a circle. Let AOE, BOF represent the epochs of the two components (the corresponding circular motion being supposed positive for each), then obviously EOF exceeds by a right angle the difference between the

Simple harmonic motions at right angles.

phases of the motions in OB and OA. Then if P, Q represent at time t the corresponding positions in the common circle, we have arc FQ = arc EP; and if perpendiculars be drawn, PM to OA, and QN to OB, their intersection S is the position at time t in the resultant motion. The locus of S is, by what has been proved above, an ellipse which touches the sides of the square CDC′D′.

When EOF is a right angle, *i.e.*, when the phases are alike, this ellipse becomes the diagonal CC′ of the square touching the circle at the extremities of AA′ and BB′. When EOF is three right angles, the ellipse becomes the diagonal DD′. When it is two right angles, or four, *i.e.*, when OB is one quarter, or three quarters, of a period in advance of OA, the ellipse becomes the circle ABA′B′. To find in any case whether it is described positively or negatively (§ 44), we have only to notice how OS turns. Now while P is near A, MS remains closely coincident with AC. If, then, Q be anywhere in the semicircle BA′B′, N moves in the direction BB′ and the angle AOS *diminishes.* Hence the ellipse is described negatively (or in the direction of the hands of a watch) if the epoch of the motion in OB exceeds that of the motion in OA by anything up to two right angles. And similar reasoning shows that, if the excess be from two to four right angles, the ellipse is described positively.

If the amplitudes be not equal, we have only to extend or foreshorten the figure parallel to OA or to OB. The square CDC′D′ becomes a rectangle, in which the orbits (all of which, with the exception of the diagonals, are now ellipses) are inscribed. Everything else is as before.

Periods nearly equal.

§ 61. When the periods in the two component motions are nearly, but not quite, equal, the phase of one gains gradually on the other, and the path passes continuously through the forms of all the possible ellipses, but remains possessed of the one property common to them all. It becomes a species of spiral, but in every convolution it touches, in succession, each side of the square or rectangle above discussed.

Simple harmonic motions of one period, in any directions.

§ 62. Similar reasoning shows that the superposition of any number of simple harmonic motions in any directions and with any amplitudes and differences of phase, provided the period is the same for all, gives rise to motion in an ellipse about the centre. But this follows more easily from analysis.

Take, first, two simple harmonic motions of the same period parallel to the axes of x and y. We have

$$x = a\cos(\omega t + \epsilon),$$
$$y = a'\cos(\omega t + \epsilon').$$

Eliminating t between these equations, we have at once

$$\frac{x^2}{a^2} - 2\frac{xy}{aa'}\cos(\epsilon' - \epsilon) + \frac{y^2}{a'^2} = \sin^2(\epsilon' - \epsilon),$$

the equation of an ellipse.

It becomes a circle when and only when

$$a = a', \qquad \cos(\epsilon' - \epsilon) = 0,$$

i.e., when the amplitudes are equal, and the phases differ by an odd number of right angles.

It becomes the straight line

$$x/a - y/a' = 0,$$

when $\epsilon' - \epsilon$ is zero; and

$$x/a + y/a' = 0,$$

when $\epsilon' - \epsilon$ is two right angles.

If SOA be called θ, we have

$$\tan\theta = \frac{y}{x} = \frac{a'\cos(\omega t + \epsilon')}{a\cos(\omega t + \epsilon)}$$
$$= \frac{a'}{a}\left(\cos(\epsilon' - \epsilon) - \sin(\epsilon' - \epsilon)\tan(\omega t + \epsilon)\right).$$

Hence, taking the fluxion of each side,

$$\sec^2\theta\,.\,\dot\theta = -\frac{a'}{a}\omega\sin(\epsilon' - \epsilon)\sec^2(\omega t + \epsilon).$$

Thus, as before, $\dot\theta$ is essentially negative, *i.e.*, the rotation in the ellipse is right-handed if $\epsilon' - \epsilon$ lie between 0 and π, left-handed if it lie between π and 2π.

For a simple harmonic motion, denoted by

$$\xi = a\cos(\omega t + \epsilon),$$

in a line whose direction cosines are l, m, n, we have the components $l\xi$, $m\xi$, $n\xi$ parallel to the three axes respectively. Hence for the resultant of any number of such, *all having the same period*, we have

$$x = \Sigma\,.\,al\cos(\omega t + \epsilon) = \cos\omega t\,\Sigma(al\cos\epsilon) - \sin\omega t\,\Sigma(al\sin\epsilon).$$

Thus we have three equations of the form

$$x = \mathrm{A}\cos\omega t - \mathrm{A}'\sin\omega t,$$
$$y = \mathrm{B}\cos\omega t - \mathrm{B}'\sin\omega t,$$
$$z = \mathrm{C}\cos\omega t - \mathrm{C}'\sin\omega t.$$

If we take three quantities λ, μ, ν, such that

$$\lambda\mathrm{A} + \mu\mathrm{B} + \nu\mathrm{C} = 0,$$
$$\lambda\mathrm{A}' + \mu\mathrm{B}' + \nu\mathrm{C}' = 0,$$

we have also

$$\lambda x + \mu y + \nu z = 0.$$

The first two equations determine without ambiguity the ratios of μ and ν to λ. Hence the third is the equation of a definite *plane* in which the path lies. We may now choose this plane as that of x, y. The value of z above becomes identically zero; and the elimination of t between the equations for x and y gives the ellipse as before.

Period not equal.

§ 63. When the periods of the simple harmonic motions are not equal we have

$$x = a\cos(\omega t + e), \qquad y = a'\cos(\omega' t + e').$$

It is easy to trace the corresponding curve by points; but, except when there is a simple numerical ratio between ω and ω', the equation cannot be presented as an algebraic one between x and y. If $2\omega' = \omega$, we may shift the epoch so that the equations may be written

$$x = a\cos(2\omega' t + a), \qquad y = a'\cos\omega' t.$$

Eliminating t from the first, by the help of the second, we have

$$\frac{x}{a} = \left(\frac{2y^2}{a'^2} - 1\right)\cos a - \frac{2y}{a'}\sqrt{1 - \frac{y^2}{a'^2}}\sin a.$$

This denotes, in general, a curve of the fourth order, of a figure-of-8 form, as in fig. 19. When $a = n\pi$ the curve is a portion of a

Fig. 19.

parabola, its vertex being to the right or left as n is odd or even. This parabola corresponds, in the present case, to the straight lines in the case of § 62. When the periods differ slightly from the ratio 2 : 1, the path passes in succession through the forms traced, forward and backward alternately; and, each time that it opens out from the parabolic form, the tracing-point describes it in the opposite direction to that in which it described it before the path collapsed into the parabola.

Composition of uniform circular motions.

§ 64. The principles already illustrated are sufficient for the examination of every case of this kind. But one or two particular cases merit special notice. The case of two uniform circular motions of equal periods, in one plane, we have already noticed (§ 54). Q describes its circle about P, P its circle about O, and the result is uniform circular motion of Q about O. The radius of this circle may be equal to the sum or difference of the radii of the separate circles, or may have any intermediate value, according to the difference of phase. If the periods be not exactly equal, the motion takes place virtually in a circle whose radius continuously oscillates between the above limits. The path is a species of spiral, which lies between two concentric circles of these radii.

§ 65. When the component circular motions are in opposite directions, we have an extremely interesting and important case. It is obvious that there must now be positions in which OP and PQ are in the same straight line. Let OA, AB (fig. 20) be one of these. Then, in any other position, OP and PQ are equally inclined to OA. The path of Q is an ellipse, of which the major semi-axis OB is the sum of the radii, and the minor axis their difference. Hence when the radii are equal the result is simple harmonic motion in the line OBB′. Thus we have the proposition, of very great importance in optics, that a simple harmonic motion may be looked upon as the resultant of two equal and opposite circular motions in one plane.

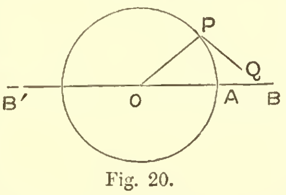

Fig. 20.

When the periods are not exactly equal, the motion may be regarded as simple harmonic motion, in a line which rotates with uniform angular velocity in a plane. This is the case of Foucault's pendulum, and of plane polarized light passing along the axis of a crystal of quartz, or through a piece of glass or other transparent substance in the magnetic field.

-cloids. § 66. Uniform circular motions, of different periods, give epicycloids, &c. A particular case is uniform circular motion superposed on uniform rectilinear motion, in which case we have cycloids, &c. But these we merely mention.

§ 67. By far the most important of the applications of simple harmonic analysis is summed up in what is called

-rier's -orem. Fourier's Theorem.—*A complex harmonic function, with a constant term added, is the proper expression for any periodic single-valued function, and, consequently, can express any single-valued function whatever between any assigned values of the variable.*

To show the importance of this in physics we need take but a single example. The one essential characteristic of a musical sound is its "periodicity." Hence it may be analysed into a series of simple harmonic disturbances. Their respective periods are the fundamental period, its half, third, fourth part, &c. The first gives the pitch of the note; the others determine its quality. The investigation which follows is not intended to prove the theorem; it is merely introduced as readily suggesting it.

The essence of periodicity of a function f is that we must have

$$f[x+\tfrac{1}{2}a]=f[x-\tfrac{1}{2}a]$$

whatever be x, provided a be the period.

We may write this as

$$\varepsilon^{\frac{a}{2}\frac{d}{dx}}f(x)=\varepsilon^{-\frac{a}{2}\frac{d}{dx}}f(x),$$

or

$$\left(\varepsilon^{\frac{a}{2}\frac{d}{dx}}-\varepsilon^{-\frac{a}{2}\frac{d}{dx}}\right)f(x)=0.$$

Now the equation

$$\varepsilon^{\frac{1}{2}\xi}-\varepsilon^{-\frac{1}{2}\xi}=0$$

has the real root

$$\xi=0,$$

and the infinite series of pairs of imaginary roots

$$\tfrac{1}{2}\xi=\pm i\pi\sqrt{-1},$$

where i is any integer. Hence

$$\varepsilon^{\frac{1}{2}\xi}-\varepsilon^{-\frac{1}{2}\xi}=\xi(1+\xi^2/2^2\pi^2)(1+\xi^2/4^2\pi^2)(1+\xi^2/6^2\pi^2)\ \ldots$$

so that the differential equation for $f(x)$ gives, besides a constant term, the infinite series of terms due to solutions of equations of the second order of which the type is

$$\left(\frac{a^2}{2^2i^2\pi^2}\left(\frac{d}{dx}\right)^2+1\right)f(x)=0.$$

The solution of this representative equation gives the following particular integral of the complete equation,

$$f(x)=\mathrm{P}_i\cos(2i\pi xa^{-1}+\mathrm{Q}_i).$$

Hence the general solution is

$$f(x)=\mathrm{A}_0+\Sigma_1^\infty \mathrm{P}_i\cos(2i\pi xa^{-1}+\mathrm{Q}_i)$$
$$=\mathrm{A}_0+\Sigma_1^\infty \mathrm{A}_i\cos 2i\pi xa^{-1}+\Sigma_1^\infty \mathrm{B}_i\sin 2i\pi xa^{-1},$$

where the constants are to be determined by special integration, according to the process already described in the article Harmonic Analysis (*q.v.*).

As a single example, suppose that the value of $f(x)$ is unity from $x=0$ to $x=a$, and zero from $x=a$ to $x=2a$. This has many applications, as, for instance, to alternate heating and cooling of one surface of a solid, alternate "make and break" with a battery and a telegraph wire, &c. In this case we have

$$f(x)=\frac{1}{2}+\frac{2}{\pi}\Sigma_1^\infty\frac{1}{2i+1}\sin\frac{(2i+1)\pi x}{a}.$$

§ 68. *A point describes a logarithmic spiral with constant angular velocity about the pole; find the acceleration.*[1] Resisted harmonic motion.

Since the angular velocity of SP (fig. 21) and the inclination of this line to the tangent are each constant, the linear velocity of P is as SP. Take a length PT, equal to e.SP, to represent it. Then the hodograph, the locus of p, where Sp is parallel and equal to PT, is evidently another logarithmic spiral, similar to the former, and described with the same constant angular velocity. Hence pt, the acceleration required, is equal to e.Sp, and makes with Sp an angle equal to SPT. Hence, if Pu be drawn parallel and equal to pt, and uv parallel to PT, the whole

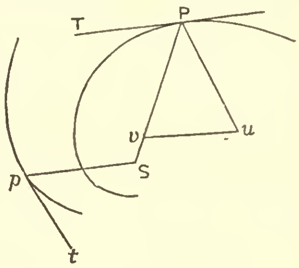

Fig. 21.

acceleration Pu may be resolved into Pv and vu; and Pvu is an isosceles triangle, whose base angles are each equal to the angle of the spiral. Hence Pv and vu bear constant ratios to Pu, and therefore also to SP or PT.

The acceleration, therefore, is composed of a central acceleration proportional to the distance, and a tangential retardation proportional to the velocity. And, if the resolved part of P's motion parallel to any line in the plane of the spiral be considered, it is obvious that in it also the acceleration will consist of two parts—one directed towards a point in the line (the projection of the pole of the spiral) and proportional to the distance from it, the other proportional to the velocity but retarding the motion. Hence a particle which, unresisted, would have a simple harmonic motion has when subject to resistance proportional to its velocity a motion represented by the resolved part of the spiral motion just described.

If α be the angle of the spiral, ω the angular velocity of SP, we have evidently PT. $\sin\alpha=\mathrm{SP}.\omega$.

Hence

$$\mathrm{P}v=\mathrm{P}u=pt=\frac{\mathrm{PT}^2}{\mathrm{SP}}=\frac{\omega}{\sin\alpha}\,\mathrm{PT}=\frac{\omega^2}{\sin^2\alpha}\,\mathrm{SP}=n^2.\,\mathrm{SP}\ \text{(suppose)};$$

and $$vu=2\mathrm{P}v\,.\,\cos\alpha=\frac{2\omega\cos\alpha}{\sin\alpha}\mathrm{PT}=2k\,.\,\mathrm{PT}\ \text{(suppose)}.$$

Thus the central acceleration at unit distance is $n^2=\omega^2/\sin^2\alpha$, and the coefficient of resistance is $2k=2\omega\cos\alpha/\sin\alpha$.

The time of oscillation is evidently $2\pi/\omega$; but, if there had been no resistance, the properties of simple harmonic motion show that it would have been $2\pi/n$; so that it is increased by the resistance in the ratio $\operatorname{cosec}\alpha : 1$, or $n:\sqrt{n^2-k^2}$.

The rate of diminution of SP is evidently

$$\mathrm{PT}\,.\,\cos\alpha=\frac{\omega\cos\alpha}{\sin\alpha}\,\mathrm{SP}=k\mathrm{SP};$$

that is, SP diminishes in geometrical progression as time increases, the rate being k per unit of time per unit of length. By an ordinary result of arithmetic (compound interest payable every instant) the diminution of log SP in unit of time is k.

[1] The physical application of this problem to pendulum motion, taking place in a medium in which there is *resistance* proportional to the velocity, will be afterwards discussed analytically.

Hence, in the resolved part of the motion, the logarithm of the amplitude is diminished, every half vibration, by $k\pi/\omega$.

This process of solution is only applicable to resistance of harmonic vibrations when n is greater than k. When n is not greater than k the auxiliary curve can no longer be a logarithmic spiral, for the moving particle never describes more than a finite angle about the pole; and then the geometrical method ceases to be simpler than the analytical one.

Relative motion.

§ 69. What we have said about composition of motions is merely a particular case of the general question of relative motion, which in its main principles is exceedingly simple. It is entirely comprehended in the following propositions,—which may be regarded as almost self-evident.

Given the motion of A with regard to a point O, and that of B with regard to A, to find that of B with regard to O.

By compounding the vectors of relative position OA, AB, we have at once the required vector OB. Thus it is obvious that we have only to add the separate components of the velocity of A with regard to O, and those of B with regard to A, to obtain those of B with regard to O. And, of course, the same rule applies to the accelerations.

If x, y, z be the coordinates of A (referred to O) at time t; x', y', z' those of B referred to parallel axes from A; ξ, η, ζ those of B referred to O; we have at once

$$\xi=x+x',\quad \eta=y+y',\quad \zeta=z+z'.$$

They give, by differentiation with regard to t,

$$\dot\xi=\dot x+\dot x',\ \&c.,\quad \ddot\xi=\ddot x+\ddot x',\ \&c.,$$

which constitute the analytical proof of the statement above.

§ 70. Hence we have the solution of the further question: *Given the motions of A and B with regard to O, to find the relative motion of B with regard to A.* In this case, of course, before compounding, the vector of A must have its sign changed.

Another very important case is that in which the motion is referred to axes which are themselves moving. So long as their *directions* remain unchanged, this reduces itself to the former investigation as a mere question of changed origin; so that we need consider only the effect of the change of direction of the axes. And this is at once deducible from the results of last section. For we have only to consider, instead of the moving point, its projections on the moving axes, and find *their* velocities and accelerations relative to fixed axes.

Revolving axes.

Thus, if the rectangular axes of x and y be fixed, and those of ξ and η be rotating in the same plane, we have a datum of the form,

$$\theta=\text{angle }\xi Ox=f(t),$$

giving the position of the moving axes in terms of the time. Let P be the moving point, and PM perpendicular to $O\xi$ (fig. 22). Then, as the polar coordinates of M are ξ, θ, we have, for its velocity,

$$\dot\xi \text{ along } O\xi,\quad \xi\dot\theta \text{ along MP}.$$

But these must be combined with the velocity of P relative to M, which consists of

$$\dot\eta \text{ along MP and } \eta\dot\theta \text{ parallel to } \xi O.$$

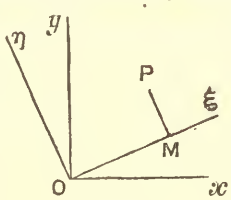

Fig. 22.

Thus the velocities parallel to fixed lines corresponding to the instantaneous positions of $O\xi$ and $O\eta$ are, respectively,

$$\dot\xi-\eta\dot\theta \text{ and } \dot\eta+\xi\dot\theta.$$

In the same way it is easy to see, by § 47, that the corresponding components of the acceleration are

$$\ddot\xi-\xi\dot\theta^2-\frac{1}{\eta}\frac{d}{dt}(\eta^2\dot\theta) \text{ and } \ddot\eta-\eta\dot\theta^2+\frac{1}{\xi}\frac{d}{dt}(\xi^2\dot\theta).$$

Kinematics of a Rigid Plane Figure, displaced in its own Plane.

§ 71. When a rigid plane figure is displaced anyhow in its own plane, the displacement may always be regarded as the result of a definite rotation about a definite axis perpendicular to the plane.

Motion of a plane figure in its plane.

The proof of this follows at once from the fact that, under the assigned conditions, the figure has only three degrees of freedom; and consequently its position is determinate whenever the positions of *any two* of its points are given. Also, a single rotation can, in general, be found which will transfer these two points from one pair of assigned positions to another.

Let A, B, A′, B′ (fig. 23) be successive positions of two points of the figure. Bisect AA′ by the line Oa perpendicular to it, and let Ob do the same for BB′. Let these perpendiculars meet in O. Then it is clear that the two triangles OAB, OA′B′ are similar and equal. Hence AB may be regarded as having passed to the position A′B′ by rotation about an axis through O perpendicular to the plane of the paper. The angle of rotation is AOA′ or BOB′.

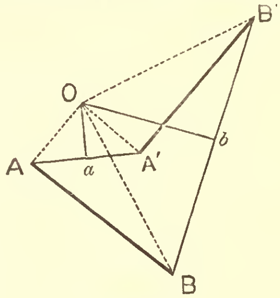

Fig. 23.

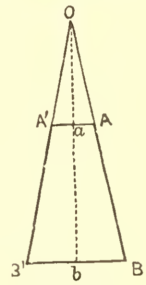

Fig. 24.

The construction fails when Oa and Ob coincide, but in this case it is evident that the required point O is the point of intersection of BA and B′A′ (fig. 24). It also fails when the bisecting perpendiculars are parallel (fig. 25). But then AA′ and BB′ are equal and parallel, and the displacement is a pure translation, the same for every point of the plane figure, which may be regarded as an infinitely small rotation about an infinitely distant axis.

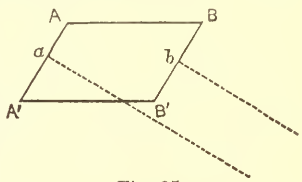

Fig. 25.

Composition of rotations about parallel axes.

§ 72. Since any displacement in one plane corresponds in general to a rotation, any two or more rotations about parallel axes can always be compounded into a single one. Of two equal and opposite rotations the resultant is simple translation. This is evident from fig. 26. In both cases A and B are the initial positions, A′ and B′ the final positions of the two axes. In the first we begin with the rotation about A, in the second with that about B.

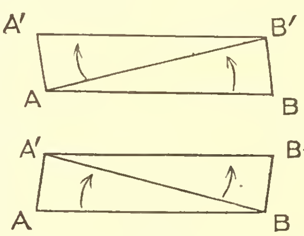

Fig. 26.

§ 73. When these equal rotations are *simultaneous* instead of *successive*, the figure becomes a rectangle; —*i.e.*, the translation is perpendicular to the line joining the axes. For in this case we may suppose the two rotations to be each broken up into successive equal but infinitesimal instalments. And the principles of infinitesimals show that two such instalments, either about the same or about different axes, produce the same ultimate effects whether they be applied simultaneously or successively. The general principle of which this is a particular case is called the "*principle of superposition of small motions.*" It is merely an application of the fact that infinitesimals of the second order may be neglected in comparison with those of the first order.

Superposition of small motions.

om-position f rotations bout arallel xes.

The consideration of simultaneous rotations is very important. Suppose a plane figure to rotate in its own plane, with angular velocity ω, about the origin. Then it is obvious that $r\omega$, in a direction perpendicular to r, is the velocity of a point whose distance from the origin is r. The components are, therefore,

$$\dot{x} = -y\omega,\ \dot{y} = x\omega .$$

If the rotation be about the point a, b, these become

$$\dot{x} = -(y-b)\omega,\ \dot{y} = (x-a)\omega .$$

Hence, when there is any number of simultaneous rotations about parallel axes, we have

$$\dot{x} = -y\Sigma\omega + \Sigma(b\omega), \quad \dot{y} = x\Sigma\omega - \Sigma(a\omega).$$

If we write $\qquad \Omega = \Sigma\omega ,$

and $\qquad \alpha = \frac{\Sigma(a\omega)}{\Sigma\omega}, \quad \beta = \frac{\Sigma(b\omega)}{\Sigma\omega};$

we have $\qquad \dot{x} = -(y-\beta)\Omega, \quad \dot{y} = (x-\alpha)\Omega .$

These are the component velocities which the point x, y would have if there were only a single rotation, with angular velocity Ω, about an axis passing through the point α, β.

When $\qquad \Sigma(\omega) = \Omega = 0,$

we see that $\qquad \dot{x} = \Sigma(b\omega), \quad \dot{y} = -\Sigma(a\omega),$

so that all points of the figure have equal velocities. This is the case of pure translation. Here α and β are (in general) each infinite;—*i.e.*, we have as resultant a vanishing angular velocity about an infinitely distant axis.

olling f curve n curve.

§ 74. As any displacement of a plane figure in its own plane is equivalent to a rotation, we may represent a series of displacements by a series of rotations. Also if we know the positions, in the figure itself, of the points which are successively the axes, and likewise the position which each of them occupies in space at the instant when the rotation about it takes place, we can construct the whole motion. Let them be O, A, B, C, &c., and O, a, b, c, &c., respectively (fig. 27). Then the figure turns about O till A coincides with a. Next it turns about A (or a) till B coincides with b, and so on. Hence the motion will be represented by the *rolling* of the polygon OABC, fixed in the moving figure, on the polygon Oabc fixed in the plane of the motion.

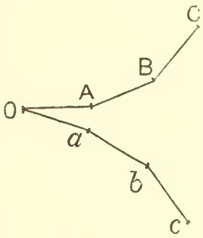

Fig. 27.

In the limit, when the axis continuously shifts its position in the figure while the rotation goes on round it, the polygons become plane curves. Thus we have the fundamental proposition that any motion of a plane figure in its own plane can be represented by the rolling of a curve attached to it, on a curve fixed in space. Both curves are situated at an infinite distance when the motion is one of pure translation.

Kinematics of a Rigid Figure.

isplacement of phere bout its entre.

§ 75. When a spherical cap, or skin, moves on the surface of a sphere of equal radius with which it is everywhere in contact, we may make the construction of § 71 with great circles bisecting the arcs AA′ and BB′. Two great circles (unless they coincide) always intersect at the extremities of one definite diameter. The case of coincidence is met exactly as it was in § 71. Hence every motion of a spherical skin on a sphere is equivalent to a rotation about a definite axis through the centre of the sphere. Thus any number of successive or simultaneous rotations about axes passing through one point can be compounded into a single rotation about an axis passing through that point. And the construction of § 74 can be carried out with spherical polygons or curves, so that we see that any motion of a rigid figure, one point of which is fixed, can be represented by the rolling of a pyramid or cone, fixed in the figure, upon another fixed in space.

Composition of rotations about axes which intersect.

§ 76. The law of composition of simultaneous angular velocities about axes which pass through one point is precisely the same as that for simultaneous linear velocities of a moving point. The following simple geometrical process establishes the proposition for two intersecting axes; and it is easy to see that it can be extended to any number of such. Let OA and OB (fig. 28) represent the two axes, and let the lengths of these lines (both drawn in the positive direction for the rotation about them) represent the angular velocities corresponding. Then a point P, in the angle between the positive ends of the axes, is raised above the plane of the paper by rotation about OA, but depressed below it by the rotation about OB. The amounts of the elevation and depression are proportional to the distance from either axis, and to the angular velocity about it, conjointly. Hence they will annihilate one another if, perpendiculars PM, PN being drawn to the axes, we have

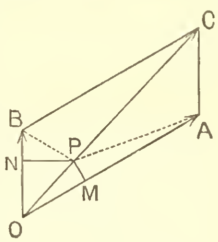

Fig. 28.

$$\text{OA . PM} = \text{OB . PN} .$$

This is equivalent to saying that the areas of the triangles OAP, OBP, are equal,—which necessitates that P should lie on the diagonal of the parallelogram of which OA, OB are conterminous sides. Let OC be the diagonal of this parallelogram. From what has been said above it is evident that the displacement of any point in the plane is necessarily proportional to the algebraic sum of the moments of OA and OB about it, and therefore (§ 46) to the moment of OC. Hence all points in the line OC remain at rest, and the figure turns about that line with an angular velocity represented by its length. This analogy to moments shows the reason for the remarkable proposition that angular velocities, about axes which intersect, are to be compounded according to the same law as linear velocities.

Analogy between linear and angular velocities.

§ 77. Any proposition regarding simultaneous linear velocities or accelerations has thus its counterpart in angular velocities and accelerations. Thus, as we have seen (§ 36) that under acceleration in one plane, always perpendicular to the direction of motion, a point moves with uniform velocity, so, if a figure be rotating about one axis, and have angular acceleration about a second axis always perpendicular to the first, the *direction* of the axis about which it rotates is changed, but not the angular velocity.

It is to be noted that in such a case the direction of the axis changes not only in space, but also in the rotating figure itself. This, however, is merely the result of § 36 in a slightly altered form.

Composition of angular velocities about intersecting axes.

If ω_z be the angular velocity of a figure about the line which, for the moment, coincides with the axis of z, the consequent displacements during time δt of a point x, y, z are (§ 73)

$$\delta x = -y\omega_z\delta t, \quad \delta y = x\omega_z\delta t .$$

Of course similar results hold for the angular velocities about lines for the moment coinciding with the axes of x and of y. The joint effect therefore is found by adding the various separate values obtained by permuting the letters x, y, z in cyclical order. Thus

$$\delta x = (z\omega_y - y\omega_z)\delta t,$$
$$\delta y = (x\omega_z - z\omega_x)\delta t,$$
$$\delta z = (y\omega_x - x\omega_y)\delta t.$$

The right hand members of these equations vanish if

$$\frac{x}{\omega_x} = \frac{y}{\omega_y} = \frac{z}{\omega_z} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1).$$

These correspond to the two equations of the instantaneous axis, and reproduce, in an analytical form, the result of § 76.

The angular velocity about this axis is

$$\Omega = \sqrt{\omega_x^2 + \omega_y^2 + \omega_z^2} .$$

For it is clear that the direction cosines of the displacement of x, y, z are proportional to

$$z\omega_y - y\omega_z ,\ x\omega_z - z\omega_x ,\ y\omega_x - x\omega_y ,$$

showing that it takes place in a line perpendicular to the plane passing through x, y, z and (1). It is therefore perpendicular to (1).

Also the whole displacement is

$$\sqrt{(\delta x)^2+(\delta y)^2+(\delta z)^2}=\delta t\sqrt{(z\omega_y-y\omega_z)^2+(x\omega_z-z\omega_x)^2+(y\omega_x-x\omega_y)^2}$$

$$=\delta t\sqrt{\omega_x^2+\omega_y^2+\omega_z^2}\sqrt{x^2+y^2+z^2-\frac{(x\omega_x+y\omega_y+z\omega_z)^2}{\omega_x^2+\omega_y^2+\omega_z^2}}\,.$$

The last factor is the distance of x, y, z from (1). Hence the second is the angular velocity about (1).

It appears at once from this result, and from the form of (1), that

$$\frac{\omega_x}{\Omega},\quad\frac{\omega_y}{\Omega},\quad\frac{\omega_z}{\Omega}$$

are the direction cosines of the instantaneous axis.

If the figure be rotating simultaneously about a number of axes,—say with angular velocity ω_1, about an axis whose direction cosines are l_1, m_1, n_1, &c.,—we have evidently

$$\omega_x=\Sigma(l\omega),\ \omega_y=\Sigma(m\omega),\ \omega_z=\Sigma(n\omega).$$

From these the single instantaneous axis is found immediately as above.

Rigid figure anyhow displaced.

§ 78. Any displacement whatever of a rigid figure may be effected by means of a screw-motion, *i.e.*, translation parallel to some definite line, accompanied by a proportionate rotation about that line. Let A and A′ be successive positions of any point in the figure, and suppose the body to be brought back by a mere translation so that A′ coincides again with A. Then we have seen (§ 75) that *one* line of the figure through A is necessarily restored to its original position. Let P be any plane section of the figure, perpendicular to this line, P′ its position after displacement. These fully determine the initial and final positions of the whole figure. Shift P into the plane of P′ by a translation perpendicular to either, and let P″ be its position. P″ can (§ 71) be brought to coincide with P′ by a rotation in its own plane. Hence the proposition. There is an exceptional case when P″ requires only translation to make it coincide with P′. But then the whole figure is merely translated.

Angular acceleration about a moving axis.

§ 79. We have seen that the straight line representing an angular velocity is to be resolved by the same process as that representing a linear velocity. If we consider a figure to be rotating about axes fixed relatively to it, accelerations of angular velocity about these will be represented by changes in the lengths of the lines representing the angular velocities, and will therefore be subject to the same conditions as the angular velocities themselves. Thus, as it is obvious that a figure is rotating at any instant with the same angular velocity about an axis fixed relatively to itself, and about another axis *fixed in space*, which at the given instant coincides with the former, it follows that the angular accelerations about these axes are equal at that instant.

This is really the same proposition as that $\dot r$ is the velocity along a fixed line coinciding with the radius-vector r (§ 47). But, just as $\ddot r$ is not the complete acceleration parallel to r, if r be rotating, so the proposition above, though true for the first fluxion of the angular velocity about a moving line, is not generally true for fluxions of higher orders.

As this subject is commonly regarded as somewhat obscure, we may give a more formal examination of it by an analytical process. Suppose ω_1, ω_2, ω_3 to be the angular velocities about rectangular axes OA, OB, OC fixed relatively to a figure, and ω the angular velocity of the figure relatively to a line OS fixed in space. Let l, m, n, be the direction cosines of the latter line with regard to the former three, then

$$\omega=l\omega_1+m\omega_2+n\omega_3\,,$$

and $$\dot\omega=l\dot\omega_1+m\dot\omega_2+n\dot\omega_3+\dot l\omega_1+\dot m\omega_2+\dot n\omega_3\,.$$

But $$l\dot l+m\dot m+n\dot n=0\,;$$

and if, at a particular instant, we have $l=1$, $m=0$, $n=0$, this gives also $\dot l=0$, so that we have

$$\dot\omega=\dot\omega_1+\dot m\omega_2+\dot n\omega_3\,.$$

Now $$m=\cos\text{BOS}=\cos\theta \text{ suppose. Hence}$$

$$\dot m=-\sin\theta\,.\,\dot\theta\,.$$

But, at the instant in question, $\theta=\frac{1}{2}\pi$ and $\dot\theta=\omega_3$,

so that $$\dot m=-\omega_3\,.$$

In the same way we see that

$$\dot n=+\omega_2\,;$$

and thus we have $$\dot\omega=\dot\omega_1\,,$$

which is the proposition above given.

Position of rigid figure in terms of rotation about axes fixed in space;

§ 80. To complete the kinematics of a rigid figure of which one point is fixed, we require to have the means of calculating its position, after the lapse of any period during which it has been rotating with given angular velocities about given axes.

If the axes about which the angular velocities are given be fixed *in space*, the formulæ of § 77 give at once, for a unit line fixed in the figure, the expressions

$$\dot l=n\omega_y-m\omega_z\,,$$
$$\dot m=l\omega_z-n\omega_x\,,$$
$$\dot n=m\omega_x-l\omega_y\,.$$

Here l, m, n are the direction cosines of the unit line at time t; and they satisfy, of course, the condition

$$l\dot l+m\dot m+n\dot n=0\,.$$

But, except in some special cases, these equations are intractable. This, however, is of little consequence, because in the applications to kinetics of a free rigid body the physical equations usually give the angular velocities about lines *fixed in the body*. Our problem, then, takes the form

fixed in the figure.

§ 81. *Given the angular velocities of a figure about each of a system of three rectangular axes which are rigidly attached to it, find at any time its position in space.*

It is clear that, if we know the positions of the revolving axes, referred to a fixed system, with which they at one instant coincided, the corresponding position of the figure is determined. The method usually employed is as follows.

About the common origin of the two sets of axes suppose a sphere of unit radius to be described. Let X, Y, Z (fig. 29) be the traces on this sphere of the fixed axes, and A, B, C those of the revolving axes. Draw a great circle ZC so as to meet in A′ the quadrant BA produced. Then it is clear that the figure can be constructed (*i.e.*, that the data are sufficient for calculation) if we know (a) the angle XZC,—this we call ψ; (b) the arc ZC, called θ; (c) the angle A′CA, or the arc A′A, called ϕ. For X, Y, Z are given. Then (a) shows how to draw the great circle ZC, whose pole is N on the great circle XY. Hence (b) gives us the points C and A′. We can next draw the great circle A′N, and A and B are found on it by (c), for A′A = NB = ϕ. We have now only to determine these angular coordinates in terms of the angular velocities of the figure about OA, OB, OC, which we denote by ω_1, ω_2, ω_3 respectively.

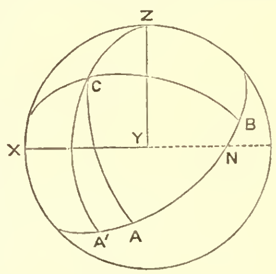

Fig. 29.

The velocity of C along ZC is $\dot\theta$. But it is produced by the rotations about A and B. Thus we have

$$\dot\theta=\omega_2\cos\phi+\omega_1\sin\phi\,.$$

The velocity of C perpendicular to ZC is $\sin\theta\,.\,\dot\psi$. This also is part of the result of the rotations about A and B, so that

$$\sin\theta\,.\,\dot\psi=\omega_2\sin\phi-\omega_1\cos\phi\,.$$

The velocity of A along AB is that of A′ together with the rate of increase of A′A. Also it is entirely due to rotation about OC. Hence

$$\cos\theta\,.\,\dot\psi+\dot\phi=\omega_3\,.$$

These three equations determine θ, ψ, ϕ when ω_1, ω_2, ω_3 are given as functions of t.

Symmetrical process.

§ 82. The process above is essentially unsymmetrical. The first suggestion of a symmetrical system is due to Euler, and depends upon the general proposition of § 75. What we must seek is the single axis, and the angle of rotation about it, which (by one operation) will bring the system or figure from its initial state determined by X, Y, Z to its state at time t, determined by A, B, C.

Let l, m, n be the direction cosines of this axis, ϖ the angle of rotation about it. Then by the elementary theorems of spherical trigonometry we find

$$\cos XA = l^2 + (1-l^2)\cos\varpi,$$
$$\cos YB = m^2 + (1-m^2)\cos\varpi,$$
$$\cos ZC = n^2 + (1-n^2)\cos\varpi.$$

Thus, as we have an independent relation among l^2, m^2, n^2, these quantities, as well as ϖ, can all be expressed in terms of the cosines of the three angles between the original and final directions of the three axes severally.

We have other six equations, of which only one need be written, viz. :—

$$\cos YA = lm(1-\cos\varpi) + n\sin\varpi.$$

Rodrigues's coordinates.

§ 83. If we put

$$w = \cos\tfrac{1}{2}\varpi,\ x = l\sin\tfrac{1}{2}\varpi,\ y = m\sin\tfrac{1}{2}\varpi,\ z = n\sin\tfrac{1}{2}\varpi,$$

which involve the equation of condition

$$w^2 + x^2 + y^2 + z^2 = 1,$$

the nine direction cosines of the new positions OA, OB, OC, referred to the fixed lines OX, OY, OZ, become

$$\begin{array}{ccc} w^2+x^2-y^2-z^2, & 2(wz+xy), & 2(xz-wy), \\ 2(yx-wz), & w^2-x^2+y^2-z^2, & 2(yz+wx), \\ 2(xz+wy), & 2(yz-wx), & w^2-x^2-y^2+z^2. \end{array}$$

These expressions, rational in terms of the four quantities w, x, y, z, are due to Rodrigues, who, however, gave them in a slightly different form.

If ω_1, ω_2, ω_3 be the angular velocities about OA, OB, OC, respectively, we have

$$\begin{aligned} 2\dot{w} &= -x\omega_1 - y\omega_2 - z\omega_3, \\ 2\dot{x} &= w\omega_1 - z\omega_2 + y\omega_3, \\ 2\dot{y} &= z\omega_1 + w\omega_2 - x\omega_3, \\ 2\dot{z} &= -y\omega_1 + x\omega_2 + w\omega_3. \end{aligned}$$

If ω_x, ω_y, ω_z be the angular velocities about OX, OY, OZ, respectively, we have

$$\begin{aligned} 2\dot{w} &= -x\omega_x - y\omega_y - z\omega_z, \\ 2\dot{x} &= w\omega_x + z\omega_y - y\omega_z, \\ 2\dot{y} &= -z\omega_x + w\omega_y + x\omega_z, \\ 2\dot{z} &= y\omega_x - x\omega_y + w\omega_z. \end{aligned}$$

Each of these sets is equivalent to three independent equations only, on account of the relation

$$w\dot{w} + x\dot{x} + y\dot{y} + z\dot{z} = 0.$$

Kinematics of a Deformable Figure. Strain.

Strain.

§ 84. So far we have considered change of position of a figure of invariable form. We must now consider changes of form and volume in the figure itself. This is required for application to physical problems, such as compression of a liquid or gas, the distortion of a piece of india-rubber, &c. Any such change of volume or form is called a "strain." The treatment of strains is entirely a kinematical question, until we come to regard them as produced in physical bodies, and consider their cause.

Stress.

The system of forces which is said to produce a strain is called a "stress." But, just as we study velocity as a preparation for the discussion of the effect of force on a free body, so we study strains as a preparation for the discussion of the effects of stress.

Heterogeneous strain.

§ 85. In order to fix the ideas, it is convenient to suppose the figure which is to undergo strain to be cut up into an infinite number of similar, equal, and similarly situated parellelepipeds. This is effected at once by supposing it to be cut by three series of planes, those of each series being parallel to one another, and equidistant. No two of these three series must be parallel, but the distance from plane to plane need not be the same in any two of the series. If the strain be *continuous* there will be no finite difference of effect upon any two neighbouring parallelepipeds;—but in general their edges, which originally formed three series of parallel straight lines, will become series of curves. No two parallelepipeds of the system will in general be altered in precisely the same manner. This is called "heterogeneous strain."

Homogeneous strain,

§ 86. We found it convenient to study uniform speed before proceeding to consider variable speed, and so we find it convenient to take up first what is called

Homogeneous Strain.—A figure is said to be homogeneously strained when all parts of it originally equal, similar, and similarly situated remain equal, similar, and similarly situated, however much they may individually have been altered in form, volume, and position.

Now recur to our set of parallelepipeds. After a homogeneous strain these remain equal, similar, and similarly situated. Hence *they must remain parallelepipeds*, for they must together still continuously make up the volume of the altered figure. Thus planes remain planes, and straight lines remain straight lines. Equal parallel straight lines remain equal and parallel. Parallel planes remain parallel, ellipses remain ellipses (as is obvious from their properties relative to conjugate diameters), ellipsoids remain ellipsoids, &c.

requires nine constants.

But we can now easily see how many conditions fully determine a homogeneous strain. For if we know how each of three conterminous edges of any one of the original parallelepipeds is altered in length and direction, we can build up the whole altered system. Hence, to fully describe a homogeneous strain, we require merely to know what changes take place in the lengths and directions of three unit lines not in one plane. Three numbers are required for the altered lengths, and two (analogous, say, to altitude and azimuth, or latitude and longitude, or R.A. and N.P.D.) for each of the altered directions. Hence, in general, a homogeneous strain depends upon, and is fully characterized by, *nine* independent numbers.

Uniform dilatation.

§ 87. The simplest form of strain is that which is due to uniform hydrostatic stress acting on a homogeneous isotropic body. Here directions remain unaltered, and the lengths of all lines are altered in the same ratio. Every portion of the original figure remains similar to itself, its linear, superficial, and volume dimensions being altered as the first, second, and third powers of that ratio.

Pure strain.

Next in order of simplicity is the case in which there are three directions, at right angles to one another, which suffer no change except as regards *length*. This state of things would be produced in a homogeneous isotropic body by three longitudinal extensions or compressions in lines at right angles to one another, or by hydrostatic pressure in a homogeneous non-isotropic solid. In this case, if the changes of length above spoken of are all different, an originally spherical figure becomes an ellipsoid, with three unequal axes parallel respectively to the lines whose directions remain unaltered. Every line in the body not originally parallel to one of these is altered in direction. If one of the principal changes of length be an extension, and another a shortening, there will be a cone formed of lines which are not altered in length. This is seen at once by describing from the centre of the ellipsoid a sphere equal to the original sphere. One axis of the ellipsoid being greater than the radius of the sphere, and another less, the ellipsoid and sphere must intersect; and all lines drawn from the common centre to the curve of intersection are unaltered in length (though all altered, as before remarked, in direction).

Pure strain.

When two only of the changes of length are equal, the ellipsoid becomes one of rotation, oblate or prolate as the case may be; and if the radius of the sphere be intermediate in value to the axes of this rotation-ellipsoid, we have a *right* cone of rays unaltered in length.

When all three changes of length are equal we have the simplest possible case,—which has been already treated.

§ 88. The essential element in these particular cases is that three lines at right angles to one another are unaltered in direction by the strain. Here there is a mere change of form, and the strain is said to be "pure," or "free from rotation." Such a strain, in its most general form, is fully characterised by *six* independent numbers. For a system of three mutually perpendicular lines is fully given in direction by *three* numbers, and three more are required for the changes of length which they severally undergo.

Rotational strain. Strain ellipsoid.

But, in general, a strain is not pure. It will be shown, however, below that the principal axes of the ellipsoid into which a sphere is changed by any strain, and which is called the "strain ellipsoid," were originally radii of the sphere at *right* angles to one another. Hence the strain may be looked upon as made up of two operations, viz., a pure strain, and a rotation through a definite angle about an axis in a definite position in space. The axes of the pure strain are lines fixed in the figure.

Conjugate of a strain.

§ 89. It is useful, in farther considering the subject, to introduce along with the original strain (thus analysed), another which is called its "conjugate." This is defined as composed of an equal pure strain with the first with an equal but opposite rotation. And the separate component operations must be taken in the opposite order in the strain and in its conjugate.

The successive application of the strain and its conjugate thus necessarily leads to the reduplication (or squaring) of the pure part of the strain, and to the annihilation of the rotation. For, call the parts, as operators, P and R. The strain and its conjugate, referred to axes fixed in space, may be either

$$RP \text{ and } PR^{-1}$$

or

$$P_1R \text{ and } R^{-1}P_1,$$

according as the pure strain or the rotation is first applied. The operations in each group are written, from right to left, in the order in which they are performed. Thus RP means the pure strain P, followed by the rotation R.

Successive application of conjugate strains.

§ 90. The final results are P^2 and P_1^2. In the first case we have the pure strain, followed by the rotation; then (by the conjugate) the rotation is undone, and the pure strain reapplied. In the second we rotate first, then apply the pure strain twice, and finally undo the rotation. Thus the student must be cautioned against the error of supposing that the results of applying PR and RP separately are generally the same. Perhaps it will be easier for the reader to consider the "reciprocal," instead of the conjugate, of a strain. For if the strain be RP, the reciprocal is obviously $P^{-1}R^{-1}$; if it be PR, the reciprocal is $R^{-1}P^{-1}$. Either pair of these, taken in either order, restores the figure to its primitive form. The one point to be noticed is that, in whatever order the direct component operations are supposed to occur in the strain, their reciprocals must be taken in the opposite order in the reciprocal strain. The reciprocal strain simply undoes the strain, and therefore differs from the conjugate by a factor, the square of the pure part of the strain.

Reciprocal strain.

From this we have at once, as will be seen later, the means of decomposing a given strain into its pure and its rotational factors. This is effected as soon as we can form the expression for the conjugate strain in terms of that for the strain itself.

Shear.

§ 91. As, in general, any strain converts a spherical portion of a figure into an ellipsoid, and as an ellipsoid has two series of parallel *circular sections*, it appears that in every strain there are two series of *planes of no distortion*.[1] The consideration of these planes leads us to a second and very different mode of analysing a strain into simpler components. Perhaps the most elementary mode of considering this subject is by thinking of the motion of water flowing slowly down a uniform channel. We know that water, at ordinary pressures, is practically incompressible; also that the upper layers of the water in a canal flow faster than those below them. Hence the definition of a "simple shear." Let one plane of a figure be fixed, and let the various planes parallel to it slide over it and over one another, all in the same direction, and with velocities proportional to their distances from the fixed plane. It is clear that this shear produces homogeneous strain in the figure, but it is mere change of form without change of volume. The fixed plane and all those parallel to it, are planes of no distortion. But we have seen that there must be two sets of such planes. To find the second set, let us suppose the plane of fig. 30 to be parallel to the common direction of sliding, and perpendicular to the fixed plane. This plane, so defined, is the plane of the shear. Let AB be the trace on it of the fixed plane, PQ that of one of the sliding planes, PP′ the amount of its sliding. Bisect PP′ in M by a perpendicular, meeting AB in A. Join AP, take AB = AP, and draw BQ parallel to AP. Consider the strain of the rhomboidal portion APQB of the figure. P moves to P′, and Q to Q′, where QQ′ = PP′. Hence the rhombus remains a rhombus, for AP′ = AP = AB. But the lengths of its diagonals have been interchanged. It has been subjected to an elongation of AQ, and a contraction of BP, each in the same ratio (so that their product, *i.e.*, double the area of the rhombus, remains unaltered), while all lines perpendicular to the plane of the figure remain unaltered. From the symmetry of the rhombus it is obvious that AQ′ and BP′ are the greatest and least axes of the strain ellipsoid, while AB and AP′ are parallel to its circular sections. Planes originally parallel to AP and perpendicular to the paper are therefore the second set of planes of no distortion. The rotational part of the shear may be measured in terms of the angle PAM, but is given directly by PBP′, and its axis is perpendicular to the plane of the figure. The most convenient measure of the shear is the ratio of PP′ to AM, or, what involves the same, the angle PAP′. Another mode of measuring it is by means of the ratio BP/AQ, = 1 + e, suppose. If e be a small quantity, as is usually the case with solids, we may write $1 \pm e$ for the measure of the shear. Here e indicates the extension per unit of length along one diagonal of the rhombus, and the contraction per unit of length along the other.

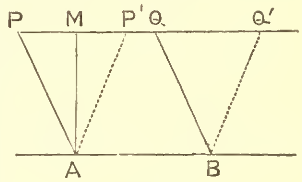

Fig. 30.

Decomposition of a strain.

§ 92. It is quite clear from what has been said that we can analyse a strain by the help of simple shears compounded with different forms of pure strain. For the shears may be taken in an infinite number of ways so as to produce the rotational part of the given strain, while also producing deformation without change of volume. The final adjustment is to be made by a pure strain, whose axes are those of the strain ellipsoid due to the shears. As a shear depends on four quantities only, two shears and a dilatation furnish the nine constants required for a homogeneous strain.

[1] We here exclude spheres and ellipsoids of rotation. The latter have only one series of circular sections, the former an infinite number.

Com- position of pure strains.

The successive application of two pure strains does not, except in special cases, give rise to a pure strain. This is, physically, a most important proposition. Thus, for instance, the instantaneous strains of each element of a perfect fluid in which there is no vortex motion are pure; and yet, if the element be followed in its motion, it will be found in general to rotate. Its motion is said to be "differentially irrotational."

To prove this proposition by the help of a particular case is simple enough. Take, for instance, a compression in one direction, followed by an equal extension in a different direction. Only when these directions are at right angles to one another is the resultant strain pure.

Analysis.

§ 93. The analytical theory of strains is, at least in its elements, an immediate application of the properties of determinants, usually of the third order. We subjoin a slight sketch of it.

We have seen that it is only necessary, for the full characterizing of a strain, that we should know what becomes of three unit lines not originally coplanar. Take these parallel to the axes (generally oblique) of x, y, z. Then if the x unit becomes a line which is the diagonal of a parallelepiped with sides a, d, g parallel to the axes, y similarly that of b, e, h, and z of c, f, i, we see at once that the coordinates of the point originally at x, y, z become

$$\left.\begin{aligned} x' &= ax+by+cz \\ y' &= dx+ey+fz \\ z' &= gx+hy+iz \end{aligned}\right\} \quad \ldots \ldots \quad (A).$$

Here it is obvious, from the premises, that the nine quantities a, b, c; d, e, f; g, h, i are all real, and altogether independent, at least so far as kinematics is concerned.[1] To obtain an idea of their nature from another point of view, let us suppose the axes to be rectangular. Let unit parallel to x become e_1, in the direction given by the cosines l_1, m_1, n_1. Similarly, let e_2, l_2, m_2, n_2 belong to a unit originally parallel to y, and e_3, l_3, m_3, n_3 to a unit parallel to z. Then the broken line x, y, z becomes x', y', z', where

$$\left.\begin{aligned} x' &= e_1l_1x + e_2l_2y + e_3l_3z \\ y' &= e_1m_1x + e_2m_2y + e_3m_3z \\ z' &= e_1n_1x + e_2n_2y + e_3n_3z \end{aligned}\right\} \quad \ldots \quad (A').$$

Though we have introduced three numbers e along with nine direction cosines, no greater generality is secured, for there are three necessary relations, one among each set of cosines.

Characteristic of pure strain.

To find the characteristic property of a pure strain, let us take it in its most general form. Thus let l_1, m_1, n_1 *now* denote a line which, without change of direction, has its length altered by the strain in the ratio $e_1 : 1$. Let l_2, m_2, n_2, e_2 and l_3, m_3, n_3, e_3 be similar data for the other two of the system of rectangular axes of the pure strain. Then to *these* axes the coordinates of x, y, z are

$$\xi = l_1x+m_1y+n_1z,$$
$$\eta = l_2x+m_2y+n_2z,$$
$$\zeta = l_3x+m_3y+n_3z.$$

The strain converts ξ into $\xi' = e_1\xi$, η into $\eta' = e_2\eta$, and ζ into $\zeta' = e_3\zeta$. Hence the final coordinates (to the original axes) of the point originally at x, y, z are

$$x' = l_1\xi' + l_2\eta' + l_3\zeta',$$
$$y' = m_1\xi' + m_2\eta' + m_3\zeta',$$
$$z' = n_1\xi' + n_2\eta' + n_3\zeta';$$

or, in terms of x, y, z,

$$\left.\begin{aligned} x' &= (e_1l_1^2+e_2l_2^2+e_3l_3^2)x + (e_1l_1m_1+e_2l_2m_2+e_3l_3m_3)y \\ &\quad + (e_1l_1n_1+e_2l_2n_2+e_3l_3n_3)z \\ y' &= (e_1m_1l_1+e_2m_2l_2+e_3m_3l_3)x + (e_1m_1^2+e_2m_2^2+e_3m_3^2)y \\ &\quad + (e_1m_1n_1+e_2m_2n_2+e_3m_3n_3)z \\ z' &= (e_1n_1l_1+e_2n_2l_2+e_3n_3l_3)x + (e_1n_1m_1+e_2n_2m_2+e_3n_3m_3)y \\ &\quad + (e_1n_1^2+e_2n_2^2+e_3n_3^2)z \end{aligned}\right\} . \quad (B).$$

If we compare this with the general expression above given for a strain, we see that the coefficient of y in the value of x' is *equal* to that of x in the value of y'. Similarly that of z in x' is equal to that of x in z'; and that of z in y' is equal to that of y in z'; or finally

$$b=d, \quad c=g, \quad f=h.$$

Conversely, when these three conditions are satisfied, and not otherwise, the strain is pure. It is to be observed that ξ, η, ζ form a rectangular system, and thus the nine direction cosines (usually involving *six* arbitrary numbers) depend here on three numbers alone. Thus there are six independent numbers, corresponding to a, e, i, b, c, f, in the general expression for the strain.

Pure strain depends on six conditions.

Change of volume by strain

It is clear, from the elements of coordinate geometry, that the determinant

$$\begin{vmatrix} a & b & c \\ d & e & f \\ g & h & i \end{vmatrix}$$

represents the ratio in which the volume is increased by the strain.[2]

Conjugate strains.

Let us now introduce, in succession to the strain

$$\begin{matrix} a & b & c \\ d & e & f \\ g & h & i \end{matrix} \quad \ldots \ldots \ldots \quad (1),$$

the connected strain

$$\begin{matrix} a & d & g \\ b & e & h \\ c & f & i \end{matrix} \quad \ldots \ldots \ldots \quad (1'),$$

which obviously produces an equal change of volume with the former.

Applying these strains in succession, we have as the final result

$$x'' = ax' + dy' + gz',$$
$$y'' = bx' + ey' + hz',$$
$$z'' = cx' + fy' + iz',$$

or, substituting for x', y', z' their values in terms of x, y, z,

$$x'' = (a^2+d^2+g^2)x + (ab+de+gh)y + (ac+df+gi)z,$$
$$y'' = (ba+ed+hg)x + (b^2+e^2+h^2)y + (bc+ef+hi)z,$$
$$z'' = (ca+fd+ig)x + (cb+fe+ih)y + (c^2+f^2+i^2)z.$$

Thus the resultant strain is

$$\begin{matrix} a^2+d^2+g^2 & ab+de+gh & ac+df+gi \\ ba+ed+hg & b^2+e^2+h^2 & bc+ef+hi \\ ca+fd+ig & cb+fe+ih & c^2+f^2+i^2 \end{matrix}$$

which, for simplicity, we will write as

$$\begin{matrix} \alpha & \delta & \gamma \\ \delta & \epsilon & \beta \\ \gamma & \beta & \iota \end{matrix} \quad \ldots \ldots \ldots \quad (2).$$

It will be observed that this group of nine numbers, if treated as a determinant, constitutes the product of the determinants formed of the two systems above.

This satisfies the criterion of a "pure strain," as given above; and we thus see that in the successive application of the strains

$$\begin{matrix} a & b & c \\ d & e & f \\ g & h & i \end{matrix} \quad \text{and} \quad \begin{matrix} a & d & g \\ b & e & h \\ c & f & i \end{matrix}$$

the rotation produced by the first is annihilated by the second.

Let A, B, C, &c., be the minors of

$$\Delta = \begin{vmatrix} a & b & c \\ d & e & f \\ g & h & i \end{vmatrix}$$

corresponding to a, b, c, &c.

Then by our original equations we have

$$\Delta x = Ax' + Dy' + Gz',$$
$$\Delta y = Bx' + Ey' + Hz',$$
$$\Delta z = Cx' + Fy' + Iz'.$$

Reciprocal of strain.

Thus the reciprocal of the strain

$$\begin{matrix} a & b & c \\ d & e & f \\ g & h & i \end{matrix} \quad \text{is} \quad \begin{matrix} A/\Delta & D/\Delta & G/\Delta \\ B/\Delta & E/\Delta & H/\Delta \\ C/\Delta & F/\Delta & I/\Delta. \end{matrix}$$

This is evident from the formulæ just written. For they express that the new strain converts x', y', z' into x, y, z.

Apply the resultant strain in succession to this reciprocal. The result is easily foreseen from separate terms like the following:—

$$A(a^2+d^2+g^2) + B(ab+de+gh) + C(ac+df+gi)$$
$$= a(Aa+Bb+Cc) + d(Ad+Be+Cf) + g(Ag+Bh+Ci)$$
$$= a\Delta; \ \&c.$$

[1] But when strain is produced in a piece of *matter*, a limitation comes in. For, to take the simplest case, the strain

$$x' = -x, \quad y' = -y, \quad z' = -z$$

implies that the figure to which it is applied has been "perverted,"— *i.e.*, changed into its image as seen in a plane mirror.

[2] When this strain is produced in a piece of *matter*, the numerical value of the determinant obviously cannot be *negative*.

Hence when we apply (2) to a figure previously strained by the reciprocal of (1) the result is the strain (1′). Hence we verify that the latter is the conjugate of (1); as it possesses the properties described in § 90, all of which are thus established.

Analysis of strain. To analyse a strain in the simplest manner, we must find the axes of the strain ellipsoid (§ 88), as well as the original radii of the unit sphere which were distorted into them. It is more direct, however, to consider the ellipsoid which becomes a unit sphere in consequence of the strain. The equation of that ellipsoid is

$$(ax+by+cz)^2+(dx+ey+fz)^2+(gx+hy+iz)^2=1\ ;$$

or, with the notation employed in (2) above,

$$\alpha x^2+\epsilon y^2+\iota z^2+2\delta xy+2\beta yz+2\gamma zx=1.$$

But the square of any radius-vector is

$$x^2+y^2+z^2=r^2, \text{ suppose.}$$

The maximum radius-vector, therefore, of the ellipsoid is found from the two equations

$$(\alpha x+\delta y+\gamma z)dx+(\delta x+\epsilon y+\beta z)dy+(\gamma x+\beta y+\iota z)dz=0,$$
$$xdx+ydy+zdz=0.$$

Hence, p being a numerical quantity to be found,

$$\begin{aligned}\alpha x+\delta y+\gamma z&=px,\\ \delta x+\epsilon y+\beta z&=py, \quad \ldots\ldots \quad (4).\\ \gamma x+\beta y+\iota z&=pz.\end{aligned}$$

Multiply respectively by x, y, z, add, and take account of the two preceding undifferentiated equations. We thus have

$$1=pr^2,$$

or p is the reciprocal of the square of the maximum semi-axis required.

But, if we eliminate x, y, and z simultaneously from the preceding linear equations, we have

$$\begin{vmatrix}\alpha-p & \delta & \gamma\\ \delta & \epsilon-p & \beta\\ \gamma & \beta & \iota-p\end{vmatrix}=0.$$

Axes of the strain ellipsoid. This equation is known to have three real positive roots, because the determinant is symmetrical. The roots are the squared reciprocals of the semi-axes of the ellipsoid, *i.e.*, they are the squares of the semi-axes of the strain ellipsoid.

When the three values of p have been found from this equation, any two of the equations (4) give in an unambiguous form the corresponding values of the ratios $x:y:z$ for each of them. Thus we know the original positions of the lines which become the axes of the strain ellipsoid. Their final positions are found from these by means of (A). And, since we thus know the original and final positions of the rectangular system, the method of Rodrigues enables us to calculate the axis and amount of the rotation.

One line, at least, unaltered in direction. In homogeneous strain, one direction at least is unchanged. This is an addition to, or extension of, the singular result of § 75. For, if x, y, z be shifted to a point on its radius-vector, we must have

$$\left.\begin{aligned}ax+by+cz&=\epsilon x\\ dx+ey+fz&=\epsilon y\\ gx+hy+iz&=\epsilon z\end{aligned}\right\}\ ;$$

so that

$$\begin{vmatrix}a-\epsilon & b & c\\ d & e-\epsilon & f\\ g & h & i-\epsilon\end{vmatrix}=0,$$

a cubic equation, which must have one real root.

Strain a mere rotation. When the figure is rigid, the strain must be a rotation only. Hence in the formulæ (A′) above we have $e_1=e_2=e_3=1$. Thus the last written equation becomes

$$\begin{vmatrix}l_1-\epsilon & l_2 & l_3\\ m_1 & m_2-\epsilon & m_3\\ n_1 & n_2 & n_3-\epsilon\end{vmatrix}=0\ ;$$

or (by the properties of the direction cosines of a set of rectangular axes)

$$1-(l_1+m_2+n_3)(\epsilon-\epsilon^2)-\epsilon^3=0.$$

This has, of course, the real root $\epsilon=1$. But we also have

$$1+\epsilon\big(1-(l_1+m_2+n_3)\big)+\epsilon^2=0.$$

This cannot have real roots if the coefficient of ϵ lie between the limits 2 or −2. But these are its greatest and its least possible values. For, first, l_1, m_2, n_3 may be each = 1 simultaneously. Here we have

$$(1-\epsilon)^2=0.$$

Or two of them may be each = −1, but then (to avoid perversion) the third must be = 1. Then we have

$$(1+\epsilon)^2=0.$$

In the first case the figure has no rotation. In the second it rotates through an angle π about the axis of $\epsilon=1$.

Composition of two pure strains. The proposition that two pure strains succeeding one another usually give a rotational strain is proved at once by analysis. Let the pure strains be such that

$$\begin{aligned}x'&=ax+dy+cz,\\ y'&=dx+ey+bz,\\ z'&=cx+by+iz;\end{aligned}$$

and

$$\begin{aligned}x''&=a'x'+d'y'+c'z',\\ y''&=d'x'+e'y'+b'z',\\ z''&=c'x'+b'y'+i'z'.\end{aligned}$$

Then, writing only the second term of x'' and the first of y'' in terms of x, y, z, we have

$$\begin{aligned}x''&=\ \ldots\ldots\ +(a'd+d'e+c'b)y+\ \ldots\\ y''&=(d'a+e'd+b'c)x+\ \ldots\ldots\ +\ \ldots\\ z''&=\ \ldots\ldots\ +\ \ldots\ldots\ +\ \ldots\end{aligned}$$

It is clear that, in general, this is *not* a pure strain. But it is also clear that a third pure strain can be found whose application in succession to the other two will give a pure strain.

For let the last equations be written

$$\begin{aligned}x''&=a''x+b''y+c''z,\\ y''&=d''x+e''y+f''z,\\ z''&=g''x+h''y+i''z;\end{aligned}$$

and let us apply further the pure strain

$$\begin{aligned}x'''&=\alpha x''+\delta y''+\gamma z'',\\ y'''&=\delta x''+\epsilon y''+\beta z'',\\ z'''&=\gamma x''+\beta y''+\iota z''.\end{aligned}$$

Then we have

$$\begin{aligned}x'''&=\ \ldots\ldots\ +(\alpha b''+\delta e''+\gamma h'')y+\ \ldots\\ y'''&=(\delta a''+\epsilon d''+\beta g'')x+\ \ldots\ldots\ +\ \ldots\\ z'''&=\ \ldots\end{aligned}$$

There are but three conditions to satisfy, that this strain may be pure. But we may accomplish this in an infinite number of ways, for we have five disposable quantities, viz., the ratios of any five of α, ϵ, ι, β, γ, δ to the remaining one. In a precisely similar manner we may show that three pure strains can be found, such that their resultant is a mere rotation. In fact, all we have to do, since two pure strains in general produce a distortion accompanied by rotation, is to apply a pure strain to annihilate the distortion, which can of course always be done.

Heterogeneous strain. § 94. In general when a figure is continuously strained, which is usually the case in physical applications, at least until cracks occur, the strain is not homogeneous. But, on account of the continuity of the strain, portions indefinitely near one another are strained indefinitely nearly alike. Hence we may treat such a case by the ordinary process for homogeneous strain, so long as we confine our attention to small regions of the figure strained. When there is discontinuity in the motion of a fluid, it is the common practice to treat the motion as continuous by the fiction of an infinitely thin vortex-sheet separating the two discontinuously moving portions. This is, in all likelihood, physically true in ordinary fluids; but, so far as the imaginary frictionless fluid of the mathematicians is concerned, it is a mere analytical artifice to enable us to carry out the investigation. See ATOM and HYDROMECHANICS, in which the mathematical theory of "vortex motion" is very fully considered.

Displacements of system of points. Suppose space to be uniformly occupied by points which are displaced in a continuous manner. Let ξ, η, ζ be the rectangular components of the displacement of a point originally situated at x, y, z. The continuity of the displacement requires merely that the differential coefficients, of all orders, of ξ, η, ζ, with respect to x, y, z (and any combination of them) shall be *finite*. That being assumed, the displacement, parallel to x, of the point whose initial coordinates were $x+\delta x$, $y+\delta y$, $z+\delta z$ (where δx, δy, δz are indefinitely small quantities of the first order) is necessarily expressed by

$$\xi+\frac{d\xi}{dx}\delta x+\frac{d\xi}{dy}\delta y+\frac{d\xi}{dz}\delta z.$$

Hence the relative coordinate of the second point with regard to the first is changed from δx to $\delta x+\frac{d\xi}{dx}\delta x+\frac{d\xi}{dy}\delta y+\frac{d\xi}{dz}\delta z$. And nstants the ise- ent ain.

similarly for the other relative coordinates. Hence the strain in the immediate vicinity of the point x, y, z is given by

$$\begin{array}{ccc} 1+\dfrac{d\xi}{dx} & \dfrac{d\xi}{dy} & \dfrac{d\xi}{dz}\,, \\ \dfrac{d\eta}{dx} & 1+\dfrac{d\eta}{dy} & \dfrac{d\eta}{dz}\,, \\ \dfrac{d\zeta}{dx} & \dfrac{d\zeta}{dy} & 1+\dfrac{d\zeta}{dz}\,. \end{array}$$

If the differential coefficients are all small quantities, whose squares and products two and two may be neglected, *i.e.*, if the strain is slight, we have for the ratio in which the volume is increased

$$1+\frac{d\xi}{dx}+\frac{d\eta}{dy}+\frac{d\zeta}{dz}:1\,.$$

ondi- on iat olume un- tered.

Hence the condition of no change of volume is

$$\frac{d\xi}{dx}+\frac{d\eta}{dy}+\frac{d\zeta}{dz}=0\,.$$

To examine this case more closely, let us suppose that it consists of a pure strain as in § 93 (B), superposed on a rotation ω_x, ω_y, ω_z about the axes of x, y, and z as in § 77. Let these be so small as not to interfere with one another. That compound strain would be

$$\begin{array}{lll} e_1l_1^2+e_2l_2^2+e_3^2l_3^2 & e_1l_1m_1+e_2l_2m_2+e_3l_3m_3-\omega_z & e_1l_1n_1+\ldots+\omega_y \\ e_1m_1l_1+e_2m_2l_2+e_3m_3l_3+\omega_z & e_1m_1^2+e_2m_2^2+e_3m_3^2 & e_1m_1n_1+\,..\,-\omega_x \\ e_1n_1l_1+e_2n_2l_2+e_3n_3l_3-\omega_y & e_1n_1m_1+\,\ldots\ldots\ldots\,+\omega_x & e_1n_1^2+e_2n_2^2+e_3n_3^2\,. \end{array}$$

Comparing with the above, we find

$$1+\frac{d\xi}{dx}=e_1l_1^2+e_2l_2^2+e_3l_3^2\,,$$

or, if we put ϵ for the "elongation," so that $e=1+\epsilon$,

$$\frac{d\xi}{dx}=\epsilon_1l_1^2+\epsilon_2l_2^2+\epsilon_3l_3^2\,,$$

with similar expressions for $\dfrac{d\eta}{dy}$ and $\dfrac{d\zeta}{dz}$.

These give

$$\frac{d\xi}{dx}+\frac{d\eta}{dy}+\frac{d\zeta}{dz}=\epsilon_1+\epsilon_2+\epsilon_3\,.$$

Again we have

$$\frac{d\eta}{dx}+\frac{d\xi}{dy}=2(e_1l_1m_1+e_2l_2m_2+e_3l_3m_3)\,,$$
$$=2(\epsilon_1l_1m_1+\epsilon_2l_2m_2+\epsilon_3l_3m_3)\,,$$

with other two of the same kind.

eter- ina- on of ie rota- ons.

Also we have three equations of the form

$$\left.\begin{array}{l} 2\omega_x=\dfrac{d\zeta}{dy}-\dfrac{d\eta}{dz} \\ 2\omega_y=\dfrac{d\xi}{dz}-\dfrac{d\zeta}{dx} \\ 2\omega_z=\dfrac{d\eta}{dx}-\dfrac{d\xi}{dy} \end{array}\right\}.$$

ondition no tation.

These expressions show, simply, that when there is no elementary rotation the quantity

$$\xi dx+\eta dy+\zeta dz=d\phi$$

is the complete differential of a function of three independent variables. If we combine the condition that there shall be no change of volume with those that there shall be no rotation, we can eliminate ξ, η, ζ; and we arrive at Laplace's equation

$$\frac{d^2\phi}{dx^2}+\frac{d^2\phi}{dy^2}+\frac{d^2\phi}{dz^2}=0\,.$$

This shows at once how a graphical representation of stationary distributions of temperature, electric potential, &c., may be given by means of a strain.

If dS be an element of a surface at the point x, y, z, and l, m, n the direction cosines of its normal, the rotation about the normal is obviously

$$l\omega_x+m\omega_y+n\omega_z$$

The integral of double of this over a finite portion of surface is

$$\iint dS\left(l\left(\frac{d\zeta}{dy}-\frac{d\eta}{dz}\right)+m\left(\frac{d\xi}{dz}-\frac{d\zeta}{dx}\right)+n\left(\frac{d\eta}{dx}-\frac{d\xi}{dy}\right)\right),$$

or

$$\iint\left\{\left(\frac{d\zeta}{dy}-\frac{d\eta}{dz}\right)dydz+\left(\frac{d\xi}{dz}-\frac{d\zeta}{dx}\right)dzdx+\left(\frac{d\eta}{dx}-\frac{d\xi}{dy}\right)dxdy\right\}.$$

This, as seems to have been first pointed out by Stokes, can be expressed as a simple integral in the form

$$\int(\xi dx+\eta dy+\zeta dz)$$

extended round the boundary of the surface. Hence the double integral has the same value for all finite surfaces having the same boundary; and, as a consequence, it vanishes when taken over a closed simply-connected surface. Hence we see at once that it vanishes for multiply-connected surfaces also. The proof of the equality of the single and double integral has only to be established for a mere surface element. For, when that is done, the common boundary of each pair of elements gives equal portions, with opposite signs, in the single integral.

Directly connected with the displacements of a group of points, we have the question, *What is the mathematical expression of the fact that the number of points is not altered?* There are many ways of answering this; but the following, which is immediately deducible from our recent investigation, seems sufficiently simple. If l, m, n be the direction cosines of the normal to an element dS of a singly-connected closed surface, the number of points which pass through the element in the time δt in consequence of the displacement $\xi\delta t$, $\eta\delta t$, $\zeta\delta t$ at the point x, y, z is (So-called equation of continuity.)

$$(l\xi+m\eta+n\zeta)\rho dS\delta t,$$

where ρ is the number of points per unit volume at x, y, z. But at every point inside the closed surface the density is altered from ρ to $\rho+\dot\rho\delta t$. It will be noticed that ξ, η, ζ now stand for the x, y, z components of velocity.

Hence, if the excess of the number of points passing into the surface over those escaping be equated to the increase of the number of points included in the closed space, which is calculated from the change of density inside, we have

$$\delta t\iint(l\xi+m\eta+n\zeta)\rho dS=\delta t\iiint\dot\rho dxdydz.$$

If we take for S an elementary rectangular parallelepiped, with edges δx, δy, δz, this becomes at once

$$-\left(\frac{d(\rho\xi)}{dx}+\frac{d(\rho\eta)}{dy}+\frac{d(\rho\zeta)}{dz}\right)\delta x\delta y\delta z\delta t=\dot\rho\delta x\delta y\delta z\delta t$$

or

$$\frac{d\rho}{dt}+\frac{d(\rho\xi)}{dx}+\frac{d(\rho\eta)}{dy}+\frac{d(\rho\zeta)}{dz}=0\,.$$

If the arrangement is incompressible this becomes, as above,

$$\frac{d\xi}{dx}+\frac{d\eta}{dy}+\frac{d\zeta}{dz}=0\,.$$

In any one of the last four forms the expression is called the "equation of continuity," another of the preposterously ill-chosen terms which have been introduced with only too great success into the nomenclature of our subject.

§ 95. In the strains which we have hitherto considered all parts of a figure were regarded as capable of changing their form and volume; and the strain of any element, when not identical with that of a proximate element, was supposed to differ only infinitesimally from it. But there is another class of changes of form, for which this restriction does not hold. The most important case, and the only one we can here consider, is that of "link-work." Here each finite piece is treated as incapable of change of form, and the change of form of the whole depends merely upon the relative motions of the parts. We will further restrict ourselves by the condition that the link-work is such that its form is determinate when the relative position of two of its parts is assigned. Thus, a jointed parallelogram is completely determined in form if the angle between two of its sides is assigned. Instead of an angle, we may assign the length of a diagonal; then the fact that the sum of the squares of the diagonals is equal to that of the squares of the sides determines the other diagonal. This gives us the kinematics of the more complex arrangement called "lazy-tongs." The most important applications of this branch of our subject are to what is called "Mechanism." One important practical problem in that branch was suggested by a stationary steam-engine, in which it was required to connect, by link-work of some kind, a point (of the piston-rod), which had a to-and-fro motion in a straight line, with another point (of the beam) which had a to-and-fro motion in a circular arc. Watt's original solution of the problem depends ultimately upon the near approach to rectilinearity of the motion of any point of a rod whose extremities move in two circles in the same plane. Thus, if OP, PQ, QO′ (fig. 31) be three bars jointed together at P and Q, having O and O′ fixed, and (Changes of figure of a jointed system of rigid parts.) (Lazy-tongs.) (Watt's parallel motion.)

the whole constrained to move in one plane, it is easy to see that the complete path of any point R of PQ is a species of figure of eight. A portion of that curve on each side of a point of inflexion (where the curvature vanishes) was found to be sufficiently straight for practical purposes.

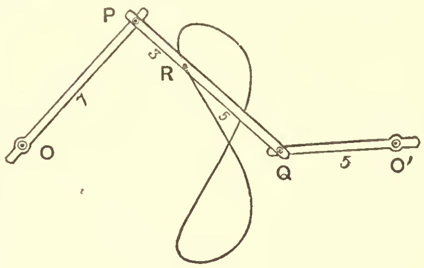

Fig. 31.

Peaucellier cell.

But the rigorous solution of this problem has only been arrived at in recent times; and the beautiful device of Peaucellier, which we will briefly explain, has led to a host of remarkable investigations and discoveries in a field regarded till lately as perfectly hopeless. A simple mode of arriving at Peaucellier's result is as follows.

Let PQ, PR (fig. 32) be *equal* links, and PO a link of a different length, all jointed together at P. Suppose O to be fixed, and Q and R constrained to move in a fixed straight line OQR, what is the relation between OQ and OR? We have, if PS be perpendicular to QR,

$$OP^2 = OS^2 + SP^2,$$
$$QP^2 = QS^2 + SP^2;$$

whence

$$OP^2 - QP^2 = OS^2 - QS^2 = OQ.OR.$$

Thus the rectangle under OQ and OR is constant; so that, if R were to describe a straight line, Q would describe a circle having O on its circumference. In practical application, to keep O, Q, R in one line, the parts of the link-work are doubled symmetrically about that line, so that it takes the form of a jointed rhombus PQP′R (fig. 33) with two equal links, PO, OP′ attached at the extremities of a diagonal. As a very curious result of this arrangement, if OQ have its length changed by any very small amount, the corresponding change of length of OR is directly as OR^2 or inversely as OQ^2. Hence, as will be seen later, a constant force (towards or from O) acting at Q will be balanced by a force (from or towards O) acting at R and varying inversely as the square of OR.

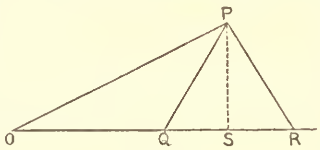

Fig. 32.

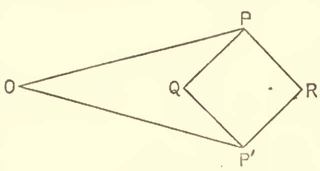

Fig. 33.

DYNAMICS.

Definitions and General Considerations.

Definition of physical particle.

§ 96. We commence with a few necessary definitions. A "physical particle" is a purely abstract conception, embodying together the ideas of inertia and of a geometrical point. It is, so to speak, a mathematical fiction, embracing only those properties which are required for our temporary purpose. Any mass, however large, can be treated as a particle, provided the forces to which it is subject are exerted in lines passing through its "centre of inertia" or "centre of mass" (this term will presently be defined), so as to be incapable of setting the mass into rotation. This is, to a first approximation, true of planetary motions, but when we look more closely into that question, so as for instance to take account of the oblate forms of the planets, we have to deal with forces which produce rotatory effects, such as "precession" and "nutation."

Mass dens

§ 97. The "quantity of matter" in a body, or the "mass," is proportional to the "volume" and the "density" conjointly. The "density" may therefore be defined as the quantity of matter in unit volume.

If M be the mass, ρ the density, and V the volume of a homogeneous body, we have at once

$$M = V\rho,$$

provided we so take our units that unit of mass is the mass of unit volume of a body of unit density. Hence the dimensions of ρ are $[ML^{-3}]$.

As will be presently explained, the most convenient unit mass is an *imperial pound*, or a *gramme*, of matter.

Mom tum.

§ 98. The "quantity of motion," or the "momentum," of a moving body is proportional to its mass and velocity conjointly. As already stated this is, like velocity, a directed quantity, or "vector." Its dimensions are, of course, $[MLT^{-1}]$.

Chan mom tum.

§ 99. "Change of quantity of motion," or "change of momentum," is proportional to the mass moving and the change of its velocity conjointly.

Change of velocity is to be understood in the general sense of § 32. Thus, with the notation of that section, if a velocity represented by OA be changed to another represented by OB, the change of velocity is represented in magnitude and direction by AB.

Rate chang mome tum.

§ 100. "Rate of change of momentum," or "acceleration of momentum," is proportional to the mass moving and the acceleration of its velocity conjointly. Thus (§ 36) the acceleration of momentum of a particle moving in a curve is $M\ddot{s}$ along the tangent, and Mv^2/ρ in the radius of absolute curvature. The dimensions of this quantity are $[MLT^{-2}]$.

Kinet energ

§ 101. The "vis viva," or "kinetic energy," of a moving body is proportional to the mass and the square of the speed conjointly. If we adopt the same units of mass and velocity as above, there is particular advantage in defining kinetic energy as *half* the product of the mass into the square of its speed. Its dimensions are $[ML^2T^{-2}]$.

Rate chang of it.

§ 102. "Rate of change of kinetic energy," thus defined, is the product of the speed into the component of acceleration of momentum in the direction of motion.

For

$$\frac{d}{dt}\left(\frac{Mv^2}{2}\right) = Mv\dot{v} = v(M\ddot{s}).$$

The dimensions are $[ML^2T^{-3}]$.

Space rate o chang of it.

§ 103. The "space-rate of change of kinetic energy" is

$$\frac{d}{ds}\left(\frac{Mv^2}{2}\right) = Mv\frac{dv}{ds} = M\frac{dv}{dt} = M\ddot{s};$$

and its dimensions are $[MLT^{-2}]$, the same as those of "force" (§ 104).

Force

§ 104. "Force," as we have already seen, is any cause which alters a body's natural state of rest, or of uniform motion in a straight line.

The three elements specifying a force, or the three elements which must be known before a clear notion of the force under consideration can be formed, are—its place of application, its direction, and its magnitude. The place of application may be a surface, as when one body presses on another; or it may be throughout the whole mass of a body, as in the case of the earth's attraction for it.

The "measure of a force" is the rate at which it produces momentum, or the momentum which it produces in unit of time, which is the same as what we have already called "rate of change of momentum." According to this method of measurement *the standard or unit force is that force which, acting on the unit of matter during the unit of* *time, generates the unit of velocity.* The dimensions of force are therefore [MLT^{-2}].

solute t ce. § 105. Hence the British absolute unit force is the force which, acting on one pound of matter for one second, generates a velocity of one foot per second.

itish stem. [According to the system followed till lately in treatises on dynamics, the unit of mass is g times the mass of the standard weight, g being the numerical value of the acceleration produced (in some particular locality) by the earth's attraction. This definition, giving a varying unit of mass, is exceedingly inconvenient. In reality, standards of weight are *masses*, not *forces*. They are employed primarily for the purpose of measuring out a definite *quantity* of matter, not an amount of matter which shall be attracted by the earth with a given force.]

§ 106. To render our standard intelligible, all that has to be done is to find how many absolute units will produce, in any particular locality, the same effect as does gravity. The way to do this is to measure the effect of gravity in producing acceleration on a body unresisted in any way. The most accurate method is indirect, by means of the pendulum. The result of pendulum experiments made at Leith Fort, by Captain Kater, is that the velocity acquired by a body falling unresisted for one second is at that place 32·207 feet per second. The variation in gravity for one degree of difference of latitude about the latitude of Leith is only ·0000832 its own amount. The average value for the whole of Great Britain differs but little from 32·2; that is, the attraction of gravity on a pound of matter in the country is 32·2 times the force which, acting on a pound for a second, would generate a velocity of one foot per second. Thus, speaking very roughly, the British absolute unit of force is equal to the weight of about half an ounce. The quantity of 32·2 feet per second per second is usually called g. Its dimensions are obviously [LT^{-2}]. And, if M be the mass . G. S. stem. of a body, its weight is Mg. In the *Centimetre-Gramme-Second* system of units, the absolute unit of force produces in one second, in a mass of one gramme, a velocity of one centimetre per second.

pre- ntation force. § 107. Forces (since they involve only direction and magnitude) may be represented, as velocities are, by vectors, that is, by straight lines drawn in their directions, and of lengths proportional to their magnitudes respectively.

Also the laws of composition and resolution of any number of forces acting at the same point are, as we shall presently show (§ 117), the same as those which we have already proved to hold for velocities; so that, with the substitution of force for velocity, § 30 is still true.

om- ponents f force. § 108. The "component" of a force in any direction is therefore found by multiplying the magnitude of the force by the cosine of the angle between the directions of the force and the component. The remaining component in this case is perpendicular to the other.

It is very generally convenient to resolve forces into components parallel to three lines at right angles to each other, each such resolution being effected by multiplying by the cosine of the angle concerned.

The magnitude of the resultant of two or of three forces in directions at right angles to each other is the square root of the sum of their squares.

entre of ass. § 109. The "centre of inertia or mass" of any system of material particles whatever (whether rigidly connected with one another, or connected in any way, or quite detached) is a point whose distance from any plane is equal to the sum of the products of each mass into its distance from the same plane, divided by the sum of the masses.

The distance from the plane yz of the centre of inertia of masses m_1, m_2, &c., whose distances from the plane are x_1, x_2, &c., is therefore

$$\bar{x} = \frac{\Sigma(mx)}{\Sigma(m)};$$

and similarly for the other coordinates.

Hence its distance from the plane

$$\delta = \lambda x + \mu y + \nu z - a = 0$$

is
$$D = \lambda\bar{x} + \mu\bar{y} + \nu\bar{z} - a = \frac{\Sigma\{m(\lambda x + \mu y + \nu z - a)\}}{\Sigma(m)} = \frac{\Sigma(m\delta)}{\Sigma(m)},$$

as stated above. And its velocity perpendicular to that plane is

$$\frac{dD}{dt} = \frac{1}{\Sigma m}\Sigma\left\{m\left(\lambda\frac{dx}{dt} + \mu\frac{dy}{dt} + \nu\frac{dz}{dt}\right)\right\} = \frac{\Sigma\left(m\frac{d\delta}{dt}\right)}{\Sigma m},$$

from which, by multiplying by Σm, and noting that δ is the distance of x, y, z from $\delta = 0$, we see that the sum of the momenta of the parts of the system in any direction is equal to the momentum in that direction of the whole mass collected at the centre of mass.

The problem of finding the centre of inertia of any given distribution of matter is a question of mere mathematics. We must confine ourselves to a few examples only. And, first, we may note that when a body is symmetrical about a plane the centre of inertia must obviously lie in that plane. Thus, as an ellipsoid and a rectangular parallelepiped have each three planes of symmetry, their centres of inertia lie at their centres of figure, where these planes meet. Again, it is obvious that, if a body can be divided into parts the centres of inertia of which lie on a straight line, the centre of inertia of the whole is in that line. Thus, as a triangular plate may be divided into strips parallel to one side, every one of which has its centre of inertia at its middle point, the centre of inertia of such a plate is the point of intersection of the bisectors of the sides. Its distance from any one side, treated as base, is therefore one-third of the height. Again, if a triangular pyramid (or tetrahedron) be divided into triangular slices by planes parallel to one face treated as base, the centres of inertia of all the slices lie in a straight line. Hence the distance of the centre of inertia from the base is one-fourth of the height. If the base be of any other form, it may be divided into triangles, and thus the whole pyramid (or cone) into tetrahedra, for each of which the same property holds. Hence the centre of inertia of a pyramid divides the line joining the vertex to the centre of inertia of the base in the ratio 3 : 1. All this is on the supposition that the solids treated of are of uniform density. When we deal either with more complex forms or with heterogeneous bodies, we must in general have recourse to integration.

For a continuous body we must take an element of mass, say $\rho\delta x\delta y\delta z$, at the point x, y, z instead of the mass m in our original formula. The sums then become integrals, and we have three expressions of the form

$$\bar{x} = \frac{\iiint \rho x dx dy dz}{\iiint \rho dx dy dz},$$

Here ρ represents the density at x, y, z; and the integration extends through the whole volume of the body.

Thus, for a homogeneous *hemisphere* of radius a we have, taking the base as the plane of yz,

$$\bar{x} = \frac{\int_0^a \pi(a^2 - x^2)x dx}{\frac{2}{3}\pi a^3} = \frac{3a}{8}.$$

The same value would be obtained for any semiellipsoid, whatever be the diametral section, provided a be the height measured perpendicular to the base; and, in general, from the position of the centre of inertia of any body we may at once find that of the same body homogeneously strained.

Recurring to the hemisphere, suppose its density to be at every point proportional to the distance from the centre. Then we have, omitting common constant factors of numerator and denominator,

$$\bar{x} = \frac{\int_0^a x dx \int_0^{\sqrt{a^2 - x^2}} r\sqrt{x^2 + r^2} dr}{\int_0^a dx \int_0^{\sqrt{a^2 - x^2}} r\sqrt{x^2 + r^2} dr} = \frac{2a}{5}.$$

A uniform hemispherical shell gives

$$\bar{x}=\tfrac{1}{2}a$$

by the well-known result due to Archimedes. From this, by taking concentric hemispherical elements, we may reproduce the preceding result for a solid hemisphere in the form

$$\bar{x}=\frac{\int_0^a 2\pi x^2 dx\,.\,x\,.\,\frac{1}{2}x}{\int_0^a 2\pi x^2 dx\,.\,x}=\frac{2a}{5}\,.$$

Here the first factor under each integral sign is the volume of the hemispherical element of radius x, and the second is proportional to its density.

If the density of a thin uniform spherical shell be everywhere proportional to the inverse cube of the distance from an internal point, that point is the centre of inertia. For, if a double cone of small angle be drawn, having that point as vertex, the volumes of the portions of the shell which it cuts out are as the squares of their distances from the vertex. Hence their masses are inversely as their distances from the vertex, which is thus their centre of inertia. The whole shell may be divided into pairs of elements for each of which this is true.

The reader may easily prove that, if the density of a solid sphere be inversely as the fifth power of the distance from an external point, the "electric image" of that point is the centre of inertia.

It may be proved in the last two examples that this point is not merely the centre of inertia of such distributions of matter, but that it is also a true "centre of gravity" in the sense that the whole attracts, and is attracted by, any other body whatever, as if its whole mass were concentrated in this point.

Moment of momentum. § 110. By introducing in the definition of moment of velocity (§ 46) the mass of the moving particle as a factor, we have an important element of dynamical science, the "moment of momentum." The laws of composition and resolution are the same as those already explained. Its dimensions are $[ML^2T^{-1}]$.

Work. § 111. A force is said to "do work" if it moves the body to which it is applied; and the work done is measured by the resistance overcome, and the space through which it is overcome, conjointly. The dimensions of work are therefore $[MLT^{-2}.\,L]$ or $[ML^2T^{-2}]$, the same as those of kinetic energy.

Thus, in lifting coals from a pit, the amount of work done is proportional to the weight of the coals lifted; that is, to the force overcome in raising them; and also to the height through which they are raised. The unit for the measurement of work, adopted in practice by British engineers, is that required to overcome the weight of a pound through the height of a foot, and is called a "foot-pound."

In purely scientific measurements, the unit of work is not the foot-pound, but the absolute unit force (§ 105) acting through unit of length.

If the weight be raised obliquely, as, for instance, along a smooth inclined plane, the distance through which the force has to be overcome is increased in the ratio of the length to the height of the plane; but the force to be overcome is not the whole weight, but only the resolved part of the weight parallel to the plane; and this is less than the weight in the ratio of the height of the plane to its length. By multiplying these two expressions together, we find, as we might expect, that the amount of work required is unchanged by the substitution of the oblique for the vertical path.

Generally, if s be an arc of the path of a particle, S the tangential component of the applied forces, the work done on the particle between any two points of its path is

$$\int S ds\,,$$

taken between limits corresponding to the initial and final positions.

Referred to rectangular coordinates, it is easy to see, by the law of resolution of forces, § 117, that this becomes

$$\int\left(X\frac{dx}{ds}+Y\frac{dy}{ds}+Z\frac{dz}{ds}\right)ds\,,$$

where X is the component force parallel to the axis of x.

§ 112. Thus it appears that, for any force, the work done during an indefinitely small displacement of the point of application is the product of the resolved part of the force in the direction of the displacement into the displacement.

From this it follows that, if the motion of a body be always perpendicular to the direction in which a force acts on it, the force does no work. Thus the mutual normal pressure between a fixed and a moving body, the tension of the cord to which a pendulum bob is attached, the attraction of the sun on a planet if the planet describe a circle with the sun in the centre, are all cases in which no work is done by the force.

In fact the geometrical condition that the resultant of X, Y, Z shall be perpendicular to ds is

$$X\frac{dx}{ds}+Y\frac{dy}{ds}+Z\frac{dz}{ds}=0\,,$$

and this makes the above expression for the work vanish.

§ 113. Work done on a body by a force is always shown by a corresponding increase of kinetic energy, if no other forces act on the body which can do work or have work done against them. If work be done against any forces, the increase of kinetic energy is less than in the former case by the amount of work so done. In virtue of this, however, the body possesses an equivalent in the form of "potential energy," if its physical conditions are such that these forces will act equally, and in the same directions, when the motion of the system is reversed. Thus there may be no change of kinetic energy produced, and the work done may be wholly stored up as potential energy. Tran mati work Pote energ

Thus a weight requires work to raise it to a height, a spring requires work to bend it, air requires work to compress it, &c.; but a raised weight, a bent spring, compressed air, &c., are *stores* of energy which can be made use of at pleasure.

As an illustration of the calculation of work, take the following question. Exam of wo

Suppose one end of an elastic string to be attached to a mass resting on the ground, what amount of work must be done, in raising the other end vertically, before the mass is lifted?

If x be at any instant the length of the string, l its original length, its tension is

$$E\frac{x-l}{l}\,.$$

Hence the value of x, when the mass is just lifted, is

$$x_1=l\left(1+\frac{W}{E}\right),$$

where W is the weight of the mass.

The whole work done is the sum of all the elementary instalments of the form

$$E\frac{x-l}{l}dx\,.$$

These must be summed up from $x=l$ to $x=x_1$, so that the result required is

$$\tfrac{1}{2}l\frac{W^2}{E}\,.$$

It is to be observed that this quantity becomes less in proportion as E is greater, *i.e.*, the less extensible is the string.

An interesting variation of the question consists in supposing the upper end of the string to be attached to the rim of a wheel, rough enough to prevent slipping. Here the various portions of the string are wound on in a more and more stretched state as the operation proceeds.

At any stage of the operation let x be the unstretched length of the part already wound on the wheel. The tension of the free part is then

$$E\frac{l-(l-x)}{l-x}\,.$$

During the next elementary step of the process a portion dx is wound on. But its stretched length is

$$\frac{ldx}{l-x}\,.$$

Hence the element of work is

$$El\frac{l-(l-x)}{(l-x)^2}dx,$$

This must be integrated between the limits 0 and W of

$$E\frac{l-(l-x)}{l-x};$$

or from $l-x=l$ to $l-x=\frac{El}{E+W}$; and the result is

$$l\left(W+E\log\frac{E}{E+W}\right);$$

which, when E is very great compared with W, gives the previous result.

Further Comments on the First Two Laws of Motion.

[Physical measurement of time.] § 114. We are now prepared to consider, more closely than we could at starting, the bearing of the various clauses of each of Newton's Laws. Thus, from the first law we may draw the following immediate consequences.

The times during which any particular body, not compelled by force to alter the speed of its motion, passes through equal distances are equal. And, again, every other body in the universe, not compelled by force to alter the speed of its motion, moves over equal distances in successive intervals, during which the particular chosen body moves over equal distances. The earth, in its rotation about its axis, presents us with a case of motion in which the condition of not being compelled by force to alter its speed is more nearly fulfilled than in any other which we can easily or accurately observe. Hence the numerical measurement of time practically rests on defining "equal intervals of time" as *times during which the earth turns through equal angles.*

§ 115. It has been objected to this statement that we begin by defining uniform motion by the description of equal spaces in equal times, and then employ this definition as a mode of measuring equal times. The objection, however, is not valid; for, if we agree to measure equal intervals by the undisturbed motion of any one physical mass, we find that in the successive intervals so determined all other absolutely free physical masses describe successive equal spaces.

[Measure of force.] § 116. Again, from the second law we see that, if we multiply the change of velocity, geometrically determined, by the mass of the body, we have the change of motion (§ 99) referred to in the law as the measure of the force which produces it. In the statement of the second law there is nothing said about the actual motion of the body before it was acted on by the force; the same force will produce precisely the same change of motion in a body whether the body be at rest or in motion with any velocity whatever. Again, nothing is said as to the body being under the action of one force only; so that we may logically put part of the second law in the following (apparently) amplified form:—

When any forces whatever act on a body, then, whether the body be originally at rest or moving with any velocity and in any direction, each force produces in the body the exact change of motion which it would have produced if it had acted singly on the body originally at rest.

[Composition of forces.] § 117. Since now forces are measured by the changes of motion they produce, and their directions assigned by the directions in which these changes are produced, and since the changes of motion of one and the same body are in the directions of and proportional to the changes of velocity, a single force, measured by the resultant change of velocity, and in its direction, will be the equivalent of any number of simultaneously acting forces. Hence

The resultant of any number of forces (applied at one point) is to be found by the same geometrical process as the resultant of any number of simultaneous velocities.

From this follows at once (§ 30) the construction of the "parallelogram of forces" for finding the resultant of two forces acting at the same point, and the "polygon of forces" for the resultant of any number of forces acting at a point. And, so far as a single particle is concerned, we have at once the whole subject of Statics.

§ 118. The second law gives us the means of measuring force, and also of measuring the mass of a body. [Measure of mass, and of force.]

For, if we consider the actions of various forces upon the same body for equal times, we evidently have changes of velocity produced which are proportional to the forces. The changes of velocity, then, give us in this case the means of comparing the magnitudes of different forces. Thus the speeds acquired in one second by the same mass (falling freely) at different parts of the earth's surface give us the relative amounts of the earth's attraction at these places.

Again, if equal forces be exerted on different bodies, the changes of velocity produced in equal times must be *inversely* as the masses of the various bodies. This is approximately the case, for instance, with trains of various lengths drawn by the same locomotive.

Again, if we find a case in which different bodies, each acted on by a force, acquire in the same time the same changes of velocity, the forces must be proportional to the masses of the bodies. This, when the resistance of the air is removed, is the case of falling bodies; and from it we conclude that the *weight of a body in any given locality, or the force with which the earth attracts it, is proportional to its mass.* This is no mere truism, but an important part of the grand *Law of Gravitation.* Gravity is not, like magnetism for instance, a force depending on the quality as well as on the quantity of matter in a particle. [Gravity.]

§ 119. It appears, lastly, from this law that every theorem of kinematics connected with acceleration has its counterpart in kinetics. Thus, for instance (§ 36), we see that the force under which a particle describes any curve may be resolved into two components, one in the tangent to the curve, the other *towards* the centre of curvature,—their magnitudes being the rate of change of momentum in the direction of motion, and the product of the momentum into the angular velocity about the centre of curvature, respectively. In the case of uniform motion, the first of these vanishes, or the whole force is perpendicular to the direction of motion. When there is no force perpendicular to the direction of motion, there is no curvature, or the path is a straight line. [Translation from kinematics into kinetics.]

Hence, if we resolve the forces acting on a particle of mass m, whose coordinates are x, y, z, into three rectangular components X, Y, Z, we have the equations originally given by Maclaurin, viz.,

$$m\frac{d^2x}{dt^2}=X,\quad m\frac{d^2y}{dt^2}=Y,\quad m\frac{d^2z}{dt^2}=Z.$$

In several of the examples which follow, these equations will be somewhat simplified by assuming unity as the mass of the moving particle. When this cannot be done, it is sometimes convenient to assume X, Y, Z as the component forces on *unit* mass, and the previous equations become

$$m\frac{d^2x}{dt^2}=mX,\ \&c.,$$

from which m may of course be omitted.

[Some confusion is often introduced by the division of forces into "accelerating" and "moving" forces; and it is even stated occasionally that the former are of *one*, and the latter of *four* linear dimensions. The fact is, however, that an equation such as

$$\frac{d^2x}{dt^2}=X$$

may be interpreted either as dynamical or as merely kinematical. If kinematical, the meanings of the terms are obvious; if dynamical, the unit of mass must be understood as a factor on the left-hand side, and in that case X is the x-component, per unit of mass, of the whole force exerted on the moving body.]

If there be no acceleration, we have of course equilibrium among the forces. Hence the equations of motion of a particle are changed into those of equilibrium by putting

$$\frac{d^2x}{dt^2}=0, \text{ \&c.}$$

Statical friction.

§ 120. We have now all that is necessary for the dynamics of a single particle, with exception of the experimental laws of friction. These, very nearly as they were established by Coulomb, we will now give.

To produce sliding of one flat-faced solid on another requires a tangential force which is directly proportional to the normal pressure between the surfaces, and whose actual magnitude is found from this pressure by means of a factor called the "coefficient of statical friction." This coefficient depends upon the nature of the solids, the roughness or smoothness of the surfaces in contact, and the amount of tallow, oil, &c., with which they have been smeared. It also depends upon the time during which they have been left in contact. It is only in extreme cases dependent on the area of the surfaces in contact.

§ 121. When the forces applied are insufficient to produce sliding, the whole amount of friction is not called into play; it is called out to an amount just sufficient to balance the other forces. Thus there are two quite distinct problems connected with the statics of friction:—the first, to determine the amount of friction called into play under given circumstances; the second, to find the limiting circumstances under which, with friction, equilibrium is possible. When motion is produced, there is

Kinetic friction.

still friction (now called "kinetic"). It follows the same laws as does statical friction, only that the coefficient, which is approximately independent of the velocity, is usually considerably less than the statical coefficient.

Statics of a Particle.

Equilibrium of a particle.

§ 122. By § 117, forces acting at the same point, or on the same material particle, are to be compounded by the same laws as velocities. Therefore the sum of their resolved parts in any direction must vanish if there is equilibrium; whence the necessary and sufficient conditions are found by resolving in three directions at right angles to one another.

They follow also directly from Newton's statement with regard to work, if we suppose the particle to have any velocity, constant in direction and magnitude (and by § 6 this is the only general supposition we can make, since absolute rest has for us no meaning). For the work done in any time is the product of the displacement during that time into the algebraic sum of the effective components of the applied forces, and there is no change of kinetic energy. Hence this sum must vanish for *every* direction. Practically, as any displacement may be resolved into three, in any three directions not coplanar, the vanishing of the work for any one such set of three suffices for the criterion. But, in general, it is convenient to assume them in directions at right angles to each other.

Hence, for the equilibrium of a material particle, it is *necessary*, and *sufficient*, that the (algebraic) sums of the applied forces, resolved in any one set of three rectangular directions, should vanish.

This statement gives at once the result that, if X_1, Y_1, Z_1, X_2, Y_2, Z_2, &c., be the components (parallel to the three axes) of the forces P_1, P_2, &c., acting on the particle, we must have

$$\Sigma(X)=0\,,\ \Sigma(Y)=0\,,\ \Sigma(Z)=0\,.$$

When these conditions are not satisfied, there is a resultant force P, with direction cosines λ, μ, ν, such that

$$P\lambda=\Sigma(X),\ P\mu=\Sigma(Y),\ P\nu=\Sigma(Z).$$

Attraction.

§ 123. By far the most extensive series of examples of the composition of forces acting on a single particle is furnished by the theory of "attraction," where each particle of the attracting mass exerts upon the attracted particle a force in the direction of the line joining them, and of magnitude depending on their masses and their mutual distance only. See Potential.

Example of particle equilibrium.

§ 124. When there are but three forces acting on the particle, their directions to give equilibrium must obviously be in one plane. For, if the third were not in the plane of the other two, it would have an uncompensated component perpendicular to that plane. Hence this case is always at once reducible to the triangle or the parallelogram of forces; and the magnitudes of each of the three forces are respectively proportional to the sines of the angles between the directions of the other two.

Thus, when a pellet is supported by two strings, as in fig. 34, we may proceed as follows to determine their tensions. Let P be the pellet, of weight W, and let AP, BP be the strings attached to points A and B respectively. Let their tensions be T and T′. The remark above shows that the strings must hang in a vertical plane, since the force W acts in a vertical line. Since A, B, and the length of the strings are given, the figure is perfectly definite. Draw $P\gamma$ vertically upwards, and make its length represent, on any assumed scale, the value of W. Draw $\gamma\beta$ parallel to AP, and let it meet BP in β. Then $\beta\gamma$ represents T, and $P\beta$ represents T′, in direction and also in magnitude, on the same scale in which γP represents W. This case leads to nothing but the determination of the tensions, since the form of the figure is definite.

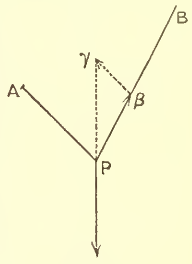

Fig. 34.

Next, let one of the tensions be given in magnitude. To effect this, we may suppose the end of PB not to be fastened at B, but to pass over a smooth pulley and support a weight Q. Let fig. 35 represent the state of equilibrium, and let the same construction as before be made. Then we must have $\gamma P : P\beta :: W : Q$; or, writing it in terms of angles,

$$\sin APB : \sin AP\gamma :: W : Q\,.$$

A and B and the direction of γP being given, this datum suffices for the drawing of the figure; *i.e.*, for the calculation of the angles. A little consideration will show that, however small Q be, provided the string supporting it be long enough, there is always *one definite* position of equilibrium. The actual calculations in such a case as this are troublesome. It was chosen mainly on that account, so as to show, in a simple case, how pure geometrical processes may occasionally save the necessity of a tedious trigonometrical investigation. But a still simpler method will be afterwards explained, viz., that, for a position of stable equilibrium, the potential energy must be a *minimum*. Now, to apply this to our example, we see that any downward displacement of Q produces an upward motion of P. But when AP is nearly vertical the vertical displacement of P is indefinitely smaller than that of Q, so that Q must go down. On the other hand if APB be nearly a straight line, a displacement of P produces an indefinitely smaller displacement of Q. Hence P must go down. And these results are in character independent of the relative magnitudes of P and Q, provided both be finite.

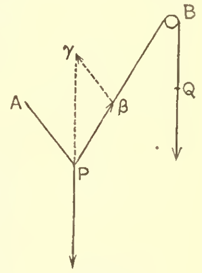

Fig. 35.

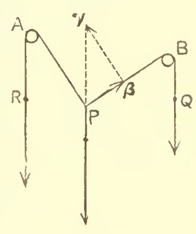

Fig. 36.

Finally, let both tensions be constant. Here we must imagine pulleys both at A and at B (fig. 36), with weights

R and Q attached to the ends of the strings. But now we see that we must have the limiting condition

$$R+Q>W.$$

This is merely the geometrical condition that

$$P\beta+\beta\gamma>P\gamma$$

Here the magnitudes of all three sides of $P\beta\gamma$ are given. Hence its angles are given, and the sole position of equilibrium is at once found.[1]

Particle on fixed surface. § 125. Now take the case of a particle resting on a surface. As we are concerned only with the portion of the surface immediately contiguous to the position of the particle, we may substitute for it its tangent plane at that point (except, of course, at singular points, where there may be an infinite number of tangent planes; but such cases we do not consider). Hence the problem reduces itself in all cases to that of a particle resting on an inclined plane.

If the plane be smooth, the particle cannot remain in equilibrium unless some force is present to prevent its sliding down. Let us suppose it to be supported by a force, F, acting upwards along the plane (fig. 37). Then we have three forces at work:—the weight P acting vertically downwards; the supporting pressure of the plane R, which necessarily acts perpendicularly to the surface; and the third force, just mentioned, which we see by previous considerations must be in the plane of the other two, and must therefore lie along the line of greatest slope of the plane. We might construct a triangle of forces as in the previous examples, but we will now vary the process, and resolve the forces in two directions at right angles to one another in their common (vertical) plane.

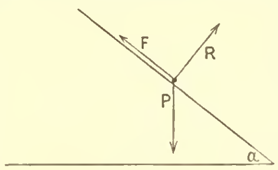

Fig. 37.

Let a be the angle of inclination of the plane to the horizon, then the algebraic sum of the components of the forces must vanish both horizontally and vertically. This gives us the two conditions

$$F\cos a-R\sin a=0\,,\quad F\sin a+R\cos a-P=0$$

From these we obtain at once

$$F=P\sin a,\quad R=P\cos a$$

Now the choice of mutually perpendicular directions in which to resolve was at our option, and we see that had we chosen to resolve *along* and *perpendicular to* the plane we should have obtained the last two equations, which are equivalent to, but simpler than, the former ones, which were obtained by resolving horizontally and vertically. Theoretically speaking, it does not matter which system we choose; in practice, however, it is well to select the directions which will give the required results in the simplest form. The full value of a proper selection will not be felt till we come to the statics of a rigid solid.

Friction. If we suppose the plane to be rough, friction alone may suffice to develop the requisite force F. But the utmost value of the friction is (§ 120) μR. Hence the particle will be on the point of sliding if

$$\mu R=F=P\sin a.$$

Divide the members of this equation by those of

$$R=P\cos a,$$

and we find

$$\mu=\tan a.$$

Hence, so long as the coefficient of friction is greater than the tangent of the inclination of the plane to the horizon, the friction will suffice to prevent sliding. More and more is called into play as the inclination of the plane increases, and finally when

Angle of repose.

$$\tan a=\mu$$

the particle is just about to slide down. This simple idea, taken along with Coulomb's results (§ 120), points to a very easy method of determining the coefficient of friction between any two substances. The limiting angle defined by

$$a=\tan^{-1}\mu$$

is called, on account of this property, the "angle of repose."

Support by elastic string. § 126. Let us now suppose the particle to be, in part, supported by an elastic string fixed at a point in the plane, and lying in the line of greatest slope. (This modification is introduced to show the nature of cases in which there are *limits* between which equilibrium is possible.) We assume "Hooke's Law," viz., that the tension of an elastic string, drawn out from its natural length l to length l', is expressed by

$$E\frac{l'-l}{l},$$

where E is a definite constant, representing theoretically the tension which would just double the length of the string.

Our equations are exactly the same as before, only that F consists now of two parts,—one due to friction, the other to the elasticity of the string. Thus

$$F=F_1+E\frac{l'-l}{l}=P\sin a\,,\qquad R=P\cos a.$$

Now, when sliding is about to commence downwards we have

$$F_1=\mu R,$$

If the particle is about to be dragged upwards,

$$F_1=-\mu R.$$

Hence for the two extreme positions of equilibrium

$$\pm\mu P\cos a+E\frac{l'-l}{l}=P\sin a.$$

Hence the limiting positions of equilibrium of the particle are given by its distance from the fixed end of the string—

$$l'=l+\frac{Pl}{E}(\sin a\mp\mu\cos a).$$

If l' be less than the smaller of these, gravity pulls the particle down; if it be greater than the larger of them, the tension of the string pulls the particle up. In intermediate positions the full available friction is not called into play.

Equilibrium with a system of equal forces tending to given points. § 127. Next, let a small ring P (fig. 38) be attached to one end of a string. Let the string pass round two smooth pulleys B, C, at different points, then be passed through the ring, then round two more pulleys D, E, and through the ring again, and so on,—the other end being either fastened to the ring or attached to a fixed point. It is required to find the position of equilibrium of the ring when the string is drawn tight, by operating on the lap of it behind two of the pulleys.

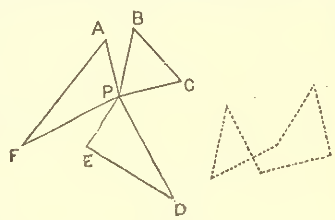

Fig. 38.

This is equivalent, from the physical point of view, to finding the position of equilibrium of a particle acted on by a number of *equal* forces each directed towards a given point. From the geometrical point of view its solution obviously answers the question, "Find the point the sum of whose distances from a number of given points is the least possible." The points need not lie all in one plane. The solution is, from the polygon of forces, that in

[1] We have assumed here, what is properly part of the results of the *third* law of motion, that the tension of a weightless string, passing over a smooth pulley, is in the direction of its length, and of the same amount at all points.

the equilibrium position the laps of the string, from the ring outwards, are parallel to the respective sides of a closed equilateral polygon, taken all in the same direction. That the solution is unique will be seen at once by considering a displacement of the ring, for the resultant of the forces obviously tends to diminish the displacement. When there are but three forces, their directions must be inclined at angles of 120° to one another (fig. 39). Thus we have immediately the solution of the celebrated geometrical problem, "Find the point the sum of whose distances from three given points is the least possible."

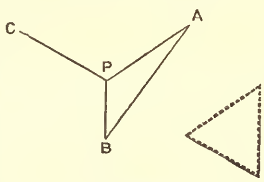

Fig. 39.

Indeterminateness of solution.

§ 128. If, in the first problem of § 124 above, the particle were supported by three strings, instead of two, each attached to a fixed point, we should first have to assure ourselves that all three are brought into play. For, if not, the problem is reduced to the former case. The obvious condition is that, when the three strings are simultaneously tight, and the points of suspension are not in one vertical plane, the particle supported shall be situated *within* the triangular prism formed by vertical planes passing through each pair of points. If this condition be satisfied, the process for determining the tensions of the strings is merely to construct a parallelepiped, three of whose edges lie along the strings, while the conterminous diagonal is vertical. This leads to an obvious geometrical construction; and, when it is carried out, the lengths of the various edges are to the diagonal as the corresponding tensions to the weight of the particle. When the three points are in one vertical plane, nothing short of infinitely perfect fitting will, in general, bring all three strings simultaneously tight; and in this case the problem, mathematically considered, is indeterminate.[1] When the strings are sufficiently extensible, all will be brought into play; and, with sufficient data, the problem is determinate.

Kinetics of a Particle with One Degree of Freedom.

§ 129. Here the motion is rectilinear, or at least takes place in some assigned curve.

The simplest case is that of a falling stone, when the effect of the resistance of the air is set aside and the acceleration due to gravity is reckoned the same at all elevations. This has already been treated with sufficient detail as a matter of pure kinematics, §§ 28, 29.

Sliding on inclined plane.

§ 130. When the particle, instead of falling freely, is constrained by a smooth inclined plane on which it slides, we see that (so long as it moves on the line of greatest slope) its weight Mg has components, $Mg\sin\alpha$ tangential to the plane and $Mg\cos\alpha$ perpendicular to it, α being the inclination of the plane to the horizon. The latter component produces the normal pressure on the plane, and is the only contributor to it, since there is no curvature. The former produces the acceleration of the motion. Thus the acceleration is now $g\sin\alpha$ only; but, with this change, the results of § 29 still hold.

Plane rough.

§ 131. If the plane be rough, with coefficient of statical friction μ, it can furnish (§ 120) a force of friction tending to prevent motion, of any amount up to

$$\mu Mg\cos\alpha\,.$$

If this be less than $Mg\sin\alpha$, motion will commence, and the force accelerating it will be

$$Mg\sin\alpha - \mu' Mg\cos\alpha\,,$$

where μ' is the coefficient of kinetic friction (§ 121). Thus the same results as in § 29 still hold, but with $g(\sin\alpha - \mu'\cos\alpha)$ instead of g. As we have seen that $\mu' < \mu$, *accelerated* motion can take place down an inclined plane in certain cases where the mass, if once at rest, would not start.

[1] Of course, physically, there is no indeterminateness, even with perfectly inextensible strings.

Body falling to earth from a great distance.

§ 132. As a slightly more complex case, let us now take again the problem of free motion in a vertical line, but allow for the diminution of gravity as the distance from the earth increases.

The weight of a particle of mass m at the earth's surface is mg. At a distance x from the centre, it is, therefore,

$$mg\frac{R^2}{x^2}\,,$$

where R is the radius of the earth, supposed spherical. This acts downwards, or in the direction opposite to that in which x increases. Hence, equating it, with its proper sign, to the rate of acceleration of momentum, we have for the equation of motion

$$m\ddot{x} = -mg\frac{R^2}{x^2}\,.$$

Here the right hand member is a function of x only.

Multiply by $\dot{x}dt$, and integrate, and we have, leaving out the extraneous factor m (the possibility of doing this showing that the motion is the same for all masses),

$$\tfrac{1}{2}\dot{x}^2 + C = \frac{R^2 g}{x}\,.$$

If V be the speed at the earth's surface (where $x = R$),

$$\tfrac{1}{2}V^2 + C = Rg\,.$$

Also if the particle turns, to come down again, at the height h above the surface,

$$C = \frac{R^2 g}{R+h}\,.$$

Hence

$$\tfrac{1}{2}V^2 = Rg\left(1 - \frac{R}{R+h}\right) = gh\frac{R}{R+h}\,.$$

This shows the amount of error in the approximate formula (§ 28) for projectiles,—

$$\tfrac{1}{2}V^2 = gh\,.$$

Meteorite.

If the particle be supposed to have been originally at rest, at a practically infinite distance from the earth (a case which may occur with a meteorite for instance), we have $\dot{x} = 0$ when $x = \infty$, and our formula becomes

$$\tfrac{1}{2}\dot{x}^2 = \frac{R^2 g}{x}\,.$$

The speed with which the mass reaches the surface (where $x = R$) is therefore $\sqrt{2gR}$, *i.e.*, that which it would acquire by falling, under constant acceleration g, through a height equal to the earth's radius.

In this special case, the second integral is

$$\tfrac{2}{3}x^{\frac{3}{2}} = \sqrt{2g}Rt + C'.$$

The second integral, in its general form, is a little complex; but we may avoid it by means of a geometrical construction, founded on the results of the investigation of planetary motion soon to be given.

Hailstone raindrop.

§ 133. Let us next take a case in which the acceleration depends upon the speed of the moving body. A sufficiently simple one is furnished by a falling raindrop, or hailstone, when the resistance of the air is taken into account. For the moderate speeds with which such bodies move, the resistance varies, at least approximately, as the square of the speed. To avoid needless complexity, we neglect here the variation of gravity due to changes of vertical height.

Suppose the particle to have been projected vertically upwards from the origin with the speed V, and let v be its speed at any time t, and x its distance from the origin at that time.

If we assume k to be the speed with which the particle must move so that the retardation due to the resistance may be equal to g, the retardation when the speed is v will be represented by $g\frac{v^2}{k^2}$.

Let the axis of x be drawn vertically upwards; then the resistance acts *with* gravity, and the equation of motion upwards is

$$\frac{dv}{dt} = -\frac{g}{k^2}(k^2 + v^2),$$

or

$$v\frac{dv}{dx} = -\frac{g}{k^2}(k^2 + v^2).$$

Integrating, and determining the constants so that, when $x=0$, $t=0$ and $v=V$, we obtain

$$\frac{gt}{k} = \tan^{-1}\frac{V}{k} - \tan^{-1}\frac{v}{k} = \tan^{-1}\frac{k(V-v)}{k^2+Vv},$$

$$\frac{2gx}{k^2} = \log\frac{k^2+V^2}{k^2+v^2}.$$

Let T be the time at which the speed becomes zero, and h the corresponding value of x, then

$$T=\frac{k}{g}\tan^{-1}\frac{V}{k}, \text{ and } h=\frac{k^2}{2g}\log\left(1+\frac{V^2}{k^2}\right).$$

After this the particle begins to return; the resistance therefore acts *against* gravity, and the equation of motion is

$$\frac{dv}{dt} = -\frac{g}{k^2}(k^2-v^2),$$

or

$$v\frac{dv}{dx} = -\frac{g}{k^2}(k^2-v^2).$$

Integrating, and determining the constants so that, when $v=0$, $x=h$ and $t=T$, we obtain

$$\frac{2g}{k}(t-T)=\log\frac{k-v}{k+v},$$

$$\frac{2g}{k^2}(h-x)=\log\frac{k^2}{k^2-v^2}.$$

(It must be remembered that v is now negative.)

Let U be the speed with which the particle returns to the point of projection; then, putting $x=0$ in the latter equation, we obtain

$$\frac{U^2}{k^2}=1-\varepsilon^{-\frac{2gh}{k^2}};$$

or, substituting for h its value,

$$\frac{U^2}{k^2}=\frac{V^2/k^2}{1+V^2/k^2},$$

whence

$$\frac{1}{U^2}-\frac{1}{V^2}=\frac{1}{k^2}.$$

rminal ocity. It is to be observed that k is the "terminal velocity," as it is called, *i.e.*, the speed to which that of a falling body continually tends, whether its original speed have been greater or less than this limit.

It is to be observed also that (strictly) we should write $g(1-a)$ for g, where a is the specific gravity of air, to take account of the apparent loss of weight of a raindrop on account of immersion in air.

When k is very large, *i.e.*, the absolute amount of resistance very small, as in the case of air, the general integrals in the second case above become, by expanding the logarithms,

$$-\frac{2g}{k}(t-T)=\frac{2v}{k}+\frac{2v^3}{3k^3}+\ldots$$

$$\frac{2g}{k^2}(h-x)=\frac{v^2}{k^2}+\frac{v^4}{2k^4}+\ldots$$

of which the terms independent of k are

$$v=-g(t-T),$$
$$v^2=2g(h-x).$$

These, if we remember that $t-T$ is the time of fall, and $h-x$ the space fallen through, are at once recognized as the ordinary formulæ of § 28. The modification due to the resistance is shown approximately by the second terms on the right-hand side of the developments above.

The necessity for this double investigation, one part for the ascent, the other for the descent, is due to the non-conservative, or "dissipative," character of the force of resistance.

mple ndu- m. § 134. As an illustration of constraint by a smooth curve, let us take the case of a simple pendulum. Let O (fig. 40) be the point of suspension, P the position of the bob at any time t. Then, if PG represent the weight of the bob, and be resolved into PH, HG respectively along, and perpendicular to, the tangent at P, we see that PH produces the acceleration of the motion, while the tension of the cord balances HG and also furnishes the acceleration perpendicular to the direction of motion which is required to produce the curvature of the path. PH is (*cæteris paribus*) proportional to the sine of PGH, that is, of POA. Hence the acceleration is proportional to the sine of the angular displacement. When that angle is small it may be used in place of its sine. Hence, for small vibrations, the acceleration is proportional to the displacement, and the motion is "simple harmonic." The time of vibration, being (§ 51) $2\pi\sqrt{\text{displacement}/\text{acceleration}}$, is here

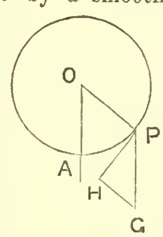

Fig. 40.

$$2\pi\sqrt{\frac{l\theta}{g\sin\theta}}=2\pi\sqrt{\frac{l}{g}}, \text{ approximately.}$$

The rigorous solution of the pendulum problem requires the use of elliptic functions.

§ 135. Some very curious properties of pendulum motion are easily proved by geometrical processes. The whole theory of the motion in a vertical plane of a particle attached by a weightless rod to a fixed point, whether it oscillate as a pendulum or perform continuous rotations, may be deduced from the two following propositions, which are easily established by geometrical processes in which corresponding indefinitely small motions are compared.

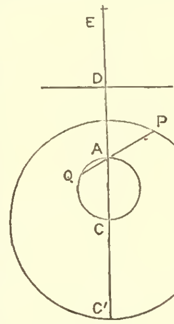

Fig. 41.

(1) To compare different cases of continuous rotation. Let DA (fig. 41) be taken equal to the tangent from D to the circle BPC′, whose centre C is vertically under D. Let PAQ be any line through A, cutting in Q the semicircle on AC. Also make DE = DA. Then, if P move under gravity with speed due to the level of D, Q moves with speed due to the level of E, the acceleration due to gravity being reduced in the ratio $AC^2 : 2BC^2$.

(2) To compare continuous rotation with oscillation. Let two circles touch one another at their lowest points O (fig. 42); compare the arcual motions of points P and p, which are always in the same horizontal line. Draw the horizontal tangent AB. Then, if P move, with speed due to g and level a, continuously in its circle, p oscillates with speed due to level AB and acceleration

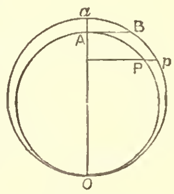

Fig. 42.

$$g\frac{aO^2}{AO^2}.$$

§ 136. Two particles are projected from the same point, in the same direction, and with the same speed, but at different instants, in a smooth circular tube of small bore whose plane is vertical, to show that the line joining them constantly touches another circle. Motion in vertical circle

Let the tube be called the circle A, and the horizontal line, to the level of which the speed is due, L. Let M, M′ (fig. 43) be simultaneous positions of the particles. Suppose that MM′ passes into its next position by turning about O, these two lines will intercept two indefinitely small arcs at M and M′ which (by a property of the circle) are in the ratio MO : OM′. Let another circle B be described touching MM′ in O, and such that L is the radical axis of A and B. Let MP, M′P′ be drawn perpendicular to L. Let M′M cut L in C. Then, by the property of the radical axis, $CO^2 = CM.CM'$; from which we have, by geometry,

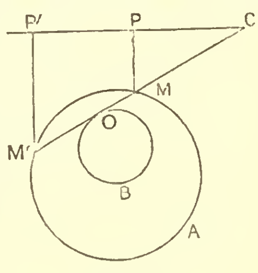

Fig. 43.

$$CM : CM' = OM^2 : OM'^2$$

or

$$OM^2 : OM'^2 = PM : P'M'.$$

But

$$(\text{speed at M})^2 : (\text{speed at M}')^2 = PM : P'M'.$$

Hence the speeds of M and M′ are as MO : OM′, and therefore, by what we have stated above about elementary arcs at M and M′, the proximate position of MM′ is also a tangent to B, which proves the proposition.

Geometrical theorem.

It is easily seen from this that, if one polygon of a given number of sides can be inscribed in one circle and circumscribed about another, an infinite number can be drawn. For this we have only to suppose a number of particles moving in A with speeds due to a fall from L, and then if they form at any time the angular points of a polygon whose sides touch B they will continue to do so throughout the motion. Fig. 44 shows two forms of a quadrilateral possessing this property.

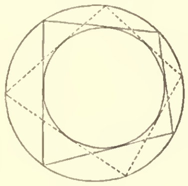

Fig. 44.

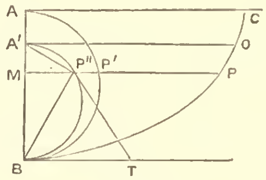

Fig. 45.

Cycloidal motion.

§ 137. *To find the time of fall from rest down any arc of an inverted cycloid.*

Let O (fig. 45) be the point from which the particle commences its motion. Draw OA′ parallel to CA, and on BA′ describe a semicircle. Let P, P′, P″ be corresponding points of the curve, the generating circle, and the circle just drawn, and let us compare the speeds of the particle at P and the point P″. Let P″T be the tangent at P″.

$$\frac{\text{Speed of P}''}{\text{Speed of P}}=\frac{\text{element at P}''}{\text{element at P}}$$

$$=\frac{\text{P}''\text{T}}{\text{BP}'}=\frac{\text{P}''\text{T}}{\text{BP}''}\sqrt{\frac{\text{A}'\text{B}}{\text{AB}}}=\frac{\text{A}'\text{B}}{2\text{A}'\text{P}''}\sqrt{\frac{\text{A}'\text{B}}{\text{AB}}}.$$

But speed of $\text{P}=\sqrt{(2g\,.\,\text{A}'\text{M})}=\sqrt{\frac{2g}{\text{A}'\text{B}}}\,.\,\text{A}'\text{P}''$.

Hence speed of $\text{P}''=\sqrt{\frac{g}{2\text{AB}}}\,.\,\text{A}'\text{B}$, a constant.

And, as the length of A′P″B is $\frac{1}{2}\pi\,.\,\text{A}'\text{B}$,

time from A′ to B in circle = time from O to B in cycloid

$$=\pi\sqrt{\frac{\text{AB}}{2g}}.$$

Tautochrone.

The time of fall to the vertex from all points of the curve is therefore the same. Hence the cycloid is called a "tautochrone."

Resisted motion of pendulum.

§ 138. As an instance of cases in which the acceleration depends upon the speed and the position jointly, take the motion of a simple pendulum in a medium whose resistance varies as the velocity directly. This is the law, at least approximately, for very small speeds, whether the pendulum oscillate in a gas or in a liquid,—and even when the resistance is due to magneto-electric induction, as when the pendulum is a magnetic needle vibrating in presence of a conducting plate or a closed coil. A synthetical solution of this problem has already been given under Kinematics in § 68.

Analytically: if l be the length of the string, θ its deflexion from the vertical at time t, m the mass of the bob, we have evidently

$$ml\ddot{\theta}=-mg\sin\theta-\kappa\dot{\theta}.$$

The ratio κ/ml may be increased (theoretically) without limit by increasing the surface which the bob exposes, without changing its mass. But it cannot be indefinitely diminished. We will write $2k$ for it. If we assume the angle of oscillation to be small, we may write the equation in the form

$$\ddot{\theta}+2k\dot{\theta}+n^2\theta=0,$$

where $n^2=g/l$, and k is essentially positive, being greater as the resistance (whether on account of the viscosity of the medium or the large surface of the bob in proportion to its mass) is greater. A particular integral of this equation is evidently

$$\theta=\varepsilon^{pt};$$

provided

$$p^2+2kp+n^2=0,$$

or

$$p=-k\pm\sqrt{k^2-n^2}.$$

Hence there are two quite distinct cases of motion, distinguished by different *forms* of solution, depending on the relative magnitudes of k and n. These are separated from one another by the unique case in which $k=n$.

(*a*) Let $k>n$, and let $k^2-n^2=n'^2<k^2$.

Then both values of p are real and negative. Thus

$$\theta=\text{A}\varepsilon^{p_1t}+\text{B}\varepsilon^{p_2t}$$

$$=\varepsilon^{-kt}(\text{A}\varepsilon^{n't}+\text{B}\varepsilon^{-n't}).$$

If A and B have the same sign, θ diminishes, without changing sign, as t increases. But if A and B have different signs, the factor in brackets may vanish for one definite value of t, and then change sign. After that the whole reaches a maximum and then diminishes without further change of sign. Examples of these cases are furnished—(1) when the pendulum is displaced from the vertical and allowed to fall back; it then approximates asymptotically to its position of equilibrium; and (2) when it is drawn aside and flung back; in this case it may pass once through the position of equilibrium and then asymptotically return to it.

(*b*) Let $n>k$ and let $n^2-k^2=n'^2<n^2$.

Here both values of p are imaginary, and we have

$$\theta=\varepsilon^{-kt}(\text{A}\varepsilon^{+n't\sqrt{-1}}+\text{B}\varepsilon^{-n't\sqrt{-1}})$$

$$=\text{P}\varepsilon^{-kt}\cos(n't+\text{Q}).$$

This may be looked upon as a "simple harmonic motion" (§ 52), of which the amplitude diminishes in a geometric ratio with the time, the decrement depending on the resistance alone, while the period is permanently lengthened in the ratio $n : n'$. This ratio depends both upon the original period and the resistance, so that for the same medium and same bob it is different for strings of different lengths. This investigation gives an approximation to the gradual dying away (by internal friction or by imperfect elasticity, &c.) of all vibratory movements. The rate of diminution of amplitude, say of torsional vibrations of a wire, is thus a valuable indication and measure of a somewhat recondite physical quantity, which, without this method, would (at present at least) be hard to measure.

(*c*) When $n=k$, *i.e.*, in the transition case, the equation becomes

$$\ddot{\theta}+2n\dot{\theta}+n^2\theta=0;$$

whose integral is known to be

$$\theta=\varepsilon^{-nt}(\text{A}+\text{B}t)=\varepsilon^{-kt}(\text{A}+\text{B}t).$$

This, also, ultimately diminishes indefinitely as t increases; but, as in case (*a*), it may either do so continuously or after having once passed through the value zero and reached a maximum, according to the relative magnitude and the signs of A and B.

§ 139. When the path is given, the determination of the motion under given forces is, as we have seen, a mere question of integration of the equation for acceleration along the tangent. But more is required if we wish to find the normal pressure on the constraining curve. This is at once supplied by compounding the resolved part of the applied forces in the direction perpendicular to the tangent, with the additional force $m\text{V}^2/\rho$ acting *from* the centre of curvature. But, strictly speaking, all such questions require the application of Law III.

Kinetics of a Particle with Two Degrees of Freedom.

§ 140. The simplest case is that of a projectile, when gravity is supposed to be uniform and to act in parallel lines throughout the whole path, and the resistance of the air is neglected. This has been sufficiently discussed in §§ 40–42. It is merely the combination of (1) the uniformly accelerated motion of a stone let fall, with (2) a uniform velocity in a definite direction. Looked at from this point of view, it gives an interesting example of the graphic method applied in § 53 to indicate the nature of simple harmonic motion.

Projectile [...] resist[...]

§ 141. We can extend these projectile results so as to take account of the alteration of direction and of intensity

Elliptic motion of projectile.

of gravity at different points of the path, by remembering that, as shown in § 49, the path of an unresisted projectile is an ellipse, one of whose foci is at the centre of the earth. The following, among many other analogous propositions, are easily proved.

(1) The locus of the second foci of the paths of all projectiles leaving a given point with a given speed, in a vertical plane, is a circle.

(2) The direction of projection, for the greatest range on a given line passing through the point of projection, bisects the angle between the vertical and the line.

(3) Any other point on the line which can be reached at all can be reached by two different paths, and the directions of projection for these are equally inclined to the direction which gives the maximum range.

(4) If a projectile meet the line at right angles, the point which it strikes is the vertex of the other path by which it may be reached.

(5) The envelop of all possible paths in a vertical plane is an ellipse, one of whose foci is the centre of the earth, and the other the point of projection.

To prove these propositions, let E (fig. 46) be the earth's centre, P the point of projection, A the point which the projectile would reach if fired vertically upwards. With centre E, and radius EA, describe a circle in the common plane of projection. This, the circle of zero velocity, corresponds to the common directrix of the parabolic paths in the ordinary theory If F be the second focus of any path, we must have EP + PF constant, because the axis major depends on the speed, not the direction, of projection. Hence (1) the locus of F is the circle AFO, centre P. Again, since, if F be the focus of the path which meets PR in Q, we must have FQ = QS, it is obvious that the greatest range Pq is to be found by the condition Oq = qs. O is therefore the second focus of this trajectory, and therefore (2) the direction of projection for the greatest range on PR bisects the angle APR. If QF = QF′ = QS, F and F′ are the second foci of the two paths by which Q may be reached; and, as ∠ F′PO = ∠ FPO, we see the truth of (3). If Q be a point reached by the projectile when moving in a direction perpendicular to PR, we must evidently have ∠ PQF′ = ∠ PQF = ∠ SQR = ∠ EQP; *i.e.*, EQ passes through F′. When this is the case, the ellipse whose second focus is F evidently meets PR at right angles; and that whose second focus is F′ has (4) its vertex at Q. The locus of q is evidently the envelop of all the trajectories. Now

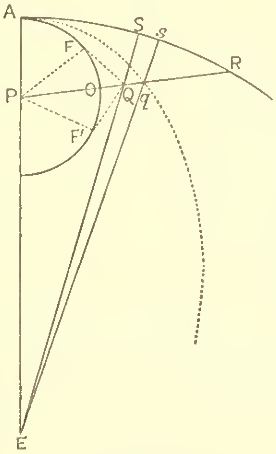

Fig. 46.

$$Pq = PO + Oq = PA + Oq ,$$
$$Eq = Es - sq = EA - Oq .$$

Hence

$$Pq + Eq = PA + AE ,$$

or (5) the envelop is an ellipse, whose foci are E and P, and which passes through A.

Planetary motion.

§ 142. One of the most important problems in this branch of our subject is that of planetary motion, which forms a good typical example of the processes to be employed in the treatment of central orbits. One or two definitions, and a general property of central orbits, must be premised.

Apse.

§ 143. *Def.* An "apse" is a point, in a central orbit, at which the path is perpendicular to the radius-vector along which the central force acts.

The length of the radius-vector is therefore, at such a point, generally a maximum or a minimum. This radius vector, drawn to an apse, is called an "apsidal line."

A central orbit is symmetrical about every apsidal line. The simplest proof of this theorem depends upon the general principle of "reversibility," which holds in all conservative systems. In fact if, at any instant, the velocity-vector of a particle, moving under the action of a conservative system of forces, be reversed, the particle will simply retrace its previous path. For if we suppose a smooth tube, in the form of the previous path, to be employed to guide it back, the speed at every point will be of the same magnitude as before. The curvature also of the path will be the same; and thus the normal component of the applied forces will balance the so-called centrifugal force,—*i.e.*, will suffice to produce the requisite curvature,—so that there will be no pressure on the tube, and it is not required. Hence since, at an apse, the velocity is perpendicular to the radius-vector, the two halves of the orbit on opposite sides of the apsidal line are similar and equal. Hence, however many apses there may be, there can be at most only two apsidal distances. For the property of symmetry about each apsidal line shows that, if there be more apses than one, the first, third, fifth, &c., must have their apsidal distances equal, as also must the second, fourth, sixth, &c. If there be one apse only, it may correspond either to a minimum or to a maximum value of the radius-vector; but, if there be more than one, they must be maxima and minima alternately.

§ 144. We now proceed to the gravitation case already promised. We will take, first, the direct problem as in § 49, where the force is assigned and the orbit is to be found.

A particle is projected from a given point in a given direction and with a given speed, and moves under the action of a central attraction varying inversely as the square of the distance; to determine the orbit. Planetary motion.

We have $P = \mu u^2$, and therefore by the last part of § 47

$$\frac{d^2u}{d\theta^2} + u - \frac{\mu}{h^2} = 0 ,$$

where h is double the constant area, or

$$\frac{d^2}{d\theta^2}\left(u - \frac{\mu}{h^2}\right) + \left(u - \frac{\mu}{h^2}\right) = 0 ,$$

the integral of which is

$$u - \frac{\mu}{h^2} = A\cos(\theta + B),$$

or, as it is usually written,

$$u = \frac{\mu}{h^2}\left\{ 1 + e\cos(\theta - \alpha)\right\} \quad . \quad . \quad . \quad . \quad . \quad (1).$$

This gives by differentiation

$$\frac{du}{d\theta} = -\frac{\mu}{h^2} e \sin(\theta - \alpha) \quad . \quad . \quad . \quad . \quad . \quad (2).$$

Let R be the distance of the point of projection from the centre, and β the angle, and V the speed, of projection; then, when $\theta = 0$,

$$u = \frac{1}{R} , \quad \cot\beta = -\left(\frac{1}{u}\frac{du}{d\theta}\right)_{\theta=0} .$$

Hence, by (1) $$\frac{h^2}{\mu R} - 1 = e\cos\alpha ,$$

and by (2) $$\frac{h^2}{\mu R}\cot\beta = -e\sin\alpha .$$

From these $$\tan\alpha = \frac{h^2\cot\beta}{\mu R - h^2} \quad . \quad . \quad . \quad . \quad . \quad . \quad (3),$$

and $$e^2 = \frac{h^4}{\mu^2 R^2}\operatorname{cosec}^2\beta - \frac{2h^2}{\mu R} + 1 \quad . \quad . \quad . \quad . \quad (4),$$

But $$h^2 = V^2 R^2 \sin^2\beta ,$$

wherefore $$\tan\alpha = \frac{V^2 R \sin\beta\cos\beta}{\mu - V^2 R\sin^2\beta} \quad . \quad . \quad . \quad . \quad (3'),$$

and $$1 - e^2 = \frac{V^2R^2\sin^2\beta}{\mu}\left(\frac{2}{R} - \frac{V^2}{\mu}\right) \quad . \quad . \quad . \quad (4').$$

Now (1) is the general polar equation of a conic section, focus the pole; and, as its nature depends on the value of the excentricity e given by (4′), we see that

if $V^2 > 2\mu/R$, $e > 1$, and the orbit is an hyperbola;
if $V^2 = 2\mu/R$, $e = 1$, and the orbit is a parabola;
if $V^2 < 2\mu/R$, $e < 1$, and the orbit is an ellipse.

But the square of the speed from rest at infinity to distance R, for the law of attraction we are considering, is $2\mu/R$, and the above conditions may therefore be expressed more concisely by saying that the orbit will be an hyperbola, a parabola, or an ellipse, according as the speed of projection is greater than, equal to, or less than, the speed from infinity. Illustrations of this proposition are found in the cases of comets and of meteor swarms.

The speed of a particle moving in a circle is also often taken as the standard of comparison for estimating the velocities of bodies in their orbits. For the gravitation law of attraction the square of the speed in a circle of radius R is μ/R; and the above conditions may be expressed in another form by saying that the orbit will be an hyperbola, a parabola, or an ellipse, according as the speed of projection is greater than, equal to, or less than $\sqrt{2}$ times the speed in a circle at the same distance.

Supposing the orbit to be an ellipse, we shall obtain its major axis and latus rectum most easily by a different process of integrating the differential equation. Multiplying it by $h^2\frac{du}{d\theta}$ and integrating, we obtain

$$\frac{1}{2}h^2\left\{\left(\frac{du}{d\theta}\right)^2 + u^2\right\} = \frac{1}{2}v^2 = C + \mu u.$$

But when $u = \frac{1}{R}$, $v = V$; which gives

$$C = \frac{1}{2}V^2 - \frac{\mu}{R};$$

hence $$\frac{1}{2}h^2\left\{\left(\frac{du}{d\theta}\right)^2 + u^2\right\} = \frac{1}{2}v^2 = \frac{1}{2}V^2 - \frac{\mu}{R} + \mu u \quad . \quad . \quad (5).$$

Now to determine the apsidal distances, we must put

$$\frac{du}{d\theta} = 0;$$

and this gives us the condition

$$u^2 - \frac{2\mu}{h^2}u + \frac{2\mu}{h^2 R} - \frac{V^2}{h^2} = 0 \quad . \quad . \quad . \quad . \quad . \quad (6),$$

which is a quadratic equation whose roots are the reciprocals of the two apsidal distances. But if a be the semi-axis major, and e the excentricity, these distances are

$$a(1-e) \text{ and } a(1+e).$$

Hence, as the coefficient of the second term of (6) is the sum of the roots with their signs changed, we have

$$\frac{1}{a(1-e)} + \frac{1}{a(1+e)} = \frac{2\mu}{h^2};$$

or $$a(1-e^2) = \frac{h^2}{\mu} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (7).$$

And the third term is the product of the roots, so that

$$\frac{1}{a^2(1-e^2)} = \frac{2\mu}{h^2 R} - \frac{V^2}{h^2};$$

or, by (7), $$\frac{1}{a} = \frac{2}{R} - \frac{V^2}{\mu} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (8).$$

Thus $$\frac{1}{2}V^2 = \frac{\mu}{R} - \frac{\mu}{2a},$$

and therefore $$\frac{1}{2}v^2 = \frac{\mu}{r} - \frac{\mu}{2a} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (9).$$

Equations (7) and (8) give the latus rectum and major axis of the orbit, and show that the major axis is independent of the direction of projection.

Equation (9) gives a useful expression for the speed at any point, and shows that the radius of the circle of zero speed is $2a$.

The time of describing any given angle is to be obtained from the formula,

$$r^2\frac{d\theta}{dt} = h = \sqrt{\{\mu a(1-e^2)\}}, \text{ by equation (7).}$$

From this, combined with the polar equation of the ellipse about the focus, we have

$$\frac{dt}{d\theta} = \frac{r^2}{\sqrt{\{\mu a(1-e^2)\}}} = \sqrt{\left(\frac{a^3(1-e^2)^3}{\mu}\right)}\frac{1}{(1+e\cos\theta)^2},$$

measuring the angle from the nearer apse.

Integrating, we find the time of describing about the focus an angle θ measured from the nearer apse, in the ellipse or hyperbola, expressed as $2/h$ of the sectorial area ASP (figure to § 147), which might have been written down from the condition of uniform moment of momentum.

In the parabola, if d be the apsidal distance, the integral becomes

$$\left[\text{since } e = 1,\ a(1-e) = d,\ a(1-e^2) = 2d\right],$$

$$t = \sqrt{\frac{2d^3}{\mu}}\left(\tan\frac{\theta}{2} + \frac{1}{3}\tan^3\frac{\theta}{2}\right).$$

From the result for the ellipse we see that the periodic time is

$$2\pi\sqrt{a^3/\mu}.$$

In the notation commonly employed for the further development of this most important question we write

$$T = 2\pi/n,$$

where n, which is called the "mean motion," is $\sqrt{\mu/a^3}$.

§ 145. By laborious calculation from an immense series of observations of the planets, and of Mars in particular, Kepler was led to enunciate the following as the kinematical laws of the planetary motions about the sun. *Kepler's laws (kinematical).*

I. The planets describe, relatively to the sun, ellipses of which the sun occupies a focus.

II. The radius vector of each planet traces out equal areas in equal times.

III. The squares of the periodic times of any two planets are as the cubes of the major axes of their orbits.

§ 146. We proceed to the *inverse* problem of § 8 (*b*), the determination of the force from the observed motions. *Consequences of Kepler's laws.*

From the second of the above laws we conclude that the planets are retained in their orbits by an attraction tending to the sun. *If the radius-vector of a particle moving in a plane describe equal areas in equal times about a point in that plane, the resultant attraction on the particle tends to that point.* For the datum is equivalent to the statement that there is no change of moment of momentum about the sun, or that the accelerations all pass through the sun viewed as a point.

From the first law it follows that the law of the intensity of the attraction is that of the inverse square of the distance.

The polar equation of an ellipse referred to its focus is

$$u = \frac{2}{l}(1 + e\cos\theta),$$

where l is the latus rectum.

Hence $$\frac{d^2u}{d\theta^2} = -\frac{2e}{l}\cos\theta,$$

and therefore the attraction to the focus requisite for the description of the ellipse is (§ 47)

$$P = h^2u^2\left(\frac{d^2u}{d\theta^2} + u\right) = \frac{2h^2}{l}u^2.$$

Hence, if the orbit be an ellipse described about a centre of attraction at the focus, the law of intensity is that of the inverse square of the distance.

From the third law it follows that the attraction of the sun (supposed fixed) which acts on unit of mass of each of the planets is the same for each planet at the same distance.

For, in the last formula in § 144, T^2 will not vary as a^3 unless μ be constant, *i.e.*, unless the strength of attraction of the sun be the same for all the planets.

We shall find afterwards that for more reasons than one Kepler's laws are only approximate, but their enunciation was sufficient to enable Newton to propound the doctrine of universal gravitation, viz., that *every particle of matter in the universe attracts every other with an attraction whose direction is that of the line joining them, and whose magnitude is as the product of the masses directly and as the square of the distance inversely*; or, according to Maxwell's formulation, *between every pair of particles there is a stress of the nature of a tension, proportional to the product of the masses of the particles divided by the square of their distance.* *Law of gravitation (physical).*

If we take into account that the sun is not absolutely fixed, then, neglecting the mutual attractions of the planets, Kepler's third law should be stated thus:—

The cubes of the major axes of the orbits are as the squares of the periodic times and the sums of the masses of the sun and the planet.

Calculation of planet's motion.

§ 147. We will now indicate, as briefly as possible, the more ordinary transformations by which the preceding formulæ are adapted (for astronomical applications) to numerical calculation.

Suppose APA′ (fig. 47) to be an elliptic orbit described about a centre of attraction in the focus S. Also suppose P to be the position of the particle at any time t. Draw PM perpendicular to the major axis ACA′, and produce it to cut the auxiliary circle in the point Q. Let C be the common centre of the curves. Join CQ.

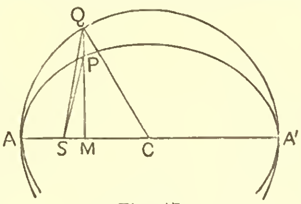

Fig. 47.

When the moving particle is at A, the nearest point of the orbit to S, it is said to be in "perihelion."

The angle ASP, or the excess of the particle's longitude over that of the perihelion, is called the "true anomaly." Let us denote it by θ.

The angle ACQ is called the "excentric anomaly," and is generally denoted by u. And, if $2\pi/n$ be the time of a complete revolution, nt is the circular measure of an imaginary angle called the "mean anomaly;" it would evidently be the true anomaly if the particle's angular velocity about S were constant.

It is easy from known properties of the ellipse to deduce the following relations between the mean and excentric, and also between the true and excentric, anomalies:—

$$nt = u - e\sin u.$$

$$\tan\frac{u}{2} = \sqrt{\left(\frac{1-e}{1+e}\right)}\tan\frac{\theta}{2}.$$

By far the most important problem is to find the values of θ and r as functions of t, so that the direction and length of a planet's radius-vector may be determined for any given time. This generally goes by the name of Kepler's Problem.

Before indicating the systematic development of u, r, and θ in terms of t from our equations, it may be useful to remark that, if e be so small that higher terms than its square may be neglected, we may easily obtain developments correct to the first three terms. Thus

$$\begin{aligned} u &= nt + e\sin u, \\ &= nt + e\sin(nt + e\sin nt) \text{ nearly}, \\ &= nt + e\sin nt + \tfrac{1}{2}e^2\sin 2nt. \end{aligned}$$

Also
$$\begin{aligned} \frac{r}{a} &= 1 - e\cos u, \\ &= 1 - e\cos(nt + e\sin nt), \\ &= 1 - e\cos nt + \tfrac{1}{2}e^2(1 - \cos 2nt). \end{aligned}$$

And
$$r^2\frac{d\theta}{dt} = \sqrt{\left\{\mu a(1-e^2)\right\}},$$

which may be written
$$\frac{a^2(1-e^2)^2}{(1+e\cos\theta)^2}\frac{d\theta}{dt} = na^2(1-e^2)^{\frac{1}{2}},$$

or
$$(1-e^2)^{\frac{3}{2}}(1+e\cos\theta)^{-2}\frac{d\theta}{dt} = n.$$

Keeping powers of e lower than the third,
$$\left(1 - 2e\cos\theta + \tfrac{3}{2}e^2\cos 2\theta\right)\frac{d\theta}{dt} = n,$$

or
$$nt = \theta - 2e\sin\theta + \tfrac{3}{4}e^2\sin 2\theta;$$

whence
$$\begin{aligned} \theta &= nt + 2e\sin\theta - \tfrac{3}{4}e^2\sin 2\theta, \\ &= nt + 2e\sin(nt + 2e\sin nt) - \tfrac{3}{4}e^2\sin 2nt, \\ &= nt + 2e\sin nt + 4e^2\cos nt\sin nt - \tfrac{3}{4}e^2\sin 2nt, \\ &= nt + 2e\sin nt + \tfrac{5}{4}e^2\sin 2nt. \end{aligned}$$

Kepler's problem.

KEPLER'S PROBLEM.—*To find r and θ as functions of t from the equations*

$$r = a(1 - e\cos u) \quad . \quad . \quad . \quad . \quad . \quad . \quad (1);$$

$$\tan\frac{\theta}{2} = \sqrt{\frac{1+e}{1-e}}\tan\frac{u}{2} \quad . \quad . \quad . \quad . \quad . \quad (2),$$

$$nt = u - e\sin u \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3).$$

These equations evidently give r, θ, and t directly for any assigned value of u, but this is of little value in practice. The method of solution which is commonly adopted is that of Lagrange, and the general principle of it is this:—

We can develop θ from equation (2) in a series ascending by powers of a small quantity, a function of e, the coefficients of these powers involving u and the sines of multiples of u. Now by Lagrange's theorem we may from equation (3) express u, $1 - e\cos u$, $\sin u$, $\sin 2u$, &c., in series ascending by powers of e, whose coefficients are sines or cosines of multiples of nt. Hence, by substituting these values in equation (1) and in the development of (2), we have r and θ expressed in series whose terms rapidly decrease, and whose coefficients are sines or cosines of multiples of nt. This is the complete practical solution of the problem. But we must refer the reader to special treatises for the full development of this subject. Compare § 52.

Stability of circular orbit.

§ 148. We may take an opportunity here of giving a sketch of a particular case of the important question of "kinetic stability." The general treatment of this subject is entirely beyond our limits. But we may investigate its conditions, in the case of a central orbit naturally circular, by a very slight modification of our equations.

Whatever be the law of central force, provided it depend on the distance alone, we can write the acceleration due to it as

$$\mu u^2 f(u),$$

where u is the now reciprocal of the radius-vector, as in § 144. The kinematics of the motion is then entirely summed up in the equations

$$\frac{d^2u}{d\theta^2} + u = \frac{\mu}{h^2}f(u), \text{ and } \frac{d\theta}{dt} = hu^2.$$

If $1/a$ be the radius of the circle, the first equation becomes simply

$$a = \frac{\mu}{h^2}f(a).$$

Now let a slight disturbance be given to the motion, such that h is unaltered, but that u becomes $a + x$. Then we have

$$\frac{d^2x}{d\theta^2} + a + x = \frac{\mu}{h^2}f(a+x).$$

Expanding to first powers of x only, and thereby assuming that x is always exceedingly small, we have

$$\frac{d^2x}{d\theta^2} + x\left(1 - \frac{\mu}{h^2}f'(a)\right) = 0,$$

the terms independent of x vanishing by the condition for a circular orbit. By eliminating the ratio μ/h^2 we have

$$\frac{d^2x}{d\theta^2} + x\left(1 - \frac{af'(a)}{f(a)}\right) = 0.$$

To secure stability, x must not be capable of increasing indefinitely. This leads to the result that the multiplier of x in the above equation must be positive; *i.e.*,

$$1 - \frac{af'(a)}{f(a)} > 0.$$

For, if the multiplier were negative, the value of x would consist of two real exponential terms, one of which would increase indefinitely with the angle θ, and would disappear from the value of x under special conditions only.

If the multiplier were zero, x would be a linear function of θ. Hence, in the only case we need consider, we have

$$x = A\cos\left(\theta\sqrt{1 - \frac{af'(a)}{f(a)}} + B\right).$$

The radius-vector is therefore a maximum and minimum (*i.e.*, apses occur) alternately as the angle θ increases by successive increments each equal to

$$\frac{\pi}{\sqrt{1 - \frac{af'(a)}{f(a)}}}.$$

Suppose the force to vary as the inverse nth power of the distance. Here $f(a) \propto a^{n-2}$, and we have $1 - \frac{af'(a)}{f(a)} = 1 - (n-2) = 3 - n$. Thus n must be less than 3; *i.e.*, a circular orbit, with the centre of force in the centre, is essentially unstable if the force vary as the inverse third, or any higher inverse power of the distance.

If $n = 2$, which is the gravitation case, the apsidal angle is evidently π.

Newton's revolving orbit.

§ 149. A very curious result, due to Newton, may be indicated here, viz., that, if any central orbit be made to revolve in its own plane with angular velocity proportional at each instant to that of the radius-vector in the fixed orbit, it will still be a central orbit; and the additional force required will be inversely as the cube of the radius-vector.

Generally, in a central orbit,

$$\ddot{r} - r\dot{\theta}^2 = P, \qquad r^2\dot{\theta} = h.$$

But suppose θ to become $c\theta_1$, where c is a constant, and we have

$$\theta = c\theta_1,$$

which is Newton's hypothesis. The above equations become

$$\ddot{r} - r\dot{\theta}_1^2 = P + (c^2-1)r\dot{\theta}_1^2, \quad r^2c\dot{\theta}_1 = h;$$

or, as they may be written,

$$\ddot{r} - r\dot{\theta}_1^2 = P + (c^2-1)h_1^2/r^3, \quad r^2\dot{\theta}_1 = h_1.$$

From these the proposition is obvious.

Other examples of central orbits will be given when we discuss general principles, such as "least action" and "varying action."

Special Problem. The Brachistochrone.

Brachistochrone. § 150. A celebrated problem in the history of dynamics is that of the "curve of swiftest descent," as it was called:—*Two points being given, which are neither in a vertical nor in a horizontal line, to find the curve joining them down which a particle sliding under gravity, and starting from rest at the higher, will reach the other in the least possible time.*

The curve must evidently lie in the vertical plane passing through the points. For suppose it not to lie in that plane, project it orthogonally on the plane, and call corresponding elements of the curve and its projection σ and σ'. Then if a particle slide down the projected curve its speed at σ' will be the same as the speed in the other at σ. But σ is *never less* than σ', and is generally greater. Hence the time through σ' is generally less than that through σ, and *never greater.* That is, the whole time of falling through the projected curve is less than that through the curve itself. Or the required curve lies in the vertical plane through the points.

Also it is easy to see that, if the time of descent through the entire curve is a minimum, that through any portion of the curve is less than if that portion were changed into any other curve.

Conditions for a maximum. And it is obvious that, *between any two contiguous equal values of a continuously varying quantity, a maximum or minimum must lie.* [This principle, though excessively simple (witness its application to the barometer or thermometer), is of very great power, and often enables us to solve problems of maxima and minima, such as require, in analysis, not merely the processes of the differential calculus but those of the calculus of variations. The present is a good example.]

Let, then, PQ, QR and PQ′, Q′R (fig. 48) be two pairs of indefinitely small sides of polygons such that the time of descending through either pair, starting from P with a given speed, may be equal. Let QQ′ be horizontal, and indefinitely small compared with PQ and QR. The brachistochrone must lie between these paths, and must possess any property which they possess in common. Hence if v be the speed down PQ (supposed uniform) and v' that down QR, drawing Qm, $Q'n$ perpendicular to RQ′, PQ, we must have

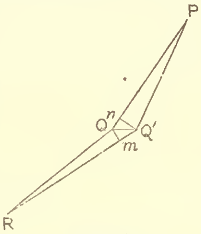

Fig. 48.

$$\frac{Qn}{v} = \frac{Q'm}{v'}.$$

Now if θ be the inclination of PQ to the horizon, θ' that of QR, $Qn = QQ'\cos\theta$, $Q'm = QQ'\cos\theta'$. Hence the above equation becomes

$$\frac{\cos\theta}{v} = \frac{\cos\theta'}{v'}.$$

This is true for any two consecutive elements of the required curve; and therefore throughout the curve

$$v \propto \cos\theta.$$

But $v^2 \propto$ vertical distance fallen through (§ 28). Hence the curve required is such that the cosine of the angle it makes with the horizontal line through the point of departure varies as the square root of the distance from that line,—which is easily seen to be a property of the cycloid, if we remember that the tangent to that curve is parallel to the corresponding chord of its generating circle. For in fig. 45, § 137,

$$\cos BP'M = \cos BAP' = \frac{AP'}{AB} = \sqrt{\frac{AM}{AB}} \propto \sqrt{AM}.$$

The brachistochrone then, under gravity, is an inverted cycloid whose cusp is at the point from which the particle descends.

§ 151. Whatever be the impressed forces, reasoning similar to that in last section would show that the osculating plane of the brachistochrone always contains the resultant force, and that

$$v'\cos\theta = v\cos\theta',$$

where θ is now the complement of the angle between the curve and the resultant of the impressed forces.

Let that resultant $= F$, and let the element $PQ = \delta s$, and $\theta' = \theta + \delta\theta$. Then

$$v'^2 - v^2 = 2F\delta s\sin\theta,$$

or

$$v\delta v = F\delta s\sin\theta.$$

But $v \propto \cos\theta$; which gives

$$\frac{\delta v}{v} = -\frac{\sin\theta}{\cos\theta}\delta\theta.$$

Hence

$$v^2\Big/\frac{\delta s}{\delta\theta} = -F\cos\theta.$$

But in the limit $\frac{\delta s}{\delta\theta} = \rho$, the radius of absolute curvature at Q; and $F\cos\theta$ is the normal component of the impressed force. Hence we obtain the result that, in any brachistochrone, the pressure on the curve is double of that due to the force acting.

§ 152. Now for the unconstrained path from P to R we have $\int v ds$ a minimum (§ 202). Hence in the same way as before, ϕ being the angle corresponding to θ, $v\cos\phi = v'\cos\phi'$ from element to element, and therefore throughout the curve, if the direction of the force be constant. Now, if the velocities in the unconstrained and brachistochrone paths be equal at any equipotential surface, they will be equal at every other. Hence, taking the angles for any equipotential surface,

$$\cos\theta\cos\phi = \text{constant}.$$

As an example, suppose a parabola with its vertex upwards to have for directrix the base of an inverted cycloid; these curves evidently satisfy the above condition, the one being the free path, the other the brachistochrone, for gravity, and the velocities being in each due to the same horizontal line. And it is seen at once that the product of the cosines of the angles which they make with any horizontal straight line which cuts both is a constant whose magnitude depends on those of the cycloid and parabola, its value being $\sqrt{l/4a}$, where l is the latus rectum of the parabola, and a the diameter of the generating circle of the cycloid.

Kinetics of a Particle Generally.

§ 153. Here we must content ourselves with a few special cases, which will be varied as much as possible. General examples.

A unit particle moves on a smooth curve, under the action of any system of forces; find the motion.

All we know directly about the pressure R on the curve is that it is perpendicular to the tangent line at any point.

Resolve then the given forces acting upon the particle into three,—one, T, along the tangent, which in all cases in nature will be a function of x, y, z and therefore of s; another, N, in the line of intersection of the normal and osculating planes (or radius of absolute curvature); and the third, P, perpendicular to the osculating plane.

Let the resolved parts of R in the directions of N and P be R_1, R_2. Now the acceleration of a point moving in any manner is compounded of two accelerations, one $\frac{d^2s}{dt^2}$ or $v\frac{dv}{ds}$ along the tangent to the path, and the other $\frac{v^2}{\rho}$ towards the centre of absolute curvature, the acceleration perpendicular to the osculating plane being zero; and therefore

$$\frac{d^2s}{dt^2} = T \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1).$$

This equation, together with the two equations of the curve, is sufficient to determine the motion completely.

Also $$\frac{v^2}{\rho}=R_1+N \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2),$$

R_1 and N being considered positive when acting towards the centre of absolute curvature; this equation determines R_1.

Now R_2 is the reaction which prevents P's withdrawing the particle from the osculating plane; and therefore

$$R_2=-P \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3).$$

(2) and (3) give the resolved parts of the pressure on the curve.

Also $R=\sqrt{(R_1^2+R_2^2)}$, and its direction makes an angle $=\tan^{-1}(R_2/R_1)$ with the osculating plane.

If the result of the investigation should show that at any time R could vanish, the particle must be treated as free until the equations of its free motion show that it is again in contact with the curve.

Particle on a smooth surface.

A particle moves, under given forces, on a given smooth surface; to determine the motion, and the pressure on the surface.

Let $$F(x, y, z)=0 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1),$$

be the equation of the surface, R the reaction, acting in the normal to the surface, which is the only effect of the constraint. Then, if λ, μ, ν be its direction cosines, we know that

$$\lambda=\frac{\left(\frac{dF}{dx}\right)}{\sqrt{\left\{\left(\frac{dF}{dx}\right)^2+\left(\frac{dF}{dy}\right)^2+\left(\frac{dF}{dz}\right)^2\right\}}} \quad . \quad . \quad . \quad (2),$$

with similar expressions for μ and ν, the differential coefficients being partial.

If X, Y, Z be the applied forces on unit of mass, our equations of motion are, evidently,

$$\left.\begin{aligned}\ddot{x}&=X+R\lambda\\ \ddot{y}&=Y+R\mu\\ \ddot{z}&=Z+R\nu\end{aligned}\right\} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3).$$

Multiplying equations (3) respectively by $\dot{x}$, $\dot{y}$, $\dot{z}$, and adding, we obtain

$$\dot{x}\ddot{x}+\dot{y}\ddot{y}+\dot{z}\ddot{z}=v\dot{v}=X\dot{x}+Y\dot{y}+Z\dot{z} \quad . \quad . \quad . \quad . \quad (4).$$

R disappears from this equation, for its coefficient is

$$\lambda\dot{x}+\mu\dot{y}+\nu\dot{z}$$

and vanishes, because the line whose direction cosines are proportional to $\dot{x}$, &c., being the tangent to the path, is perpendicular to the normal to the surface.

If we suppose X, Y, Z to be a conservative system of forces, the integral of (4) will be of the form

$$\tfrac{1}{2}v^2=\phi(x, y, z)+C \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (5),$$

and the velocity at any point will depend only on the initial circumstances of projection, and not on the form of the path pursued.

To find R, resolve along the normal, then

$$v^2/\rho=X\lambda+Y\mu+Z\nu+R\,,$$

which gives the reaction of the surface; ρ being the radius of curvature of the normal section of the surface through the tangent to the path, and the mass of the particle being taken as unity.

To find the curve which the particle describes on the surface.

For this purpose we must eliminate R from equations (3). By this process we obtain

$$\frac{\ddot{x}-X}{\lambda}=\frac{\ddot{y}-Y}{\mu}=\frac{\ddot{z}-Z}{\nu} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (6),$$

two equations, between which if t be eliminated, the result is the differential equation of a second surface intersecting the first in the curve described.

If there be no applied forces, or if the component of the applied force in the tangent plane coincide with the direction of motion of the particle, then the osculating plane of the path of the particle, which contains the resultant of R and the applied force, will be a normal plane, and therefore the path will be a geodesic on the surface.

Thus a particle under no forces on a smooth (or rough) surface will describe a geodesic.

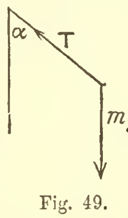

Fig. 49.

Conical pendulum.

§ 154. An excellent and important example is furnished by the simple pendulum, when its vibrations are not confined to one vertical plane. When the bob moves in a horizontal plane, the arrangement is called a "conical" pendulum, and it is a very simple matter, as follows, to find the motion. For the vertical component of the tension of the string must support the weight of the bob; *i.e.*,

$$T\cos\alpha=mg\,,$$

where α is the inclination of the string to the vertical. Also the horizontal component of the tension must supply the force mV^2/R (§ 49) requisite for the production of the curvature of the path, *i.e.*,

$$T\sin\alpha=m\frac{V^2}{l\sin\alpha}\,.$$

Eliminating m/T from these equations, we have

$$\frac{\cos\alpha}{\sin^2\alpha}=\frac{gl}{V^2}\,.$$

But, if τ be the time of revolution of the bob,

$$V\tau=2\pi l\sin\alpha\,.$$

Hence $$\frac{\cos\alpha}{\tau^2}=\frac{gl}{4\pi^2l^2}\,,$$

or $$\tau=2\pi\sqrt{\frac{l\cos\alpha}{g}}\,;$$

i.e., the conical pendulum revolves in the period of the small vibrations of a simple pendulum whose length is the vertical component of that of the conical pendulum (§ 134).

To carry the investigation to cases in which the pendulum describes a tortuous curve, we require (except for approximate results) the use of elliptic functions. We thus obtain, among others, the following results:—

The motion will be comprised between two horizontal circles. Let the depths of these circles below the centre be $b+c$ and $b-c$; then the vertical motion of the bob of the pendulum will be the same as that of a point on a simple pendulum of length l^2/c performing complete revolutions in the same periodic time as the spherical pendulum.

But for one of the most important applications the deflexion from the vertical is always very small, and it is easy to obtain a sufficiently accurate working approximation without the use of elliptic functions. If we put p and q for the semidiameters of the small elliptic orbit which will then be described by the pendulum bob, we find for the apsidal angle

$$\frac{\pi}{2}\left(1+\frac{3pq}{8a^2}+\ .\ .\ .\ \right).$$

Hence, when a pendulum is slightly disturbed in any way, the motion is to a first approximation elliptic as in § 50. But the second approximation shows that this ellipse rotates in its own plane, and in the same sense as that in which it is described, with an angular velocity proportional to its area. Hence the necessity for extreme care, in making Foucault's experiment (presently to be described), lest the path should even slightly deviate from a vertical plane.

Blackburn's pendulum.

§ 155. Another very important and useful example is furnished by Blackburn's pendulum, which is simply a pellet supported by three threads or fine wires knotted together at one point C (fig. 50). The two other ends of two of them are attached to fixed points A and B, and the third supports the pellet P. The motion of P is virtually executed on a smooth surface, whose principal curvatures near the lowest point are 1/CP in the plane of the three threads, and 1/PE in the plane perpendicular to them,—E being the intersection of the vertical through C with the line AB. Hence for small disturbances of this system, P has a simple harmonic motion in the plane of the paper whose period is $2\pi\sqrt{CP/g}$, and another at right angles to it, with period $2\pi\sqrt{PE/g}$. The amplitudes of these motions are arbitrary, and, with the difference of phase, depend entirely on the initial disturbance. Thus we have a very simple mechanical means of producing the combinations treated in § 63; for we have only to make

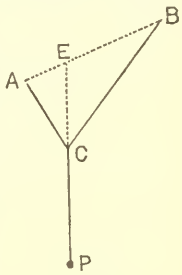

Fig. 50.

$$PE:PC::\omega^2:\omega'^2,$$

and give the bob its proper initial motion.

§ 156. When CE is very small compared with CP, we have a realization of the case of § 61, in which the orbit is (at any instant) an ellipse, but in which the ellipse gradually changes its form and position, so as to be always inscribed in a definite rectangle. This experimental arrangement is exceedingly instructive. To avoid as far as may be the effects of resistance of the air, the vibrations should be slow, *i.e.*, the wires should be as long as possible. The bob should be a ball of lead, containing a tube full of ink which slowly escapes from a fine orifice at its lower end, so as to make a permanent record of the path on a sheet of paper placed below the plane of motion of the bob, but parallel and very close to it. Or, the bob may be furnished with a spike at its lower end, from which induction sparks may be taken so as to pierce a sheet of paper laid on a copper plate below it.

By mere alterations of the point of suspension A, the ratio of ω, ω′ may be varied at pleasure, provided that AC and BC are long enough compared with CP.

Lissajoux's tuning-forks.

§ 157. Lissajoux produced similar curves by attaching plane mirrors to the legs of tuning-forks, and allowing a ray of light, after successive reflexions from two such mirrors, to fall on a screen. But it seems to have been first pointed out much earlier by Sang, and afterwards developed by Wheatstone, that the same result is obtained by fixing firmly one end of a steel rod, and setting the free end in vibration. There are two planes of greatest and least flexural rigidity (§ 274) in all wires, however carefully drawn. These are at right angles to one another; and the motion of the free end of the wire when slightly disturbed is therefore precisely that of the bob of the Blackburn pendulum. Another interesting mode of producing the same result is by causing a ray of sunlight to be reflected in succession from four mirrors, all attached, nearly at right angles, to parallel axes. One pair is made to rotate, the two in opposite directions, with one angular velocity. A ray reflected in succession from these is (§ 65) made to oscillate according to the simple harmonic law, in a plane which can be varied at pleasure by altering the relative position of the normals to the two mirrors. The other pair of mirrors supplies the other simple harmonic motion, also in any desired plane.

Foucault pendulum.

§ 158. We must next consider the effect of the earth's rotation upon the motion of a simple pendulum. Strange to say it was left for Foucault to point out, in February 1851, that the plane of vibration of a simple pendulum suspended at either pole would *appear* to turn through four right angles in twenty-four hours,—the plane, in fact, remaining constant in position while objects beneath the pendulum were carried round by the diurnal rotation. At the equator, it was pretty obvious that no such effect would occur, at least if the original plane of vibration was east and west. By some process, of which he gives no account, Foucault arrived at the result that the plane of oscillation must, in any latitude, appear to make a complete revolution in $24^h \times$ cosec latitude. This curious result has been amply verified by experiment.

The equations of motion of the pendulum, referred to rectangular axes fixed in direction in space and drawn from the earth's centre, the polar axis being that of z, are obviously

$$m\frac{d^2x}{dt^2} = -\mathrm{T}\frac{x-a}{l} + m\mathrm{X},$$

with similar expressions in y and z (a, b, c being the coordinates of the point of suspension, T the tension, l the length of the string, and X, Y, Z the components of gravity).

The equations of motion referred to a new set of axes parallel to the former, but drawn through the point of suspension, are

$$\left.\begin{array}{c} m\dfrac{d^2(x-a)}{dt^2} = -\mathrm{T}\dfrac{x-a}{l} + m\left(\mathrm{X} - \dfrac{d^2a}{dt^2}\right) \\ \text{\&c.} = \text{\&c.} \end{array}\right\} \quad . \quad . \quad . \quad (1).$$

Let us now refer the motion to axes turning with the earth, but drawn from the point of suspension. If the axis of ξ be drawn vertically, and the axes of η, ζ respectively southwards and eastwards; and if ωt be the angle at time t between the planes of xz and $\xi\eta$, λ being the co-latitude of the point of suspension, we have (assuming that ξ intersects z)

$$\cos x\xi = \sin\lambda\cos\omega t,$$
$$\cos y\xi = \sin\lambda\sin\omega t,$$
$$\cos z\xi = \cos\lambda, \text{ \&c.}$$

By means of these expressions we can at once find the values of $x-a$, $y-b$, $z-c$ in terms of ξ, η, ζ, t, as follows:

$$x - a = \xi\sin\lambda\cos\omega t + \eta\cos\lambda\cos\omega t - \zeta\sin\omega t,$$
$$y - b = \xi\sin\lambda\sin\omega t + \eta\cos\lambda\sin\omega t + \zeta\cos\omega t,$$
$$z - c = \xi\cos\lambda \qquad - \eta\sin\lambda.$$

Let γ be the acceleration due to the attraction of gravity alone, and ν the angle (nearly equal to λ) which its direction makes with the polar axis. [We have above in effect assumed that its direction lies in the plane of $z\xi$, as we have assumed that the axis of ξ intersects the polar axis, while we know that the centrifugal force lies in their common plane.] Let r be the distance of the point of suspension from the earth's centre, μ the angle its direction makes with the polar axis. Then

$$a = r\sin\mu\cos\omega t, \quad b = r\sin\mu\sin\omega t, \quad c = r\cos\mu.$$

With these data we transform equations (1) from x, y, z to ξ, η, ζ. The equations immediately obtained are inconveniently long for our columns. But they are easily simplified as follows.

We contemplate small vibrations only; so we may treat ξ as being practically equal to $-l$, and omit its differential coefficients. We also omit powers and products of η, ζ, and all terms in ω^2, except those in which it is multiplied by a large quantity. For it is known that the centrifugal force at the equator is about 1/289th of gravity, or that approximately

$$r\omega^2 = g/289.$$

With these considerations, and the condition that to the degree of approximation desired we have $\mathrm{T} = mg$, we still further simplify our equations. We are led to recognize that $\gamma\cos\nu = g\cos\lambda$; and thus we have finally

$$\left.\begin{array}{l} \dfrac{d^2\eta}{dt^2} - 2\omega\cos\lambda\dfrac{d\zeta}{dt} + \dfrac{g}{l}\eta = 0 \\ \dfrac{d^2\zeta}{dt^2} + 2\omega\cos\lambda\dfrac{d\eta}{dt} + \dfrac{g}{l}\zeta = 0 \end{array}\right\} \quad . \quad . \quad . \quad . \quad . \quad (2).$$

These are the equations of the motion of the bob, referred to a horizontal plane fixed to the earth. The middle terms obviously depend upon the earth's rotation.

To interpret equations (2) it is convenient to employ a second change of coordinates—to refer the motion to axes revolving uniformly in the plane of η, ζ, with angular velocity Ω. If $\mathfrak{y}$, $\mathfrak{z}$ be the coordinates referred to the new axes, we have by analytical geometry

$$\eta = \mathfrak{y}\cos\Omega t - \mathfrak{z}\sin\Omega t, \quad \zeta = \mathfrak{y}\sin\Omega t + \mathfrak{z}\cos\Omega t,$$

the substitution of which in (2) leads to the equations

$$\frac{d^2\mathfrak{y}}{dt^2} + \frac{g\mathfrak{y}}{l} = 0, \qquad \frac{d^2\mathfrak{z}}{dt^2} + \frac{g\mathfrak{z}}{l} = 0 \quad . \quad . \quad . \quad . \quad . \quad (3),$$

provided we take $\qquad \Omega = -\omega\cos\lambda \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4),$

and omit as before terms of the order ω^2.

(4) shows that the new axes rotate, in the *opposite* direction to that of the earth, with the component of the earth's angular velocity about the vertical at the place. And, in the plane so revolving, we see by (3) that the bob of the pendulum describes an approximately elliptic orbit, of which a straight line is a particular case.

A *circular* path being obviously possible, let us assume as particular integrals of (2)

$$\eta = c\cos(pt + a), \quad \zeta = c\sin(pt + a).$$

The substitution of these values gives the same result

$$p^2 + 2\omega p\cos\lambda - g/l = 0$$

in each of equations (2).

Put $g/l = n^2$, then the values of p are, to the degree of approximation above employed, $\pm n - \omega\cos\lambda$, so that the (apparent) angular velocity of a conical pendulum is increased or diminished by $\omega\cos\lambda$ according as its direction of rotation is negative or positive.

§ 159. The preceding problem is a particular case of the following general one. *To find the motion of a particle subjected to the action of given forces and under varying constraint.* It would lead us to details incompatible with our limits to enter upon a full discussion of so wide a question, but we give one or two simple and useful cases to show the commoner forms of procedure.

Varying constraint.

A particle under any forces, and resting on a smooth horizontal plane, is attached by an inextensible string to a point which moves *in a given manner in that plane; to determine the motion of the particle.*

Let x, y, $\bar{x}$, $\bar{y}$ be the coordinates, at time t, of the particle and point, a the length of the string, R the tension of the string, and m the mass of the particle.

For the motion of the particle we have

$$\left.\begin{aligned} m\frac{d^2x}{dt^2} &= mX - R\frac{x-\bar{x}}{a} \\ m\frac{d^2y}{dt^2} &= mY - R\frac{y-\bar{y}}{a} \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1),$$

with the condition $(x-\bar{x})^2+(y-\bar{y})^2=a^2$.

Now $\bar{x}$, $\bar{y}$ are given functions of t. Take from both sides of the equations (1) the quantities $m\dfrac{d^2\bar{x}}{dt^2}$, $m\dfrac{d^2\bar{y}}{dt^2}$, respectively, and we have the equations of *relative* motion

$$\left.\begin{aligned} m\frac{d^2(x-\bar{x})}{dt^2} &= mX - R\frac{x-\bar{x}}{a} - m\frac{d^2\bar{x}}{dt^2} \\ m\frac{d^2(y-\bar{y})}{dt^2} &= mY - R\frac{y-\bar{y}}{a} - m\frac{d^2\bar{y}}{dt^2} \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad (2).$$

These are precisely the equations we should have had if the point had been fixed, and in addition to the forces X, Y, and R acting on the particle, we had applied, reversed in direction, the accelerations of the point's motion with the mass as a factor. It is evident that the same theorem will hold in three dimensions. The accelerations $\dfrac{d^2\bar{x}}{dt^2}$, $\dfrac{d^2\bar{y}}{dt^2}$ are known as functions of t, and therefore the equations of relative motion are completely determined.

Let there be no impressed forces, and suppose first that the point moves with constant velocity in a straight line.

Here $\dfrac{d\bar{x}}{dt}$, $\dfrac{d\bar{y}}{dt}$ are constant, and therefore no terms are introduced in the equations of motion.

Again, *suppose the point's motion to be rectilinear, but uniformly accelerated.*

The relative motion will evidently be that of a simple pendulum from side to side of the point's line of motion. In certain cases, when the angular velocity exceeds a certain limit, we shall have the string occasionally untended; and this will give rise to an impact when it is again tended. While the string is untended the particle moves, of course, in a straight line.

Suppose the point to move, with constant angular velocity ω, in a circle whose radius is r and centre origin.

Here, supposing the point to start from the axis of x,

$$\bar{x}=r\cos\omega t, \quad \bar{y}=r\sin\omega t.$$

Hence the equations of motion are, since

$$\frac{d^2\bar{x}}{dt^2}=-\omega^2\bar{x}, \quad \frac{d^2\bar{y}}{dt^2}=-\omega^2\bar{y},$$

$$\left.\begin{aligned} \frac{d^2(x-\bar{x})}{dt^2} &= -R\frac{x-\bar{x}}{a}+\omega^2\bar{x}, \\ \frac{d^2(y-\bar{y})}{dt^2} &= -R\frac{y-\bar{y}}{a}+\omega^2\bar{y}, \\ (x-\bar{x})^2&+(y-\bar{y})^2=a^2. \end{aligned}\right\}$$

Whence
$$(x-\bar{x})\frac{d^2(y-\bar{y})}{dt^2}-(y-\bar{y})\frac{d^2(x-\bar{x})}{dt^2}$$
$$=\omega^2\left\{(x-\bar{x})\bar{y}-(y-\bar{y})\bar{x}\right\};$$

or, in polar coordinates, for the relative motion,

$$\frac{d}{dt}\left(a^2\frac{d\theta}{dt}\right)=-\omega^2ar\sin(\theta-\omega t),$$

or
$$\frac{d^2(\theta-\omega t)}{dt^2}=-\omega^2\frac{r}{a}\sin(\theta-\omega t).$$

Now $\theta-\omega t$ is the inclination of the string to the radius passing through the point; call it ϕ, and we have

$$\frac{d^2\phi}{dt^2}=-\omega^2\frac{r}{a}\sin\phi,$$

the equation of motion of a simple pendulum whose length is $\dfrac{ga}{r\omega^2}$.

The particle therefore moves, with reference to the uniformly revolving radius of the circle described by the point, just as a simple pendulum with reference to the vertical.

A particle moves in a smooth straight tube which revolves with constant angular velocity round a vertical axis to which it is perpendicular; to determine the motion.

Here, referring the particle to polar coordinates in the plane of motion of the tube, we have $\dot{\theta}=\text{constant}=\omega$, $P=0$ (§ 47), and thus for the acceleration along the tube

$$\ddot{r}-r\omega^2=0;$$

whence
$$r=A\varepsilon^{\omega t}+B\varepsilon^{-\omega t}.$$

Suppose the motion to commence at time $t=0$ by the cutting of a string, length a, attaching the particle to the axis. The velocity of the particle at that instant along the tube is zero. Hence at $t=0$

$$r=a=A+B,$$
$$\dot{r}=0=A-B;$$

so that $A=B=\frac{1}{2}a$, and $r=\frac{1}{2}a(\varepsilon^{\omega t}+\varepsilon^{-\omega t})$.

In fig. 51 let OM be the initial position of the tube and A that of the particle, and let OL and Q be the tube and particle at time t. Then $OA=a$, arc $AP=a\omega t$, $OQ=r$, and we have

$$OQ=\tfrac{1}{2}OA\left(\varepsilon^{\frac{\text{arc AP}}{\text{OA}}}+\varepsilon^{-\frac{\text{arc AP}}{\text{OA}}}\right).$$

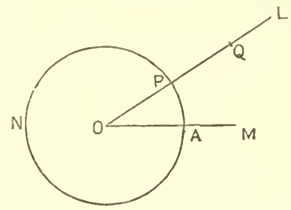

Fig. 51.

From this we see that OQ and the arc AP are corresponding values of the ordinate and abscissa of a catenary whose parameter is OA. Here the vertical pressure on the tube is equal to the weight of the particle, while the horizontal pressure is

$$-\frac{m}{r}\frac{d}{dt}(r^2\dot{\theta})=-2m\omega\dot{r}=-m\omega^2a(\varepsilon^{\omega t}-\varepsilon^{-\omega t}).$$

From this equation, combined with the value of r, we easily deduce for the horizontal pressure the value

$$2m\omega^2\sqrt{(r^2-a^2)},$$

and it is therefore proportional at any instant to the tangent drawn from Q to the circle APN.

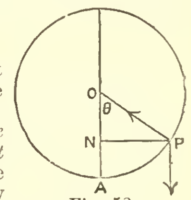

Fig. 52.

Let the tube be in the form of a circle turning with constant angular velocity about a vertical diameter. Let AO (fig. 52) be the axis, P the position of the particle at any time. Let $POA=\theta$ denote the particle's position, and R the pressure on the tube in the direction of OP.

We have
$$a\frac{d^2\cos\theta}{dt^2}=g-R\cos\theta,$$
$$a\frac{d^2\sin\theta}{dt^2}-\omega^2a\sin\theta=-R\sin\theta.$$

Eliminating R,

$$a\frac{d^2\theta}{dt^2}-a\omega^2\sin\theta\cos\theta=-g\sin\theta \quad . \quad . \quad . \quad . \quad (1).$$

The position of equilibrium will therefore be given by

$$\sin\theta=0; \text{ or by } \theta=\gamma, \text{ where } \cos\gamma=\frac{g}{a\omega^2}.$$

Integrating (1),

$$\left(\frac{d\theta}{dt}\right)^2=C+2\omega^2\cos\gamma\cos\theta-\omega^2\cos^2\theta \quad . \quad . \quad . \quad (2).$$

Suppose the particle to pass through the lowest point with velocity $a\omega_1$, we have

$$\left(\frac{d\theta}{dt}\right)^2=\omega_1^2-2\omega^2\cos\gamma(1-\cos\theta)+\omega^2\sin^2\theta$$
$$=\omega^2\left\{(1-\cos\gamma)^2+\frac{\omega_1^2}{\omega^2}-(\cos\theta-\cos\gamma)^2\right\},$$

and $\dfrac{d\theta}{dt}$ can never vanish if $\dfrac{\omega_1^2}{\omega^2}>4\cos\gamma$, or $\omega_1^2>\dfrac{4g}{a}$, that is, if the velocity at the lowest point be greater than that due to the level of the highest point.

If $\omega_1^2<\dfrac{4g}{a}$, the particle will oscillate; and, if $\dfrac{d\theta}{dt}=0$, when $\theta=\alpha$,

then
$$\left(\frac{d\theta}{dt}\right)^2=\frac{2g}{a}(\cos\theta-\cos\alpha)-\omega^2(\cos^2\theta-\cos^2\alpha),$$
$$=\omega^2(\cos\theta-\cos\alpha)\left(\frac{2g}{a\omega^2}-\cos\alpha-\cos\theta\right),$$
$$=\omega^2(\cos\theta-\cos\alpha)(2\cos\gamma-\cos\alpha-\cos\theta);$$

and therefore, if $2\cos\gamma-\cos\alpha>1$, the particle will oscillate through the lowest point.

If $1>2\cos\gamma-\cos\alpha>-1$, then, putting

$$2\cos\gamma-\cos\alpha=\cos\beta,$$
$$\left(\frac{d\theta}{dt}\right)^2=\omega^2(\cos\theta-\cos\alpha)(\cos\beta-\cos\theta),$$

and the particle will oscillate on one side of the vertical diameter.

In each of these three cases the complete solution of the problem can be exhibited in terms of elliptic functions. In the last two cases, when the arcs of oscillation are very small, a sufficient solution may easily be obtained by the usual methods of approximation. This is a particularly instructive example.

§ 160. As a final example of constrained motion of a particle, let us find the form of a curve such that a particle will slide down any arc of it, from the origin, in the same time as down the chord of that arc. If OA, OB (fig. 53) be any two chords, it is plain that the difference of the times down these chords must be equal to the time of describing the arc AB. But, if OA make an angle θ with the vertical, the time of descent along it is

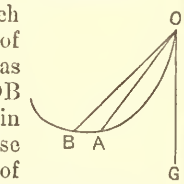

Fig. 53.

$$\sqrt{\frac{2\text{OA}}{g\cos\theta}},$$

And the velocity at A is $\sqrt{2g\text{OA}\cos\theta}$, so that the time of describing AB (considered as infinitesimal) is

$$\text{AB}/\sqrt{2g\text{OA}\cos\theta}.$$

If we put r for OA, our condition gives at once

$$\frac{d}{d\theta}\sqrt{\frac{2r}{g\cos\theta}}=\frac{\frac{ds}{d\theta}}{\sqrt{2gr\cos\theta}},$$

where s is the length of the arc OA. This equation is easily integrated, and the resulting relation is

$$r^2=a^2\sin 2\theta,$$

which belongs to the well-known lemniscate of Bernoulli. From its form we see that the vertical line from which θ is measured is a tangent at O; so that the motion in arc commences vertically.

Disturbed motion. § 161. To complete this elementary sketch of the dynamics of a single particle we take an instance or two of "disturbed motion." The essence of this question is usually that the disturbing forces are, at any instant, small in comparison with the forces producing the motion; so that, during any brief period, the motion is practically the same as if no disturbing cause had been at work. But, in time, the effects of the disturbance may become so great as entirely to change the dimensions and form of the orbit described. The mathematical method which has been devised to meet this question depends upon what has just been said. The *character* of the path is not, at any particular instant, affected by the disturbance; but its form and dimensions are. Hence, as the first depends upon the *form* of the equations which represent it, while the latter depend upon the actual and relative magnitudes of the constants involved, we settle, once for all, the *form* of the equation as if no disturbing cause had acted. But we are thus entitled to assume that the constants which it involves are quantities which vary with the time in consequence of the slight, but persistent, effects of the disturbance. And, as we know that, if at any moment the disturbance were to cease, the motion would forthwith go on for ever in the orbit *then being described*, we may assume that in the expressions for the components of the velocity no terms occur depending on the rate of alteration of the values of the constants. This, as will be seen below, very much simplifies the mathematical treatment of such questions.

Pendulum. *Suppose a cycloidal pendulum, or a simple pendulum vibrating through very small arcs, to be subjected to a simple harmonic disturbance in the direction of its motion.* The equation of motion will obviously be of the form

$$\ddot{\theta}+n^2\theta=\text{A}\cos mt,$$

where $n^2=l/g$, as in § 134.

The integral of this equation is

$$\theta=\text{P}\cos(nt+\text{Q})-\frac{\text{A}}{m^2-n^2}\cos mt.$$

We see then that the result is the superposition of a new simple harmonic motion on the natural simple harmonic motion of the undisturbed bob, and that it is altogether independent of the amplitude and phase of the undisturbed motion. So long as the disturbance is very small, this new part of the motion may be neglected, unless m is very nearly equal to n. For in that case the amplitude of the disturbance may become much greater than that of the original motion. When m is equal to n, the integral changes its form, and we have

$$\theta=\text{P}\cos(nt+\text{Q})+\text{A}\frac{t}{2n}\sin nt.$$

Harm[onic] motion with [dis]turba[nce] of san[me] period. This shows that, in the special case of a disturbance of the same period as the undisturbed motion, the nature of the motion is entirely changed. Thus, suppose the pendulum to be at rest at its lowest point when the disturbance is applied; then we have merely

$$\theta=\text{A}\frac{t}{2n}\sin nt,$$

a simple harmonic motion whose amplitude increases in proportion to the time elapsed since the disturbance commenced.

Point [of] suspen[sion] di[s]turbed. § 162. As another illustration, *suppose the point of suspension of a simple pendulum to have a simple harmonic motion of small amplitude in a horizontal line.*

Here the equations of motion are (to horizontal and vertical axes)

$$m\ddot{x}=-\text{T}\frac{x-\xi}{l},$$

$$m\ddot{y}=mg-\text{T}\frac{y}{l}.$$

But if we suppose the oscillations to be small, we may write $x-\xi=l\theta$, $y=l$, where l is the length of the pendulum, and θ the angle it makes with the vertical. Then we have

$$\ddot{x}=l\ddot{\theta}+\ddot{\xi}=l\ddot{\theta}+\text{A}\cos mt,\text{ suppose, and }\ddot{y}=0.$$

Hence $mg=\text{T}$,

and $l\ddot{\theta}+\text{A}\cos mt=-g\theta$,

which is precisely the equation of the preceding investigation.

Motion of a sli[ng]. We see from this how to explain the somewhat puzzling phenomenon which we observe when we produce complete rotations of a stone in a sling by a comparatively trifling motion of the hand. All that is necessary is that the hand should have a slight to and fro horizontal motion, in a period nearly equal to that in which the sling and stone would vibrate as a pendulum. This result of particle kinetics is (like that in § 161) of great value in other branches of physics, especially sound, light, and radiant heat.

Disturb[ance] general. To illustrate the general principle, let us take the case of one degree of freedom. Then the equation of motion of an unit mass must be of the form

$$\ddot{\theta}=\Theta+\Theta_1,$$

where Θ represents the normal force, and Θ_1 the abnormal or disturbing force. Leaving out Θ_1 for the moment, let the integral of $\ddot{\theta}=\Theta$ be

$$\theta=f(\alpha,\ \beta,\ t),$$

in which α and β are two arbitrary constants. We may now suppose α and β to be variable in such a way that the equation shall still be satisfied by this value of θ when the disturbing forces are included. This imposes only one condition on the two independent quantities α and β, so that to determine them completely we must impose a second. This we do, as already explained, by making the expression for the speed independent of the rates of alteration of α and β, and we gain the advantage that our solution will accord at every instant with what would be the actual future motion if the disturbance were suddenly to cease. The speed is

$$\dot{\theta}=f'(\alpha)\dot{\alpha}+f'(\beta)\dot{\beta}+f'(t).$$

We therefore assume

$$f'(\alpha)\dot{\alpha}+f'(\beta)\dot{\beta}=0.$$

Taking account of this and differentiating again, we have

$$\ddot{\theta}=\frac{d}{d\alpha}f'(t)\,.\,\dot{\alpha}+\frac{d}{d\beta}f'(t)\,.\,\dot{\beta}+f''(t).$$

Hence we have, for the determination of α and β, the equations

$$f'(\alpha)\frac{d\alpha}{dt}+f'(\beta)\frac{d\beta}{dt}=0,$$

$$\frac{d}{d\alpha}f'(t)\,.\,\frac{d\alpha}{dt}+\frac{d}{d\beta}f'(t)\,.\,\frac{d\beta}{dt}=\Theta_1.$$

These give the values of $\frac{d\alpha}{dt}$ and $\frac{d\beta}{dt}$, and so completely solve the problem.

Impulsive change of velocity. § 163. In a somewhat similar way we may treat the effects of a slight disturbance, made once for all, in the motion of a particle describing a definite path under given forces. A single example must suffice.

Thus, we have in an elliptic orbit about the focus, § 144 (9),

$$\frac{1}{2}v^2 = \frac{\mu}{r} - \frac{\mu}{2a}.$$

At the end of the major axis farthest from the focus this becomes

$$V^2 = \frac{\mu}{a}\,\frac{1-e}{1+e}.$$

Now if at this point V be made $V+\delta V$, without change of direction, we have the condition that in the new orbit $a(1+e)$ shall have the same value as in the old, since this will still be the apsidal distance.

Hence
$$\delta(V^2) = \delta\left(\frac{\mu}{a}\,\frac{1-e}{1+e}\right),$$

and
$$\delta\left\{a(1+e)\right\} = 0\;;$$

$$\therefore\; 2V\delta V = -\frac{\mu}{a}\,\frac{\delta e}{1+e},$$

or
$$\delta e = -2\sqrt{\left\{\frac{a}{\mu}(1-e^2)\right\}}\,\delta V,$$

and
$$\delta a = -\frac{a}{1+e}\delta e,$$

$$= 2\sqrt{\left(\frac{a^3}{\mu}\,\frac{1-e}{1+e}\right)}\delta V,$$

which determine the increase of the major axis and the diminution of the excentricity; and the same method is applicable to more complicated cases.

A very excellent series of examples of the elementary geometrical treatment of disturbed orbits is to be found in Airy's *Gravitation*.

Third Law. Kinetics of Two or More Particles.

Stress between particles. § 164. We have, by means of the first two laws, arrived at a *definition* and a *measure* of force, and have found how to compound, and therefore how to resolve, forces, and also how to investigate the conditions of equilibrium or motion of a single particle subjected to given forces. But more is required before we can completely understand the more complex cases of motion, especially those in which we have mutual actions between or amongst two or more bodies,—such as, for instance, tensions or pressures or transference of energy in any form. This is perfectly supplied by the third law, on which Newton comments nearly as follows.

Newton's comments on third law. § 165. If one body presses or draws another, it is pressed or drawn by this other with an equal force in the opposite direction. If any one presses a stone with his finger, his finger is pressed with an equal force in the opposite direction by the stone. A horse, towing a boat on a canal, is dragged backwards by a force equal to that which he impresses on the towing-rope forwards. By whatever amount, and in whatever direction, one body has its "motion" changed by impact upon another, this other body has its "motion" changed by the same amount in the opposite direction; for at each instant during the impact they exerted on each other equal and opposite pressures. When neither of the two bodies has any rotation, whether before or after impact, the changes of velocity which they experience are inversely as their masses. When one body attracts another from a distance, this other attracts it with an equal and opposite force.

Stress. § 166. We shall for the present take for granted that the mutual action between two particles may in every case be imagined as composed of equal and opposite forces in the straight line joining them, two such equal and opposite forces constituting a "stress" between the particles. From this it follows that the sum of the quantities of motion, parallel to any fixed direction, of the particles of any system influencing one another in any possible way, remains unchanged by their mutual action; also that the sum of the moments of momentum of all the particles round any line in a fixed direction in space, and passing through any point moving uniformly in a straight line in any direction, remains constant. From the first of these propositions we infer that the centre of mass of any system of mutually influencing particles, if in motion, continues moving uniformly in a straight line, except in so far as the direction or speed of its motion is changed by stresses between the particles and some other matter not belonging to the system; also that the centre of mass of any system of particles moves just as all their matter, if concentrated in a point, would move under the influence of forces equal and parallel to the forces really acting on its different parts. From the second we infer that the axis of resultant rotation through the centre of mass of any system of particles, or through any point either at rest or moving uniformly in a straight line, remains unchanged in direction, and the sum of moments of momentum round it remains constant, if the system experiences no force from without, or only forces whose resultant passes through the centre of inertia of the system. This principle is sometimes called "conservation of areas," a very misleading designation. Conservation of momentum, and of moment of momentum.

Consequences of Newton's scholium. § 167. Newton's scholium, which we treat as a fourth law, points out that resistances against acceleration are to be reckoned as reactions equal and opposite to the actions by which the acceleration is produced. Thus, if we consider any one material point of a system, its reaction against acceleration must be equal and opposite to the resultant of the forces which that point experiences, whether by the actions of other parts of the system upon it, or by the influence of matter not belonging to the system. In other words, it must be in equilibrium with these forces. Hence Newton's view amounts to this, that all the forces of the system, with the reactions against acceleration of the material points composing it, form groups of equilibrating systems for these points considered individually. Hence, by the principle of superposition of forces in equilibrium, all the forces acting on points of the system form, with the reactions against acceleration, an equilibrating set of forces on the whole system. This is the celebrated principle first explicitly stated and very usefully applied by D'Alembert in 1742, and still known by his name. D'Alembert's principle.

Abstract theory of energy. § 168. Thus Newton lays, in an admirably distinct and compact manner, the foundations of the abstract theory of "energy," which recent experimental discovery has raised to the position of the grandest of known physical laws. He points out, however, only its application to mechanics. The *actio agentis*, as he defines it, which is evidently equivalent to the product of the effective component of the force into the velocity of the point at which it acts, is simply, in modern English phraseology, the rate at which the agent works, called the "power" of the agent. The subject for measurement here is precisely the same as that for which Watt, a hundred years later, introduced the practical unit of a "horse-power," or the rate at which an agent works when overcoming 33,000 times the weight of a pound through the distance of a foot in a minute,—that is, producing 550 foot-pounds of work per second. The unit, however, which is most generally convenient is that which Newton's definition implies, namely, the rate of doing work in which the unit of work or energy is produced in the unit of time. Horse-power.

§ 169 Looking at Newton's words in this light, we see that they may be converted into the following:—

"Work done on any system of bodies (in Newton's

Newton's scholium. statement, the parts of any machine) has its equivalent in work done against friction, molecular forces, or gravity, if there be no acceleration; but if there be acceleration, part of the work is expended in overcoming the resistance to acceleration, and the additional kinetic energy developed is equivalent to the work so spent."

When part of the work is done against molecular forces, as in bending a spring, or against gravity, as in raising a weight, the recoil of the spring and the fall of the weight are capable, at any future time, of reproducing the work originally expended. But in Newton's day, and long afterwards, it was supposed that work was absolutely lost by friction.

§ 170. If a system of bodies, given either at rest or in motion, be influenced by no forces from without, the sum of the kinetic energies of all its parts is augmented in any time by an amount equal to the whole work done in that time by the stresses which we may imagine as taking place between its points. When the lines in which these stresses act remain all unchanged in length, the sum of the kinetic energies of the whole system remains constant. If, on the other hand, one of these lines varies in length during the motion, the stress in that line will do work or will consume work, according as the distance varies with or against it.

Conservative system. § 171. Experiment has shown that the mutual actions between the parts of any system of natural bodies always perform, or always consume, the same amount of work during any motion whatever, by which the system can pass from one particular configuration to another; so that each configuration corresponds to a definite amount of kinetic energy. Hence no arrangement is possible in which a gain of kinetic energy can be obtained when the system is restored to its initial configuration. In other words, "the perpetual motion" is impossible.

Potential energy. The "potential energy" (§ 113) of such a system, in the configuration which it has at any instant, is the amount of work that its mutual forces perform during the passage of the system from any one chosen configuration to the configuration at the time referred to. It is generally convenient so to fix the particular configuration chosen for the zero of reckoning of potential energy that the potential energy in every other configuration practically considered shall be positive.

As particular instances of this we may notice many of the results already given: for instance, the ordinary expression for the velocity acquired by a falling stone (§ 28), $\frac{1}{2}v^2 = gx$; for here $\frac{1}{2}mv^2$ is the kinetic energy acquired, while $mg.x$ is the work done by the weight (mg) during the fall. Similarly, we have in the motion of a planet, the expression $v^2 = \mu\left(\frac{2}{r} - \frac{1}{a}\right)$, which leads to $m\frac{v^2 - v_1^2}{2} = \frac{m\mu}{rr_1}(r_1 - r)$. Here $\frac{m\mu}{rr_1}$ is the "mean value" of the force for distances from r to r_1, and therefore the right-hand side is the work done by the force, while the left-hand side is the increase of kinetic energy produced.

To put this in an analytical form, we have merely to notice that, by what has just been said, the value of

$$\Sigma\int\left(X\frac{dx}{ds} + Y\frac{dy}{ds} + Z\frac{dz}{ds}\right)ds$$

is independent of the paths pursued from the initial to the final positions, and therefore that

$$\Sigma(Xdx + Ydy + Zdz)$$

is a complete differential. If, in accordance with what has just been said, this be called $-dV$, V is the potential energy, and

$$X_1 = -\frac{dV}{dx_1}, \ . \ . \ . \ .$$

Also, by the second law of motion, if m_1 be the mass of a particle of the system whose coordinates are x_1, y_1, z_1 we have

$$m_1\frac{d^2x_1}{dt^2} = X_1, \ \&c. = \&c.$$

and

Conservation of energy.

$$\Sigma\left\{m\left(\frac{dx}{dt}\frac{d^2x}{dt^2} + \frac{dy}{dt}\frac{d^2y}{dt^2} + \frac{dz}{dt}\frac{d^2z}{dt^2}\right)\right\}dt = \Sigma(Xdx + Ydy + Zdz) = -dV.$$

The integral is

$$\tfrac{1}{2}\Sigma(mv^2) + V = H,$$

that is, *the sum of the kinetic and potential energies is constant.* This is called the "*conservation of energy.*"

Friction dissipation. In abstract dynamics, with which alone this article is concerned, there is loss of energy by friction, impact, &c. This we simply leave as loss, to be accounted for by Thermodynamics.

Other side stress. § 172. Hitherto, as we have been dealing with the motion of a single particle only, we have not required the assistance of even the third law. For, in those cases, already treated, in which one of the forces was not given, it was at all events due to a given constraint, and the geometrical circumstances of the constraint supplied the means of determining it. In fact we were not, in any case, concerned with reaction; or, to use the more modern form of expression, we were engaged with one half, only, of a stress. When a stone's motion was investigated, no account was taken of the stone's attraction for the earth; when we dealt with central forces, the centre was supposed to be fixed; and, even in the cases in which variable constraint was supposed, the curve which produced it was assumed to move in a manner absolutely determined beforehand, and in no way affected by the reaction of the mass acted upon.

But, in nature, circumstances are not so simple. Though, for all practical purposes, we may calculate the motion of an ordinary projectile as if its attraction had no influence upon the motion of the earth, we cannot do so in the case of the motion of the moon about the earth. The mass of the moon is about $\frac{1}{80}$th of that of the earth, and its gravitation effects on the motion of the earth cannot be neglected. The moon, in fact, moves faster round the earth than would a projectile of less mass, though moving in precisely the same relative orbit (§ 146). If the earth's motion were not accelerated by the reaction of the moon, the sole crest of the lunar tide-wave would be on the side of the earth next the moon, and there would be full-tide once only in a single rotation of the earth about its axis. We need not give further instances here; they will present themselves in almost every case we investigate.

Examples of third law. § 173. To give a general notion of the applications of, and necessity for, the third law, we choose a few special cases, selected so as to give, in short compass, a sufficiently general glance at the whole subject.

Atwood's machine. We take, first, the case of two stones or bullets connected by an inextensible string passing over a smooth pulley. Let their masses be m and m'. Our physical condition is that the tension of the string, whatever be its value, is the same throughout; and this is accompanied by the geometrical condition that the length of the string is constant, or that the speeds of the two masses are equal but in opposite directions. Hence the amounts of increase of momentum in a given time are as the masses. But they are also as the forces, by the second law. Thus

$$m : m' :: T - mg : m'g - T.$$

This gives, at once,

$$T = \frac{2\,mm'}{m + m'}g;$$

so that the whole downward force on m' is

$$m'g - T = m'\frac{m' - m}{m' + m}g,$$

and the whole upward force on m is

$$T - mg = m\frac{m' - m}{m' + m}g.$$

The motion of the system is therefore of precisely the same character as that of a free mass falling in a vertical line, but the acceleration is less, in the ratio of the difference of the two masses to their sum.

§ 174. This is the essence of the arrangement called *Atwood's Machine*, which used to be employed for the demonstration (in a rough way) of the first and second laws of motion, in certain simple cases. The main feature of the method is the artificial reduction of the acceleration, so that the motion of the falling body is rendered slow enough to be followed by the eye with some degree of accuracy. To prove the first law, a bar of metal was laid across one of two equal masses suspended as in the example; and the system was allowed to move under acceleration until the preponderating mass passed through a ring which arrested the bar. The subsequent motion, with no acceleration, was then observed by noting the passage of the falling mass in front of a vertical scale, while the observer also listened to the ticking of a pendulum escapement. For the verification of the second law, so far as uniform force is concerned, the apparatus was adjusted by trial so that the extra load was detached from the preponderating mass after 1, 2, 3, &c., beats of the pendulum; and the subsequent uniform speed was found to be nearly in proportion to these numbers. And, again, to prove that momentum acquired is, *cæteris paribus*, proportional to the force, the effects of bars of different masses were compared by the same process.

If x and $l-x$ be the portions of the string on opposite sides of the pulley at time t, we have

$$m\frac{d^2x}{dt^2}=mg-\mathrm{T}=m\ddot{x},$$

$$m'\frac{d^2}{dt^2}(l-x)=m'g-\mathrm{T}=-m'\ddot{x}.$$

Hence by elimination of T we have

$$\frac{m-m'}{m+m'}g=\ddot{x},$$

and by elimination of $\ddot{x}$

$$\mathrm{T}=\frac{2mm'}{m+m'}g,\text{ as before.}$$

When one of the masses is vibrating pendulum-wise, the problem assumes a very much more difficult aspect. We will take it later as an example of the application of Lagrange's general method.

§ 175. Let us now suppose these masses, so connected, to be thrown like a chain-shot. We see by § 166 that their centre of inertia moves as if the masses were concentrated there. Also that the moment of momentum is unaffected. Hence we have only to find the initial position and motion of the centre of inertia, and the plane and amount of the initial moment of momentum; and the complete determination of the motion follows. This case is precisely the same as that of a well-thrown quoit, the rotation of which is about its axis of symmetry. It is, so far as § 166 goes, the case of an ill-thrown quoit, which appears to wabble about in an irregular manner. But these are matters properly to be treated under Kinetics of a Rigid System.

§ 176. Suppose, next, two masses m_1 and m_2 to be connected together by an elastic string, the extension of the string being proportional to the tension. Let m_1 be held in the hand, while m_2 hangs at rest. Then let the system be allowed to fall. What is the nature of the motion? Without mathematical investigation it is easy to see that, the moment the masses are left free to fall, the tension of the stretched string will gradually draw them together. When it has thus contracted to its normal length, l, the *relative* speed of the two masses will have a definite value. This will continue to be the relative speed until they have passed one another and again arrived at a mutual distance l. At that instant the tension of the string comes into play again; the relative speed becomes less and less, finally vanishing when the distance between the masses is what it was at starting. Then the relative speed becomes again one of approach, increasing steadily till the distance between the masses is l. This maximum speed of approach continues till, after again passing one another, the particles once more reach the relative distance l. And so on. All this time, however, their common centre of inertia has been steadily falling with uniformly accelerated speed, as if the masses had been concentrated at it into one. Since l is the unstretched length of the string, if we call E its modulus of elasticity, its tension at any other length, λ, is

$$\mathrm{T}=\mathrm{E}\frac{\lambda-l}{l}$$

by Hooke's law. Hence, if initially m_1 were at the origin, and the axis of x be taken vertically downwards, we have for the initial coordinate of m_2

$$(x_2)_0=\left(\frac{m_2g}{\mathrm{E}}+1\right)l.$$

When the masses are moving, the third law informs us that the tension of the string acts equally and in opposite directions on them. Thus the equations of motion are

$$m_1\ddot{x}_1=m_1g+\mathrm{T},$$
$$m_2\ddot{x}_2=m_2g-\mathrm{T}.$$

By eliminating T we have at once

$$m_1\ddot{x}+m_2\ddot{x}_2=(m_1+m_2)g.$$

But
$$m_1x_1+m_2x_2=(m_1+m_2)\xi,$$

if ξ be the coordinate of the centre of inertia of the two masses. Hence

$$\ddot{\xi}=g,$$

the ordinary equation for the fall of a stone. Thus

$$m_1x_1+m_2x_2=\mathrm{A}+\mathrm{B}t+\tfrac{1}{2}(m_1+m_2)gt^2.$$

Since $x_1=0$, $\dot{x}_1=0$, $x_2=\left(\frac{m_2g}{\mathrm{E}}+1\right)l$, $\dot{x}_2=0$, when $t=0$, we have

$$\mathrm{A}=m_2\left(\frac{m_2g}{\mathrm{E}}+1\right)l,\quad \mathrm{B}=0,$$

and thus
$$m_1x_1+m_2x_2=m_2\left(\frac{m_2g}{\mathrm{E}}+1\right)l+\tfrac{1}{2}(m_1+m_2)gt^2.$$

So long as $x_2-x_1>l$ we have also

$$\mathrm{T}=\mathrm{E}\left(\frac{x_2-x_1}{l}-1\right).$$

Hence, multiplying the first of the equations of motion by m_2, and the second by m_1, and taking the difference, we have

$$m_1m_2(\ddot{x}_2-\ddot{x}_1)=-(m_1+m_2)\mathrm{E}\left(\frac{x_2-x_1}{l}-1\right).$$

The integral is

$$x_2-x_1=l+\mathrm{P}\cos(nt+\mathrm{Q}),$$

where
$$n^2=\frac{m_1+m_2}{lm_1m_2}\mathrm{E}.$$

Also, by the data at starting, we have

$$\mathrm{Q}=0,\qquad \mathrm{P}=\frac{m_2gl}{\mathrm{E}}.$$

Hence, finally,

$$x_1=\frac{1}{m_1+m_2}\left(m_2\left(\frac{m_2g}{\mathrm{E}}+1\right)l+\tfrac{1}{2}(m_1+m_2)gt^2-m_2l-\frac{m_2^2gl}{\mathrm{E}}\cos nt\right).$$

$$=\tfrac{1}{2}gt^2+\frac{m_2^2gl}{\mathrm{E}(m_1+m_2)}(1-\cos nt),$$

whence the value of x_2 can easily be found.

As soon as we have $nt>\frac{1}{2}\pi$ these values cease to represent the coordinates of the two masses, because they are deduced from equations involving constraint which, in the case supposed, has ceased for a time.

At the instant $nt=\frac{1}{2}\pi$ the relative speed of the masses is

$$-\frac{m_2gl}{\mathrm{E}}\sqrt{\frac{(m_1+m_2)\mathrm{E}}{m_1m_2l}},$$

and their distance l.

This distance diminishes thenceforward with the above speed until the uppermost stone, having passed the lower one, falls below it to a distance l. We must, in order to trace the next part of the motion, reapply the differential equations above,—integrating them, and determining the constants by the new conditions. This we leave to the reader.

Complex pendulum.

§ 177. Next let us take the case of a *Complex Pendulum*,—the motion of two or more pellets attached, at different points, to the same thread, supported at one end. The general solution of this question presents considerable difficulties, but if we confine our attention to slight disturbances it is easily treated by very elementary processes. In fact, just as a simple pendulum, *slightly* disturbed in a vertical plane, has simple harmonic motion which may be regarded as the resolved part of conical pendulum motion, so we may treat of a complex conical pendulum, and resolve its motions parallel to any vertical plane.

If there be but two masses attached to the string, it is clear that they must, if the motion is to be a persistent conical one, be always in one vertical plane with the point of suspension. And there are obviously *two* dispositions of the string which are consistent with kinetic stability.

Let A (fig. 54) be the point of suspension, then the masses may rotate steadily in either of the two configurations sketched. To keep either mass moving in a horizontal circle, all that is required is that the resultant force on it shall be horizontal, directed towards the centre, and producing an acceleration equal to V^2/R, as in § 34. Let the whole system turn with angular velocity ω, and let the lengths of the strings be a and b, their directions making angles θ, ϕ with the vertical.

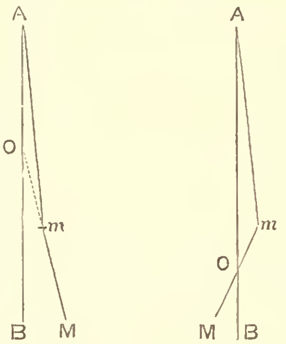

Fig. 54.

We will treat only the case in which these angles are so small that the arcs may be written in place of their sines. Then m requires a horizontal resultant force $ma\theta\omega^2$ directed towards the axis, and M requires $M(a\theta+b\phi)\omega^2$ similarly directed. Also, as the strings are both very nearly vertical, the tension of the lower string may be taken as the weight of M, and that of the upper as the sum of the weights of M and m. Treating it, then, as a statical problem, we have for the mass m

$$ma\theta\omega^2=(M+m)g\theta-Mg\phi\,;$$

and for M

$$M(a\theta+b\phi)\omega^2=+Mg\phi\,.$$

These formulæ correspond to the first configuration, but a change of sign of ϕ adapts them to the second.

These two equations involve three unknown quantities ω^2, θ, ϕ. But the *ratio*, only, of θ and ϕ is involved, so that two equations are sufficient. [We have confined ourselves to small values of θ and ϕ, but have not assigned any limit to their smallness; so that their ratio has still an infinite range of values.]

Eliminate the ratio ϕ/θ between the two equations; and we have, putting ψ for g/ω^2,

$$Ma\psi=(\psi-b)((M+m)\psi-ma)\,,$$

or

$$(\psi-a)(\psi-b)=\frac{M}{M+m}ab\,.$$

It is clear that, because the right-hand member is essentially less than ab, there are always two real values of ψ, both positive, but one greater than the greater of a, b, the other less than the lesser. These correspond to two values of ϕ/θ, one positive, the other negative.

§ 178. The most general motion, then, of the double complex pendulum, when it vibrates in one plane, consists (for each of the masses) of the resultant of two simple harmonic motions, whose periods are

$$2\pi/\omega-2\pi\sqrt{\psi/g}\,,$$

ψ having one or other of the two positive values given by the equation above, and being therefore the length of the equivalent simple pendulum. Thus the double complex pendulum supplies at once the mechanical means of tracing (by ink, sand, electric sparks, &c., § 156) a graphical representation of the composition of two simple harmonic motions, of different periods, in one line.

Analytically thus. For *any* displacement in one plane we have, θ and ϕ being, as before, the deflexions and T, T′ the tensions of the strings,

$$ma\left(\frac{d}{dt}\right)^2\sin\theta=-T\sin\theta+T'\sin\phi\,,$$

$$ma\left(\frac{d}{dt}\right)^2\cos\theta=mg-T\cos\theta+T'\cos\phi\,,$$

$$M\left(\frac{d}{dt}\right)^2(a\sin\theta+b\sin\phi)=-T'\sin\phi$$

$$M\left(\frac{d}{dt}\right)^2(a\cos\theta+b\cos\phi)=Mg-T'\cos\phi\,,$$

four equations to determine θ, ϕ, T, and T′. They become much more manageable if we assume that θ and ϕ are so small that their squares may be neglected. For then we have $\sin\theta=\theta$, $\cos\theta=1$, &c., and the equations become

$$ma\ddot\theta=-T\theta+T'\phi,\qquad 0=mg-T+T',$$

$$M(a\ddot\theta+b\ddot\phi)=-T'\phi,\qquad 0=Mg-T'.$$

Thus $\quad T'=Mg\,,\ T=(M+m)g\,,$

and we have $\quad ma\ddot\theta=-(M+m)g\theta+Mg\phi\,,$

$$a\ddot\theta+b\ddot\phi=-g\phi\,.$$

Introducing an arbitrary multiplier λ, we have

$$\left(\frac{d}{dt}\right)^2\Big\{(m+\lambda)a\theta+\lambda b\phi\Big\}=-g\Big\{(M+m)\theta+(\lambda-M)\phi\Big\}\,.$$

If we choose λ so that

$$\frac{\lambda b}{(m+\lambda)a}=\frac{\lambda-M}{M+m}=e,\quad\ldots\ldots\quad(1).$$

the equation can be put in the form

$$\left(\frac{d}{dt}\right)^2(\theta+e\phi)=-\frac{g(M+m)}{(m+\lambda)a}(\theta+e\phi).$$

Now (1) is a quadratic equation in λ, and has obviously real roots, a positive root greater than M, and a negative root numerically less than m. Write (1) as the equation of an hyperbola, in the form

$$\mu=\frac{\lambda b}{(m+\lambda)a}-\frac{\lambda-M}{M+m}\,,$$

and we see that $\lambda+m=0$ is an asymptote. The branch on the positive side of this asymptote lies mainly below the axis of λ. But μ is positive for $\lambda=M$, and also for $\lambda=0$.

Hence μ must pass through the value zero while λ is greater than M, and for another value of λ between zero and $-m$. But it is obvious that, for each of these values of λ, $m+\lambda$ is positive. Hence the equation may be written

$$\left(\frac{d}{dt}\right)^2(\theta+e\phi)=-n^2(\theta+e\phi)\,,$$

where e and n have two sets of real values given as above; and thus we have the complete solution, with the four requisite arbitrary constants, in the form

$$\theta+e_1\phi=P_1\cos(n_1t+Q_1)\,,$$

$$\theta+e_2\phi=P_2\cos(n_2t+Q_2)\,.$$

This applies to every possible set of values of a, b, m, M; for, as we have seen, the two values of λ are essentially different, at least *so long as neither of the masses becomes zero*. Thus, in this particular case, we are not met by the difficulty of equal roots. But it is very interesting to contrast this case, when m is much greater than M, and $a=b$, with the case discussed in § 162 where the point of suspension of a simple pendulum has a horizontal simple harmonic motion of the period of the pendulum and in the vertical plane in which it vibrates. There the oscillations increase indefinitely; here they are in all cases essentially finite, in accordance with the assumptions made. There is, in fact, no increase of the energy of the system.

A very slight modification of the process gives us the result of small displacements not in one plane.

Kinetics of a System of Free Particles.

§ 179. A system of free particles is subject only to their mutual attractions; to investigate the motion of the system.

System of free particles. Let, at time t, x_n, y_n, z_n be the coordinates of the particle whose mass is m_n, and let $\phi'(D)$ be the law of attraction. Let ${}_pr_q$ express the distance between the particles m_p and m_q; then we have, for the motion of m_1,

$$m_1\frac{d^2x_1}{dt^2} = \Sigma\left\{ m_1 m_n \phi'({}_1r_n)\frac{x_n - x_1}{{}_1r_n}\right\} \quad . \quad . \quad . \quad . \quad (1),$$

$$m_1\frac{d^2y_1}{dt^2} = \Sigma\left\{ m_1 m_n \phi'({}_1r_n)\frac{y_n - y_1}{{}_1r_n}\right\} \quad . \quad . \quad . \quad . \quad (2),$$

$$m_1\frac{d^2z_1}{dt^2} = \Sigma\left\{ m_1 m_n \phi'({}_1r_n)\frac{z_n - z_1}{{}_1r_n}\right\} \quad . \quad . \quad . \quad . \quad (3),$$

with similar equations for each of the others, the summations being taken throughout the system. Before we can make any attempt at a solution of these equations, we must know their number, and the laws of attraction between the several pairs of particles. But some general theorems, independent of these data, may easily be obtained.

Conservation of momentum. First, we have *Conservation of Momentum*. In the expression for $m_p\frac{d^2x_p}{dt^2}$, we have a term $m_p m_q \phi'({}_pr_q)\frac{x_q - x_p}{{}_pr_q}$,

and in $m_q\frac{d^2x_q}{dt^2}$ we have $m_q m_p \phi'({}_qr_p)\frac{x_p - x_q}{{}_qr_p}$.

Hence, if we add all the equations of the form (1) together, the result will be

$$m_1\frac{d^2x_1}{dt^2} + m_2\frac{d^2x_2}{dt^2} + \quad . \quad . \quad . \quad . \quad = 0\,;$$

or

$$\Sigma\left(m\frac{d^2x}{dt^2}\right) = \frac{d^2\bar{x}}{dt^2}\Sigma(m) = 0\,.$$

Similarly $\frac{d^2\bar{y}}{dt^2}\Sigma(m) = 0$, and $\frac{d^2\bar{z}}{dt^2}\Sigma(m) = 0$,

where (§ 109) $\bar{x}$, $\bar{y}$, $\bar{z}$ is the centre of inertia of the system.

These equations show that the speed of the centre of inertia parallel to each of the coordinate axes remains invariable during the motion; that is, that *the centre of inertia of the system remains at rest, or moves with constant speed in a straight line.*

Of moment of momentum. Next we have *Conservation of Moment of Momentum*. For if we multiply in succession equation (1) by y_1, and equation (2) by x_1, and subtract, and take the sum of all such remainders through the system of equations of the forms (1) and (2), we have

$$\Sigma[m(x\ddot{y} - y\ddot{x})] = 0\,.$$

Integrating once, we have

$$\Sigma[m(x\dot{y} - y\dot{x})] = 2A_3\,,$$

where the left-hand member is the moment of momentum of the system about the axis of z.

This equation shows (since xy is any plane) that generally in the motion of a free system of particles, subject only to their mutual attractions, *the moment of momentum about every axis remains constant.*

Of energy. Finally, we have *Conservation of Energy*. Multiply (1) by $\frac{dx_1}{dt}$, (2) by $\frac{dy_1}{dt}$, (3) by $\frac{dz_1}{dt}$; and, treating similarly all the other equations, add them all together.

Let us consider the result as regards the term on the right-hand side involving the product m_pm_q.

Written at length it is

$$\frac{m_pm_q\phi'({}_pr_q)}{{}_pr_q}\left\{(x_q - x_p)\frac{dx_p}{dt} + (x_p - x_q)\frac{dx_q}{dt}\right.$$
$$\left. + \text{similar terms in } y \text{ and } z\right\};$$

and the portion in brackets is equal to

$$-\left\{(x_q - x_p)\frac{d}{dt}(x_q - x_p) + \text{similar terms in } y, z\right\};$$

or

$$-{}_pr_q\frac{d}{dt}({}_pr_q)\,;$$

hence

$$\Sigma\left\{m\left(\frac{dx}{dt}\frac{d^2x}{dt^2} + \frac{dy}{dt}\frac{d^2y}{dt^2} + \frac{dz}{dt}\frac{d^2z}{dt^2}\right)\right\}$$
$$+ \Sigma\left\{m_pm_q\phi'({}_pr_q)\frac{d}{dt}({}_pr_q)\right\} = 0\,;$$

therefore, on integration,

$$\tfrac{1}{2}\Sigma(mv^2) + \Sigma\{m_pm_q\phi({}_pr_q)\} = H\,.$$

We see therefore that *the change in the kinetic energy of the system in any time depends only on the relative distances of the particles at the beginning and end of that time.*

Virial. Another general expression for the kinetic energy of a system of particles, in terms of a function of the mutual forces, and the constraining forces if there be such, is readily found as follows.

If x, y, z be the coordinates, at time t, of the particle m, we have

$$\left(\frac{d}{dt}\right)^2\Sigma m(x^2 + y^2 + z^2) = 2\Sigma m(\dot{x}^2 + \dot{y}^2 + \dot{z}^2) + 2\Sigma m(x\ddot{x} + y\ddot{y} + z\ddot{z})\,.$$

But if X, Y, Z be the components of the forces (of whatever kind) acting on m, we have (§ 119)

$$m\ddot{x} = X,\ m\ddot{y} = Y,\ m\ddot{z} = Z\,.$$

Thus

$$\left(\frac{d}{dt}\right)^2\Sigma m(x^2 + y^2 + z^2) = 2\Sigma m(\dot{x}^2 + \dot{y}^2 + \dot{z}^2) + 2\Sigma(Xx + Yy + Zz)\,.$$

This expression was originally devised by Clausius for application to the kinetic theory of gases. The quantity $\Sigma m(x^2 + y^2 + z^2)$ is obviously half the sum of the three principal moments of inertia of the group of particles about the origin (§ 234).

In all cases of motion of a group, in which this sum is either constant or oscillates in an extremely short period about a constant value, the left-hand side may be regarded as (on the average at least) a vanishing quantity. Thus an equivalent of the kinetic energy is expressible as

$$-\tfrac{1}{2}\Sigma(Xx + Yy + Zz)\,.$$

This expression is called the "virial."

In so far as it arises from the mutual action between two particles m_p and m_q, its value is (in the notation above)

$$-\tfrac{1}{2}\left(m_p\,m_q\phi'({}_pr_q)\frac{x_q - x_p}{{}_pr_q}x_p + m_q\,m_p\phi'({}_pr_q)\frac{x_p - x_q}{{}_pr_q}x_q\right),$$

with corresponding terms in y and z, altogether

$$= \tfrac{1}{2}m_p\,m_q\phi'({}_pr_q){}_pr_q\,.$$

Hence if we write, generally, r for the distance between two of the particles, and R for the stress between them as depending on their mutual action, the corresponding part of the virial is

$$\tfrac{1}{2}\Sigma(Rr)\,.$$

This is positive when the stresses are of the nature of tension.

When the mutual action is due to gravity only,

$$\phi'({}_pr_q) = \frac{1}{{}_pr_q^2}\,,$$

and the part of the virial corresponding to this is

$$\tfrac{1}{2}m_p\,m_q/{}_pr_q\,,$$

expressing half the exhaustion of the potential energy of the system.

Virial of a gas contained in a vessel. When the particles are in very great numbers, and enclosed in a vessel from the sides of which they rebound—as is supposed in the kinetic gas theory—the pressure p, per unit of surface, on the walls of the vessel must be taken into account. If l, m, n be the direction cosines of the normal to the element dS of the wall of the vessel whose coordinates are x, y, z, the corresponding part of the virial is

$$\tfrac{1}{2}p\iint dS(lx + my + nz)$$

extended over the whole internal surface. We here assume that p is constant. But $lx + my + nz$ is the perpendicular from the origin on the plane of dS, so that the integral expresses three times the volume V of the vessel. Hence this part of the virial is

$$\tfrac{3}{2}pV.$$

Thus, in the case of a gas not acted on by external forces, the kinetic energy is

$$\tfrac{3}{2}pV + \tfrac{1}{2}\Sigma(Rr)\,.$$

Impact of Smooth Spheres.

§ 180. There remains to be treated, so far as particle dynamics is concerned, the self-contained subject of *Impact*. (Impact.) In connexion with it we must once more refer to the second and third of Newton's laws. We are now dealing with forces which produce, in finite masses, finite changes of momentum in excessively short periods of time. It is clear from this statement that their effects may be treated altogether independently of finite forces, which may be acting along with them, but which produce during the very short periods in question only infinitesimal results. And, as in general we have no knowledge of the actual force exerted at any instant during the impact, nor of the time during which the action lasts, we confine ourselves to the quantity, called the "impulse," which measures the amount of momentum lost by one of the impinging bodies and acquired by the other. (Impulse.)

Impact of small spheres.

§ 181. When two balls of glass or ivory impinge on one another, the portions of the surfaces immediately in contact are disfigured and compressed until the molecular reactions thus called into play are sufficient to resist further distortion and compression. At this instant it is evident that the points in contact are moving with the same velocity. But as solids in general possess a certain degree of elasticity both of form and of volume, the balls tend to recover their spherical form, and an additional impulse is generated. This is proportional, as Newton found by experiment, to that exerted during the compression, provided neither of the bodies is permanently distorted. The coefficient of proportionality is a quantity determinable by experiment, and may be conveniently termed the "coefficient of restitution." It is always less than unity.

§ 182. The method of treating questions involving actions of this nature will be best explained by taking as an example the case of *direct impact of one spherical ball on another.* It is evident that in the case of direct impact of smooth or non-rotating spheres we may consider them as mere particles, since everything is symmetrical about the line joining their centres. If the impinging masses are of large dimensions, of the size of the earth, for instance, we cannot treat the effects of the impact independently of the other forces involved; for the duration of collision in such a case may be one of hours instead of fractions of a second.

§ 183. Suppose that a sphere of mass M, moving with a speed v, overtakes and impinges on another of mass M′, moving in the same straight line with speed v', and that, at the instant when the mutual compression is completed, the spheres are moving with a common speed V. Let R be the impulse during the compression, then

$$M(v-V)=M'(V-v')=R\,;$$

whence
$$V=\frac{Mv+M'v'}{M+M'}\,,\ \text{and}\ R=\frac{MM'}{M+M'}(v-v')\quad . \quad . \quad . \quad (1).$$

From these results we see that the whole momentum after impact is the same as before, and that the common speed is that of the centre of inertia before impact. The quantity V can vanish only if

$$Mv+M'v'=0\,,$$

that is, if the momenta were originally equal and opposite.

This is the complete solution of the problem if the balls be inelastic, or have no tendency to recover their original form after compression.

§ 184. If the balls be elastic, there will be generated, by their tendency to recover their original forms, an additional impulse proportional to R.

Let e be the coefficient of restitution, and v_1, v_1' the speeds of the balls when finally separated. Then, as before,

$$M(V-v_1)=eR\,,$$
$$M'(v_1'-V)=eR\,;$$

whence
$$Mv_1=M\frac{Mv+M'v'}{M+M'}-e\frac{MM'}{M+M'}(v-v')\,,$$

and
$$v_1=\frac{(M-eM')v+M'(1+e)v'}{M+M'}=v-\frac{M'}{M+M'}(1+e)(v-v')\,;$$

with a similar expression for v_1'.

These results may be more easily obtained by the simple consideration that the whole impulse is $(1+e)R$; for this gives at once $M(v-v_1)=M'(v_1'-v')=(1+e)R$.

Impact on fixed plane.

If M′ be infinite, and $v'=0$, we have the result of direct impact on a *fixed* surface, viz., $v-v_1=(1+e)v$ or $v_1=-ev$. The ball rebounds from the fixed surface with a speed e times that with which it impinged.

§ 185. Suppose, now, $M=M'$, $e=1$; that is, let the balls be of equal mass, and their coefficient of restitution unity (or, in the usual but most misleading phraseology, suppose the balls to be "perfectly elastic"); then $2R=M(v-v')$; $v_1=v'$, and similarly $v_1'=v$; or the balls, whatever be their speeds, interchange them, and the motion is the same as if they had passed through one another without exerting any mutual action whatever.

Thus if a number of equal solitaire balls or billiard balls be arranged in contact in a horizontal groove, and another equal ball impinge on one extremity of the row, it is reduced to rest, and the ball at the other end of the row goes off with the original speed of impact. If two impinge, two go off, and so on.

§ 186. We may write the above expressions in terms of the impulse, thus

Conservation of momentum.

$$\left.\begin{aligned} v_1&=v-\frac{R(1+e)}{M}\\ v_1'&=v'+\frac{R(1+e)}{M'}\end{aligned}\right\}\quad . \quad . \quad . \quad . \quad . \quad . \quad (2).$$

Hence $Mv_1+M'v_1'=Mv+M'v'$, whatever e be, or there is no momentum lost. This is, of course, a direct consequence of the third law of motion.

Again
$$\begin{aligned}\tfrac{1}{2}Mv_1^2+\tfrac{1}{2}M'v_1'^2&=\tfrac{1}{2}Mv^2+\tfrac{1}{2}M'v'^2\\ &\quad-R(1+e)(v-v')+\tfrac{1}{2}R^2(1+e)^2\frac{M+M'}{MM'}\\ &=\tfrac{1}{2}Mv^2+\tfrac{1}{2}M'v'^2-\tfrac{1}{2}R^2(1-e^2)\frac{M+M'}{MM'}\\ &=\tfrac{1}{2}Mv^2+\tfrac{1}{2}M'v'^2-\tfrac{1}{2}(1-e^2)\frac{MM'}{M+M'}(v-v')^2\,.\end{aligned}$$

Loss of energy.

The last term of the right hand side is therefore the kinetic energy apparently destroyed by the impact. When $e=0$, its magnitude is greatest, and equal to

$$\frac{1}{2}\frac{MM'}{M+M'}(v-v')^2=\tfrac{1}{2}R(v-v')\,.$$

When $e=1$, its magnitude is zero; that is, when the coefficient of restitution is unity no kinetic energy is lost.

The kinetic energy which appears to be destroyed in any of these cases is, as we see from § 171, only transformed—partly it may be into heat, partly into sonorous vibrations, as in the impact of a hammer on a bell. But, in spite of this, the elasticity may be "perfect." Hence the absurdity of the designation alluded to in § 185. Also by (2)

$$\begin{aligned}v_1'-v_1&=v'-v+R(1+e)\frac{M+M'}{MM'}\\ &=e(v-v')\ \text{by (1)}.\end{aligned}$$

Hence the velocity of separation is e times that of approach.

Oblique impact.

§ 187. *Two smooth spheres, moving in given paths and with given speeds, impinge; to determine the impulse and the subsequent motion.*

Let the masses of the spheres be M, M′, their speeds before impact v and v', and let the original directions of motion make with the line which joins the centres at the instant of impact the angles α, α', which may be calculated from the data, if the radii of the spheres be given.

Since the spheres are smooth, the entire impulse takes place in the line joining the centres at the instant of impact, and the future motion of each sphere will be in the plane passing through this line and its original direction of motion.

Let R be the impulse, e the coefficient of restitution; then, since the speeds in the line of impact are $v\cos\alpha$ and $v'\cos\alpha'$, we have for their final values v_1, v_1', after restitution, by § 184 the expressions

$$v_1=v\cos\alpha-\frac{M'}{M+M'}(1+e)(v\cos\alpha-v'\cos\alpha')\,,$$

$$v_1'=v'\cos\alpha'+\frac{M}{M+M'}(1+e)(v\cos\alpha-v'\cos\alpha')\,,$$

and the value of R is

$$\frac{MM'}{M+M'}(1+e)(v\cos\alpha-v'\cos\alpha')\,.$$

Hence, the sphere M has finally a speed v_1 in the line joining the centres, and a speed $v \sin \alpha$ in a known direction perpendicular to this, namely, in the plane through this and its original direction of motion. And similarly for the sphere M′. Thus the consequences of the impact are completely determined.

§ 188. When a sphere of mass M impinges directly, with speed V, on another M′ at rest, the speed acquired by M′ is

$$\frac{MV(1+e)}{M+M'}.$$

But, if another sphere of mass μ, also at rest, be interposed between them, M′ will acquire a speed

$$\frac{\mu MV(1+e)^2}{(M+\mu)(M'+\mu)}.$$

This is greatest when μ is the geometric mean of M and M′, and its value is then

$$\frac{MV(1+e)^2}{(\sqrt{M}+\sqrt{M'})^2}.$$

The ratio of this to the speed which M′ would have acquired without the interposition of the third sphere is

$$\frac{1+e}{1+\frac{2\sqrt{MM'}}{M+M'}}.$$

There is thus a gain by the interposition if, and only if,

$$e > \frac{2\sqrt{MM'}}{M+M'}.$$

This condition is always satisfied when the coefficient of restitution is unity, except in the special case of equal masses. If an infinite number of spheres be interposed between M and M′, so adjusted as to give the greatest possible speed to M′, that greatest speed is $V\sqrt{M'/M}$, provided we have $e=1$.

Continuous Succession of Indefinitely Small Impacts.

Infinite series of infinitesimal impacts. § 189. We may now consider the case of a continuous series of indefinitely small impacts, whose effect is comparable with that of a finite force. One obvious method of considering such a problem is to estimate *separately* the changes in the velocity produced by the finite forces and by the impacts, in the same indefinitely small time δt, and compound these for the actual effect on the motion in that period.

Another way, of course, is to equate the rate of increase of momentum per unit of time to the force producing it.

A mass, under no forces, moves through a uniform cloud of little particles which are at rest. Those it meets adhere to it. Find the motion.

At time t let μ be the mass, and let x denote its position in its line of motion. Then, as there is no loss of momentum, we have

$$\frac{d}{dt}(\mu\dot{x})=0.$$

But if M be the original mass, μ_0 the mass of the particles picked up in unit of length, obviously

$$\mu = M+\mu_0 x.$$

Substitute and integrate, supposing $x=0$, $\dot{x}=V$, when $t=0$; and we get

$$(M+\mu_0 x)\dot{x}=MV,$$

from which x can be easily found.

It is interesting to observe that we have

$$\ddot{x} = -\frac{\mu_0 M^2 V^2}{(M+\mu_0 x)^3};$$

so that the mass moves as if acted on by an attraction varying inversely as the cube of the distance from a point in its line of motion.

This problem obviously leads to the same result as the following:—*A cannon-ball attached to one end of a chain, which is coiled up on a smooth horizontal plane, is projected along the plane. Determine its motion.*

Rocket. § 190. Another excellent instance of the application of this process is furnished by the motion of a rocket, where the motive power depends on the fact that a portion of the mass is detached with considerable relative velocity. The increase of the momentum of the rocket due to this cause is equal to the relative momentum with which the products of combustion escape. If we suppose the rocket, originally of mass M, to lose eM in unit of time, projected from it with relative velocity V, the gain of momentum in time δt due to this cause is

$$eMV\delta t.$$

The total upward acceleration is therefore

$$\frac{eMV}{M-eMt}-g.$$

Unless this be positive the rocket cannot rise. It will rise at once if $V>g/e$, and it cannot rise at all unless $MV/M' > g/e$, M′ being the mass of the case, stick, &c., which are not burned away.

From the above data it is easy to calculate that the greatest speed acquired during the flight (the resistance of the air being left out of account) is

$$V\log\frac{M}{M'}-\frac{g}{e}\left(1-\frac{M'}{M}\right).$$

Dynamics of a System of Particles Generally.

§ 191. The law of energy, in abstract dynamics, may be expressed as follows:—the whole work done in any time, on any limited material system, by applied forces, is equal to the whole effect in the forms of potential and kinetic energy produced in the system, together with the work lost in friction. This principle may be regarded as comprehending the whole of abstract dynamics, because the conditions of equilibrium and of motion, in every possible case, may be derived from it. Motion of a system of particles.

§ 192. A material system, whose relative motions are unresisted by friction, is in equilibrium in any configuration if, and is not in equilibrium unless, the rate at which the applied forces perform work at the instant of passing through it is equal to that at which potential energy is gained, in every possible motion through that configuration. This is the celebrated principle of "virtual velocities," which Lagrange made the basis of his *Mécanique Analytique.* Condition of equilibrium. Virtual velocities.

§ 193. To prove it, we have first to remark that the system cannot possibly move away from any particular configuration except by work being done upon it by the forces to which it is subject; it is therefore in equilibrium if the stated condition is fulfilled. To ascertain that nothing less than this condition can secure the equilibrium, let us first consider a system having only one degree of freedom to move. Whatever forces act on the whole system, we may always hold it in equilibrium by a single force applied to any one point of the system in its line of motion, opposite to the direction in which it tends to move, and of such magnitude that, in any infinitely small motion in either direction, it shall resist or shall do as much work as the other forces, whether applied or internal, altogether do or resist. Now, by the principle of superposition of forces in equilibrium, we might, without altering their effect, apply to any one point of the system such a force as we have just seen would hold the system in equilibrium, and another force equal and opposite to it. All the other forces being balanced by one of these two, they and it might again, by the principle of superposition of forces in equilibrium, be removed; and therefore the whole set of given forces would produce the same effect, whether for equilibrium or for motion, as the single force which is left acting alone. This single force, since it is in a line in which the point of its application is free to move, must move the system. Hence the given forces, to which the single force has been proved equivalent, cannot possibly be in equilibrium unless their whole work for an infinitely small motion is nothing, in which case the single equivalent force is reduced to nothing. But whatever amount of freedom to move the whole system may have, we may always, by the application of frictionless constraint, limit it to one degree of freedom only; and this may be freedom to execute any particular motion whatever, possible under the given conditions of the system. If, therefore, in any such infinitely small motion there is variation of potential energy uncompensated by work of the applied forces, constraint limiting the freedom of the system to only this motion will bring us to the case in which we have just demonstrated there cannot be equilibrium. But the application of constraints limiting motion cannot possibly disturb equilibrium, and therefore the given system under the actual conditions cannot be in equilibrium in any particular configuration if the rate of doing work is greater than that at which potential energy is stored up in any possible motion through that configuration.

Neutral equilibrium.

§ 194. If a material system, under the influence of internal and applied forces, varying according to some definite law, is balanced by them in any position in which it may be placed, its equilibrium is said to be neutral. This is the case with any spherical body of uniform material resting on a horizontal plane. A right cylinder or cone, bounded by plane ends perpendicular to the axis, is also in neutral equilibrium on a horizontal plane. Practically, any mass of moderate dimensions is in neutral equilibrium when its centre of inertia only is fixed, since, when its longest dimension is small in comparison with the earth's radius, the action of gravity is, as we shall see (§ 222), approximately equivalent to a single force through this point.

Stable equilibrium.

§ 195. But if, when displaced infinitely little in any direction from a particular position of equilibrium, and left to itself, it commences and continues vibrating, without ever experiencing more than infinitely small deviation, in any one of its parts, from the position of equilibrium, the equilibrium in this position is said to be stable. A weight suspended by a string, a uniform sphere in a hollow bowl, a loaded sphere resting on a horizontal plane with the loaded side lowest, an oblate body resting with one end of its shortest diameter on a horizontal plane, a plank, whose thickness is small compared with its length and breadth, floating on water, are all cases of stable equilibrium,—if we neglect the motions of rotation about a vertical axis in the second, third, and fourth cases, and horizontal motion in general in the fifth, for all of which the equilibrium is neutral.

Unstable equilibrium.

§ 196. If, on the other hand, the system can be displaced in any way from a position of equilibrium, so that when left to itself it will not vibrate within infinitely small limits about the position of equilibrium, but will move farther and farther away from it, the equilibrium in this position is said to be unstable. Thus a loaded sphere resting on a horizontal plane with its load as high as possible, an egg-shaped body standing on one end, a board floating edgewise in water, would present, if they could be realized in practice, cases of unstable equilibrium.

§ 197. When, as in many cases, the nature of the equilibrium varies with the direction of displacement, if unstable for any possible displacement it is practically unstable on the whole. Thus a circular disk standing on its edge, though in neutral equilibrium for displacements in its plane, yet being in unstable equilibrium for those perpendicular to its plane, is practically unstable. A sphere resting in equilibrium on a saddle presents a case in which there is stable, neutral, or unstable equilibrium according to the direction in which it may be displaced by rolling; but practically it is unstable.

Energy test of equilibrium.

§ 198. The theory of energy shows a very clear and simple test for discriminating these characters, or determining whether the equilibrium is neutral, stable, or unstable, in any case. If there is just as much potential energy stored up as there is work performed by the applied and internal forces in any possible displacement, the equilibrium is neutral, but not unless. If in every possible infinitely small displacement from a position of equilibrium there is more potential energy stored up than work done, the equilibrium is thoroughly stable, and not unless. If in any or in every infinitely small displacement from a position of equilibrium there is more work done than energy stored up, the equilibrium is unstable. It follows that if the system is influenced only by internal forces, or if the applied forces follow the law of doing always the same amount of work upon the system while passing from one configuration to another by all possible paths, the whole potential energy must be constant in all positions for neutral equilibrium, must be a minimum for positions of thoroughly stable equilibrium, and must be either a maximum for all displacements or a maximum for some displacements and a minimum for others when there is unstable equilibrium.

Formation of general equation of motion.

§ 199. We have seen that, according to D'Alembert's principle, as explained above, forces acting on the different points of a material system, and their reactions against the accelerations which they actually experience in any case of motion, are in equilibrium with one another. Hence, in any actual case of motion, not only is the actual work by the forces equal to the kinetic energy produced in any infinitely small time, in virtue of the actual accelerations, but so also is the work which would be done by the forces, in any infinitely small time, if the velocities of the points constituting the system were at any instant changed to any possible infinitely small velocities, and the accelerations unchanged. This statement, when put into the concise language of mathematical analysis, constitutes Lagrange's application of the "principle of virtual velocities" to express the conditions of D'Alembert's equilibrium between the forces acting and the resistances of the masses to the acceleration. It comprehends, as we have seen, every possible condition of every case of motion. The "equations of motion" in any particular case are, as Lagrange has shown, deduced from it with great ease.

Commencing again with the equations of motion of a particle

$$m\ddot{x}=X+X',\ m\ddot{y}=Y+Y',\ m\ddot{z}=Z+Z',$$

let us introduce quantities δx, &c., consistent with the conditions, otherwise perfectly arbitrary, and we have the general equation

$$\Sigma m(\ddot{x}\delta x+\ .\ .\ .\ )=\Sigma(X\delta x+\ .\ .\ .\ ),$$

in which, by D'Alembert's principle, the forces X′, Y′, Z′, due to the constraints, do not appear.

If the system be conservative the right-hand member of this is, of course, equal to the loss of potential energy, so that

$$-\delta V=\Sigma(X\delta x+\ .\ .\ .\ ),$$

and therefore, quite generally in such a system,

$$\Sigma m(\ddot{x}\delta x+\ .\ .\ .\ )=-\delta V\ .\ \ .\ \ .\ \ .\ \ .\ \ .\ \ (1).$$

In the actual motion of any system we have, for each particle, $\delta x=\dot{x}\delta t$, &c., so that we have

$$\Sigma m(\dot{x}\ddot{x}+\dot{y}\ddot{y}+\dot{z}\ddot{z})=\Sigma(X\dot{x}+Y\dot{y}+Z\dot{z})\,.$$

This is the complete statement of Newton's scholium, § 2 above.

The right-hand member is the expression of the algebraic sum of the *actiones agentium* and of the *reactiones resistentium*, so far as these depend upon gravity, friction, &c., and the left-hand member that of the *reactiones* due to the accelerations of the several particles.

If the system be conservative, this becomes

$$\Sigma m(\dot{x}\ddot{x}+\dot{y}\ddot{y}+\dot{z}\ddot{z})=-\frac{dV}{dt}\,,$$

whose integral

$$\tfrac{1}{2}\Sigma m(\dot{x}^2+\dot{y}^2+\dot{z}^2)+V=H$$

is of course, the general statement of the conservation of energy.

In Lagrange's general equation above, as we have stated, the variations δx, &c., are not usually independent. We must take account of the various constraints imposed on the system. If these retain the same character throughout the motion they may be expressed by a (generally finite) number of equations of the form

$$f(x_1, y_1, z_1, x_2, y_2, z_2, \ldots) = 0 .$$

Each of these gives rise to a purely kinematical relation affecting some one or more of the quantities δx, &c., of the form

$$\Sigma\left(\left(\frac{df}{dx}\right)\delta x + \left(\frac{df}{dy}\right)\delta y + \ldots\right) = 0 .$$

By introducing, as usual, a set of undetermined multipliers μ, one for each of the conditions of constraint, we obtain on adding all these equations to the general equation above

$$\Sigma m(\ddot{x}\delta x + \ldots) = \Sigma\left[\left(X + \mu\left(\frac{df}{dx}\right) + \mu_1\left(\frac{df_1}{dx}\right) + \ldots\right)\delta x + \ldots\right] (2).$$

If there be p particles of the system, there are $3p$ coordinates x, y, z, connected by (say) q equations of constraint, so that there are $3p-q$ degrees of freedom, and therefore $3p-q$ independent coordinates.

Equating separately to zero the multipliers of δx_1, δy_1, &c., in the resultant equation above, we have $3p$ equations of which we write only one as a type, viz.,

$$m\ddot{x} = X + \Sigma\mu\left(\frac{df}{dx}\right) \quad . \quad . \quad . \quad . \quad . \quad . \quad (3).$$

Taken along with the q equations of the form

$$f = 0$$

these form a group of $3p+q$ equations, theoretically necessary and sufficient to determine the $3p$ quantities x_1, y_1, z_1, &c., and the q quantities μ, in terms of t. Thus we have the complete analytical statement of the conditions, and the rest of the solution is a question of pure mathematics.

Non-conservative system. When we deal with a non-conservative system (which is equivalent in nature to saying "when we take an incomplete view of the question"), some of the conditions may vary in character during the motion. This will be expressed analytically by the entrance of t explicitly into one or more of the equations of condition f. But, if we think of the mode of formation of Lagrange's equation, we see that it was built up of separate equations, such as

$$m\ddot{x} = X + X',$$

which are true whether the equations of condition involve t explicitly or not. Each of these was multiplied by a quantity δx, &c., the only limitation on which was that it should be consistent with the conditions of the system at the instant considered, whatever instant that might be. Hence equation (2) still holds good.

When, however, we introduce in that equation multipliers corresponding to the actual motion of the system, so that

$$\delta x = \dot{x}\delta t , \text{ \&c.},$$

we find a remarkably simple expression for the energy given to, or withdrawn from, the system in consequence of the varying conditions. For the unintegrated equation (2) now becomes

$$\frac{d}{dt}\left(\tfrac{1}{2}\Sigma m(\dot{x}^2 + \dot{y}^2 + \dot{z}^2)\right) = \Sigma(X\dot{x} + Y\dot{y} + Z\dot{z}) - \Sigma\mu\left(\frac{df}{dt}\right) ,$$

where the differential coefficient of f is partial. This follows at once from equations of the form

$$\frac{df}{dt} = \left(\frac{df}{dt}\right) + \left(\frac{df}{dx}\right)\dot{x} + \text{\&c.} = 0 ,$$

which are obtained by differentiating the equations of condition with regard to t. When the conditions do not vary, the quantities $\left(\frac{df}{dt}\right)$, &c., all vanish, and we see that the constraint does not alter the energy of the system.

Least and Varying Action.

Action. § 200. To complete our sketch of kinetics of a particle we will now briefly consider the important quantity called "action." This, for a single particle, may be defined either as the space integral of the momentum or as double the time integral of the kinetic energy, calculated from any assumed position of the moving particle, or from an assigned epoch. For a system its value is the sum of its separate values for the various particles of the system. No one has, as yet, pointed out (in the simple form in which it is all but certain that they can be expressed) the true relations of this quantity. It was originally introduced into kinetics to suit the metaphysical necessity that something should be a minimum in the path of a luminous corpuscle (see an extract from Hamilton in the article LIGHT, vol. xiv. p. 598). But there can be little doubt that it is destined to play an important part in the final systematizing of the fundamental laws of kinetics.

The importance of the quantity called action, so far as is at present known, depends upon the two principles of "least action" and of "varying action," the first as old as Maupertuis, the other discovered by Hamilton about half a century ago.

The first is—*If the sum of the potential and kinetic energies of a system is the same in all its configurations, then, of all the sets of paths by which the parts of the system can be guided by frictionless constraint to pass from one given configuration to another, that one for which the action is least is the natural one or requires no constraint.* Least action.

§ 201. Unfortunately it is not easy to give examples of this important principle which can be satisfactorily treated by elementary methods,—except, indeed, the very simplest, such as those furnished by the corpuscular theory of light. Thus it is obvious that, as long as a medium is homogeneous and isotropic, the speed of a corpuscle in it is constant. The action is thus reduced to the product of the constant speed of the corpuscle by the length of its path. Hence the principle at once shows that the path must be a straight line. When the corpuscle is refracted from one such medium into another, the path is a broken line such that the product of each of its parts by the corresponding speed of the corpuscle is the least possible. This gives the law of the sines, but to agree with experiment the speed would have to be greater in the denser medium than in the rarer.

§ 202. The problem *to find change of action as depending on change (nowhere finite) of the mode of passage from one given configuration to another* (restricted by the condition already mentioned), is expressed mathematically by Change of action.

$$\delta A = \delta\int\Sigma m\dot{s}ds = \delta\int\Sigma m(\dot{x}dx + \dot{y}dy + \dot{z}dz) ,$$

while $\quad T = \tfrac{1}{2}\Sigma m\dot{s}^2 = \tfrac{1}{2}\Sigma m(\dot{x}^2 + \dot{y}^2 + \dot{z}^2) = H - V ,$

H being the constant energy of the system, and the integral being taken between limits supplied by the two given configurations.

The first equation gives

$$\delta A = \int\Sigma m(dx\delta\dot{x} + dy\delta\dot{y} + dz\delta\dot{z} + \dot{x}d\delta x + \dot{y}d\delta y + \dot{z}d\delta z)$$
$$= \Sigma m(\dot{x}\delta x + \ldots) + \int\Sigma m(dx\delta\dot{x} + dy\delta\dot{y} + dz\delta\dot{z} - d\dot{x}\delta x - d\dot{y}\delta y - d\dot{z}\delta z)$$

by partial integration. But the integrated part

$$\Sigma m(\dot{x}\delta x + \dot{y}\delta y + \dot{z}\delta z), \quad . \quad . \quad . \quad . \quad . \quad . \quad (A)$$

obviously vanishes at both limits, because the initial and final configurations are given.

If we now take the corresponding variation of the expressions for the kinetic energy, we have

$$\delta T = \Sigma m\dot{s}\delta\dot{s} = \Sigma m(\dot{x}\delta\dot{x} + \dot{y}\delta\dot{y} + \dot{z}\delta\dot{z}),$$

from which we have

$$\int\Sigma m(dx\delta\dot{x} + dy\delta\dot{y} + dz\delta\dot{z}) = \int\delta T dt .$$

Also we have

$$d\dot{x}\delta x + d\dot{y}\delta y + d\dot{z}\delta z = (\ddot{x}\delta x + \ddot{y}\delta y + \ddot{z}\delta z)dt ;$$

so that finally

$$\delta A = \int dt\left[\delta T - \Sigma m(\ddot{x}\delta x + \ddot{y}\delta y + \ddot{z}\delta z)\right] ,$$

which so far is a mere kinematical result. But it can be rendered physical by putting $-\delta V$ for δT, in accordance with the above condition. This we will suppose done.

If now we desire to make δA vanish, so as to obtain what is called the "stationary condition," we must make the factor in square brackets in the integral vanish; *i.e.*, we must have

$$\Sigma m(\ddot{x}\delta x + \ddot{y}\delta y + \ddot{z}\delta z) + \delta V = 0$$

for all admissible simultaneous values of δx, δy, δz for the various particles of the system. But this is precisely the general equation which, as we found in § 199 (1), determines the undisturbed motion of the system.

§ 203. The expression $\delta A = 0$ really signifies that any infinitesimal change from the natural mode of passage produces an infinitely smaller change in the corresponding amount of the action between the terminal configurations. Stationary action.

§ 204. It will be noticed that the essential characteristic of the modes of passage considered in this investigation is that all shall have the same terminal configurations, and that the system shall

Varying action.

always have the same definite amount of energy. All, except the natural mode of passage, in general require constraint in order that they may be described. Hamilton's grand extension of the subject depended on comparing the actions in a number of *natural* modes of passage, differing from one another by slight changes in their terminal configurations, and slight changes in the whole initial energy.

In this new form of statement the unintegrated part of the expression for δA vanishes, since all the modes of passage contemplated are natural. The alteration of the whole energy, however, adds a special term to the equation, and we can at once write, from the expression (A) § 202, the equation for the change in the action under the new conditions, viz.,

$$\delta A = \left[\Sigma m(\dot{x}\delta x + \dot{y}\delta y + \dot{z}\delta z)\right] + t\delta H,$$

the part in brackets having to be taken between limits corresponding to the terminal configurations, and the variations δx, δy, δz at these being subject to the conditions of the system.

We cannot here consider this equation in its general form. We content ourselves with the simpler special deductions from it required for completing our sketch of Kinetics of a Particle.

The last given equation, written in full for a single particle of unit mass, is

$$\delta A = [\dot{x}\delta x + \dot{y}\delta y + \dot{z}\delta z] - (\dot{x}_0\delta x_0 + \dot{y}_0\delta y_0 + \dot{z}_0\delta z_0) + t\delta H,$$

where x_0, y_0, z_0 is the initial point, and x, y, z any other point, of the path. If the particle be altogether free, the seven variations on the right-hand side are independent of one another; and thus we have the following remarkable properties of the quantity A, regarded as a function of seven independent variables (the initial and final coordinates of the particle, and its constant energy), viz.,

$$\left(\frac{dA}{dx}\right) = \frac{dx}{dt}, \quad \left(\frac{dA}{dx_0}\right) = -\frac{dx_0}{dt},$$

$$\left(\frac{dA}{dy}\right) = \frac{dy}{dt}, \quad \left(\frac{dA}{dy_0}\right) = -\frac{dy_0}{dt},$$

$$\left(\frac{dA}{dz}\right) = \frac{dz}{dt}, \quad \left(\frac{dA}{dz_0}\right) = -\frac{dz_0}{dt},$$

$$\left(\frac{dA}{dH}\right) = t.$$

From these we gather at once that A satisfies the partial differential equations

$$\left(\frac{dA}{dx}\right)^2 + \left(\frac{dA}{dy}\right)^2 + \left(\frac{dA}{dz}\right)^2 = v^2 = 2(H - V) \quad . \quad . \quad (1),$$

$$\left(\frac{dA}{dx_0}\right)^2 + \left(\frac{dA}{dy_0}\right)^2 + \left(\frac{dA}{dz_0}\right)^2 = v_0^2 = 2(H - V_0) \quad . \quad . \quad (2).$$

Characteristic function.

§ 205. The whole circumstances of the motion are thus dependent on the function A, called by Hamilton the "characteristic function." The determination of this function is troublesome, even in very simple cases of motion; but the fact that such a mode of representation is possible is extremely remarkable.

§ 206. More generally, omitting all reference to the initial point, and the equation § 204 (2) which belongs to it, let us consider A simply as a function of x, y, z. Then

Any function, A, which satisfies the partial differential equation

$$\left(\frac{dA}{dx}\right)^2 + \left(\frac{dA}{dy}\right)^2 + \left(\frac{dA}{dz}\right)^2 = v^2 = 2(H - V) \quad . \quad . \quad . \quad (1),$$

possesses the property that $\frac{dA}{dx}, \frac{dA}{dy}, \frac{dA}{dz}$ *represent the rectangular components of the velocity of a particle in a motion possible under the forces whose potential is V.*

For, by partial differentiation of (1) we have

$$\frac{d}{dt}\left(\frac{dx}{dt}\right) = \frac{d^2x}{dt^2} = X = -\frac{dV}{dx} = \frac{dA}{dx}\frac{d^2A}{dx^2} + \frac{dA}{dy}\frac{d^2A}{dxdy} + \frac{dA}{dz}\frac{d^2A}{dxdz},$$

with other two equations of the same form.

But we have also three equations of the form

$$\frac{d}{dt}\left(\frac{dA}{dx}\right) = \frac{dx}{dt}\frac{d^2A}{dx^2} + \frac{dy}{dt}\frac{d^2A}{dxdy} + \frac{dz}{dt}\frac{d^2A}{dxdz}.$$

Comparing, we see that

$$\frac{dx}{dt} = \frac{dA}{dx}, \quad \frac{dy}{dt} = \frac{dA}{dy}, \quad \frac{dz}{dt} = \frac{dA}{dz}$$

satisfy simultaneously the two sets of equations.

§ 207. Also if α, β be constants, which, along with H, are involved in a complete integral of the above partial differential equation *the corresponding path, and the time of its description, are given by*

$$\left(\frac{dA}{d\alpha}\right) = \alpha_1, \quad \left(\frac{dA}{d\beta}\right) = \beta_1, \quad \left(\frac{dA}{dH}\right) = t + \epsilon,$$

where α_1, β_1, ϵ *are three additional arbitrary constants.*

For these equations give, by complete differentiation with regard to t,

$$\left.\begin{aligned} \frac{d^2A}{dxd\alpha}\frac{dx}{dt} + \frac{d^2A}{dyd\alpha}\frac{dy}{dt} + \frac{d^2A}{dzd\alpha}\frac{dz}{dt} &= 0 \\ \frac{d^2A}{dxd\beta}\frac{dx}{dt} + \frac{d^2A}{dyd\beta}\frac{dy}{dt} + \frac{d^2A}{dzd\beta}\frac{dz}{dt} &= 0 \\ \frac{d^2A}{dxdH}\frac{dx}{dt} + \frac{d^2A}{dydH}\frac{dy}{dt} + \frac{d^2A}{dzdH}\frac{dz}{dt} &= 1 \end{aligned}\right\} \quad . \quad . \quad . \quad (a).$$

But, differentiating § 206 (1) with respect to α, β, H respectively, we get

$$\left.\begin{aligned} \frac{d^2A}{d\alpha dx}\frac{dA}{dx} + \frac{d^2A}{d\alpha dy}\frac{dA}{dy} + \frac{d^2A}{d\alpha dz}\frac{dA}{dz} &= 0 \\ \frac{d^2A}{d\beta dx}\frac{dA}{dx} + \frac{d^2A}{d\beta dy}\frac{dA}{dy} + \frac{d^2A}{d\beta dz}\frac{dA}{dz} &= 0 \\ \frac{d^2A}{dHdx}\frac{dA}{dx} + \frac{d^2A}{dHdy}\frac{dA}{dy} + \frac{d^2A}{dHdz}\frac{dA}{dz} &= 1 \end{aligned}\right\} \quad . \quad . \quad . \quad (b).$$

The values of $\frac{dx}{dt}$, &c., in (a) are evidently equal respectively to those of $\frac{dA}{dx}$, &c., in (b). Hence the proposition.

§ 208. "Equiactional surfaces," *i.e.*, those whose common equation is — Surfaces of equal action.

$$A = \text{const.},$$

are cut at right angles by the trajectories.

For the direction cosines of the normal are obviously proportional to

$$\left(\frac{dA}{dx}\right), \left(\frac{dA}{dy}\right), \left(\frac{dA}{dz}\right), \text{ that is, to } \frac{dx}{dt}, \frac{dy}{dt}, \frac{dz}{dt}.$$

Thus the determination of equiactional surfaces is resolved into the problem of finding the orthogonal trajectories of a set of given curves in space, whenever the conditions of the motion are given.

The distance between consecutive equiactional surfaces is, at any point, inversely as the velocity in the corresponding path.

This may be seen at once as follows: the element of the action, which is the same at all points, is $v\delta s$ (where δs, being an element of the path, is the normal distance between the surfaces).

§ 209. In consequence of the importance of the method we will take two examples of its application. First a direct example, then one depending on the equiactional surfaces. — Planetary motion.

To deduce from the principle of "varying action" the form and mode of description of a planet's orbit.

In this case it is obvious that $-\frac{dV}{dr}$ represents the attraction of gravity ($-\mu/r^2$). Hence the right-hand member of § 206 (1) may be written $2(H + \mu/r)$.

Let us take the plane of xy as that of the orbit, then the equation § 206 (1) becomes

$$v^2 = \left(\frac{dA}{dx}\right)^2 + \left(\frac{dA}{dy}\right)^2 = 2\left(H + \frac{\mu}{r}\right) \quad . \quad . \quad . \quad . \quad (1).$$

It is not difficult to obtain a satisfactory solution of this equation, but the operation is very much simplified by the use of polar coordinates. With this change, (1) becomes

$$\left(\frac{dA}{dr}\right)^2 + \frac{1}{r^2}\left(\frac{dA}{d\theta}\right)^2 = 2\left(H + \frac{\mu}{r}\right) \quad . \quad . \quad . \quad . \quad (2),$$

which is obviously satisfied by

$$\left.\begin{aligned} \left(\frac{dA}{d\theta}\right) &= \text{constant} = \alpha, \\ \left(\frac{dA}{dr}\right)^2 &= 2\left(H + \frac{\mu}{r}\right) - \frac{\alpha^2}{r^2} \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad (3).$$

Hence $$A = \alpha\theta + \int dr\sqrt{2(H + \mu/r) - \alpha^2/r^2} \quad . \quad . \quad . \quad . \quad (4).$$

The final integrals are therefore, by § 207,

$$\left(\frac{dA}{d\alpha}\right) = \alpha_1 = \theta - \alpha\int\frac{dr}{r^2\sqrt{2(H + \mu/r) - \alpha^2/r^2}} \quad . \quad . \quad . \quad (5),$$

and $$\left(\frac{dA}{dH}\right) = t + \epsilon = \int\frac{dr}{\sqrt{2(H + \mu/r) - \alpha^2/r^2}} \quad . \quad . \quad . \quad (6).$$

These equations contain the complete solution of the problem, for they involve four constants, α_1, α, H, ϵ. (5) gives the equation of the orbit, and (6) the time in terms of the radius-vector.

To complete the investigation, let us assume

$$\mu/\alpha^2 = 1/l, \qquad 2H/\alpha^2 = (e^2 - 1)/l^2,$$

where l and e are two new arbitrary constants introduced in place of α and H. With these (5) becomes

$$\alpha_1=\theta-\int\frac{dr}{r^2\sqrt{(e^2-1)/l^2+2/lr-1/r^2}}$$

$$=\theta-\int\frac{dr}{r^2\sqrt{e^2/l^2-(1/r-1/l)^2}}=\theta-\cos^{-1}\frac{l}{e}(r^{-1}-l^{-1}),$$

or

$$r=\frac{l}{1+e\cos(\theta-\alpha_1)},$$

the general polar equation of conic sections referred to the focus.

Also by differentiating (5) with respect to r, we have

$$\frac{\alpha dr}{r^2\sqrt{2(\mathrm{H}+\mu/r)-\alpha^2/r^2}}=d\theta,$$

from which, by (6), we immediately obtain

$$t+\epsilon=\frac{1}{\alpha}\int r^2d\theta=\frac{1}{\sqrt{\mu l}}\int r^2 d\theta.$$

This involves, again, the equation of equable description of areas. Compare § 144.

Action in orbit of planet. § 210. In a planet's elliptic orbit *the time is measured by the area described about one focus, and the action by that described about the other.*

For with the usual notation we have

$$d\mathrm{A}=vds=\frac{h}{p}ds,$$

by the result of § 47. But in the ellipse or hyperbola, p' being the perpendicular from the second focus,

$$pp'=\pm b^2.$$

Hence

$$d\mathrm{A}=\pm\frac{h}{b^2}p'ds,$$

which expresses the result stated above.

It is easy to extend this to a parabolic orbit, for which, indeed, the theorem is even more simple.

Example. § 211. *Unit particles are projected simultaneously and horizontally in all directions from every point of a vertical axis, all having the same total energy at starting; find the surfaces of equal action.*

We may obviously confine ourselves to a plane section through the axis. Let x be the vertical coordinate of a particle, measured downwards from the level at which the common energy is wholly potential, k the coordinate of the point in the axis from which it was projected. Then we have, after the lapse of time t,

$$\left.\begin{aligned}x&=k+\tfrac{1}{2}gt^2\\ y&=\sqrt{2gk}\,t\end{aligned}\right\}.$$

Eliminating t, we have the equation of the parabolic path—

$$x=k+\frac{y^2}{4k}.$$

To find the orthogonal trajectory (the meridian section of the surface of equal action), differentiate, put $-\frac{dx}{dy}$ for $\frac{dy}{dx}$, and eliminate k. We thus have

$$-\frac{dy}{dx}=\frac{y}{2k}=\frac{y}{x+\sqrt{x^2-y^2}}=\frac{\sqrt{x+y}-\sqrt{x-y}}{\sqrt{x+y}+\sqrt{x-y}}$$

or

$$-\sqrt{x+y}(dx+dy)+\sqrt{x-y}(dx-dy)=0,$$

so that

$$(x+y)^{\frac{3}{2}}\pm(x-y)^{\frac{3}{2}}=\text{const}.$$

If we turn the axes through $\frac{1}{4}\pi$ in their own plane, the coordinates being now ξ and η, this equation becomes

$$\xi^{\frac{2}{3}}+\eta^{\frac{2}{3}}=a^{\frac{2}{3}}.$$

In fig. 55, AM is the axis. A few of the paths are shown by full lines, and two of the sections of surfaces of equal action by dotted lines. These sections indicate cusps lying on the line AH, which makes an angle $\frac{1}{4}\pi$ with the vertical, and is touched by all the paths. The path whose vertex is G touches this line in H, and therefore passes through the cusp of which the branches are HK and HL. HK belongs to all paths whose vertices are above G, HL to those (such as ML) whose vertices are below G.

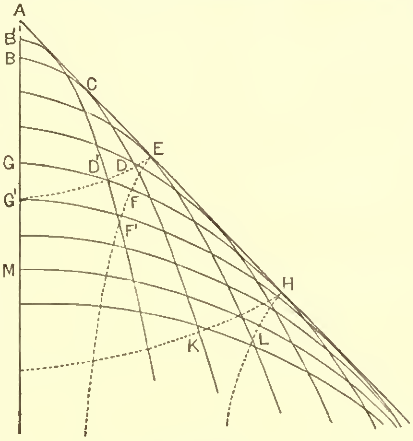

Fig. 55.

It is worthy of note that, by the first equations above,

$$x\pm y=(\sqrt{k}\pm\sqrt{\tfrac{1}{2}g}.t)^2,$$

by the substitution of which in the equation of action we see how the time of reaching a particular surface of equal action depends upon the position of the starting point.

Plane currents. § 212. A very interesting plane example, which has elegant applications in fluid motion, and in the conduction of electric currents in plates of uniform thickness, is furnished by assuming

$$\mathrm{A}=\log r,\ \text{or}\ \mathrm{A}'=\theta,$$

where r and θ are the polar coordinates of the moving particle.

In the former, where the curves of equal action are circles with the origin as centre, we have

$$\frac{d\mathrm{A}}{dx}=\dot{x}=\frac{x}{r^2},\qquad \frac{d\mathrm{A}}{dy}=\dot{y}=\frac{y}{r^2},$$

so that the paths are radii vectores described with velocity $1/r$. Also we have

$$2(\mathrm{H}-\mathrm{V})=\left(\frac{d\mathrm{A}}{dx}\right)^2+\left(\frac{d\mathrm{A}}{dy}\right)^2=\frac{1}{r^2};$$

so that the force is central, and its value is

$$-\frac{d\mathrm{V}}{dr}=-\frac{1}{r^3}.$$

In the second case, where the curves of equal action are radii drawn from the pole and

$$\mathrm{A}'=\theta=\tan^{-1}\frac{y}{x},$$

we have

$$\frac{d\mathrm{A}'}{dx}=\dot{x}=-\frac{y}{r^2},\quad \frac{d\mathrm{A}'}{dy}=\dot{y}=\frac{x}{r^2}.$$

The kinetic energy is still $1/2r^2$, and the central force $-1/r^3$, but the paths are circles with the origin as centre. Thus the lines of equal action and the paths of individual particles are convertible.

We have also, in each of these cases,

$$\left(\frac{d\dot{x}}{dx}\right)+\left(\frac{d\dot{y}}{dy}\right)=0.$$

This shows (as in § 94) that, whatever be originally the grouping of a set of particles moving all according to one or other of these conditions, the density at any part of the group remains unchanged during the motion. In fact, as it is easy to prove, A and A′ are elementary solutions of the partial differential equation

$$\frac{d^2\mathrm{A}}{dx^2}+\frac{d^2\mathrm{A}}{dy^2}=0\quad .\ .\ .\ .\ .\ .\ .\quad (1);$$

and they are conjugate, in the sense that

$$\frac{d\mathrm{A}}{dx}=\frac{d\mathrm{A}'}{dy},\quad \frac{d\mathrm{A}}{dy}=-\frac{d\mathrm{A}'}{dx}.$$

For this reason the paths belonging to the two systems are everywhere orthogonal to one another.

Also, as the differential equation (1) for A is linear, any linear function of particular integrals is an integral. Thus, for instance, we may take (p being any constant)

$$\mathrm{A}=\log r-p\theta,$$

with

$$\mathrm{A}'=p\log r+\theta.$$

These, representing orthogonal sets of logarithmic spirals, possess the same properties with regard to action as did the concentric circles and their radii, which, in fact, are the mere particular case when $p=0$.

Graphic method. § 213. It is easy to give graphic methods of tracing these curves of action by means of an old process recently much developed by Clerk Maxwell. The present example, though a very simple one, is quite sufficient to illustrate the process.

Draw, as in fig. 56, a set of circles whose radii are ε^{a}, ε^{2a}, ε^{3a}, &c., and a set of radii vectores making with the initial line the successive angles, $\frac{a}{p}$, $2\frac{a}{p}$, $3\frac{a}{p}$, &c., a being a quantity which may have any convenient value. These lines will form a network, finer as a is smaller. Now suppose we wish to trace the curve

$$\mathrm{A}=na.$$

We take the intersection of the circle whose radius is ε^{sa} with the radius-vector corresponding to the angle

$$(s-n)\frac{a}{p}.$$

Thus we have for the value of A at the point of intersection

$$\mathrm{A}=\log\varepsilon^{sa}-p\frac{s-n}{p}a$$

$$=na,\ \text{as required}.$$

By marking the intersections corresponding to different values of s, we have a series of points in the required curve which, by adjustment of the value of a, may be made to lie as close together as is found necessary for tracing the curve of action through them *libera manu*.

In fig. 56 portions of three separate sets of mutually orthogonal logarithmic spirals have been traced, by using the intersections of the fundamental straight lines and circles.

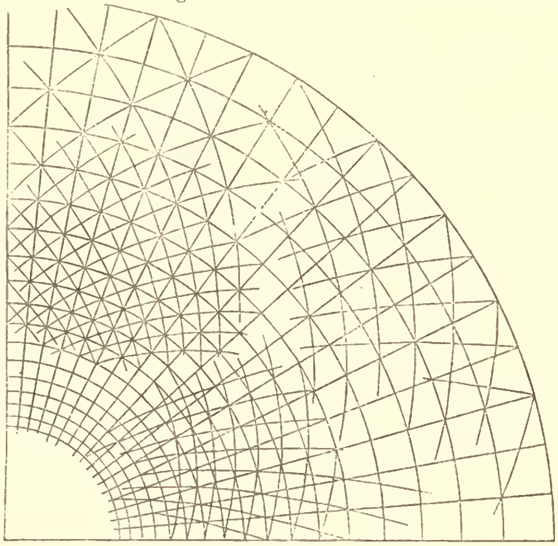

Fig. 56.

We may pursue the subject much farther, by combining particular solutions like those given but taken from different origins. We can afford space for one only. Let P, Q (fig. 57) be points on the axis of x, distant a and $-a$ from the origin, R any point in the plane of the figure. Let $PR=r$, $\angle RPx=\theta$, $RQ=r_1$, $\angle RQx=\theta_1$. Then if

$$A=\log r-\log r_1\,,$$
$$A'=\theta-\theta_1\,,$$

we must have, not only the equation

$$\frac{d^2A}{dx^2}+\frac{d^2A}{dy^2}=0$$

satisfied by each of A and A′, but also the conditions

$$\frac{dA}{dx}=\frac{dA'}{dy}\,,\quad \frac{dA}{dy}=-\frac{dA'}{dx}\,.$$

This follows at once from the fact that all the equations are linear.

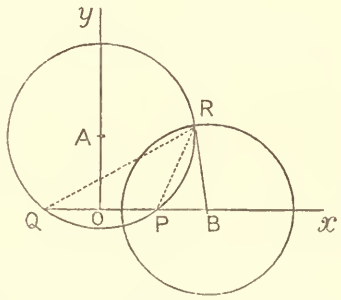

Fig. 57.

§ 214. In fig. 57 we have $\epsilon^A=PR/QR$. Hence the locus of R is a circle, whose centre, B, is on QP produced.

Again $A'=\angle RPx-\angle RQx=\angle PRQ$. The locus of R is, in this case, any circle passing through P and Q.

These circles evidently cut one another orthogonally in R; for BR, which is a radius of the one, is a tangent to the other.

Thus particles moving in a plane, so that the speed at any point R is inversely as PR . RQ, may describe circles in which PQ is a chord. In this case the curves of equal action are circles defined by the condition that the ratio PR : RQ is constant. Or they may move in the latter system of circles, in which case the former system gives the lines of equal action. For the equations in the preceding section give

$$v^2=\left(\frac{dA}{dx}\right)^2+\left(\frac{dA}{dy}\right)^2=\left(\frac{dA'}{dx}\right)^2\quad\left(\frac{dA'}{dy}\right)^2=\frac{4a^2}{r^2r_1^2}\,;$$

from which the conclusion is obvious.

We may easily extend this example to other sets of orthogonal curves whose equations are

$$A_1=pA+A',$$
$$A_1'=-A+pA',$$

where A and A′ have their recent values. Or we may extend the example by assuming at starting

$$A=m\log r-m_1\log r_1\,,$$

in which case it will be found that we must have

$$A'=m\theta-m_1\theta_1\,.$$

These pairs may again be combined into

$pA+A'$ and $-A+pA'$, and so on.

It will be noticed that in these examples the curves of equal action and the paths of the particles correspond in steady fluid motion to curves of equal pressure and lines of flow, and in electric conduction to equipotential lines and current lines. In such cases in fact, where there is no vortex-motion, the action is closely analogous to what is called the "velocity potential" in a fluid. Analogy between action and velocity potential.

Generalized Coordinates.

§ 215. By the help of the result already obtained in connexion with least action, we may easily obtain in a simple, though indirect, way the remarkable transformation of the equations of motion of a system which was first given by Lagrange. We are not prepared to give here the transformation to *Generalized Coordinates* in its most general form; but, even in the restricted form to which we proceed, it is almost invaluable in the treatment of the motion of conservative systems of particles in which the number of degrees of freedom is less than three times that of the particles. The one point to be noticed is that, when we restrict ourselves to a system of this kind, the expression for the kinetic energy, T, is necessarily a pure quadratic function of the rates of increase of the generalized coordinates. This is obvious from § 19. Repeating with generalized coordinates the investigation of § 202, we have Generalized coordinates.

$$A=2\int Tdt=\int(T+H-V)dt.$$

Hence
$$\delta A=\int(\delta T+\delta H-\delta V)dt\,.$$

Now let θ, ϕ, ψ, &c., be the generalized coordinates, and we have

$$2T=P\dot\theta^2+2Q\dot\theta\dot\phi+R\dot\phi^2+\;.\;.\;.\;.\;.\;.\;.\;.\;.\;.$$

where P, Q, R, . . . are in general functions of θ, ϕ, ψ, . . . Of course V is a function of θ, ϕ, ψ . . . alone, and does not involve $\dot\theta$, $\dot\phi$, $\dot\psi$, &c.

Thus we have, writing for one only of the generalized coordinates,

$$\delta A=\Sigma\int\left(\left(\frac{dT}{d\dot\theta}\right)\delta\dot\theta+\left(\frac{dT}{d\theta}\right)\delta\theta-\left(\frac{dV}{d\theta}\right)\delta\theta\right)dt+t\delta H$$

$$=\Sigma\left(\frac{dT}{d\dot\theta}\delta\theta\right)+t\delta H-\int dt\Sigma\left[\left(\frac{d}{dt}\left(\frac{dT}{d\dot\theta}\right)-\frac{dT}{d\theta}+\frac{dV}{d\theta}\right)\delta\theta\right]\,.$$

But we saw that, for any natural motion, the unintegrated part of δA necessarily vanishes. Thus, as θ, ϕ, ψ . . . . , and, therefore, their variations, are by their very nature independent of one another, the vanishing of the unintegrated part gives us one equation of motion for each degree of freedom, the type being in all of them the same, viz.,

$$\frac{d}{dt}\left(\frac{dT}{d\dot\theta}\right)-\left(\frac{dT}{d\theta}\right)+\left(\frac{dV}{d\theta}\right)=0.$$

To exemplify the use of these equations we will take again a few of the more important cases of constraint already treated, and will then proceed to some others of interest as well as of somewhat greater complexity. Examples.

In the simple pendulum, l being again the length of the string, and θ the inclination to the vertical at time t, we have obviously

$$T=\tfrac{1}{2}ml^2\dot\theta^2,\quad V=C-mgl\cos\theta\,.$$

Hence
$$\left(\frac{dT}{d\dot\theta}\right)=ml^2\dot\theta\,,\quad\left(\frac{dT}{d\theta}\right)=0\,,\quad\left(\frac{dV}{d\theta}\right)=mgl\sin\theta\,.$$

Thus the equation of motion is

$$ml^2\ddot\theta+mgl\sin\theta=0$$

or
$$\ddot\theta+\frac{g}{l}\sin\theta=0\,,$$

as in § 134.

Suppose the same pendulum to be moving anyhow, θ still denoting its inclination to the vertical, and ϕ denoting the azimuth of the plane in which it is displaced, we have

$$T=\tfrac{1}{2}ml^2(\dot\theta^2+\sin^2\theta.\dot\phi^2)\,,\quad V=C-mgl\cos\theta$$

These give at once

$$\left(\frac{dT}{d\dot\theta}\right)=ml^2\dot\theta,\quad\left(\frac{dT}{d\theta}\right)=ml^2\sin\theta\cos\theta.\dot\phi^2,\quad\left(\frac{dV}{d\theta}\right)=mgl\sin\theta\,,$$

$$\left(\frac{dT}{d\dot\phi}\right)=ml^2\sin^2\theta.\dot\phi,\quad\left(\frac{dT}{d\phi}\right)=0,\quad\left(\frac{dV}{d\phi}\right)=0.$$

Hence the two equations are

$$\ddot\theta-\sin\theta\cos\theta.\dot\phi^2+\frac{g}{l}\sin\theta=0\,,$$

$$\frac{d}{dt}(\sin^2\theta.\dot\phi)=0.$$

Pendulum with extensible cord. Still keeping to easy examples, suppose the cord of the ordinary simple pendulum to be extensible, according to Hooke's law. Let λ be its length at time t. Then the tension is $E(\lambda - l)/l$, and the work it can do in contracting is the integral of this with regard to λ from l to λ, *i.e.*,

$$E(\lambda - l)^2/2l .$$

Hence we have
$$V = C + E(\lambda - l)^2/2l - mg\lambda\cos\theta ,$$
$$T = \tfrac{1}{2}m(\lambda^2\dot\theta^2 + \dot\lambda^2) .$$

Thus Lagrange's equations become

$$\frac{d}{dt}(\lambda^2\dot\theta) + g\lambda\sin\theta = 0 ,$$
$$m\ddot\lambda - m\lambda\dot\theta^2 + E(\lambda - l)/l - mg\cos\theta = 0 ;$$

equations which could be obtained immediately from the application of the second law, with the help of the kinematical expressions for acceleration perpendicular to, and along, the radius-vector of a plane curve (§ 47).

Instead of the complex pendulum treated in § 177, we will now take the case of two masses attached at different points to an elastic string, or light helical spring, and consider their *vertical* vibrations.

Let a, b be the unstretched lengths of the parts of the string, M and m the masses. Then if ξ, η be the vertical displacements at time t, we have

$$T = \tfrac{1}{2}(M\dot\xi^2 + m(\dot\xi + \dot\eta)^2) ,$$
$$V = \frac{E}{2}\left(\frac{\xi^2}{a} + \frac{\eta^2}{b}\right) - Mg\xi - mg(\xi + \eta) ;$$

so that Lagrange's equations are

$$\frac{d}{dt}(M\dot\xi + m(\dot\xi + \dot\eta)) + E\frac{\xi}{a} - (M + m)g = 0 ,$$
$$\frac{d}{dt}(m(\dot\xi + \dot\eta)) + E\frac{\eta}{b} - mg = 0 .$$

The equilibrium positions are found by supposing the accelerations to vanish, so that, if we suppose ξ and η to be measured from them, the terms in g will disappear. Hence the solution is of exactly the same nature as that already given for an apparently different problem (§ 178).

Setting a watch. We may mention that equations practically the same as these are obtained when we consider the motions of a watch and its balance-wheel, the watch being supported in a horizontal position by means of a wire, and oscillating in its own plane by the torsion-elasticity of the wire. The reader of § 242 below will have no difficulty in obtaining this result. It suggests a practical method of "setting" a watch to true time, without turning the hands forward or backward, and without letting it run down.

Transference of energy. The following is a simple, but very instructive, example of the transference of energy (back and forward) between two parts of a system. Two bar-magnets of equal mass, length, and strength (fig. 58), are supported horizontally by pairs of parallel strings, so that when at rest they are in one line. One of them is slightly displaced in the direction of its length, find the subsequent motion of both.[1]

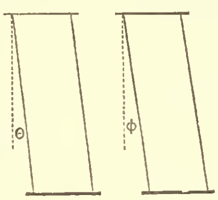

Fig. 58.

If we can, by any process, find two fundamental states of motion which, once established, will be permanent, any other possible motion of the system will be a superposition of these two. The amplitudes and phases in the components may have any values, so long as the whole disturbance is small. This follows from the fact that the system has two degrees of freedom only,—since we are concerned only with motions in the plane of the figure.

(A) Now one obviously possible motion is a simple harmonic vibration of the whole, without change of distance between the magnets. The period of this vibration is obviously the same as that of either magnet if the other were removed.

(B) Another obviously possible motion is that in which the magnets are, at every instant, equally and oppositely deflected. The period of this oscillation will be less or greater than that of the former according as the poles attract or repel one another.

[1] We suppose the bars to be so long, in comparison with the distance between them, that we need take account only of the action of their poles which are turned towards one another.

Now the initial state of motion proposed evidently consists of the superposition of (A) and (B) in such a way that there is, at starting, no displacement of either mass, but a definite velocity of one of them only. This corresponds to simultaneous zero of displacement, with equal velocities, for each of (A) and (B). There is therefore at that instant no displacement of either mass; and one is at rest while the other is moving with double the assigned velocity. If $2\pi/n$, $2\pi/n'$ be the periods of the two motions, it is obvious that after the time $\pi/(n - n')$ the magnets will have interchanged their states so that the arrangement will present exactly the same appearance as at first, *if looked at from the other side.*

Let a be the distance between the ends of the bars when all four strings are vertical. Then, if θ, ϕ be at time t the inclinations of the pairs of strings to the vertical, a becomes

$$D = a + l(\phi - \theta) ,$$

where l is the common length of the strings. The expression for the potential energy due to magnetism is of the form μ/D, where μ is positive if like poles be turned to one another.

Hence

$$T = \tfrac{1}{2}ml^2(\dot\theta^2 + \dot\phi^2) ,$$
$$V = \tfrac{1}{2}mgl(\theta^2 + \phi^2) + \frac{\mu}{a + l(\phi - \theta)} .$$

Forming the equations as usual, and omitting powers of θ and ϕ above the first, we have

$$ml^2\ddot\theta = -mgl\theta + \frac{\mu l}{a^2}\left(1 - \frac{2l}{a}(\phi - \theta)\right) ,$$
$$ml^2\ddot\phi = -mgl\phi - \frac{\mu l}{a^2}\left(1 - \frac{2l}{a}(\phi - \theta)\right) ;$$

from which the results already given may be deduced.

Atwood's machine. Finally, let us take the case of Atwood's machine (§ 173) when the masses are equal, and one of them is vibrating through small arcs.

One mass vibrating. Let r, θ be the polar coordinates of the vibrating mass; then, neglecting powers of θ higher than the second, we have the generalized equations

$$2\ddot r - r\dot\theta^2 = -\tfrac{1}{2}g\theta^2 ,$$
$$\frac{d}{dt}(r^2\dot\theta) = -gr\theta .$$

Put $\tfrac{1}{2}gr$ for r, and $\theta\sqrt{2}$ for θ, and we get

$$\ddot r - r\dot\theta^2 = -\theta^2 ,$$
$$\frac{1}{r}\frac{d}{dt}(r^2\dot\theta) = -2\theta .$$

Transform to rectangular coordinates in the plane of motion, x being vertically downwards; then

$$\ddot x = y^2/x^2 , \qquad \ddot y = -2y/x .$$

This shows that the vertical acceleration of the vibrating particle is very small, but constantly downward. Hence the energy of the vibratory motion is steadily converted into energy of translation of the masses.

When both the equal masses vibrate through small arcs, it is found that the mass whose angular range is the greater has downward acceleration with diminishing angular range. Hence it would appear that, if the string be long enough, the entire motion would be periodic.

§ 216. Before leaving this subject we may form, from the complete value of δA given in last section, the generalized equations corresponding to those of Hamilton's "varying action," as given in § 204.

We have at once

$$\left(\frac{dA}{d\theta}\right) = \left(\frac{dT}{d\dot\theta}\right) , \left(\frac{dA}{d\phi}\right) = \left(\frac{dT}{d\dot\phi}\right) , \ . \ . \ . \ , \left(\frac{dA}{dH}\right) = t .$$

But, by the value of T, we have

$$\left(\frac{dT}{d\dot\theta}\right) = P\dot\theta + Q\dot\phi + \ . \ . \ .$$
$$\left(\frac{dT}{d\dot\phi}\right) = Q\dot\theta + R\dot\phi + \ . \ . \ .$$
$$\&c. = \&c.$$

These equations give θ, ϕ, . . . as homogeneous linear functions of $\left(\frac{dT}{d\dot\theta}\right)$, $\left(\frac{dT}{d\dot\phi}\right)$, . . . that is, of $\left(\frac{dA}{d\theta}\right)$, $\left(\frac{dA}{d\phi}\right)$, . . . Thus, if we substitute these expressions in the equation

$$2T = \Sigma\left[\dot\theta\left(\frac{dT}{d\dot\theta}\right)\right] = \Sigma\left[\dot\theta\left(\frac{dA}{d\theta}\right)\right],$$

which is obviously true, because T is a homogeneous function of $\dot\theta$, $\dot\phi$, . . . of the second degree, we have a partial differential equation of the form

$$p\left(\frac{dA}{d\theta}\right)^2 + 2q\left(\frac{dA}{d\theta}\right)\left(\frac{dA}{d\phi}\right) + r\left(\frac{dA}{d\phi}\right)^2 + \;.\;\;. = 2(H - V),$$

from which A is to be found.

The coefficients p, q, r . . . are, in general, like P, Q, R, . . . functions of θ, ϕ, . . .

As an illustration, take again the example in last section, where two masses are attached to a helical spring, and vibrate in a vertical line. From the value of T there given we have

$$\left(\frac{dA}{d\xi}\right) = \left(\frac{dT}{d\dot\xi}\right) = (M + m)\dot\xi + m\dot\eta,$$

$$\left(\frac{dA}{d\eta}\right) = \left(\frac{dT}{d\dot\eta}\right) = m\dot\xi + m\dot\eta.$$

From these we have the equation for A

$$m\left(\frac{dA}{d\xi}\right)^2 - 2m\left(\frac{dA}{d\xi}\right)\left(\frac{dA}{d\eta}\right) + (M + m)\left(\frac{dA}{d\eta}\right)^2 = 2Mm(H - V).$$

The value of V is given above. This equation is, of course, to be treated according to the process illustrated in § 209.

Statics of a Rigid Solid.

Equilibrium of rigid solid. § 217. A rigid body, as we have already seen, has at the utmost six degrees of freedom, three of translation and three of rotation. According to Newton's scholium, the conditions of equilibrium of such a body, under the action of any system of forces, are that the algebraic sum of the rates of doing work by and against the forces shall be *nil* whatever uniform velocity of translation or of rotation the body may have. For, if this were not so, there would be work done against acceleration, and the body would gain or lose kinetic energy. And this gain or loss would take place even if the body were originally at rest, *i.e.*, it would not be in equilibrium. To ensure equilibrium then, all that is necessary is that the sums of the components of the forces in any three non-coplanar directions shall vanish, along with the sums of their moments about any three non-coplanar lines. For simplicity it is usual to assume for these directions a system of rectangular axes, and for the lines another system parallel to them and passing through some definite point (say the centre of inertia) of the body.

The six conditions. Thus we have at once

$$\Sigma(X) = 0,\ \Sigma(Y) = 0,\ \Sigma(Z) = 0;$$

$$\Sigma(Zy - Yz) = 0,\ \Sigma(Xz - Zx) = 0,\ \Sigma(Yx - Xy) = 0,$$

where X, Y, Z are the components, parallel to the axes, of a force acting at the point x, y, z of the body. If P, with direction cosines λ, μ, ν, represent the force acting at x, y, z, these equations may be written in the form

$$\Sigma(P\lambda) = 0,\ \Sigma(P\mu) = 0,\ \Sigma(P\nu) = 0$$

$$\Sigma[P(\nu y - \mu z)] = 0,\ \Sigma[P(\lambda z - \nu x)] = 0,\ \Sigma[P(\mu x - \lambda y)] = 0.$$

These equations correspond to the six degrees of freedom involved.

It is easy to see that it is a mere matter of convenience through what point of the body we draw the lines about which moments are taken. For, if we shift it by quantities a, b, c respectively, the moments become

$$\Sigma\{Z(y - b) - Y(z - c)\},\ \&c.;$$

but these are $\quad \Sigma(Zy - Yz) - b\Sigma(Z) + c\Sigma(Y),\ \&c.;$

and, by the first three equations, these quantities are seen to reduce themselves to their first terms. Hence, in forming the equations of equilibrium, simplicity will be gained by choosing as origin a point through which the line of action of one or more of the applied forces passes.

Again, the point of application of any one of the forces may be shifted at will anywhere along the line in which the force acts. For the equations of the line in which the force at x, y, z acts are

$$\frac{x' - x}{X} = \frac{y' - y}{Y} = \frac{z' - z}{Z},$$

and these give $\quad Zy' - Yz' = Zy - Yz,\ \&c.,$

so that the expressions for the moments are unaltered if the point of application of the force be shifted to any position along the line in which it acts.

§ 218. In the great majority of treatises on Statics the fundamental propositions of the subject, above given, are deduced from the assumption (as a thing to be proved experimentally) of the result just established, which is designated the "principle of the transmission of force." Along with it are assumed the parallelogram of forces, and the principle of the "superposition of systems of forces in equilibrium." Since the publication of the *Principia*, the continued use of such methods must be looked upon as a retrograde step in science.

§ 219. From this category we cannot quite except (so far Couple. at least as the usual modes of treating it are concerned) the valuable idea of the "couple," due to Poinsot. But the term is in such common use, and the idea in its applications sometimes of such importance, that it cannot be omitted here.

A couple is a pair of equal forces acting on the same body in opposite directions and in parallel lines.

From the general conditions already given we see that a couple produces a definite moment of force about a particular axis, but that the axis is determinate merely as regards direction, and not as regards position in space. The forces of a couple do not appear in the first three of the equations of equilibrium. On the other hand, the left hand members of the other three equations may all be regarded as moments of couples. All the properties of couples are contained in these statements. Thus, for instance, it is obvious that, so far as its effects are concerned—

1. A couple may be shifted by translation to any other Transference of couple. position in its own plane.
2. It may be shifted to any parallel plane.
3. In either of these it may be turned through any angle.
4. Its forces may be increased or diminished in any Arm of couple. ratio, provided the distance between their lines of action (which is called the "arm" of the couple) be proportionately diminished or increased.

A couple is therefore completely determined by means Axis of couple. of its "axis," which is a line drawn perpendicular to its plane, and of length representing its moment. And two couples are obviously to be compounded by treating their axes as if they were forces acting at one point.

§ 220. We will now examine the consequences of the Reduction of a system to a force and a couple. six conditions of equilibrium (§ 217) in some of the more common cases which present themselves. But, before doing so, it may make matters clearer if we restate these conditions in a somewhat different form.

The resultant of any number of forces, acting at any points of a rigid body, may be represented by a single force acting at the origin, and a couple of definite moment about a definite line passing through the origin.

For equilibrium of the body this force and couple must separately vanish.

Thus if, in fig. 59, P, acting at Q, be any one of the forces, and O the origin (chosen at random), we may introduce at O a pair of equal and opposite forces ± P, parallel to P. The original force, taken along with − P at the origin, gives a couple; and in addition there is + P acting at the origin.

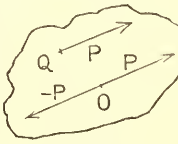

Fig. 59.

§ 221. When only two forces act on a body, the first condition above shows that they must be equal and opposite, and the second that they must act in the same line, if they are to maintain equilibrium. When only three forces act, the first condition shows that their directions must lie in one plane, the second that their lines of action must be parallel or must meet in one point, if they are to maintain equilibrium.

If their directions meet in one point we have again the problem of the equilibrium of a single particle under three forces; for there can be no moment about this point.

When the directions are parallel, one of the forces must obviously be equal to the sum of the other two, and must act in the opposite direction. Also its line of action must lie between those of the other two, for their moments about any point in it must be equal and opposite. Hence it is impossible that any single force should balance a couple, unless we adopt the mathematical fiction of an infinitely small force acting in a line everywhere at an infinite distance; so that its moment may be finite, and equal and opposite to that of the couple.

rallel rces. § 222. When any number of parallel forces act simultaneously on a rigid body, their resultant is a single force equal to their algebraic sum, with a couple whose plane is obviously parallel to the common direction of the forces. The forces of this couple may be made, by lengthening or shortening the arm, equal to the resultant force. One of them will neutralize it, and the other remains the final resultant, which passes through a definite point called the "centre of parallel forces." Thus any set of parallel forces necessarily has a single force as a resultant, excepting in the special case when their algebraic sum is zero.

entre."

avity. § 223. Excellent examples are furnished by heavy bodies of moderate dimensions, where the weights of their parts are forces practically in parallel lines. The single resultant force, in such cases, is the whole weight of the body. Its direction always passes through the centre of inertia (§ 109) because weight (in any one locality) is proportional to mass. For this reason all heavy bodies of moderate dimensions are said to have a "centre of gravity," which coincides with the centre of inertia. But it must be noticed that the two ideas are radically different, and that, while every piece of matter has a true centre of inertia, it is, in general, only approximately that we can predicate of it that it has a centre of gravity. In fact a body has a true centre of gravity only when it attracts, and is attracted by, all other gravitating matter as if its whole mass were concentrated in that point. See POTENTIAL. When there is a centre of gravity in a body, it is necessarily coincident with the centre of inertia. In gravitation cases, where bodies of moderate size are concerned, the resultant is, at least approximately, a single force. But, when we deal with large non-barycentric bodies like the earth, we find that the resultant of the sun's attraction is a force (determining the orbit) and a couple (producing precession, &c.).

ntre of avity.

When a mass is laid on a three-legged table, we find the pressure which each leg supports by simply taking moments about the line joining the upper ends of the other two. The leg is thus seen to support a fraction of the weight of the mass, whose numerator is the distance of the centre of gravity of the mass from this line, and its denominator the distance of the leg from the same line. Thus we have a physical proof of the geometrical proposition that if any point, P, be taken in the plane of a triangle ABC (fig. 60), and perpendiculars be drawn from it and from the angles, we have

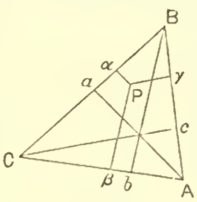

Fig. 60.

$$\frac{P\alpha}{Aa}+\frac{P\beta}{Bb}+\frac{P\gamma}{Cc}=1.$$

If the mass of the table is to be reckoned, P must be taken as the centre of gravity of the system of table and load together. If the table be of uniform material, triangular, and supported by legs at its corners, similar reasoning shows that when it is unloaded (or loaded at its centre of gravity) each leg supports one third of the weight.

§ 224. Examples in which the resultant is a single couple are found in rigidly magnetized bodies placed in a uniform magnetic field. As the amounts of N. and S. magnetism in a body are always equal, there is no force of translation in a uniform field. The resultant couple depends for its magnitude on the orientation of the body, and the positions of equilibrium are those for which its moment vanishes. Resultant a couple.

§ 225. Let P at x, y, z, be one of a system of parallel forces, their direction cosines being λ, μ, ν. Let Q be the resultant force, and R, with direction cosines λ', μ', ν', the axis of the resultant couple. Then our conditions become

$$Q=\Sigma(P),$$

$$\lambda'R=\Sigma[P(\nu y-\mu z)],\quad \mu'R=\Sigma[P(\lambda z-\nu x)],\quad \nu'R=\Sigma[P(\mu x-\lambda y)].$$

The last three equations give the following conditions determining R, λ', μ', ν':—

$$\begin{aligned}\lambda'R\quad &+\mu\Sigma(Pz)-\nu\Sigma(Py)=0,\\ -\lambda\Sigma(Pz)&+\mu'R\quad+\nu\Sigma(Px)=0,\\ +\lambda\Sigma(Py)&-\mu\Sigma(Px)+\nu'R\quad=0.\end{aligned}$$

From these we have the equation of condition

$$\lambda\lambda'+\mu\mu'+\nu\nu'=0,$$

showing that the axis of the couple is at right angles to the common direction of the parallel forces.

We have also

$$R^2=(\Sigma(Px))^2+(\Sigma(Py))^2+(\Sigma(Pz))^2-(\lambda\Sigma(Px)+\mu\Sigma(Py)+\nu\Sigma(Pz))^2.$$

This expression is of the same form as that in § 77, and we therefore conclude that, if λ'', μ'', ν'' be the direction cosines of a line in the body such that

$$\frac{\lambda''}{\Sigma(Px)}=\frac{\mu''}{\Sigma(Py)}=\frac{\nu''}{\Sigma(Pz)},$$

the magnitude of the resultant couple is directly as the sine of the angle between this line and the common direction of the parallel forces. In fact the mere form of the three equations above proves this result.

In the case of a body of moderate dimensions, acted on by gravity, P is the weight of the element at x, y, z, and therefore proportional to its mass, so that if the centre of inertia be taken as the origin we have

$$\Sigma(Px)=0,\quad \Sigma(Py)=0,\quad \Sigma(Pz)=0,$$

and there is no couple. The whole effect is therefore the same as if the mass were condensed at the centre of inertia.

In the case of a magnet,

$$\Sigma(P)=0,$$

and there is no translatory force. The couple, as we have seen, depends upon the orientation of the body as regards the direction of the line of the earth's magnetic force.

§ 226. We have seen that any system of forces acting on a rigid body may be reduced to a force and a couple; also that when the force is in the plane of the couple the resultant can always be put in the form of a single force acting in a definite line in the body. When the force is not in the plane of the couple, we may resolve the couple into two components, the plane of one being parallel, of the other perpendicular, to the force. The first, when compounded with the force, merely shifts the line in which it acts. Thus any system of forces may be reduced to a single force, acting in a definite line called the "central axis," and a couple in a plane perpendicular to it. One of the forces of the couple may now be compounded with the single force, and thus we obtain, as the resultant of any system of forces, a pair of forces in non-intersecting lines not perpendicular to one another. This is only one of an infinite number of ways in which fancy, or convenience, may lead us to represent the equivalent of a group of forces. Many very curious theorems have been met with in investigations on this subject. For instance, by compounding one of the forces of the resultant couple with the resultant force (not Reduction to two forces. Central axis.

now necessarily perpendicular to its plane) we have a system of two forces acting in non-intersecting lines. Then we have the following curious proposition, which may easily be proved from the formulæ already given:—

When a system of forces is reduced in any manner whatever to two, the volume of the tetrahedron of which these are opposite edges is constant.

Symmetrical reduction.

§ 227. The most symmetrical pair of resultant forces is found thus. Take any point P (fig. 61) in the central axis, and draw through it a line APA′, perpendicular to it, and bisected at P. Substitute for the single force at P its halves acting at A and A′ respectively. Combine these respectively with the forces AQ, A′Q′ of the couple when AA′ is made its arm. The system is thus reduced to two equal forces AR, A′R′, whose directions are interchangeable by a rotation of two right angles about the central axis.

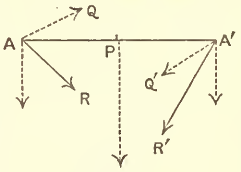

Fig. 61.

General reduction.

Let P with direction cosines λ, μ, ν be one of the forces, and let x, y, z be its point of application. Then

$$X = \Sigma(P\lambda)\,,\quad Y = \Sigma(P\mu)\,,\quad Z = \Sigma(P\nu)$$

are the components of the single force at the origin.

Also

$$\begin{aligned} L &= \Sigma[P(\nu y - \mu z)] \\ M &= \Sigma[P(\lambda z - \nu x)] \\ N &= \Sigma[P(\mu x - \lambda y)] \end{aligned}$$

are the components of the resultant couple.

If we shift the origin to the point a, b, c the first three quantities are unaltered, but the couples become

$$\begin{aligned} L' &= L + cY - bZ \\ M' &= M + aZ - cX \\ N' &= N + bX - aY. \end{aligned}$$

The point a, b, c is on the central axis if the axis of the resultant couple be parallel to the single force, *i.e.*, if

$$\frac{L'}{X} = \frac{M'}{Y} = \frac{N'}{Z} = e, \text{ suppose ;}$$

or

$$\begin{aligned} L &= \quad eX - cY + bZ, \\ M &= \quad cX + eY - aZ, \\ N &= -bX + aY + eZ. \end{aligned}$$

Either of these sets gives the equations of the central axis.

The resultant force and couple are in one plane, and therefore the resultant is a single force in the central axis, when

$$L'X + M'Y + N'Z = 0\,.$$

By the values of L′, M′, N′, above, we see that this is equivalent

$$LX + MY + NZ = 0\,.$$

When this last condition is not satisfied, we see that the value of the left hand member which, from the way in which it occurs, must obviously be an invariant, is

$$e(X^2 + Y^2 + Z^2)\,,$$

where e has the same value as in the three equations above.

Minding's theorem.

§ 228. One of the most remarkable of the many curious theorems connected with the single resultant of a system of forces is that of Minding. We have seen that, in general, the resultant may be put in the form of a single force and a couple in a plane perpendicular to it. If we now suppose the system of forces to be shifted into a new position such that their points of application, their magnitudes, and the angles between their directions two and two, all remain unchanged, the resultant force will be of the same magnitude as before, but the couple will in general be different. Of the infinitely infinite number of possible positions which the forces may assume, an infinite number correspond to a zero couple. Minding has shown that the lines of action of these single resultants consist of all lines passing through each of two curves, fixed in the body, an ellipse and an hyperbola, in planes perpendicular to each other. The proof of the proposition gives an interesting example of the use of Rodrigues's coordinates (§ 83).

The most obvious mode of attacking this question would be to resolve the applied forces into three groups, parallel respectively to three rectangular axes which revolve with them, and to choose those axes so that the sum of the resolved parts does not vanish parallel to any one of the three. Each of these systems of parallel forces has its own "centre" (§ 222),—so that the final resolution gives three forces, each of a given magnitude, acting in any mutually perpendicular directions at three definite points in the body. This, however, is not analytically so simple as the following.

We refer the body to fixed axes Ox, Oy, Oz, to be afterwards specified. As the origin and the directions of these axes are at our disposal, we may impose six conditions. Now suppose the forces to be resolved parallel to a set of rectangular axes Ox', Oy', Oz' which will be considered afterwards to rotate with them. Such a system of axes may, at starting, have any assigned position. This gives us three conditions more. Let then A, B, C be the components, parallel to the second set of axes, of the force applied at the point whose coordinates referred to the first system are a, b, c. Let the direction cosines of the second system in any of its future positions, referred to the first system, be l_1, m_1, n_1; l_2, m_2, n_2; l_3, m_3, n_3 respectively.

Then the force at a, b, c has the following components:—

$$\begin{aligned} &Al_1 + Bl_2 + Cl_3\,, &&\text{parallel to O}x \\ &Am_1 + Bm_2 + Cm_3\,, &&\quad ,, \quad ,, \ \text{O}y \\ &An_1 + Bn_2 + Cn_3\,, &&\quad ,, \quad ,, \ \text{O}z\,. \end{aligned}$$

The expressions for the resultant force and couple at the origin will evidently depend upon the following twelve quantities, besides the direction cosines, viz:—

$$\begin{aligned} &\Sigma A, \quad \Sigma B, \quad \Sigma C, \\ &\Sigma(Aa),\ \Sigma(Ab),\ \Sigma(Ac)\,, \\ &\Sigma(Ba),\ \Sigma(Bb),\ \Sigma(Bc)\,, \\ &\Sigma(Ca),\ \Sigma(Cb),\ \Sigma(Cc)\,. \end{aligned}$$

Assume $\Sigma B = 0$, $\Sigma C = 0$, *i.e.*, let Ox' be always parallel to the direction of the resultant force. Next, let

$$\Sigma(Aa) = 0,\ \Sigma(Ab) = 0,\ \Sigma(Ac) = 0\,,$$

i.e., let the origin be chosen as the "centre" (§ 222) of the forces parallel to the resultant force. As we have still four conditions to impose, we select the following:—

$$\Sigma(Ba) = 0,\ \Sigma(Bc) = 0,\ \Sigma(Ca) = 0,\ \Sigma(Cb) = 0.$$

These express that the plane of the couple due to the forces C passes through Oy, while that of the forces B passes through Oz.

Write now

$$\Sigma(A) = \mathfrak{A}\,,\ \Sigma(Bb) = \mathfrak{A}\beta,\ \Sigma(Cc) = \mathfrak{A}\gamma.$$

The force and couple at the origin are

$$\begin{aligned} &\mathfrak{A}l_1\,, &&\mathfrak{A}m_1\,, &&\mathfrak{A}n_1\,, \\ &\mathfrak{A}(n_2\beta - m_3\gamma), &&\mathfrak{A}l_3\gamma, &&-\mathfrak{A}l_2\beta\,. \end{aligned}$$

These are equivalent to a single force if (§ 227)

$$(l_1n_2 - n_1l_2)\beta - (l_1m_3 - m_1l_3)\gamma = 0\,,$$

or

$$m_3\beta - n_2\gamma = 0 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1).$$

This is the required condition. When it is satisfied, the equations of the line in which the single force $\mathfrak{A}$ acts are any two of

$$\left.\begin{aligned} n_1\eta - m_1\zeta &= \quad n_2\beta - m_3\gamma\,, \\ l_1\zeta - n_1\xi &= \quad l_3\gamma\,, \\ m_1\xi - l_1\eta &= -l_2\beta \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad . \quad . \quad (2),$$

the condition that these three agree being (1).

Eliminate l_1 between the last two, and we get

$$\xi(m_1\zeta - n_1\eta) = l_3\gamma\eta - l_2\beta\zeta\,. \quad . \quad . \quad . \quad . \quad . \quad . \quad (3).$$

Now introduce in (1), in the first of (2), and in (3), Rodrigues's values of the cosines (§ 83), and they become respectively

$$\begin{aligned} &(yz - wx)\beta - (yz + wx)\gamma = 0\,, \\ &(xz - wy)\eta - (wz + xy)\zeta = (yz + wx)\beta - (yz - wx)\gamma\,, \\ &\zeta\xi(wz + xy) - \xi\eta(xz - wy) = (xz + wy)\gamma\eta - (xy - wz)\beta\zeta. \end{aligned}$$

Rearranging according to y, z, and yz,

$$\begin{aligned} &(\beta - \gamma)yz - (\beta + \gamma)wx = 0\,, \\ &(\beta - \gamma)yz + (w\eta + x\zeta)y - (x\eta - w\zeta)z + (\beta + \gamma)wx = 0\,, \\ &[\zeta(\xi + \beta)x + \eta(\xi - \gamma)w]y + [\zeta(\xi - \beta)w - \eta(\xi + \gamma)x]z = 0\,, \end{aligned}$$

the second of which may be put, by means of the first, in the form

$$(w\eta + x\zeta)y - (x\eta - w\zeta)z + 2(\beta + \gamma)wx = 0.$$

These three equations involve w, x, y, z in the form of the ratios only of the last three to the first. The last two are linear in $\frac{y}{w}$, $\frac{z}{w}$. Solving them, and substituting in the first we find, finally, a biquadratic in $\frac{x}{w}$.

Hence, if particular values be assigned to ξ, η, ζ, we find four values of $\frac{x}{w}$. Thus, in general, there are four positions of the single resultant force passing through any point.

But, without forming the biquadratic, we may easily obtain Minding's theorem. Suppose we seek the locus of all points in which the plane $\xi\eta$ can be cut by the line of action of the single force. We have $\zeta=0$, and the equations above are reduced to

$$(\beta-\gamma)yz-(\beta+\gamma)wx\ =0\,,$$
$$\eta(wy-xz)+2(\beta+\gamma)wx=0\,,$$
$$(\xi-\gamma)wy-(\xi+\gamma)xz\ =0\,.$$

From the last two we find

$$-\gamma\eta z=(\beta+\gamma)(\xi-\gamma)w\,,$$
$$-\gamma\eta y=(\beta+\gamma)(\xi+\gamma)x\,,$$

so that finally, by the first,

$$(\beta^2-\gamma^2)(\xi^2-\gamma^2)=\gamma^2\eta^2\,,$$

or

$$\frac{\xi^2}{\gamma^2}-\frac{\eta^2}{\beta^2-\gamma^2}=1 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4).$$

Had we put $\eta=0$, we should have found, by a similar process,

$$\frac{\xi^2}{\beta^2}+\frac{\zeta^2}{\beta^2-\gamma^2}=1 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (5).$$

(4) and (5) represent an hyperbola and an ellipse, or an ellipse and an hyperbola, respectively, according as β^2 is greater or less than γ^2. In either case the vertices of the hyperbola coincide with the foci of the ellipse; so that the two curves are linked together.

It is now easy to see that, from any assigned point of space, the two curves will appear to intersect one another in four points. Two, or all, of these may in special cases coincide. Lines drawn to these points give the four positions of the single force which can pass through the assigned point.

Examples of Statical Methods and Theorems.

adder aning gainst a all.

§ 229. Suppose a ladder to be leaning against a vertical wall. If there be no friction, what force, applied at the lower end, will just suffice to support it?

In the treatment of all questions of this kind the student should commence by making a rough sketch of the situation, indicating all the forces concerned, with the directions in which they act. As shown in fig. 62, the wall exerts an outward thrust S on the upper end of the ladder, the ground an upward thrust R on the lower end. The only other force is gravity, which may be supposed to produce a downward force at the middle of the ladder, equal to its whole weight. Unless there be some other horizontal force to balance S, the ladder will obviously slide down. Suppose then a horizontal force F to be applied at the lower end, and let the ladder be inclined at an angle α to the horizon. Then our conditions become

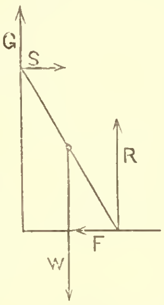

Fig. 62.

horizontally $\quad S-F=0\,,$

vertically $\quad W-R=0\,,$

and for the couple in the plane of the figure, l being the length of the ladder,

$$\tfrac{1}{2}Wl\cos\alpha-Sl\sin\alpha=0\,.$$

[The last equation is obtained by taking moments about the lower end of the ladder, this point being chosen (§ 217) because the directions of two of the forces pass through it.] From these equations we find at once

$$F=S=\tfrac{1}{2}W\cot\alpha\,.$$

It is to be observed that the requisite force F is very small while the ladder is nearly vertical, but increases without limit as it becomes more nearly horizontal.

Jse of riction.

§ 230. Next let us vary the question by supposing the coefficient of friction on the ground to be μ. The equations are precisely the same as before, and the limiting value of α for which equilibrium is possible is now to be found by putting

$$F=\mu R=\mu W\,.$$

Thus

$$2\mu=\cot\alpha$$

gives the smallest value of α for which equilibrium is possible. For any larger value of α less friction is called into play.

§ 231. If next we assume the wall also to be rough, a new friction force, G, comes in. The equations (for any given value of α) are

$$S-F=0\,,$$
$$W-R-G=0\,,$$
$$\tfrac{1}{2}Wl\cos\alpha-Sl\sin\alpha-Gl\cos\alpha=0\,.$$

Here there is a certain amount of indeterminateness which our formulæ cannot escape (although of course it does not exist in nature) so long as we are not dealing with the limiting case in which motion is about to commence. In that case we have the additional conditions

$$G=\mu S\,,\quad F=\mu R\,.$$

Thus, in all, there are five equations. These are requisite and necessary because there are four forces S, G, R, F to be determined, as well as the special value of the angle α. The result of eliminating the four forces is

$$\tan\alpha=\frac{1-\mu^2}{2\mu}\,.$$

§ 232. We may still further vary the question by supposing a man of weight w to ascend the ladder. Let e represent the fraction of the ladder's length which he has ascended. The equations are Man on ladder.

$$S-F=0\,,$$
$$W+w-R-G=0\,,$$
$$(\tfrac{1}{2}W+ew)l\cos\alpha_1-Sl\sin\alpha_1-Gl\cos\alpha_1=0\,.$$

Introducing the condition that slipping is just about to commence, we obtain

$$\frac{\tan\alpha_1}{\tan\alpha}=\frac{1+2\frac{w}{W}\frac{(1+\mu^2)e-\mu^2}{1-\mu^2}}{1+\frac{w}{W}}\,.$$

where α has the value given in § 231. Hence the limiting angle is increased or diminished by the load on the ladder according as

$$2(1+\mu^2)e-2\mu^2\gtrless 1-\mu^2\,,$$

i.e., $\quad 2e\gtrless 1\,.$

The ratio w/W does not appear in this condition. But it shows its importance when e is either greater or less than $\frac{1}{2}$.

Hence, when the ladder is just about to slip, a man makes it more stable if he stands anywhere on the lower half of it, but brings it down if he mounts higher. We conclude that, so far as sliding is concerned, it is advantageous to make the lower half of a ladder more massive than the upper half.

§ 233. Suppose a ladder, with its lower end resting against a wall, to be supported by a horizontal rail parallel to the wall (fig. 63). This case is chosen because it illustrates definite limits within which stability is ensured.

Let a be the half length of the ladder, α its inclination to the horizon, b the distance of the rail from the wall. Suppose the ladder in such a position that if there were no friction it would slip downwards. Then the equations of equilibrium are

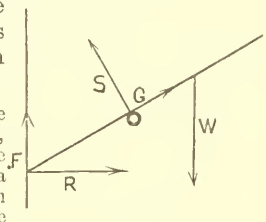

Fig. 63.

$$R+G\cos\alpha-S\sin\alpha=0\,,$$
$$F+S\cos\alpha+G\sin\alpha-W=0\,,$$
$$Sb\sec\alpha-Wa\cos\alpha=0\,.$$

In the third of these equations the lower end of the ladder has been chosen as the point about which moments are taken, because the lines of action of three of the forces pass through it. Here again there is indeterminateness, because there are two places at which friction comes in, and we do not know at which it is most freely exerted. But if the whole be on the point of slipping, we have as before the additional data

$$F=\mu R\,,\quad G=\mu S\,.$$

These lead to the equation

$$(1-\mu^2)\cos\alpha+2\mu\sin\alpha=\frac{b}{a}\sec^2\alpha\,.$$

If we introduce an angle ν, such that

$$\cos\nu=\frac{1-\mu^2}{1+\mu^2}\,,\quad \sin\nu=\frac{2\mu}{1+\mu^2}$$

this equation becomes

$$\cos^2\alpha\cos(\alpha-\nu)=\frac{b}{a(1+\mu^2)}=\frac{b}{a}\cos^2\frac{\nu}{2}\,,$$

the right-hand member of which must necessarily be less than 1.

This determines the lowest position of the lower end consistent with equilibrium, and the mere change of sign of μ, and therefore of ν, alters it into the equation for the highest. The signs of the friction terms are changed when the direction of slipping is supposed to be reversed.

Kinetics of a Rigid Solid.

Rotation of rigid solid.

§ 234. The motion of a rigid body is, as we have seen, completely determined when we know the motion of one of its points and the relative motion of the body about that point. The point usually chosen is the centre of inertia of the body, and the investigation of its motion comes under the kinetics of a particle, which we have already sufficiently discussed. For we are permitted to suppose the whole mass to be concentrated at that point, and to be acted on by all the separate forces, each unaltered in direction and magnitude. Hence we may now confine ourselves to the study of the motion about the centre of inertia which, for the moment, we may look on as fixed.

To illustrate, in a very simple manner, the new conceptions which are required for the study of this question, let us take a uniform circular ring of matter, of radius R, revolving with angular velocity ω about an axis through its centre, and perpendicular to its plane. Its moment of momentum is obviously

$$M\,.\,R\omega\,.\,R\ \text{ or }\ MR^2\,.\,\omega\,.$$

Its kinetic energy is

$$\tfrac{1}{2}M(R\omega)^2\ \text{ or }\ \tfrac{1}{2}MR^2\,.\,\omega^2\,.$$

If it be acted on by a couple C, in its plane, C is the rate of increase of the moment of momentum, or

$$MR^2\,.\,\dot\omega=C\,.$$

The work done by the couple in time δt is

$$C\omega\delta t\,,$$

and the increase of kinetic energy is

$$MR^2\,.\,\omega\dot\omega\delta t\,.$$

By equating these we have (after dividing both sides by ω) the same equation as we obtained from the rate of increase of moment of momentum. It will be observed that these equations are of exactly the same form as those for the motion of a particle parallel to one of the coordinate axes, only that ω takes the place of a velocity (such as $\dot x$) while the expression MR^2 takes the place of M, and the right-hand side is the moment of a force, not a force simply.

Moment of inertia.

§ 235. Hence, generally, we define as follows :—

Def. The "moment of inertia" of a body about any axis is the sum of the products of the mass of each particle of the body into the square of its (least) distance from the axis.

The following theorem enables us at once to find the moment of inertia about any line, as axis, from that about a parallel axis through the centre of inertia.

Let the line be chosen as the axis of z, then the moment of inertia about it is

$$\Sigma m(x^2+y^2)\,.$$

But, if $\bar x$, $\bar y$ be the coordinates of the centre of inertia, ξ, η the coordinates of m with reference to that centre, we have

$$x=\bar x+\xi\,,\ y=\bar y+\eta\,,$$

and the above expression for the moment of inertia becomes

$$\Sigma m(\bar x^2+\bar y^2+2\bar x\xi+2\bar y\eta+\xi^2+\eta^2)\,.$$

By the property of the centre of inertia, § 109,

$$\Sigma(m\xi)=0\,,\quad \Sigma(m\eta)=0\,.$$

Hence the above expression consists of two parts:—

$$\Sigma m(\xi^2+\eta^2)$$

the moment of inertia about a parallel axis through the centre of inertia, and

$$\Sigma(m)\,.\,(\bar x^2+\bar y^2)$$

the moment of inertia of the whole mass supposed concentrated at its centre of inertia.

§ 236. Hence we need study only the moments of inertia about axes passing through the centre of inertia. But we will commence with an origin assumed at hazard.

If the direction cosines of an axis through the origin be λ, μ, ν, the square of the distance of the mass m at x, y, z from it is

$$x^2+y^2+z^2-(\lambda x+\mu y+\nu z)^2\,.$$

Hence the moment of inertia is

$$\mathfrak{I}=\Sigma m(x^2+y^2+z^2-(\lambda x+\mu y+\nu z)^2)$$
$$=\Sigma m((y^2+z^2)\lambda^2+(z^2+x^2)\mu^2+(x^2+y^2)\nu^2-2xy\lambda\mu-2yz\mu\nu-2zx\nu\lambda)\,,$$

which may be written

$$\mathfrak{I}=A\lambda^2+2G_3\lambda\mu+B\mu^2+2G_1\mu\nu+2G_2\nu\lambda+C\nu^2\,.$$

If we measure off, on the axis, a quantity ρ whose square is the reciprocal of $\mathfrak{I}$, and call its terminal coordinates ξ, η, ζ, this equation becomes by multiplying both sides by ρ^2

$$1=A\xi^2+2G_3\xi\eta+B\eta^2+2G_1\eta\zeta+2G_2\zeta\xi+C\zeta^2\,.$$

As the moment of inertia is essentially a positive quantity, this equation represents an ellipsoid. It must of course have three principal axes ; and, when these are taken as the coordinates axes, the terms in $\xi\eta$, $\eta\zeta$, and $\zeta\xi$ in the above expression must disappear.

Princ[ipal] axes [of] inerti[a].

§ 237. Hence at every point of every rigid body there are three "principal axes" of inertia, at right angles to one another. One of them is the axis of absolute maximum moment, another that of absolute minimum.

Our equation now becomes, when referred to these axes,

$$1=A\xi^2+B\eta^2+C\zeta^2\,,$$

or, dividing by ρ^2,

$$\mathfrak{I}=A\lambda^2+B\mu^2+C\nu^2.$$

Thus the moment of inertia about any axis is found from those about the principal axes at that point by multiplying each by the square of the corresponding direction cosine, and adding the results.

For the quantity A was written originally as

$$\Sigma m(y^2+z^2)\,,$$

i.e., it is the moment of inertia about the axis of x. We see also that, at every point of a body, there are three rectangular axes such that the expressions

$$\Sigma(mxy)\,,\ \Sigma(myz)\,,\ \Sigma(mzx)$$

vanish when these are taken as coordinate axes.

Distri[bu]tion o[f] princi[pal] axes. Radiu[s] of gyr[a]tion.

To find how these axes are distributed in a body, let us suppose it referred to the principal axes through its centre of inertia, and let Mk_1^2, Mk_2^2, Mk_3^2 be the moments of inertia about them. The quantities k_1, k_2, k_3 are called the principal "radii of gyration." Then, by the results above, the moment of inertia about a line λ, μ, ν through the point α, β, γ is

$$\mathfrak{I}=M\{\alpha^2+\beta^2+\gamma^2-(\lambda\alpha+\mu\beta+\nu\gamma)^2\}+M(\lambda^2k_1^2+\mu^2k_2^2+\nu^2k_3^2)\,.$$

For a principal axis this is to be a maximum or minimum, with the sole condition

$$\lambda^2+\mu^2+\nu^2=1\,.$$

Hence, if p be an undetermined multiplier, we have

$$(k_1^2+p)\lambda - \alpha(\alpha\lambda+\beta\mu+\gamma\nu)=0\,,$$
$$(k_2^2+p)\mu - \beta(\alpha\lambda+\beta\mu+\gamma\nu)=0\,,$$
$$(k_3^2+p)\nu - \gamma(\alpha\lambda+\beta\mu+\gamma\nu)=0\,.$$

But, if we consider a surface of the second order

$$\frac{x^2}{k_1^2+p}+\frac{y^2}{k_2^2+p}+\frac{z^2}{k_3^2+p}=1\,,$$

confocal with the ellipsoid

$$\frac{x^2}{k_1^2}+\frac{y^2}{k_2^2}+\frac{z^2}{k_3^2}=1\,, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (a),$$

the direction cosines of its normal at x, y, z are

$$\lambda:\mu:\nu::\frac{x}{k_1^2+p}:\frac{y}{k_2^2+p}:\frac{z}{k_3^2+p}\,.$$

Hence, if this surface pass through the point α, β, γ, we have

$$(k_1^2+p)\lambda = \mathrm{P}\alpha\,,$$
$$(k_2^2+p)\mu = \mathrm{P}\beta\,,$$
$$(k_3^2+p)\nu = \mathrm{P}\gamma\,,$$

where P is determined by the equation

$$\alpha\lambda+\beta\mu+\gamma\nu=\mathrm{P}\left(\frac{\alpha^2}{k_1^2+p}+\frac{\beta^2}{k_2^2+p}+\frac{\gamma^2}{k_3^2+p}\right)=\mathrm{P}.$$

Substitute this value of P in the preceding equations, and they become identical with those above given for determining the principal axes at α, β, γ. Hence Binet's Theorem :—

The principal axes at any point of a body are normals to the three surfaces of the second order which pass through that point and are confocal with the ellipsoid (a).

ncipal ments iner-

§ 238. We will here tabulate the values of the moments of inertia about principal axes through the centre of inertia, in a few specially useful cases.

1. Plane uniform circular disk.

Divide it into concentric rings, of radius r, of breadth δr. Then the moment of inertia about the axis through the centre, and perpendicular to the plane, of the circle is

$$\rho\int_0^a 2\pi r^3 dr = \tfrac{1}{2}\pi a^4\rho\,,$$

where a is the radius, and ρ the mass of a square unit, of the disk. But the mass is $\pi a^2\rho$,

so that $\qquad k_1^2=\tfrac{1}{2}a^2.$

This of course, applies to a circular cylinder. Obviously, in the disk

$$k_2^2=k_3^2=\tfrac{1}{2}k_1^2=\tfrac{1}{4}a^2.$$

In fact the moment of inertia about an axis drawn perpendicular to any plane figure at any point is equal to the sum of the other two about rectangular axes which lie in the plane. The one is $\Sigma m(x^2+y^2)$, and the others are Σmx^2 and Σmy^2 respectively.

2. Uniform rod of length l, ρ mass per unit length.

$$\mathrm{M}=l\rho\,,\quad \mathrm{M}k_1^2=0\,,\quad \mathrm{M}k_2^2=\mathrm{M}k_3^2=2\rho\int_0^{\frac{1}{2}l}x^2dx=\frac{\rho l^3}{12}\,,$$

so that $\qquad k_2^2=k_3^2=\tfrac{1}{12}l^2.$

3. Uniform rectangular plate, sides a and b, axis parallel to b.

$$\mathrm{M}k^2=2b\rho\int_0^{\frac{a}{2}}x^2dx=\frac{a^3b}{12}\rho\,,$$

so that $\qquad k_1^2=\tfrac{1}{12}a^2,$ and $k_2^2=\tfrac{1}{12}b^2.$

Hence, by the remark above,

$$k_3^2=\tfrac{1}{12}(a^2+b^2)\,.$$

4. Uniform sphere, radius a, ρ mass per unit volume. Here

$$\Sigma(mx^2)=\Sigma(my^2)=\Sigma(mz^2)\,,$$

and therefore the sum of any two is

$$=\tfrac{2}{3}\Sigma m(x^2+y^2+z^2)\,.$$

Thus $\qquad \mathrm{M}k_1^2=\mathrm{M}k_2^2=\mathrm{M}k_3^2=\tfrac{2}{3}4\pi\rho\int_0^a r^4dr=\tfrac{8}{15}\pi\rho a^5\,.$

But $\qquad \mathrm{M}=\tfrac{4}{3}\pi\rho a^3,$

and thus $\qquad k_1^2=k_2^2=k_3^2=\tfrac{2}{5}a^2.$

5. Plane uniform elliptic disk, semiaxes a, b ; ρ mass of unit area. Moment of inertia about a is

$$\mathrm{M}k_1^2=2\rho\int_0^a\frac{y^3}{3}dx=\frac{\pi ab^3\rho}{4}\,,$$

so that $\qquad k_1^2=\tfrac{1}{4}b^2.$

From this follows immediately

6. Ellipsoid, semiaxes a, b, c, and of uniform density :—

$$k_1^2=\tfrac{1}{5}(b^2+c^2),\quad k_2^2=\tfrac{1}{5}(c^2+a^2),\quad k_3^2=\tfrac{1}{5}(a^2+b^2).$$

From these we can, of course, reproduce the result for a sphere.

7. Rectangular parallelepiped, edges a, b, c :—

$$k_1^2=\tfrac{1}{12}(b^2+c^2),\quad k_2^2=\tfrac{1}{12}(c^2+a^2),\quad k_3^2=\tfrac{1}{12}(a^2+b^2).$$

The determination of moments of inertia is, like that of centres of inertia, a purely mathematical matter, the full discussion of which would lead us away from the proper objects of this article.

§ 239. The simplest cases that can present themselves so far as rotation is concerned (for the translational effects on a rigid body are treated precisely as if it were a mere particle,—a process already sufficiently illustrated) are those in which there is one degree of freedom to rotate, *i.e.*, when the body is rigidly attached to a fixed axis. Here the physical condition is simply that the rate of increase of moment of momentum is equal to the moment of the resultant couple about the axis of rotation. Rotation about fixed axis.

§ 240. Let us recur to Atwood's machine as a first example, and suppose the string not to slip on the pulley, so that the pulley must turn. In this case we must observe that the two free parts of the string are now, as it were, separate strings, so that we have no right to assume their tensions to be equal. In fact if they were equal there would be no acceleration of the rotation of the pulley, nor of course of the common velocity of the two masses. We assume that the pulley is symmetrical, and the axis through its centre of inertia. Pulley of Atwood's machine.

Let a be the radius of the pulley, and ω its angular velocity, then $a\omega$ is the linear velocity of either mass. Thus the linear acceleration of each of the masses is equal to a times the angular acceleration of the pulley. But the linear acceleration multiplied by the mass is the measure of the force producing it; while the angular acceleration multiplied by the moment of inertia is the measure of the moment of the couple producing it. Thus we have (M being the mass of the pulley, and k its radius of gyration)

$$\mathrm{M}k^2\times\text{angular acceleration} = (\mathrm{T}'-\mathrm{T})a\,,$$
$$m'\times\text{linear acceleration} = m'g-\mathrm{T}'\,,$$
$$m\times\text{linear acceleration} = \mathrm{T}-mg\,.$$

Eliminating T and T′, and taking account of the above relation between the accelerations, we find at once

$$\text{Linear Acceleration}=\frac{m'-m}{m'+m+\mathrm{M}k^2/a^2}g\,;$$

from which, by the last two of our equations, the separate values of T and T′ may be found.

If we compare this result with that obtained in § 173, on the supposition that the pulley was perfectly smooth, we see that the only difference is in the addition of $\mathrm{M}k^2/a^2$ to the sum of the two masses. Otherwise the nature of the motion remains unaffected.

§ 241. Let us next take the case of a body of any form attached to a horizontal axis which does not pass through its centre of inertia. In such a case gravity is the force producing motion, and we have what is called a "compound pendulum." Draw through the centre of inertia a line parallel to the axis; let h be the distance between these lines, and θ the angle which their plane makes (at a given time) with the vertical. The moment producing angular acceleration is obviously Compound pendulum.

$$-mgh\sin\theta\,.$$

Divide by the moment of inertia about the axis, which by a previous proposition (§ 235) is

$$m(k^2+h^2)$$

(where k is the radius of gyration about the line drawn through the centre of inertia), and we have for the angular acceleration

$$-\frac{gh\sin\theta}{k^2+h^2}\,.$$

In the case of a simple pendulum of length l, we saw that the angular acceleration is

$$-\frac{g\sin\theta}{l}.$$

Hence the motion of the compound pendulum will be identical with that of the simple pendulum when, and only when,

$$l=\frac{k^2+h^2}{h}=2k+\frac{(k-h)^2}{h}.$$

As h and k are necessarily positive (or rather *signless*) quantities, the smallest value of l is evidently when $k=h$. Hence the shortest time in which the mass can vibrate about any axis parallel to the original one corresponds to that of a simple pendulum of length $2k$. When h is made either less or greater than k, the length of the equivalent simple pendulum increases, and for any assigned value of l greater than $2k$ there are two corresponding values of h, one less and the other greater than k. Their sum, however, as we see by the coefficient of the second term in the equation

$$h^2-lh+k^2=0,$$

is always equal to l.

If then we can find two parallel axes in a rigid body, lying in one plane with the centre of inertia, and on opposite sides of that point, such that the time of oscillation is the same for each, the distance between them is the length of the equivalent simple pendulum. Kater made use of this proposition in his determination of the length of the second's pendulum, under the circumstances in which it was defined by Act of Parliament as a datum for restoring, in case of loss, the standard yard.

Complex compound pendulum.

§ 242. Suppose now that a second body is attached to the first by an axis parallel to that about which the first is constrained to move; and, for simplicity, suppose the centre of inertia of the first body to be in the plane containing the two axes. Here we have a *complex compound pendulum*, and it is interesting to compare the motion with that of the complex simple pendulum of §§ 177, 178.

Let m', h', ϕ correspond, for the second body, to m, h, θ for the first, and let a be the distance between the axes. For variety we will adopt Lagrange's method. We have clearly

$$T=\tfrac{1}{2}\,(mk^2\dot\theta^2+mh^2\dot\theta^2+m'k'^2\dot\phi^2+m'(a^2\dot\theta^2+h'^2\dot\phi^2+2ah'\cos(\phi-\theta)\dot\phi\dot\theta),$$
$$V=C-mgh\cos\theta-m'g(a\cos\theta+h'\cos\phi).$$

These would enable us at once to write down the equations of motion, however large be the disturbance, but they are too complex for our present work. Let us then assume ϕ and θ to be very small, and we have

$$\{m(k^2+h^2)+m'a^2\}\ddot\theta+m'ah'\ddot\phi=-(mh+m'a)g\theta,$$
$$m'(k'^2+h'^2)\ddot\phi+m'ah'\ddot\theta=-m'gh'\phi.$$

Combining, as before, by means of an undetermined multiplier, we have

$$(m(k^2+h^2)+m'a^2+\lambda m'ah')\ddot\theta+(m'ah'+\lambda m'(k'^2+h'^2))\ddot\phi$$
$$=-g\{(mh+m'a)\theta+\lambda m'h'\phi\}.$$

Thus the two values of λ are given by the equation

$$\frac{m'ah'+\lambda m'(k'^2+h'^2)}{m(k^2+h^2)+m'a^2+\lambda m'ah'}=\frac{\lambda m'h'}{mh+m'a}.$$

This may be written in the form

$$\frac{A+\lambda}{B+\lambda}=\frac{\lambda}{C},$$

where B is greater than A; and A, B, C are all essentially positive, if the bodies have been only slightly displaced from the position of stable equilibrium. The equation gives

$$\lambda^2+(B-C)\lambda-AC=0,$$

so that the values of λ are essentially real and of opposite signs. If we write $\mu-B$ for λ, this equation becomes

$$\mu^2-(B+C)\mu+(B-A)C=0,$$

so that the values of $\lambda+B$ are both positive, and therefore the motion of either mass is the resultant of two simple harmonic motions.

§ 243. A well-known puzzle in connexion with this subject used to be "How to distinguish between two hollow shells, one of gold the other of silver, if their diameters and masses be alike, and both be painted." If we observe that the volumes of equal masses are inversely as the densities, the volume of the gold shell is seen to be less than that of the silver one, and therefore, on the whole, its mass is farther from the centre, and its moment of inertia greater. Hence any form of experiment in which the moment of inertia comes in will suffice to decide the question. Thus they might be alternately clamped tight to the end of a rod, and the system swung as a pendulum, when the gold sphere would vibrate more slowly than the silver one. Or they might be allowed to *roll*, not *slide*, down a rough plane. In this case the work done by gravity on each is the same when they have fallen through equal spaces. But its equivalent is in the form of kinetic energy, partly translational and partly rotational. The relative amounts of these two depend on the moments of inertia of the spheres, for the ratio of the translational velocity to the angular velocity is the same for each. Hence the gold sphere, having the greater moment of inertia, will have the smaller velocity of translation. Another form of this question was to have a shell with a spherical mass inside, which might be either free to rotate on gimbals, or else be keyed to the outer skin. The keying would of course retard the motion of the whole down a rough plane, for part of the energy due to gravity would then be shared by the internal mass in the form of energy of rotation, from which it would otherwise have been free. Another very instructive form is that of a spherical shell full of fluid. If the fluid be perfect, the moment of inertia is that of the shell alone; if it be infinitely viscous, the moment of inertia is that of shell and fluid as if they constituted one rigid solid; and we may have every intermediate amount. If we suppose the rotation of the outer shell to be suddenly stopped, the infinitely viscous contents would be reduced to rest also. But if they be not infinitely viscous they will not at once be brought to rest, but will be able to put the shell in rotation again if it be at once set free. Thus, in practice, we can tell a raw egg from a hard-boiled egg. The first is with difficulty made to rotate, and sets itself in motion again if it be stopped and at once let go. The second behaves, practically, like a rigid solid.

Rolling of hollow shells.

§ 244. The problem of the rolling of a sphere down a rough inclined plane is solved at once, as above, by applying the conservation of energy. For, if x be the coordinate of its centre parallel to the plane, θ the angle through which it has turned, and a its radius, we have the kinematical condition

$$x=a\theta$$

(due to the perfect roughness of the plane).

Also the potential energy lost is

$$Mgx\sin\alpha,$$

where α is the inclination of the plane to the horizon; and the kinetic energy gained is made up of the two parts,—$\tfrac{1}{2}M\dot x^2$ translational, and $\tfrac{1}{2}Mk^2\dot\theta^2$ rotational.

Hence $$M(k^2+a^2)\dot\theta^2=2Mga\theta\sin\alpha,$$

or $$\dot x^2=2\frac{a^2g}{k^2+a^2}x\sin\alpha.$$

This shows that the motion is the same as that of a particle sliding down a *smooth* plane of the same inclination, under gravity diminished in the ratio $a^2:k^2+a^2$. And it shows how friction may retard motion without producing any dissipation of energy.

§ 245. Suppose one point of a rigid plane sheet be made to move in any manner in the plane of the sheet, what will be the consequent rotation?

Let M be the mass, and ξ, η, given in terms of t, the coordinates v·ying c· s·int o·ne p·rt of a·dy.

of the point of the sheet whose motion is assigned. Let a, θ be the relative polar coordinates of the centre of inertia, then

$$M[\ddot{\xi}+a(\cos\theta)^{\cdot\cdot}]=X\,,\quad M[\ddot{\eta}+a(\sin\theta)^{\cdot\cdot}]=Y\,,$$
$$Mk^2\ddot{\theta}=-Ya\cos\theta+Xa\sin\theta\,;$$

where X and Y are the forces requisite to produce the motion. Eliminating them, we find

$$(k^2+a^2)\ddot{\theta}=-a(\ddot{\eta}\cos\theta-\ddot{\xi}\sin\theta),$$

with which we can do no more until further data are specified.

Suppose ξ, η to move with uniform acceleration p in a direction assigned by α, then

$$\ddot{\xi}=p\cos\alpha\,,\quad \ddot{\eta}=p\sin\alpha\,,\ \text{and}$$
$$(k^2+a^2)\ddot{\theta}=-ap(\sin\alpha\cos\theta-\cos\alpha\sin\theta)=ap\sin(\theta-\alpha)\,.$$

The centre of inertia of the mass therefore moves, relatively to the constrained point, precisely as does a simple pendulum; but the direction of p is reversed.

Again suppose the constrained point to move uniformly in a circle of radius b, with angular velocity ω. We have

$$\xi=b\cos\omega t\,,\quad \eta=b\sin\omega t\,,$$

and
$$(k^2+a^2)\ddot{\theta}=+\omega^2ab(\sin\omega t\cos\theta-\cos\omega t\sin\theta)\,,$$

or
$$(k^2+a^2)\left(\frac{d}{dt}\right)^2(\theta-\omega t)=-\omega^2ab\sin(\theta-\omega t)\,.$$

This is, again, the equation of motion of a simple pendulum, but the angle of displacement $\theta-\omega t$ is no longer measured from a fixed line but from the uniformly rotating radius of the guide circle. Hence the mass oscillates, pendulum-wise, about this uniformly revolving line.

·llistic ·ndu·l·m.

§ 246. Let us take, as an instance of impulse, the case of Robins's "ballistic pendulum,"—a massive block of wood movable about a horizontal axis at a considerable distance above it,—employed to measure the velocity of a cannon or musket shot. The shot is usually fired into the block in a horizontal direction perpendicular to the axis. The impulsive penetration is so nearly instantaneous, and the mass of the block so large compared with that of the shot, that the ball and pendulum are moving on as one mass before the pendulum has been sensibly deflected from the position of equilibrium. This is the essential peculiarity of the ballistic method,—which is used also extensively in electromagnetic researches and in practical electric testing, when the integral quantity of the electricity which has passed in a current of short duration is to be measured. The line of motion of the bullet at impact may be in any direction whatever, but the only part which is effective is the component in a plane perpendicular to the axis. We may therefore, for simplicity, consider the motion to be in a line perpendicular to the axis, though not necessarily horizontal.

Let m be the mass of the bullet, v its velocity, and p the distance of its line of motion from the axis. Let M be the mass of the pendulum with the bullet lodged in it, and k its radius of gyration. Then, if ω be the angular velocity of the pendulum when the impact is complete,

$$mvp=Mk^2\omega\,,$$

from which the solution of the question is easily determined. For the kinetic energy after impact is changed into its equivalent in potential energy when the pendulum reaches its position of greatest deflexion. Let this be given by the angle θ; then the height to which the centre of inertia is raised is $h(1-\cos\theta)$, if h be its distance from the axis. Thus

$$Mgh(1-\cos\theta)=\tfrac{1}{2}Mk^2\omega^2=\tfrac{1}{2}\frac{m^2v^2p^2}{Mk^2}\,,$$

or
$$2\sin\frac{\theta}{2}=\frac{m}{M}\,\frac{p}{k}\,\frac{v}{\sqrt{gh}}\,,$$

an expression for the chord of the angle of deflexion. In practice the chord of the angle θ is measured by means of a light tape or cord attached to a point of the pendulum, and slipping with small friction through a clip fixed close to the position occupied by that point when the pendulum hangs at rest.

§ 247. As another example of impulse let us consider the case of a body moving in any way in a plane perpendicular to one of its principal axes. It is required to find what point of the body must be suddenly fixed in order that the whole may be brought to rest; also, what will be the consequent impulsive pressure at this point. It is easy to see that this is exactly the same question as to find the impulse, and its point of application, so that it may produce a given motion of a body in a plane perpendicular to one of its principal axes.

Impulse required for a given motion.

The impulse must obviously act in a plane passing through the centre of inertia. And the physical conditions are that the change of momentum of translation is equal to, and in the direction of, the impulse, while the change of moment of momentum about the centre of inertia is equal to the moment of the impulse. Let the impulse acting at the point ξ, η have components R, S parallel to rectangular coordinates in the plane of motion, and let ω be the angular velocity, u, v the linear velocities, generated by it. Then the physical conditions are

$$Mu=R\,,\quad Mv=S\,,\quad Mk^2\omega=S\xi-R\eta\,.$$

When u, v, ω are given, R and S are found from the first two equations, and the third is then the equation of the line in which the impulse must act. Similarly, when the impulse and its line of action are given, we have in terms of these data the quantities u, v, ω.

§ 248. As a simple practical example, suppose one strikes a hard object with a stick in such a way that his hand is at rest at the instant of the impact; with what part of the stick must he strike so that there may be no jar on his hand?

Centre of percussion.

Let ξ be measured along the stick from its centre of inertia in the direction which it has at the instant of impact. Then the kinematical condition is

$$v=a\omega\,,$$

where a is the distance from the hand to the centre of inertia of the stick. Thus, as the impulse S is the sole cause of the stick's being brought to rest, we have

$$Mv+S=0\,,\quad Mk^2v/a+S\xi=0\,;$$

so that
$$\xi=k^2/a\,.$$

Hence if the stick be uniform and be held by one end, so that its length is $2a$, and therefore $3k^2=a^2$, we have

$$\xi=\tfrac{1}{3}a\,;$$

and $a+\xi$, the distance of the point of impact from the hand, is

$$a+\tfrac{1}{3}a=\tfrac{2}{3}\,.\,2a\,,$$

i.e., it is at two-thirds of the length of the stick.

If, however, the hand be moving, at the instant of impact, perpendicularly to the stick with velocity V, the kinematical condition is $v-V=a\omega$, which introduces a corresponding change in the result.

§ 249. The reaction of the axis is easily calculated. If the axis about which the body is constrained to rotate be perpendicular to a plane though the centre of inertia about which the body is symmetrical, and if the applied forces act in that plane, it is clear that the reaction of the axis is a single force in that plane. Let its components be Ξ and H. Then

Reaction on axis.

$$\Sigma(m\ddot{x})=\Sigma(X)+\Xi\,,\quad \Sigma(m\ddot{y})=\Sigma(Y)+H\,,$$
$$\Sigma m(x\ddot{y}-y\ddot{x})=\Sigma(xY-yX)\,.$$

Let a, θ, be the polar coordinates of the centre of inertia, then $\dot{\theta}$, $\ddot{\theta}$ are the angular velocity and the angular acceleration for all particles of the mass, and we have

$$-Ma\cos\theta\,.\,\dot{\theta}^2-Ma\sin\theta\,.\,\ddot{\theta}=\Sigma(X)+\Xi\,,$$
$$-Ma\sin\theta\,.\,\dot{\theta}^2+Ma\cos\theta\,.\,\ddot{\theta}=\Sigma(Y)+H\,,$$
$$M(k^2+a^2)\ddot{\theta}=\Sigma(xY-yX)\,.$$

From the third we find θ, and the others give Ξ and H.

When there is no plane of symmetry perpendicular to the axis, there must be two points of it at which reactions are exerted on the revolving body. Let the coordinates of these bearings be c, c', and the reactions there Ξ, H, Z, Ξ', H$'$, Z$'$ respectively.

Then we have the six equations (in which $\ddot{z}=0$)

$$\Sigma(m\ddot{x})=\Sigma(X)+\Xi+\Xi',$$
$$\Sigma(m\ddot{y})=\Sigma(Y)+H+H',$$
$$\Sigma(m\ddot{z})=\Sigma(Z)+Z+Z';$$
$$\Sigma m(x\ddot{y}-y\ddot{x})=\Sigma(xY-yX),$$
$$\Sigma m(y\ddot{z}-z\ddot{y})=\Sigma(yZ-zY)-cH-c'H',$$
$$\Sigma m(z\ddot{x}-x\ddot{z})=\Sigma(zX-xZ)+c\Xi+c'\Xi'.$$

The fourth equation, as before, determines θ, and we have then four equations to determine Ξ, Ξ', H, H'. The remaining equation determines only the sum $Z+Z'$. In fact by more or less perfect *fitting* we can throw more or less of the force parallel to the axis on one or other of the bearings. There is really no indeterminateness in nature, but we cannot get the information required to evaluate separately Z and Z'.

§ 250. When impulsive forces are applied to the body, exactly the same methods may be employed, with the exception that $u'-u$ must be written for $\ddot{x}$, &c., and $\omega'-\omega$ for $\ddot{\theta}$. The quantities X, Y, Z, Ξ, H, Z, Ξ', H', Z' now denote impulses and not forces.

As a single example of the use of these formulæ, take the case of a body rotating, under the action of no force, about an axis through its centre of inertia. Here $\Sigma(mx)=0$, &c., and z is constant. The first two of the six equations last written show that the pairs of forces Ξ, Ξ' and H, H' form couples. The fourth equation gives $\theta=\omega t$; and with this the remaining two become

$$\Sigma(mzy).\omega^2=-cH-c'H'=-(c-c')H,$$
$$\Sigma(mzx).\omega^2=-c\Xi-c'\Xi'=-(c-c')\Xi.$$

The multipliers of ω^2 are each zero if the axis of rotation be a principal axis, and thus, in this case, there is no stress perpendicular to the axis. When the axis is not a principal axis the left hand terms are generally finite but they vary as the body turns. It is easy to see, however, that together these terms constitute a constant couple always in a plane passing through the axis, rotating with the body and dependent directly on the square of the angular velocity. Thus, to analyse the factor $\Sigma(mzy)$, we note that z is constant, and

$$y=r\sin(\omega t+\alpha),$$

where r, α were the polar coordinates of the mass m at time $t=0$.

Hence $\Sigma(mzy)=\sin\omega t\Sigma(mzx_1)+\cos\omega t\Sigma(mzy_1)$,

where $x_1=r\cos\alpha$ and $y_1=r\sin\alpha$ were the coordinates of m at $t=0$.

Similarly we have

$$\Sigma(mzx)=\cos\omega t\Sigma(mzx_1)-\sin\omega t\Sigma(mzy_1).$$

These expressions prove the preceding statements.

One point suddenly stopped.

§ 251. As a final instance of impulse in this branch of the subject, suppose that a rigid plate, moving anyhow in its own plane, has one of its points suddenly fixed, what will be the subsequent motion? Let the position in space at which the point is to be fixed be chosen as origin, and let the axis of x be chosen so as to pass through the centre of inertia at the moment of fixture. Then, if u, v be the velocities of the centre of inertia, ω the angular velocity about it, a its distance from the point to be fixed, the conditions of the impact are

$$u'=u-\Xi/M,$$
$$v'=v-H/M,$$
$$\omega'=\omega+Ha/Mk^2,$$

—three equations with five unknown quantities. But the conditions that the point in question is reduced to rest are evidently

$$u'=0,\quad v'-\omega' a=0.$$

These furnish the requisite additional data, and the solution is complete. If we eliminate H between the two equations which contain it, we have

$$k^2\omega'+av'=k^2\omega+av,$$

whence by the relation between v' and ω' we have

$$(k^2+a^2)\omega'=k^2\omega+av.$$

These equal quantities, each multiplied by M, represent respectively the moment of momentum about the point before and after its fixture.

§ 252. Thus, as a little consideration will show, we might have solved the problem at once, so far as the impulsive change of *motion* is concerned, by noticing that as the impulse is applied at the origin, the moment of momentum about that point will not be altered by it. In fact many problems, which present serious complexity when treated by the direct methods, are solved with comparative ease by such general considerations as the conservation of moment of momentum, or the conservation of energy. The first principle holds good when there is no resultant couple, or impulsive couple, round the origin; the second when no work on the whole is done by or against the forces or impulses.

Combined rolling and sliding.

§ 253. We have given instances of pure sliding, and of pure rolling, in one plane, and will now give a single instance of combined rolling and sliding. A common but instructive case of the problem we propose to consider is that of a hoop thrown forwards and at the same time made to rotate, so that after a time it stops, and finally rolls backwards to the hand. Other cases are furnished by a "following stroke" or a "screw-back" with a billiard ball.

Let the axis of x be parallel to the motion of translation of a sphere or cylinder moving on a horizontal plane. Then we have, if F be the friction, a the radius of the hoop or ball, the rate of change of momentum = F, and that of moment of momentum about the centre = Fa.

So long as sliding continues, F is constant, and equal to the product μMg of the normal pressure and the coefficient of kinetic friction. Hence at time t, if u_0 and ω_0 be the initial velocities of translation and of rotation,

$$u=u_0-\mu gt,$$
$$k^2\omega=k^2\omega_0-\mu gat.$$

These equations cease to be true when the sliding ceases, *i.e.*, when we have pure rolling, of which the geometrical condition is

$$u+a\omega=0.$$

This gives $\quad u_0+a\omega_0-\mu g(a^2/k^2+1)t_0=0,$

or $\quad t_0=\dfrac{k^2(u_0+a\omega_0)}{\mu g(a^2+k^2)}.$

At time t_0 and ever after we have

$$u=u_0-\frac{k^2(u_0+a\omega_0)}{k^2+a^2}=a\frac{au_0-k^2\omega_0}{k^2+a^2},$$

$$\omega=\omega_0-\frac{au_0+a^2\omega_0}{k^2+a^2}=\frac{k^2\omega_0-au_0}{k^2+a^2}.$$

Hence, if the body be projected in the positive direction, its ultimate motion will be in the negative direction if $au_0-k^2\omega_0$ be negative, *i.e.*, if the initial angular velocity be positive, and greater than au_0/k^2; which is $\frac{5}{2}u_0/a$ in the case of a sphere. Thus, at starting, the linear velocity of the point of contact with the plane must bear to that of translation of the ball a ratio of over 7 : 2 if it is to stop and return. In the case of a hoop this ratio must be at least 2 : 1.

Rigid body with point fixed.

§ 254. We pass now to the case of a rigid body one point only of which is fixed. As we have already seen (§ 234) this has only to be compounded with the motion of the whole mass, supposed concentrated at the point, in order to give the most general motion of which a rigid body is capable. The geometrical processes which have been applied to this problem, though in many respects of great power and elegance, cannot be introduced here. We will therefore give the more important results in a brief analytical form, and then geometrically exhibit their application.

Recurring to the general equations

$$\Sigma m(x\ddot{y}-y\ddot{x})=\Sigma(xY-yX)=N,\ \&c.,$$

we may transform the left hand members as follows.

Let ω_x, ω_y, ω_z be the angular velocities of the body about the fixed axes of x, y, z respectively. Then (§ 77) we have

$$\dot{x}=z\omega_y-y\omega_z,\ \&c.$$

From these we have three equations of the type

$$\ddot{x}=z\dot{\omega}_y-y\dot{\omega}_z+\dot{z}\omega_y-\dot{y}\omega_z$$
$$=z\dot{\omega}_y-y\dot{\omega}_z+(y\omega_x-x\omega_y)\omega_y-(x\omega_z-z\omega_x)\omega_z.$$

Thus we have

$$x\ddot{y} - y\ddot{x} = (x^2 + y^2)\dot{\omega}_z - yz\dot{\omega}_y - xz\dot{\omega}_x + xz\omega_y\omega_z - zy\omega_x\omega_z + (x^2 - y^2)\omega_x\omega_y - xy(\omega_x^2 - \omega_y^2) .$$

Now if the fixed axes be taken so as to coincide at a particular instant with the principal axes of the body passing through the point which is regarded as fixed, the terms involving factors of the form $\Sigma(mxy)$, &c., necessarily vanish (§ 237). Also we have

$$\Sigma m(x^2 - y^2) = \Sigma m(x^2 + z^2 - y^2 - z^2) ,$$

so that, if the principal moments of inertia of the body be A, B, C respectively, the dynamical equations become

$$C\dot{\omega}_z + (B - A)\omega_x\omega_y = N , \ \&c.$$

But it was proved in § 79 that when the angular velocities of a rigid body are referred to moving and to fixed axes, which coincide at a particular instant, not only are the angular velocities but also the angular accelerations equal at that instant in the two systems. Thus, if ω_1, ω_2, ω_3 be the angular velocities of the body about its principal axes, the equations just obtained take the form (due to Euler)

$$A\dot{\omega}_1 + (C - B)\omega_2\omega_3 = L ,$$
$$B\dot{\omega}_2 + (A - C)\omega_3\omega_1 = M ,$$
$$C\dot{\omega}_3 + (B - A)\omega_1\omega_2 = N .$$

When ω_1, ω_2, ω_3 are found, in any particular case, from these equations, the actual orientation of the body at any time can be calculated from them by the kinematical processes of § 81. The position in space of the point of the body which has been hitherto treated as fixed is to be calculated separately by the processes already explained for kinetics of a particle, and thus the motion of the body is completely determined—in the sense that the difficulties of the further steps are of a purely mathematical nature.

igid ody nder no rces. When the forces applied to the body have a single resultant, which either vanishes or passes through the origin, the right-hand terms disappear from Euler's equations. Multiply the equations by ω_1, ω_2, ω_3 respectively, and add. We thus obtain

$$A\omega_1\dot{\omega}_1 + B\omega_2\dot{\omega}_2 + C\omega_3\dot{\omega}_3 = 0 ,$$

whence

$$A\omega_1^2 + B\omega_2^2 + C\omega_3^2 = 2T \quad . \quad . \quad . \quad . \quad . \quad (1),$$

—the statement that the kinetic energy is constant. Again, multiply by $A\omega_1$, $B\omega_2$, $C\omega_3$ respectively, and add. Then we have

$$A^2\omega_1\dot{\omega}_1 + B^2\omega_2\dot{\omega}_2 + C^2\omega_3\dot{\omega}_3 = 0 ,$$

whence

$$A^2\omega_1^2 + B^2\omega_2^2 + C^2\omega_3^2 = D^2 \quad . \quad . \quad . \quad . \quad . \quad . \quad (2),$$

expressing the constancy of *amount* of moment of momentum.

But if, in these equations, we now choose to regard ω_1, ω_2, ω_3 as the coordinates, parallel to the principal axes, of the extremity of a line which represents, in magnitude and direction, the instantaneous axis, we see that that axis is a central vector of each of the ellipsoids (1) and (2). Hence the instantaneous axis describes, relatively to the body, a cone of the second order. Since T and D are the only arbitrary coefficients in the equations, all the ellipsoids (1) or (2) are similar and similarly situated. The curve of intersection of (1) and (2) projected on the plane of the axes A and B has the equation

$$A(C - A)\omega_1^2 + B(C - B)\omega_2^2 = 2TC - D^2.$$

This represents an ellipse if the terms on the left have the same sign, *i.e.*, if C is either greater or less than each of A and B. Hence, if the body be originally rotating about an axis nearly coinciding either with the axis of greatest or that of least moment of inertia, it will continue to do so. These two cases are exemplified respectively by a quoit and by an elongated rifle bullet,—at least in so far as the resistance of the air does not interfere with their motion. But if the body be originally rotating about an axis nearly coinciding with the axis of intermediate moment of inertia, the curve indicated by the equation above is an hyperbola or a pair of straight lines through the origin; and the instantaneous axis travels, in general, far away from its first position in the body. We will henceforth look on A, B, C as in descending order of magnitude. It is obvious from the mode in which they are formed that $A = B + C$ only when the body is a plate. Hence, generally, any two of A, B, C are together greater than the third. Also by multiplying (1) by A, and comparing it term by term with (2), we see that $2AT > D^2$; similarly $2CT < D^2$.

To complete the examination of the immediate results of Euler's equations in this case, let us find how the length of the instantaneous axis, considered as a common vector-radius of the ellipsoids (1) and (2), depends on the time.

Let

$$\Omega^2 = \omega_1^2 + \omega_2^2 + \omega_3^2 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3);$$

$$\Omega\dot{\Omega} = \omega_1\dot{\omega}_1 + \omega_2\dot{\omega}_2 + \omega_3\dot{\omega}_3$$
$$= -\left(\frac{C - B}{A} + \frac{A - C}{B} + \frac{B - A}{C}\right)\omega_1\omega_2\omega_3 = -\frac{\Delta}{ABC}\omega_1\omega_2\omega_3 ,$$

where Δ is the determinant

$$\begin{vmatrix} 1 & 1 & 1 \\ A & B & C \\ A^2 & B^2 & C^2 \end{vmatrix} = -(C - B)(B - A)(A - C) .$$

Now (1), (2), (3) are linear equations in ω_1^2, ω_2^2, ω_3^2, and from them we have three equations like

$$\Delta\omega_1^2 = BC(C - B)\Omega^2 + 2T(B^2 - C^2) + D^2(C - B)$$
$$= BC(C - B)\{\Omega^2 - a\} ,$$

where

$$a = \frac{2T(B + C) - D^2}{BC}$$

is, by the remark above, essentially positive. Hence

$$\Delta^3\omega_1^2\omega_2^2\omega_3^2 = A^2B^2C^2(C - B)(B - A)(A - C)(\Omega^2 - a)(\Omega^2 - b)(\Omega^2 - c)$$
$$= A^2B^2C^2\Delta(a - \Omega^2)(b - \Omega^2)(c - \Omega^2) .$$

Thus

$$\Omega\dot{\Omega} = \sqrt{(a - \Omega^2)(b - \Omega^2)(c - \Omega^2)} ;$$

whence Ω^2 is at once found by elliptic functions. Ω known, we have ω_1, ω_2, ω_3, and then by the method of § 81 we have the complete analytical determination of the position of the body in terms of the time.

§ 255. Such a solution, however, fails to give so clear a conception of the nature of the motion as is afforded by the very elegant geometrical representation discovered by Poinsot. We may arrive at it by considering the tangent plane to (1) at the extremity of the radius Ω. If x, y, z be the current coordinates of that plane, its equation is — Poinsot's rolling ellipsoid.

$$A\omega_1(\omega_1 - x) + B\omega_2(\omega_2 - y) + C\omega_3(\omega_3 - z) = 0 ,$$

so that the perpendicular from the origin upon it is equal, by (2), to $2T/D$, a constant. The direction cosines of this perpendicular are proportional to $A\omega_1$, $B\omega_2$, $C\omega_3$, the component moments of momentum. Hence it is the axis of resultant moment of momentum, and is therefore (§ 166) fixed in direction in space. The tangent plane to (1) at the extremity of the instantaneous axis is therefore a fixed plane, and the ellipsoid (1) rolls upon it as if it were perfectly rough. From this we can of course find the equation of the curve of contact with the plane, and thence that of the cone, fixed in space, on which the cone of instantaneous axes in the body rolls, as in § 75. The latter cone is of course given by the intersection of (1) and (2).

To complete this beautiful representation of the motion, all that is necessary is a method of measuring time, something to show the rate of rolling of the ellipsoid on the fixed plane. Many constructions have been given for this purpose, such as Poinsot's "rolling and sliding cone," &c., but none can compare in elegance with that invented by Sylvester. We can only sketch a particular case—sufficient, however, to completely solve the question. — Sylvester's addition to Poinsot's construction.

Writing l, m, n for the direction cosines of the fixed line referred to the principal axes, we have

$$l = A\omega_1/D, \quad m = B\omega_2/D, \quad n = C\omega_3/D \quad . \quad . \quad . \quad . \quad (4).$$

Our equations (1) and (2) may now be written

$$l^2/A + m^2/B + n^2/C = 2T/D^2 \quad . \quad . \quad . \quad . \quad (1),$$
$$l^2 + m^2 + n^2 = 1 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2).$$

Introducing a factor p, of dimensions the same as $1/A$, we have from these a third equation

$$l^2(1/A + p) + m^2(1/B + p) + n^2(1/C + p) = 2T/D^2 + p \quad . \quad (5).$$

Now consider an ellipsoid

$$\frac{x^2}{1/A + p} + \frac{y^2}{1/B + p} + \frac{z^2}{1/C + p} = E \quad . \quad . \quad . \quad (6),$$

which is similar, and similarly situated, to one of the ellipsoids confocal with (1) of § 254. Draw to it a tangent plane perpendicular to the line OL, whose direction cosines are (4). We obtain for the determination of the point of contact Q three equations of the form

$$l = \frac{x}{S(1/A + p)} , \quad m = \frac{y}{S(1/B + p)} , \quad n = \frac{z}{S(1/C + p)} \quad . \quad (7),$$

where

$$S^2 = \frac{x^2}{(1/A + p)^2} + \frac{y^2}{(1/B + p)^2} + \frac{z^2}{(1/C + p)^2} .$$

Here x, y, z are the coordinates of Q, and the distance of the tangent plane from the origin is E/S.

Now (6) gives at once by means of (7)

$$S^2[l^2(1/A + p) + m^2(1/B + p) + n^2(1/C + p)] = E ;$$

whence, by (5),
$$S^2 = \frac{E}{2T/D^2 + p}.$$
This is constant, and therefore the new tangent plane is fixed in space.

Let us now find the angular velocity about the fixed line OL of this plane's point of contact Q with the ellipsoid (6).

The direction cosines of the instantaneous axis OP are as $\omega_1, \omega_2, \omega_3$. Those of OQ are as x, y, z.

And we have obviously by (4) and (7)
$$\begin{vmatrix} \omega_1 & \omega_2 & \omega_3 \\ x & y & z \\ A\omega_1 & B\omega_2 & C\omega_3 \end{vmatrix} = 0.$$

Hence the line OQ lies in the plane containing the instantaneous axis OP and the fixed line OL. The motion of ellipsoid (6) is therefore one of combined sliding and rolling along the new tangent plane. To find the sliding, we must find the angular velocity of Q about the line OL. It is to that about OP, which is Ω, in the ratio of the sines of the angles POQ and QOL.

But
$$\sin^2 POQ = 1 - \frac{(x\omega_1 + y\omega_2 + z\omega_3)^2}{(x^2+y^2+z^2)\Omega^2},$$
and
$$\sin^2 QOL = 1 - \frac{(A\omega_1 x + B\omega_2 y + C\omega_3 z)^2}{(x^2+y^2+z^2)D^2}.$$
By means of the equations (1) and (7) above we find easily
$$\frac{\sin^2 POQ}{\sin^2 QOL} = \frac{D^2p^2}{\Omega^2}.$$

Hence the angular velocity of Q about OL is Dp, a constant. Now suppose the plane on which the ellipsoid (6) rolls and slides to become perfectly rough, and to be capable of rotating round OL as an axis, there will no longer be sliding of Q, but the plane will be made to rotate with the constant angular velocity Dp. Thus the time of any portion of the motion of the body will be measured out by the angle of forced rotation of this plane.

Quoit. § 256. As a simple example, let us take the case of a quoit, in which A, the moment of inertia about the axis of figure, is greater than either of the equal quantities B and C, which may be referred to any two perpendicular lines in the plane of the quoit. The equations become
$$A\dot\omega_1 = 0, \text{ so that } \omega_1 \text{ is constant,}$$
$$B\dot\omega_2 + (A-B)\omega_3\omega_1 = 0,$$
$$B\dot\omega_3 + (B-A)\omega_1\omega_2 = 0.$$
Put for a moment $\frac{A-B}{B}\omega_1 = n$, then we have
$$\dot\omega_2 + n\omega_3 = 0, \quad \dot\omega_3 - n\omega_2 = 0.$$
These give by eliminating ω_3
$$\ddot\omega_2 + n^2\omega_2 = 0.$$
Hence
$$\omega_2 = P\cos(nt+Q),$$
$$\omega_3 = -n^{-1}\dot\omega_2 = P\sin(nt+Q).$$

The resultant of these is an angular velocity P, about an axis in the plane of the axes of B and C, and making an angle $nt+Q$ with the axis of B. Hence the instantaneous axis describes in the body a right cone whose axis is that of figure; it moves round it in the *same* direction as that in which the body is rotating, and with angular velocity n. The fixed cone in space is also, obviously, a right cone and the other rolls on it *externally*.

Cylinder. If instead of a quoit the body be a long stick or cylinder, we have $A = B > C$, and the equations become
$$A\dot\omega_1 + (C-A)\omega_2\omega_3 = 0,$$
$$A\dot\omega_2 + (A-C)\omega_3\omega_1 = 0,$$
$$C\dot\omega_3 = 0.$$
The last gives ω_3 = constant, and, if
$$n = \frac{A-C}{A}\omega_3,$$
the first two equations are
$$\dot\omega_1 - n\omega_2 = 0, \quad \dot\omega_2 + n\omega_1 = 0.$$
Thus
$$\ddot\omega_1 + n^2\omega_1 = 0, \quad \omega_1 = P\cos(nt+Q),$$
and
$$\omega_2 = -P\sin(nt+Q).$$
This indicates a rotation of the axis of constant angular velocity P in the *negative* direction. Everything else is as before, but the cone fixed in the body rolls on the *inside* of that fixed in space.

Gyroscopic pendulum. § 257. Next let us take the case of a pendulum bob, supported by a flexible but untwistable wire, and containing a gyroscope whose axis is in the direction of the length of the pendulum. Here we may use, for variety, Lagrange's equations. For simplicity we suppose the centres of inertia of the bob and gyroscope to lie in the axis, and the bob to be symmetrical about the direction of the length of the pendulum.

Let the moment of inertia of the whole about the axis of symmetry be A when the gyroscope is supposed to be prevented from turning relatively to the bob, and let the other two principal moments about the point of suspension be B. Let that of the gyroscope about its axis be C. Then, if θ be the inclination to the vertical, ϕ the azimuth of the pendulum, and ψ a quantity denoting the position of the gyroscope with reference to a definite plane in the bob passing through its axis, we easily find
$$2T = A(1-\cos\theta)^2\dot\phi^2 + B(\dot\theta^2 + \sin^2\theta\dot\phi^2) + C[\dot\psi - (1-\cos\theta)\dot\phi]^2,$$
$$V = Mgl(1-\cos\theta) = V_0(1-\cos\theta), \text{ suppose,}$$
where M is the whole mass, and l the distance from the point of suspension to the centre of inertia of the whole.

The general treatment of this complex problem cannot be attempted here. We may, however, easily obtain useful and characteristic results in some special simple cases, which will enable us to form a general idea of the nature of the motion.

Thus, suppose if possible θ to be constant. This is the *Conical Gyroscopic Pendulum*. We easily find the equations Conical gyroscopic pendulum.
$$\dot\psi - (1-\cos\theta)\dot\phi = \Omega = \text{const.}$$
$$(A(1-\cos\theta) + B\cos\theta)\dot\phi^2 - C\Omega\dot\phi = V_0.$$
For any assigned values of Ω and θ, this shows what will be the corresponding value of $\dot\phi$. But it also shows that if we change simultaneously the signs only of Ω and $\dot\phi$, the value of θ is unaltered. Thus, reversal of the direction of rotation of the gyroscope involves reversal of the direction of motion of the bob, if the time of rotation is to be unaltered. But to any assigned values of θ and Ω two values of $\dot\phi$ correspond. As θ cannot, in the case considered, exceed $\frac{1}{2}\pi$, the multiplier of $\dot\phi^2$ is essentially positive. So is $V_0 = Mgl$. Hence the values of $\dot\phi$ are real; and one is positive, the other negative. Thus the pendulum, with any rate of rotation of the gyroscope, may be made to move in any horizontal circle; but the angular velocity will be greater when it is in the same sense as that of the rotation of the gyroscope than when it is in the opposite sense. When θ is so small that θ^2 may be neglected, we have
$$B\dot\phi^2 - C\Omega\dot\phi = V_0,$$
or
$$2B\dot\phi = C\Omega \pm \sqrt{4BV_0 + C^2\Omega^2}.$$
To give a numerical example, let the mass of the gyroscope be $\frac{n-1}{n}M$; let $B = Ml^2$, $C = \frac{n-1}{n}M\frac{l^2}{c^2}$, then
$$2\dot\phi = \frac{(n-1)\Omega}{nc^2} \pm \sqrt{4\frac{g}{l} + \left(\frac{n-1}{nc^2}\right)^2\Omega^2}.$$
If $n=5$, $c=10$, $g=10l$ (which are fair approximations to the dimensions of the ordinary form of the instrument),
$$\dot\phi = \frac{2\Omega}{500} \pm \sqrt{10 + \frac{4}{(500)^2}\Omega^2}.$$
Suppose the gyroscope to revolve 100 times per second, then $\Omega = 200\pi$ practically, and
$$\dot\phi = \tfrac{4}{5}\pi \pm \sqrt{10 + \tfrac{16}{25}\pi^2} = 2{\cdot}513 \pm 4{\cdot}039$$
$$= 6{\cdot}552 \text{ or } -1{\cdot}526.$$
The angular velocity, when the gyroscope is not rotating, would be that of the corresponding conical pendulum,
$$\sqrt{g/l} = \pm 3{\cdot}162;$$
so that in this case the gyroscopic pendulum would rotate about twice as fast, or only about half as fast, as the ordinary conical pendulum, according as it rotated with or against the gyroscope.

If we had taken $\Omega = 10\pi$ we should have found
$$\dot\phi = 3{\cdot}29 \text{ or } -3{\cdot}04, \text{ nearly.}$$
Thus the slower the gyroscope rotates the slower is the conical pendulum motion in the same direction, and the quicker that in the opposite direction.

Statics of a Chain or Perfectly Flexible Cord.

§ 258. Axiom.—*When a body or system is in equilibrium under the action of any forces, additional constraints will not disturb the equilibrium.* Compare § 193.

This principle is of very great use in forming the fundamental equations of fluid equilibrium, and thence those of motion. And we find it of advantage, as will be presently seen, in reducing to elementary geometry the problem of the equilibrium of a chain, or perfectly flexible cord.

We may treat this problem, called that of a "catenary," Catenary. by any one of the following methods:—(1) by investigating, as a question of statics of a particle, the conditions of equilibrium of a single link; (2) by imagining a finite portion of the chain to become rigid in its equilibrium form,—assuming, by the axiom above, that it will remain in equilibrium, and then treating the question by the methods employed for a rigid body; (3) by employing the energy test of equilibrium as in § 198.

§ 259. We exemplify each of these methods in the specially important case of the ordinary catenary.

Common catenary.

A uniform chain hangs between two fixed points, find the tension at any point and the curve in which the chain hangs.

First Method.—Let μ be the mass of unit length of the chain; T the tension at the point x, y, z; s the length of the chain to x, y, z from some assigned point; and let the axis of y be taken vertically. Then we have for the equilibrium of the element δs, considered as a material particle,

$$T\frac{dx}{ds} - \left(T\frac{dx}{ds} + \frac{d}{ds}\left(T\frac{dx}{ds}\right)\delta s\right) = 0,$$

$$T\frac{dy}{ds} + \mu g \quad - \left(T\frac{dy}{ds} + \frac{d}{ds}\left(T\frac{dy}{ds}\right)\delta s\right) = 0,$$

$$T\frac{dz}{ds} - \left(T\frac{dz}{ds} + \frac{d}{ds}\left(T\frac{dz}{ds}\right)\delta s\right) = 0.$$

Omitting the terms which cancel one another, and dividing by δs, these become

$$\frac{d}{ds}\left(T\frac{dx}{ds}\right) = 0, \quad \frac{d}{ds}\left(T\frac{dy}{ds}\right) = \mu g, \quad \frac{d}{ds}\left(T\frac{dz}{ds}\right) = 0.$$

From the first and third it follows that dz/dx is constant, *i.e.*, the chain hangs in a vertical plane. We may take it as that of xy, and the equations are reduced to the first two.

The first gives

$$T\frac{dx}{ds} = T_0,$$

showing that the horizontal component of the tension is constant throughout the whole length of the chain. Substituting for T in the second, it becomes

$$\frac{d}{ds}\left(\frac{dy}{dx}\right) = \frac{\mu g}{T_0}.$$

The quantity on the right is evidently of $[L^{-1}]$ dimensions, because that on the left is so; and thus we may write

$$\frac{\mu g}{T_0} = \frac{1}{a}, \quad \text{or} \quad T_0 = \mu g a.$$

Hence a is the length of a portion of the chain whose weight is equal to the constant horizontal component of the tension.

The equation now becomes

$$\frac{d^2y}{dx^2} = \frac{1}{a}\frac{ds}{dx} = \frac{1}{a}\sqrt{1 + \left(\frac{dy}{dx}\right)^2}.$$

Integrating, we have

$$\frac{dy}{dx} + \sqrt{1 + \left(\frac{dy}{dx}\right)^2} = C\varepsilon^{\frac{x}{a}}.$$

If we now assume that the axis of y passes through the point at which the chain is horizontal, we have at that point $x = 0, \frac{dy}{dx} = 0$, and therefore $C = 1$. Thus

$$\sqrt{1 + \left(\frac{dy}{dx}\right)^2} + \frac{dy}{dx} = \varepsilon^{\frac{x}{a}}.$$

Taking the reciprocal of each side, we have

$$\sqrt{1 + \left(\frac{dy}{dx}\right)^2} - \frac{dy}{dx} = \varepsilon^{-\frac{x}{a}}.$$

Subtracting,

$$2\frac{dy}{dx} = \varepsilon^{\frac{x}{a}} - \varepsilon^{-\frac{x}{a}},$$

or

$$2\frac{y}{a} = \varepsilon^{\frac{x}{a}} + \varepsilon^{-\frac{x}{a}};$$

no constant being added if we assume the axis of x so that $y = a$, $x = 0$ together. This is the equation of the curve required.

If we take the sum, instead of the difference, of the above equations, we find

$$2\frac{ds}{dx} = \varepsilon^{\frac{x}{a}} + \varepsilon^{-\frac{x}{a}};$$

so that

$$\frac{2s}{a} = \varepsilon^{\frac{x}{a}} - \varepsilon^{-\frac{x}{a}},$$

s being measured from the axis of y.

But the tension at x, y is, as above,

$$T = T_0\frac{ds}{dx} = T_0\frac{y}{a} = \mu g y.$$

Hence the tension at any point of the chain is equal to the weight of a length of the chain equal to the ordinate at that point.

Chain over parallel rails.

Thus if a chain of finite length be laid over two smooth parallel rails, its ends, when the whole is equilibrium, will be in the horizontal line corresponding to the axis of x in the above investigation, the middle part of the chain forming part of the catenary. When a given length $2l$ of chain rests in equilibrium on two smooth parallel rails at the same level, we have therefore $s + y = l$, while $x = b$, the half distance between the rails.

By the above expressions for y and s in terms of x, this leads to the equation

$$a\varepsilon^{\frac{b}{a}} = l,$$

which determines a when b and l are given. From this equation, as the minimum value of the left-hand side occurs when $a = b$, we see that the least length of chain for which equilibrium is possible under the conditions is equal to ε times the distance between the rails.

§ 260. *Second Method.*—The chain being in equilibrium, suppose any finite arc of it, as PQ (fig. 64), to become rigid. The forces acting on PQ are three—the tensions T_1 and T_2 at its ends, and its weight W acting at its centre of inertia. But three forces in equilibrium are in one plane (§ 221). Hence the curve is in one vertical plane. Also, as the two tensions are not parallel to one another, the lines of action of all three forces meet in one point. Hence there is no couple, and the conditions are simply

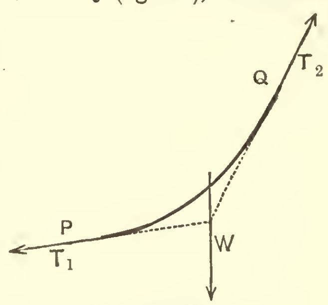

Fig. 64.

$$T_2\cos\theta_2 - T_1\cos\theta_1 = 0,$$
$$T_2\sin\theta_2 - T_1\sin\theta_1 - W = 0;$$

where θ_1, θ_2 are the inclinations to the horizon of the tangents at the ends of the portion solidified. The first asserts that the horizontal part of the tension is the same at P and Q, *i.e.*, all through the chain. The second asserts that the difference of the vertical parts of the tensions at any two points is equal to the weight of the part of the chain between them. By proper mathematical methods these data lead to the results already obtained. In fact the equations we have just obtained are the first integrals of the equations in § 259.

§ 261. *Third Method.*—The potential energy of the chain is

$$\mu g\int y\frac{ds}{dx}dx,$$

with the sole condition

$$\int\frac{ds}{dx}dx = \text{constant},$$

the limits of integration being fixed, and the same for each expression. Hence, by the rules of the calculus of variations, we have the same equations as before.

Mass of chain to hang in given curve.

§ 262. Still supposing gravity to be the only applied force, there are many forms of important questions which can be solved by either of these methods. We will take some simple, but varied, examples.

Find how the mass of unit length of a chain must vary from point to point so that the catenary may be an assigned plane curve.

We have, as before,

$$\frac{d}{ds}\left(T\frac{dx}{ds}\right) = 0;$$

but our second equation is now

$$\frac{d}{ds}\left(T\frac{dy}{ds}\right) = \mu g,$$

where μ is an unknown function of s. The third equation, being of the same form as the first, shows that the curve is in a vertical plane, and is thenceforth unnecessary.

As before, we have

$$T\frac{dx}{ds} = T_0 ,$$

and

$$\frac{d}{ds}\left(\frac{dy}{dx}\right) = \frac{\mu g}{T_0} .$$

Now, from the assigned equation of the catenary, the left-hand member can be expressed as a function of s, and thus we have the solution of the problem. For example, suppose the chain is to hang in an arc of an assigned circle. Referred to the lowest point of the circle, the equation is

$$x^2 = 2ay - y^2,$$

where a is the radius. From this we have

$$\frac{dy}{dx} = \frac{x}{a-y} = \tan\frac{s}{a} ,$$

so that

$$\mu = \frac{T_0}{ag}\sec^2\frac{s}{a} .$$

The tension at the lowest point is thus equal to the weight of a piece of chain like that at the vertex, and of length equal to the radius of the circle; the mass per unit length becomes infinite at the end of a horizontal diameter.

Suspension bridge.

Next *find the form of the chain when the mass of any arc is proportional to its horizontal projection.* This is a rough approximation to the case of a suspension bridge where the roadway is uniform, and much more massive than the chains, to which it is attached throughout by vertical ties. The equations are as before, but the additional condition takes the form

$$\mu\frac{ds}{dx} = \mu_0 , \text{ a constant.}$$

This gives

$$\frac{d^2y}{dx^2} = \frac{\mu_0 g}{T_0} ,$$

and the chain forms a parabola whose vertex is downwards, and whose axis is vertical.

Catenary of uniform strength.

As a final example, we have what is called the *catenary of uniform strength*; that is, *the form in which a chain hangs when the tension at every point is proportional to the breaking stress at that point.* Here we suppose the strength to be proportional to the section, *i.e.*, to the mass per unit length. This gives the condition

$$T = c\mu .$$

Hence

$$\frac{d}{ds}\left(\frac{dy}{dx}\right) = \frac{g}{cT_0}T = \frac{g}{c}\frac{ds}{dx} ,$$

or

$$\frac{d^2y}{dx^2} = \frac{1}{a}\left(\frac{ds}{dx}\right)^2 = \frac{1}{a}\left(1 + \left(\frac{dy}{dx}\right)^2\right) ,$$

where $a = c/g$.

This gives

$$\frac{dy}{dx} = \tan\left(\frac{x}{a} + C\right) ;$$

and the complete integral may be written, by proper selection of origin, in the final form

$$\varepsilon^{\frac{y}{a}} = \sec\frac{x}{a} .$$

Limit of span.

This curve has obviously two vertical asymptotes distant $\pm\frac{1}{2}\pi a$ from the axis of y. The quantity a is directly as the tenacity of the material; and thus we see that there is a limit (even in this simplest case) to the span of a chain, however strong, formed of any known kind of matter.

It is a very curious fact that, if we write the equation of this catenary in terms of the arc and the radius of curvature, it becomes identical with that of the common catenary in terms of Cartesian coordinates, horizontal and vertical. For we see at once that

$$\frac{ds}{dx} = \sec\frac{x}{a} ,$$

so that

$$\varepsilon^{\frac{s}{a}} = \sqrt{\left(1 + \sin\frac{x}{a}\right)\left(1 - \sin\frac{x}{a}\right)} ;$$

while by the previous equations

$$\frac{1}{\rho} = \frac{\frac{d^2y}{dx^2}}{\left(\frac{ds}{dx}\right)^3} = \frac{1}{a\frac{ds}{dx}} = \frac{\cos\frac{x}{a}}{a} .$$

Thus finally,

$$\frac{2\rho}{a} = \varepsilon^{\frac{s}{a}} + \varepsilon^{-\frac{s}{a}} . \quad \text{Compare § 259.}$$

Catenary general.

§ 263. When the chain is not uniform, and when it is subject to the action of other forces than, or besides, gravity, the equations are

$$\frac{d}{ds}\left(T\frac{dx}{ds}\right) = -\mu X , \quad \frac{d}{ds}\left(T\frac{dy}{ds}\right) = -\mu Y , \quad \frac{d}{ds}\left(T\frac{dz}{ds}\right) = -\mu Z ,$$

where X, Y, Z are the component forces on unit mass. These three equations involve the unknown quantities T, x, y, z, and s only; for μ is supposed to be given in terms of s. Two relations only among x, y, and z are wanted (for s is known in terms of x, y, z); so that the equations are necessary and sufficient to give these relations and the remaining unknown T.

The first members of these equations consist each of two terms:—

$$\frac{dT}{ds} \text{ multiplied respectively by } \frac{dx}{ds} , \frac{dy}{ds} , \frac{dz}{ds} ,$$

and

$$\frac{T}{\rho} \text{ multiplied by } \rho\frac{d^2x}{ds^2} , \quad \rho\frac{d^2y}{ds^2} , \quad \rho\frac{d^2z}{ds^2} ;$$

ρ being the radius of curvature of the chain. Hence (§ 22) we conclude that, so far as the tension alone is concerned, the forces on an elementary unit of length of the chain are dT/ds in the direction of the tangent, and T/ρ in the direction of the radius of absolute curvature. These must balance the corresponding components of the external forces on the element. Hence we see that the resultant of the applied forces lies, at every point, in the osculating plane. Thus we have

$$\frac{dT}{ds} = -\mu\left(X\frac{dx}{ds} + Y\frac{dy}{ds} + Z\frac{dz}{ds}\right) = -S ,$$

$$\frac{T}{\rho} = -\mu\left(X\rho\frac{d^2x}{ds^2} + Y\rho\frac{d^2y}{ds^2} + Z\rho\frac{d^2z}{ds^2}\right) = -N .$$

Here S and N are the tangential and normal components of the applied forces per unit length of the chain.

Catenary as path of particle.

But when a unit particle moves in a curve, we have always

$$\frac{dv}{dt} = v\frac{dv}{ds} = S', \text{ and } \frac{v^2}{\rho} = N',$$

where S′ and N′ are the normal and tangential components of the requisite force. If we write these in the form

$$\frac{dv}{ds} = \frac{S'}{v} , \quad \frac{v}{\rho} = \frac{N'}{v} ,$$

and suppose that the curve in which the particle moves is the same as the catenary above, while the speed at each point has the same numerical value as the tension, we see that we must have

$$\frac{S'}{v} = \frac{S'}{T} = -S , \quad \frac{N'}{v} = \frac{N'}{T} = -N ;$$

or

$$S' = -ST , \quad N' = -NT .$$

Thus the catenary will be the free path of the particle provided the force applied at any point is equal to the reverse of the product of that acting on the chain by the numerical value of the tension of the chain at that point.

Conversely, if we take any case of free motion of a particle, a uniform chain will hang in the corresponding orbit under the action of the same forces each reversed, and divided by the numerical value of the speed at the corresponding point of the orbit. Thus we can at once pass from particle kinetics to corresponding cases of catenaries.

Parabolic catenary.

In the case of a projectile, the path is a parabola, the force is constant and parallel to the axis, and the speed is as the square-root of the distance from the directrix. Hence, that the parabola may be a catenary under gravity, it must be turned vertex downwards; and the mass of the chain per unit length at any point must be inversely as the square root of the distance from the directrix. It is easily found from this that the mass of any arc of the chain must be proportional to the length of its horizontal projection, as in the second problem solved in § 262.

Elliptic catenary.

In the case of a planet we have

$$v^2 = \mu(2/r - 1/a) .$$

Hence a chain will hang in an ellipse if it be *repelled* from one focus by a force varying inversely as the square of the distance, the mass per unit length of the chain being directly as the square root of the distance from that focus and inversely as the square root of the distance from the other. If the chain be uniform, the law of the repulsive force from the first focus must be $1/\sqrt{r^3r'}$ instead of $1/r^2$, where r, r' are the distances from the two foci.

Pressure of cord on surface.

§ 264. When a chain or string is stretched over a curved surface, the surface must exert a reaction on it to keep it in its curved form. The preceding investigation has shown that the force normal to a chain per unit length at any point is balanced by T/ρ per unit of length, which must therefore be the magnitude of the reaction. We may establish this, however, in a very simple manner, as follows:—

Let AB (fig. 65) be a small portion of the cord, and AC, CB the tangents at its extremities; and let the (small) exterior angle at C be θ. Then, p being the pressure per unit length of the string, we have at once

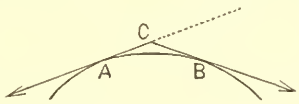

Fig. 65.

$$p.\text{AB} = 2\text{T}\sin\tfrac{1}{2}\theta = \text{T}\theta$$

ultimately. But $\text{AB} = \rho\theta$, so that

$$p = \text{T}/\rho\,.$$

Rope coiled on rough cylinder.

If there be friction, and if the element of the rope be just about to slip, in consequence of the difference of the tensions at its ends, we have

$$\text{T}' - \text{T} = \mu p.\text{AB} = \mu\text{T}\theta\,,$$

so that

$$\text{T}' = \text{T}(1 + \mu\theta)\,.$$

This leads to the formula for the growth of a sum at compound interest at μ per cent. payable every instant. Hence for a *finite* angle a we have

$$\text{T}_a = \varepsilon^{\mu a}\text{T}_0\,.$$

It is to be remarked here that neither the dimensions nor the form of the curve on which the cord is stretched, provided only it be plane, have any influence on this result, which involves only the coefficient of friction and the angle between the two free portions of the cord.

Kinetics of a Chain or Perfectly Flexible Cord.

§ 265. The equations of motion of a chain, under the action of any finite forces, are at once formed from those of equilibrium by introducing the forces of resistance to acceleration according to Newton's principle. Here we enter on a subject of extreme importance, but also (at least in the majority of cases) of great mathematical difficulty. One valuable result, however, can be obtained by very simple means.

Wave-velocity on stretched cord.

A uniformly heavy and perfectly flexible cord, placed in the interior of a smooth tube in the form of any curve, and subject to no external forces, will exert no pressure on the tube if it have everywhere the same tension, and move with a certain definite speed.

For, as in § 264, the statical pressure due to the curvature of the rope is $\text{T}\theta/\sigma$ per unit of length (where σ is the length of the arc AB in that figure) directed inwards to the centre of curvature. Now, the element σ, whose mass is $m\sigma$ (if m be the mass per unit of length), is moving in a curve whose curvature is θ/σ, with speed v (suppose). The requisite force is $\frac{mv^2\sigma\theta}{\sigma} = mv^2\theta$, and for unit of length $mv^2\theta/\sigma$. Hence if $\text{T} = mv^2$ the theorem is true. If we suppose a portion of the tube to be straight, and the whole to be moving with speed v parallel to this line, and against the motion of the cord, we shall have the straight part of the cord reduced to rest, and an undulation, of any, but unvarying, form and dimensions, running along it with linear speed $\sqrt{\text{T}/m}$.

Suppose the tension of the cord to be equal to the weight of W pounds, and suppose its length l feet and its own mass w pounds. Then $\text{T} = \text{W}g$, $lm = w$, and the speed of the undulation is $\sqrt{\text{W}lg/w}$ feet per second.

Reflected wave.

266. As will be shown later, when such an undulation reaches a fixed point of the cord or chain, it is *reflected*, and runs back along the cord with the same definite speed. But the reflected form differs from the incident form in being turned about in its own plane through two right angles. When the string is fixed at both ends any disturbance runs along it, backwards and forwards, with this speed, and thus (in a piano or harp) administers periodic shocks to the sounding board, causing it to give out a musical note. The interval between these periodic shocks is of course the time taken by the disturbance in running from end to end of the string. Dividing the length l of the string by the speed above reckoned, we find for this interval the value

$$\sqrt{wl/\text{W}g} = l\,\sqrt{m/\text{W}g}\,,$$

the reciprocal of which is the number of impulses per second. It is thus seen to be directly as the square-root of the tension of the string, inversely as the square-root of its mass per unit of length, and also inversely as its length. These are well-known facts in Acoustics. It is to be observed that there is no necessity for limiting the proposition above to a plane curve, though we have treated the question as if it were such. The demonstration applies even to a knot of any form.

Vibrati[ons] of musi[cal] string.

267. We will now consider more particularly the vibrations of a musical string, whose tension is great and its own mass small.

Forming the equations of motion as above hinted, we have three of the type

$$\frac{d}{ds}\left(\text{T}\frac{dx}{ds}\right) = -\mu(\text{X} - \ddot{x})\,.$$

In the special case of a tightly stretched inextensible string, performing very small transverse oscillations, we may greatly simplify these by assuming that no external forces act. This practically means that the weight of the string is negligible in comparison with the tension. If the axis of x be taken to coincide with the undisturbed position of the string, we have to the second order of small quantities

$$s = x\,.$$

With this the equation above written becomes

$$\frac{d\text{T}}{ds} = 0\,,$$

or the tension is the same throughout. The second and third equations now become

$$\text{T}\frac{d^2y}{dx^2} = \mu\ddot{y}\,, \qquad \text{T}\frac{d^2z}{dx^2} = \mu\ddot{z}\,.$$

The y and z disturbances are therefore of the same general character, and perfectly independent of one another. We will therefore confine our attention to one of them. From the equations we see that T/μ must be of two linear dimensions, and we will therefore write for it a^2. As this quantity must also be of two negative dimensions in time, a represents a speed. What speed will be seen immediately.

The equation in y is now

$$a^2\frac{d^2y}{dx^2} = \ddot{y}\,;$$

whose integral is known to be

$$y = f(at - x) + \text{F}(at + x)\,,$$

where f and F are arbitrary functions. As we have already seen (§ 53), the first part of the value of y expresses a wave running with speed a along the axis of x in the positive direction; the second part a wave in the negative direction with the same speed. Thus we see that any small disturbance whatever, of a stretched string, gives rise to two series of waves propagated in opposite directions with equal speeds. Also, as the equation is linear, the sum of any two or more particular integrals is also an integral.

One en[d] fixed.

If we suppose one extremity of the string to be fixed at the origin, we have the condition $x = 0$, $y = 0$, and therefore

$$0 = f(at) + \text{F}(at)\,.$$

As this holds for all values of t, the function F is simply the negative of f, so that

$$y = f(at - x) - f(at + x)\,.$$

To investigate what becomes of a disturbance which runs along the cord to the fixed end, let us suppose that $f(r)$ (which, by the remark above, may represent any *part* of a disturbance of the string) is a function which vanishes for all values of r which do not lie between the positive limits p and q, but which for values of r between these limits takes definite values. Then at time $t = 0$ we have

$$y = -f(x)\,,$$

for, by hypothesis, $f(r)$ vanishes for all negative values of r. This denotes a disturbance of the string originally extending from $x = p$

to $x=q$, which runs up to the origin. After the lapse of any interval greater than q/a we have

$$y=f(at-x)\,,$$

for $at+x$ has now become greater than q. This is a wave of exactly the same form as before, but the sign of the disturbance and the direction of its propagation are both reversed. Every portion of a wave is therefore reflected, with simple *reversal* of the displacement, as soon as it reaches the fixed end. For we may take the limits p and q as close together as we choose.

Both ends fixed.

Now suppose the string to have another fixed point at $x=l$. Then we have

$$0=f(at-l)-f(at+l)\,.$$

Thus f is (§ 67) a periodic function, of period $2l/a$, and can therefore be expressed as a series of simple harmonic terms of the full period, half period, one-third period, &c. Hence we may write, the coefficient $\frac{1}{2}$ being put in for convenience,

$$y=\tfrac{1}{2}\Sigma_1^\infty \mathrm{A}_m\cos\pi ml^{-1}(at-x)+\tfrac{1}{2}\Sigma_1^\infty \mathrm{B}_m\sin\pi ml^{-1}(at-x)$$
$$-\tfrac{1}{2}\Sigma_1^\infty \mathrm{A}_m\cos\pi ml^{-1}(at+x)-\tfrac{1}{2}\Sigma_1^\infty \mathrm{B}_m\sin\pi ml^{-1}(at+x)$$
$$=\Sigma_1^\infty \mathrm{A}_m\sin\pi ml^{-1}at\sin\pi ml^{-1}x-\Sigma_1^\infty \mathrm{B}_m\cos\pi ml^{-1}at\sin\pi ml^{-1}x\,.$$

This expression contains the complete solution of the problem. To adapt it to any particular case, we must know at some definite time (say $t=0$) the value of y in terms of x, *i.e.*, the initial disturbance; also the corresponding value of $\dot{y}$. We have then

$$y_0=-\Sigma_1^\infty \mathrm{B}_m\sin\pi ml^{-1}x\,,$$

$$\dot{y}_0=\frac{\pi a}{l}\Sigma_1^\infty m\mathrm{A}_m\sin\pi ml^{-1}x\,.$$

As y_0, $\dot{y}_0$ are given in terms of x, we can find, by the process of § 67, the values of A_m and B_m, and thence the required value of y.

Oscillations of a chain fixed at one end.

268. As another example, suppose a uniform chain to be suspended by one end, and to make small oscillations in a vertical plane.

We cannot enter here into details; so we simply assume that elementary persistent harmonic solutions are possible, or, what comes to the same thing, that there are *permanent* forms in which the chain can rotate about the vertical from the point of suspension.

If the axis of x be vertical, the equations of motion are

$$\frac{d}{ds}\left(\mathrm{T}\frac{dx}{ds}\right)=-\mu(g-\ddot{x})\,,\qquad \frac{d}{ds}\left(\mathrm{T}\frac{dy}{ds}\right)=\mu\ddot{y}\,;$$

where μ is the mass of unit length of the chain. As the oscillations are supposed to be small, we may neglect the change in the vertical ordinate of any point of the chain, because it must be of the second order of small quantities if the horizontal displacement is of the first order. Hence we may put everywhere x for s, and therefore consider x to be independent of t. Thus the first equation becomes

$$\frac{d\mathrm{T}}{dx}=-\mu g\,;$$

whence $\mathrm{T}=\mu g(l-x)\,,$

where l is the length of the chain. The second equation then becomes

$$(l-x)\frac{d^2y}{dx^2}-\frac{dy}{dx}=\frac{1}{g}\ddot{y}\,;$$

or, if we measure x from the lower end of the chain upwards,

$$x\frac{d^2y}{dx^2}+\frac{dy}{dx}=\frac{1}{g}\ddot{y}\,.$$

The complete integral of this equation would be much more general than we require, for it would express every possible small motion of the chain, however apparently irregular. What we seek are the fundamental modes of simple harmonic oscillation, any number of which, as in the case of a musical string, may be superposed. Hence we may write

$$y=\eta\sin(nt+\alpha)\,,$$

where n is a numerical quantity as yet undetermined, but which is confined to one or other of a series of definite values; η, on the other hand, is a function of x only. With this value of y the equation becomes

$$x\frac{d^2\eta}{dx^2}+\frac{d\eta}{dx}+\frac{n^2}{g}\eta=0\,.$$

By the usual method of undetermined coefficients we easily find the particular integral

$$\eta_0=\mathrm{A}\left(1-\frac{n^2x}{g}+\frac{n^4x^2}{2^2g^2}-\frac{n^6x^3}{2^23^2g^3}+\&\mathrm{c.}\right)\,. \qquad (1).$$

This series is obviously convergent for all finite values of n^2x/g.

The general integral is of the form

$$\eta=\mathrm{B}(\eta_1+\eta_0\log x)+\mathrm{A}\eta_0\,;$$

where η_1 is a function of x, finite for all values of x, but which we need not determine. For it is clear that, to suit our present purpose, we must put $\mathrm{B}=0$; otherwise we should have η infinite at $x=0$. Thus (1) is the expression we require under the limitations above imposed.

The quantity A represents the semi-amplitude of oscillation of the lower extremity of the chain. The condition that the upper end is fixed gives $\eta_0=0$ for $x=l$, *i.e.*,

$$0=1-\frac{n^2l}{g}+\frac{n^4l^2}{2^2g^2}-\frac{n^6l^3}{2^23^2g^3}+\&\mathrm{c.}$$

The roots of this equation (which are all real and positive) give the values of n for the several fundamental modes of vibration.

We have $\eta_0=0$ for the following values of n^2l/g: 1·454, 7·62, 18·74, 34·79, &c.

From these we find for the periods of the various simple disturbances the following multiples of the period of a simple pendulum equal in length to the chain, viz., 0·83, 0·36, 0·23, 0·17, &c. When n^2l/g has the least of the above values, the chain is always entirely on one side of the vertical, and the time of a complete oscillation is to that of a simple pendulum of the same length as 5 : 6 nearly.

Impulsive tension.

269. When a free chain, at rest, has an impulsive tension applied at one end, the calculation of the consequent impulsive tension at different parts of the chain and the velocities generated is very simple.

For, calling the instantaneous speeds along the tangent and along the radius of absolute curvature v_s and v_ρ respectively, we have

$$\delta\mathrm{T}=\mu v_s\delta s\,,\qquad \mathrm{T}/\rho=\mu v_\rho\,,$$

where μ is the mass of unit length of chain at s. It is obvious that there can be no impulsive speed perpendicular to the osculating plane. The kinematical condition is simply that an elementary arc δs is not altered in length. But the tangential increment of speed alone would imply an increase of the length of δs in the ratio $1+\frac{dv_s}{ds}\delta t:1$ in time δt. Also the impulsive speed v_ρ would imply a diminution of its length in the ratio $1-v_\rho\delta t/\rho:1$ by virtually making it an arc of a circle of smaller radius, but subtending the same angle at the centre. Hence, neglecting the square of δt as compared with its first power, we find for the kinematical condition

$$\frac{dv_s}{ds}-\frac{v_\rho}{\rho}=0\,.$$

This gives, by eliminating the impulsive velocities,

$$\frac{d}{ds}\left(\frac{1}{\mu}\,\frac{d\mathrm{T}}{ds}\right)-\frac{1}{\mu}\,\frac{\mathrm{T}}{\rho^2}=0\,.$$

If the chain be uniform, this becomes

$$\frac{d^2\mathrm{T}}{ds^2}-\frac{\mathrm{T}}{\rho^2}=0\,.$$

The whole kinetic energy generated in the chain by the impulse is

$$\tfrac{1}{2}\int\frac{ds}{\mu}\left(\left(\frac{d\mathrm{T}}{ds}\right)^2+\frac{\mathrm{T}^2}{\rho^2}\right)\,;$$

and the condition that this shall be a maximum is the differential equation above. This is a particular case of a general theorem due to Sir W. Thomson, viz.:—

A material system of any kind, given at rest, and subjected to an impulse in any specified direction and of any given magnitude, moves off so as to take the greatest amount of kinetic energy which the specified impulse can give it.

The direction in which an element of the chain begins to move is inclined to the tangent at an angle ϕ where

$$\tan\phi=\frac{v_\rho}{v_s}=\frac{\mathrm{T}}{\rho\frac{d\mathrm{T}}{ds}}\,.$$

Waves of extension of a string.

270. It is to be observed that, in such questions as those just treated, the possibility of an impact's being propagated instantaneously along the whole length of a chain depends upon its assumed inextensibility. When a wire (such as that employed for a distance-signal on railways) is regarded as *extensible*, there is a definite speed with which a disturbance of the nature of extension is transmitted along it.

Thus, recurring to the equations of § 267, we see that for the motion of a stretched elastic string in the direction of its length we have

$$\frac{d\mathrm{T}}{ds}=-\mu(\mathrm{X}-\ddot{x})\,.$$

If there be no applied forces, $\mathrm{X}=0$. Also, if we use x instead of s to characterize a particular point of the string, we must put $x+\xi$ for x and x for s, ξ being a function of x and t which denotes at any instant the displacement of that point.

The physical condition is expressed by Hooke's Law in the form

$$E\frac{d\xi}{dx}=T.$$

Hence

$$E\frac{d^2\xi}{dx^2}=\mu\ddot{\xi}.$$

This expresses (as in § 267) the passage of simultaneous waves. They are now waves of condensation and extension, not of transverse displacement. The nature of the interpretation of the equation is of the same general character as before, the speed being $\sqrt{E/\mu}$.

Dynamics of an Elastic Solid.

§ 271. This subject, which is a very extensive and difficult one, and in its generality quite unsuitable for discussion here, has already been to some extent treated of under Elasticity. We therefore content ourselves with one or two examples, whose treatment is comparatively simple, while their applications are frequent and considerable practical importance.

Cylindrical or prismatic wire, originally straight. § 272. Even so restricted a problem as that of determining the form assumed by a wire or thin rod of homogeneous isotropic elastic material, under the action of given forces and couples, presents somewhat formidable difficulties unless in its unstrained state the wire be straight and truly cylindrical or prismatic. And, even with these limitations, the problem again becomes formidable if we introduce the consideration of non-isotropic material; while, in any case, if the radius of curvature at each point is not very large in proportion to the thickness of the rod in the plane of bending, the problem is to no appreciable extent simplified by the limitation of form of the body. We will therefore give the comparatively simple case of the mere bending and twist of a homogeneous isotropic wire whose natural form is cylindrical or prismatic, the amounts of these from various sources being so small as to be superposable. Bending. Bending lengthens one set of lines of particles originally parallel to the axis of the wire and shortens others. Twist. Twist lengthens all but one such line, forming them into helices. The more detailed investigation, which we cannot give here, shows that there is one line of particles (the "elastic central line") which passes through the centre of inertia of each transverse section, and which may be treated (under our present limitations) as rigorously unchanged in length. The mutual molecular action of the parts of the wire on opposite sides of any transverse section may of course be reduced to a force and a couple, and the force may be conveniently treated as passing through the centre of inertia of the section. Also the twist and curvature of the wire near this section obviously depend on the couple and not on the force. For the moment of the couple is in general finite, while that of the force (about any point in the corresponding element of the wire) is infinitesimal.

§ 273. Let any two planes, at right angles to one another, be drawn through the elastic central line before distortion; and let them be cut in lines PR and PS by a transverse section through a point P of the central line. Also let PT be a tangent to that line. Suppose a similar construction to be carried out for every point P of the central line. Then it is clear that the form of the distorted wire will be completely determined if we know the form assumed by the central line, and the positions taken by the lines PR and PS drawn from each point in it. In their new positions P′T′, P′R′, and P′S′ will still form (in consequence of the limitations we have imposed) a rectangular system; and the nature of the distortion will be clearly indicated by the change of position of this rectangular system as it passes from point to point of the distorted central line. The plane of rotation of P′T′ is the osculating plane of the bending; its rate of rotation in that plane per unit length of the central line is the amount of bending; and the rate of rotation of the system P′R′, P′S′, about P′T′, per unit length of the central line, is the rate of twist. Suppose P′ to move with unit velocity along the distorted central line, and let ρ, σ, τ be the angular velocities of the system about P′R′, P′S′, P′T′ respectively, then ρ represents the curvature (or bending) resolved in the plane S′P′T′, σ that in R′P′T′, while τ represents the twist.

Expressions for force and couple in terms of bending and twist. Now, if the elastic forces constitute a conservative system, the amount of work done on an element of the body corresponding to a length δs of the central line is to be calculated entirely from its change of form. It must therefore be expressible in the form

$$w\delta s$$

where w is a function of ρ, σ, τ; which must be such that the couples producing the bending are

$$\frac{dw}{d\rho} \text{ and } \frac{dw}{d\sigma},$$

while that producing the twist is

$$\frac{dw}{d\tau}.$$

These again, are functions of ρ, σ, τ, and they must, on account of the principle of superposition, be linear and homogeneous. For, within the limits to which we have restricted ourselves, the doubling alike of bending and twist must involve the doubling of each of the couples. Thus w must be a homogeneous function of ρ, σ, τ of the second degree. Hence we may assume

$$w=\tfrac{1}{2}(A\rho^2+B\sigma^2+C\tau^2+2D\rho\sigma+2E\sigma\tau+2F\tau\rho),$$

where A, B, C, D, E, F are quantities depending on the form of the section of the wire and the nature of its material at each point. This gives

$$\frac{dw}{d\rho}=A\rho+D\sigma+F\tau,\quad \frac{dw}{d\sigma}=D\rho+B\sigma+E\tau,\quad \frac{dw}{d\tau}=F\rho+E\sigma+C\tau.$$

Hence, when the couples are assigned, the amounts of bending and twist are at once calculated from them. But the expression above is much more general than we require for the limited case we are considering. For, if the only couples applied to a portion of the prism or cylinder considered be in planes perpendicular to its length, twist only will be produced. Thus, for $\frac{dw}{d\rho}=0$, $\frac{dw}{d\sigma}=0$, we ought to have also $\rho=0$, $\sigma=0$. Hence E and F both vanish and we have simply

$$w=\tfrac{1}{2}(A\rho^2+2D\rho\sigma+B\sigma^2+C\tau^2).$$

This may be reduced, by properly selecting the planes originally drawn through the elastic central line, to the form

$$w=\tfrac{1}{2}(A\rho^2+B\sigma^2+C\tau^2).$$

Now we see that

$$\frac{dw}{d\rho}=A\rho,\quad \frac{dw}{d\sigma}=B\sigma,\quad \frac{dw}{d\tau}=C\tau.$$

§ 274. In a prismatic or cylindrical wire of homogeneous isotropic material, the elastic central line is thus a torsion axis simply. Equal and opposite couples, applied to the ends of such a wire, in planes perpendicular to its length, produce twist in direct proportion to the moments of the couples. There are two planes perpendicular to one another, and passing through this line, such that, if equal and opposite couples in either of these planes be applied at any parts of the wire, the portion between is bent into a circular arc in that plane. These are the principal planes of flexure. The quantities A and B which, when multiplied by the amount of bending in either of these planes, give the moment of the corresponding couple are called the principal "flexure rigidities" of the wire. Flexure rigidity. When they are equal (as in the case of a wire of circular, square, equilateral triangular, &c., section) any plane through the axis is a principal plane of flexure. Torsional rigidity. C is the torsional rigidity of the wire. In general, when the wire is fixed at one end and a couple applied at the other, the wire assumes the form of a circular helix. The exceptions (or rather particular cases) are:—(*a*) when the plane of the couple contains the elastic central line, and there is mere flexure, without twist; (*b*) when the plane of the couple is perpendicular to the wire, and there is twist simply.

§ 275. As an example of the preceding theory, take first

Flexure of plank by its own weight.

the case of a uniform plank clamped horizontally at one end, and otherwise unsupported. This is obviously the same as the case of a plank of double the length, supported by a trestle placed under its middle. We assume as before that the radius of curvature is always very large compared with the thickness of the plank.

In all such cases we may at once apply the principle of § 258, and suppose one portion of the plank up to a section P to be fixed in its equilibrium position. The curvature immediately contiguous to P will then be simply proportional to the moment about P of the forces acting on the unfixed portion. Hence at the free end there will be no curvature, and the curvature at points near that end will be of the second order of infinitesimals; *i.e.*, its rate of increase at the end vanishes.

Let x be the length of the fixed portion, l the whole length of the plank. Then, as the deflexion y from the horizontal is always very small, the curvature is expressed (§ 22) by

$$\frac{d^2y}{dx^2},$$

so that we have at once

$$E\frac{d^2y}{dx^2} = -\mu g\int_0^{l-x} x'dx' = -\tfrac{1}{2}\mu g(l-x)^2,$$

where E is the "flexural rigidity" of the plank, and μ its mass per unit of length.

Successive integrations give

$$E\frac{dy}{dx} = B + \tfrac{1}{6}\mu g(l-x)^3,$$

and

$$Ey = A - B(l-x) - \tfrac{1}{24}\mu g(l-x)^4.$$

The terminal conditions are

for $x=0$, $\quad y=0, \quad \frac{dy}{dx}=0;$

and for $x=l$, $\quad \frac{d^2y}{dx^2}=0, \quad \frac{d^3y}{dx^3}=0.$

The last two are obviously satisfied.

The two former give

$$B = -\frac{\mu g l^3}{6}, \quad A = Bl + \tfrac{1}{24}\mu g l^4 = -\tfrac{1}{8}\mu g l^4.$$

Hence

$$Ey = -\tfrac{1}{24}\mu g(3l^4 - 4l^3(l-x) + (l-x)^4).$$

Thus the droop of the free extremity ($x=l$) is

$$\frac{\mu g}{8}\frac{l^4}{E} = \frac{Wl^3}{8E},$$

where W is the whole weight.

If the plank had been weightless, but loaded at the free end with a weight W, our equation would have been

$$E\frac{d^2y}{dx^2} = -W(l-x),$$

and we should have had

$$E\frac{dy}{dx} = B' + \tfrac{1}{2}W(l-x)^2,$$

$$Ey = A' - B'(l-x) - \tfrac{1}{6}W(l-x)^3.$$

The terminal conditions at $x=0$ are as before, so that

$$B' = -\tfrac{1}{2}Wl^2, \quad A' = -\tfrac{1}{2}Wl^3 + \tfrac{1}{6}Wl^3 = -\tfrac{1}{3}Wl^3,$$

and the droop of the free end is $\frac{Wl^3}{3E}$, greater than before in the ratio of 8 : 3.

If the plank be again looked on as heavy, but its free end be supported on a trestle which is pressed upwards till it acts with a force W, we find directly

$$E\frac{d^2y}{dx^2} = W(l-x) - \tfrac{1}{2}\mu g(l-x)^2,$$

$$E\frac{dy}{dx} = B'' - \tfrac{1}{2}W(l-x)^2 + \tfrac{1}{6}\mu g(l-x)^3,$$

$$Ey = A'' - B''(l-x) + \tfrac{1}{6}W(l-x)^3 - \tfrac{1}{24}\mu g(l-x)^4.$$

The terminal conditions, at $x=0$, are still as in the first case, and they give

$$B'' = \tfrac{1}{2}Wl^2 - \tfrac{1}{6}\mu g l^3,$$

when the amount by which the free end is raised is

$$\frac{A''}{E} = [l(\tfrac{1}{2}Wl^2 - \tfrac{1}{6}\mu g l^3) - \tfrac{1}{6}Wl^3 + \tfrac{1}{24}\mu g l^4]/E = \frac{5Wl^3}{24E}.$$

This is obviously the same as the amount of depression of the middle of a plank of length $2l$ supported by trestles at each end.

§ 276. Hence the droop of the middle of a plank resting on trestles at its ends is to that of the ends when the plank rests on a single trestle at the middle in the ratio of 5 : 3.

If the equation expressing the curvature in the first or third cases above be twice differentiated, the common result is

$$E\frac{d^4y}{dx^4} = -\mu g.$$

Horizontal plank under any vertical forces.

The simplicity of this expression leads us to seek for the most general form. Suppose the plank to be exposed to any system of forces in lines perpendicular to its length and breadth. Then, if any transverse section be made, the stress between the two portions of the plank will consist of forces ($\pm$G) and couples ($\pm$H) in the plane of length and thickness. Let the applied forces be N per unit of length. Suppose also, as before, that the radius of curvature is very great compared with the thickness. Then the equations of equilibrium of an element are

$$\frac{dG}{dx} + N = 0, \quad \frac{dH}{dx} + G = 0.$$

We have also the condition of bending, viz.,

$$E \times \text{curvature} = E\frac{d^2y}{dx^2} = H.$$

Eliminating H and G among these equations, we have

$$E\frac{d^4y}{dx^4} = \frac{d^2H}{dx^2} = -\frac{dG}{dx} = N,$$

which of course includes all the previous particular cases. We may now determine (under the limits imposed) the form of a uniform plank of any length, supported in a nearly horizontal position at different points in its length, and loaded at any assigned points with any weights. The importance of this in practice is obvious.

Vibration of plank or flat spring.

§ 277. But we may easily take a further step, and investigate the oscillatory motion, so long at least as the acceleration parallel to the length of the plank and its rotation are negligible. For in such a case, if μ be the mass per unit of length, the equation of motion is (§ 199)

$$E\frac{d^4y}{dx^4} = N - \mu\ddot{y}.$$

We will consider only the case in which the applied force N may be neglected. This is practically the case of a uniform wire or flat rectangular spring. Suppose, further, that it is fixed at one end and free at the other, like Wheatstone's "kalcidophone," or like the tongue of a reed organ-pipe.

Then, writing n^4 for the fraction μ/E, we have

$$\frac{d^4y}{dx^4} + n^4\ddot{y} = 0.$$

A particular integral may obviously be found in the form

$$y = \eta\cos(i^2t/n^2 + \alpha) \quad \ldots\ldots \quad (1),$$

where η (a function of x) and i/n (a constant number) have to be found; α is any constant. The substitution of this value of y leads to

$$\frac{d^4\eta}{dx^4} - i^4\eta = 0,$$

the complete integral of which is

$$\eta = A\varepsilon^{ix} + B\varepsilon^{-ix} + C\cos(ix + D).$$

Now, provided the value of i be properly determined, the motion represented by (1), with the above value of η, can exist by itself; and the most general motion of which the spring is capable (under the limits imposed) consists of superposition of a number of separate motions of a similar character. Hence this may be treated by itself. Our limiting conditions in the present case are

$x=0$, $\quad \eta=0, \ \frac{d\eta}{dx}=0$ at the fixed end;

and $\quad x=l$, $\quad \frac{d^2\eta}{dx^2}=0, \ \frac{d^3\eta}{dx^3}=0$ at the free end.

Now, from the value of η above, we have

$$\frac{1}{i}\frac{d\eta}{dx}=\mathrm{A}\varepsilon^{ix}-\mathrm{B}\varepsilon^{-ix}-\mathrm{C}\sin(ix+\mathrm{D}),$$

$$\frac{1}{i^2}\frac{d^2\eta}{dx^2}=\mathrm{A}\varepsilon^{ix}+\mathrm{B}\varepsilon^{-ix}-\mathrm{C}\cos(ix+\mathrm{D}),$$

$$\frac{1}{i^3}\frac{d^3\eta}{dx^3}=\mathrm{A}\varepsilon^{ix}-\mathrm{B}\varepsilon^{-ix}+\mathrm{C}\sin(ix+\mathrm{D}).$$

Hence we have

$$\begin{aligned}0&=\mathrm{A}+\mathrm{B}+\mathrm{C}\cos\mathrm{D},\\0&=\mathrm{A}-\mathrm{B}-\mathrm{C}\sin\mathrm{D},\\0&=\mathrm{A}\varepsilon^{il}+\mathrm{B}\varepsilon^{-il}-\mathrm{C}\cos(il+\mathrm{D}),\\0&=\mathrm{A}\varepsilon^{il}-\mathrm{B}\varepsilon^{-il}+\mathrm{C}\sin(il+\mathrm{D}).\end{aligned}$$

Eliminating C and D, we have

$$\begin{aligned}0&=\mathrm{A}\varepsilon^{il}+\mathrm{B}\varepsilon^{-il}+(\mathrm{A}+\mathrm{B})\cos il+(\mathrm{A}-\mathrm{B})\sin il,\\0&=\mathrm{A}\varepsilon^{il}-\mathrm{B}\varepsilon^{-il}-(\mathrm{A}+\mathrm{B})\sin il+(\mathrm{A}-\mathrm{B})\cos il.\end{aligned}$$

Eliminate the ratio A/B, which is all that these equations furnish, and we have

$$(\varepsilon^{il}+\varepsilon^{-il})\cos il+2=0.$$

From this equation the values of i must be determined. It is clear that the multiplier of $\cos il$ is always greater than 2, except in the special case of $i=0$, which we obviously need not consider, as it gives $y=0$, and therefore belongs to the statical problem already considered. Hence as, to make $\cos il$ negative, il must be greater than $\frac{1}{2}\pi$; and, as $\varepsilon^{\frac{1}{2}\pi}+\varepsilon^{-\frac{1}{2}\pi}=5$ nearly, it is clear that the excess of the first value of il over $\frac{1}{2}\pi$ is somewhere about 0·3. The next value falls short of $\frac{3}{2}\pi$ by a quantity of the order $\frac{1}{100}$, the next exceeds $\frac{5}{2}\pi$ by a quantity of the order $\frac{1}{2500}$, &c. The required values arrange themselves in two groups, one of either group being taken alternately. The first group involves arcs a little greater than but rapidly approaching to the values of $(4m+1)\frac{1}{2}\pi$; the second consists of arcs a little less than but rapidly approaching to those of $(4m+3)\frac{1}{2}\pi$.

Effects of pressure on tubes and spherical shells.

§ 278. Some of the simplest, but at the same time most practically useful, of questions connected with elasticity of solids relate to the changes of form or volume experienced by circular cylindrical tubes or spherical shells exposed to hydrostatic pressure. A steam-boiler, the cylinders and tubes of an hydraulic press, a fowling-piece or cannon and (on a much smaller scale) Örsted's piezometer, deep-sea thermometers, &c., afford common instances. All that is necessary for attacking such questions is given in §§ 45, 46 of the article ELASTICITY. For it is there shown that, if a homogeneous isotropic elastic solid be subjected to a simple longitudinal stress P, uniform and in a definite direction throughout its whole substance, the result will be linear extension $=\mathrm{P}\left(\frac{1}{3n}+\frac{1}{9k}\right)$ in the direction of P, and linear contraction $=\mathrm{P}\left(\frac{1}{6n}-\frac{1}{9k}\right)$ in all directions perpendicular to P. The quantities n and k, as explained in the article referred to, are respectively the "rigidity" and the reciprocal of the "compressibility" of the solid operated on.

Equal pressures within and without piezometer.

§ 279. The case of the piezometer, in which the vessel holding the liquid whose compression is to be measured is exposed both inside and outside to the same hydrostatic pressure, is seen to correspond to three equal stresses in directions at right angles to one another. These directions may be any whatever, and in each of them the linear extension is obviously

$$\mathrm{P}\left\{\left(\frac{1}{3n}+\frac{1}{9k}\right)-2\left(\frac{1}{6n}-\frac{1}{9k}\right)\right\}=\frac{\mathrm{P}}{3k}.$$

P is negative, as the stress is a pressure. Hence the strain consists in a simple alteration of volume measured by P/k. Every part of the walls of the vessel, as well as its external bulk, and its interior content, is altered to the same extent.

Cylinder under internal pressure.

§ 280. In the case of a cylinder, when the internal and external pressures are different, it is clear from symmetry that the stresses may be resolved at any point of the walls into three at right angles to one another, the first (P_1) parallel to, the second (P_2) at right angles to, the axis, and the third (P_3) perpendicular to each of the other two. In a transverse section of the cylinder, the second of these is radial and the third is tangential to a coaxal cylinder passing through the element considered. We suppose the cylinder closed at both ends, and we make the further assumption (quite exact enough for practical applications, and most important from the point of view of simplicity of calculation) that all transverse sections of the cylinder remain, after distortion, transverse sections. This is equivalent to assuming P_1 to be constant throughout the walls of the cylinder. Hence, if there be interior pressure only, the value of this stress must be

$$\mathrm{P}_1=\frac{\text{pressure on end of interior of cylinder}}{\text{area of transverse section of walls of cylinder}}=\frac{\Pi a_0^2}{a_1^2-a_0^2},$$

where Π is the interior hydrostatic pressure, and a_0, a_1 are the internal and external radii. This stress represents a longitudinal *tension* of the walls of the cylinder.

Let us consider an element of the cylindrical wall, defined as follows in the unstrained state:—

Draw two transverse sections at distances x and $x+\delta x$ from one end, two planes through the axis making an (infinitesimal) angle θ with one another, and two cylinders of radii r and $r+\delta r$ about the common axis. In the strained state θ is unchanged, but x becomes $x+\xi$, and r becomes $r+\rho$. The distance between the transverse sections was δx; it becomes $\delta x+\frac{d\xi}{dx}\delta x$, so that the linear extension parallel to the axis is $\frac{d\xi}{dx}$. The distance between the cylinders was δr; it becomes $\delta r+\frac{d\rho}{dr}\delta r$, so that the radial extension is $\frac{d\rho}{dr}$. The breadth of the base of the wedge-shaped element was $r\theta$; it becomes $(r+\rho)\theta$, so that the linear extension perpendicular alike to the radial line and to the axis is $\frac{\rho}{r}$.

If we now write, for simplicity,

$$e=\frac{1}{3n}+\frac{1}{9k},\quad f=\frac{1}{6n}-\frac{1}{9k},$$

the three requisite equations between stresses and strains are at once obvious in the form

$$\frac{d\xi}{dx}=e\mathrm{P}_1-f\mathrm{P}_2-f\mathrm{P}_3,$$

$$\frac{d\rho}{dr}=-f\mathrm{P}_1+e\mathrm{P}_2-f\mathrm{P}_3,$$

$$\frac{\rho}{r}=-f\mathrm{P}_1-f\mathrm{P}_2+e\mathrm{P}_3.$$

We have, however, four unknown quantities ξ, ρ, P_2, and P_3, so that another equation is required. This must be supplied by one of the statical conditions of equilibrium of the element above defined, when in its strained state. There is obviously equilibrium in the axial direction, and also parallel to the base of the element; but radially we have a case resembling that of an element of a cord as in § 264. Neglecting small quantities of a higher order than those retained, this consideration gives

$$\mathrm{P}_3\delta\theta\delta x\delta r=\frac{d}{dr}(\mathrm{P}_2r\delta\theta\delta x)\delta r,\quad\text{or}\quad\mathrm{P}_3=\frac{d}{dr}(\mathrm{P}_2r).$$

Solving the four equations, and taking account of the boundary conditions

$$\mathrm{P}_2=-\Pi\text{ when }r=a_0,\text{ and }\mathrm{P}_2=0\text{ when }r=a_1,$$

we obtain the following values:—

$$\frac{d\xi}{dx}=\Pi\frac{a_0^2}{a_1^2-a_0^2}(e-2f),$$

$$\frac{\rho}{r}=\Pi\frac{a_0^2}{a_1^2-a_0^2}\left[(e-2f)+\frac{a_1^2}{r^2}(e+f)\right],$$

$$\frac{d\rho}{dr}=\Pi\frac{a_0^2}{a_1^2-a_0^2}\left[(e-2f)-\frac{a_1^2}{r^2}(e+f)\right]:$$

or, reintroducing the values of e and f,

$$\frac{d\xi}{dx}=\frac{\Pi a_0^2}{a_1^2-a_0^2}\frac{1}{3k},$$

$$\frac{\rho}{r}=\frac{\Pi a_0^2}{a_1^2-a_0^2}\left(\frac{1}{3k}+\frac{a_1^2}{r^2}\frac{1}{2n}\right).$$

$$\frac{d\rho}{dr}=\frac{\Pi a}{a_1^2-a_0^2}\left(\frac{1}{3k}-\frac{a_1^2}{r^2}\frac{1}{2n}\right).$$

§ 281. Thus the nature of the distortion produced in the walls of a cylindrical tube by internal pressure may be described as made up of a uniform dilatation, whose linear measure in every direction is $\frac{\Pi a_0^2}{a_1^2 - a_0^2}\frac{1}{3k}$, combined with a shear in each transverse section, whose measure is $1 \pm \frac{\Pi a_0^2 a_1^2}{(a_1^2 - a_0^2)r^2}\frac{1}{2n}$. § 91.

The shorter axis of this shear is radial, and the magnitude of the shear is obviously greater for smaller values of r. The inner layer of the walls is thus the most distorted. The amount of the distortion is directly as the pressure, and inversely as the area of the section of the walls.

When the walls are very thin the shear is practically the same throughout their thickness. When they are very thick, the shear near the inner surface is nearly $1 \pm \frac{\Pi}{2n}$, however fine be the bore. That near the outer surface is nearly $1 \pm \frac{a_0^2}{a_1^2}\frac{\Pi}{2n}$, which vanishes when the bore is very fine. Thus it appears that, if a stout tube bursts by the shear produced by internal pressure, little is gained either by making it of extremely great thickness or by making it of very small bore.

The diagrams A and B in fig. 66 show, necessarily on a greatly exaggerated scale, the nature of the distortion produced at different

A B C D

Fig. 66.

parts of the wall of the tube. They represent transverse sections of small, originally spherical, elements made by planes at right angles to the axis. The radial diameters are horizontal. A is an element close to the external surface, B an element near the inner surface. The increase per unit volume of the interior of the tube is

$$\frac{\Pi a_0^2}{a_1^2 - a_0^2}\left(\frac{1}{k} + \frac{a_1^2}{a_0^2}\frac{1}{n}\right);$$

so that, if the tube be very thick in comparison with its bore, the increase is nearly Π/n. In flint glass this is approximately about $\frac{1}{1000}$, when Π is a ton-weight per square inch.

Cylinder under external pressure.

§ 282. The reader who has followed the above investigation will find no difficulty in obtaining the corresponding results for a cylindrical tube, closed at both ends and exposed to external pressure Π, in the form

$$\frac{d\xi}{dx} = -\frac{\Pi a_1^2}{a_1^2 - a_0^2}\frac{1}{3k},$$

$$\frac{\rho}{r} = -\frac{\Pi a}{a_1^2 - a_0^2}\left(\frac{1}{3k} + \frac{a_0^2}{r^2}\frac{1}{2n}\right),$$

$$\frac{d\rho}{dr} = -\frac{\Pi a_1^2}{a_1^2 - a_0^2}\left(\frac{1}{3k} - \frac{a_0^2}{r^2}\frac{1}{2n}\right).$$

The only comments we need make are (1) that the signs of these distortions are now negative; (2) that they are (so far as change of volume is concerned) greater than for the internal pressure, as a_1^2 has taken the place of a_0^2 as a factor in each term involving k; (3) that the terms involving the rigidity are, except as regards sign, unchanged.

The change of volume of every part of the walls is

$$-\frac{\Pi a_1^2}{a_1^2 - a_0^2}\frac{1}{k},$$

and the change of volume of the interior is

$$-\frac{\Pi a_1^2}{a_1^2 - a_0^2}\left(\frac{1}{k} + \frac{1}{n}\right).$$

The numerical value of the factor $\Pi\left(\frac{1}{k} + \frac{1}{n}\right)$ is about $\frac{1}{1000}$ for flint glass and about $\frac{1}{4000}$ for steel, when Π is a ton-weight per square inch. There is, however, a peculiarity which (when the walls are thick enough) distinguishes this from the preceding case. For k is usually considerably greater than n, so that *a fortiori* $3k$ is greater than $2n$. Hence, in the value of $d\rho/dr$, the term in n is always greater than that in k so long as the pressure is internal. Thus the radial effect is compression at all parts of the walls. But, when the pressure is external, we may (if the walls be thick enough) find a value of r for which

$$\frac{1}{3k} = \frac{a_0^2}{r^2}\frac{1}{2n}.$$

In glass, this occurs when $r = 1{\cdot}6a_0$ nearly. At this distance from the axis there is no radial change of length; at greater distances there is radial compression, and at smaller radial extension. This is indicated in the diagrams C and D in fig. 66, which like the former are greatly exaggerated. They represent the distortion of small spherical elements of a thick tube,—the first at the inner wall, the second at the outer surface. As before, these are sections made by a plane perpendicular to the axis of the cylinder.

Spher[ical] shell under exter[nal] press[ure].

§ 283. In a spherical shell of internal and external radii a_0 and a_1, the equations become a little more simple on account of the more complete symmetry.

Using the same notation, so far as it is now applicable, we have

$$\frac{d\rho}{dr} = -2f\text{P}_1 + e\text{P}_2, \qquad \frac{\rho}{r} = (e-f)\text{P}_1 - f\text{P}_2.$$

The statical equation is

$$2r\text{P}_1 = \frac{d}{dr}(r^2\text{P}_2).$$

With these we obtain, for external pressure Π, the result

$$\frac{\rho}{r} = -\Pi\frac{a_1^3}{a_1^3 - a_0^3}\left(\frac{1}{3k} + \frac{a_0^3}{r^3}\frac{1}{4n}\right),$$

from which the other equation may be derived by differentiation.

§ 284. The propagation of plane waves in an elastic solid has been discussed in Elasticity, and the mechanics of fluids is discussed under Hydromechanics.

General Considerations.

Gener[al] considerations.

§ 285. The preceding view of the subject of Abstract Dynamics has been based entirely upon Newton's Laws of Motion, which were adopted without discussion, as a complete and perfectly definite foundation; and the terms employed, as well as the mode of treatment in general, have somewhat closely followed Newton's system. The only considerable apparent departure from that system is connected with the development of the idea of energy, and its application to the simplification of many of the methods and results. This also was, as we have seen, really introduced by Newton; but it has been immensely extended since his time both by mathematical and by experimental processes. It is time that we should now return to the laws of motion, and examine more closely, in the light of what we have learned, one or two of the more prominent ideas which they embody. To do so fairly we must go back to Newton's own definitions of the terms which he employs. About many of these, which have already been quoted in §§ 97–113, there is no difference of opinion But it is otherwise when we come to the definition of "force" (§§ 5, 104).

Force

There can be no doubt that the proper use of the term "force" in modern science is that which is implied in the statement of the first law of motion, as we rendered it in § 1 from Newton's Latin. It is thus seen to be the English equivalent of the term *vis impressa*. Newton uses the word *vis* in other connexions, and with a certain vagueness inevitable at a time when the terminology of science was still only shaping itself; but his idea of "force" was perfectly definite, and when *this* is in his mind the vague word *vis* is (when necessary) always qualified and rendered precise, either by the addition of *impressa* or in some equally unambiguous way. To render *vis* by "force," wherever it stands without the *impressa* or its equivalents, is to introduce a quite gratuitous confusion for which Newton is not responsible. We have only to think of the multitude of terms, such as *vis insita* (inertia), *vis acceleratrix* (acceleration), *vis viva* (kinetic energy), &c., &c., to see that all such complex expressions must be regarded as *wholes*, and that *vis* does not mean "force" in any one of them.

§ 286. Thus in Newton's view *force is whatever changes* (but not "*or tends to change*") *a body's state of rest or of uniform motion in a straight line.*

He mentions, as instances, percussion, pressure, and central force.[1] Under the last of these heads he expressly includes magnetic as well as gravitational force. Thus

[1] *Vis centripeta.* It has been already explained that such words as *centripeta* include *impressa*, so that the above rendering of Newton's phrase is the obvious one.

force may have different origins, but it is always one and the same; and it produces, in any body to which it is applied, a change of momentum in its own direction, and in amount proportional to its magnitude and to the time during which it acts.

Equilibrium.

§ 287. Thus, from Newton's point of view, equilibrium is not a balancing of forces, but a balancing of the effects of forces. When a mass rests on a table, gravity produces in it a vertically downward velocity which is continually neutralized by the equal upward velocity produced by the reaction of the table; and these forces, whose origins and places of application are alike so widely different, are (as forces), in every respect except direction, similar and equal. And they are so because they produce, in equal times, equal and opposite quantities of motion.

Origin of the idea of force.

§ 288. The idea of "force" was undoubtedly suggested by the "muscular sense"; and there can be no question as to the vividness of the sensation of effort we experience when we try to lift a heavy weight or to open a massive gate. In this, as in other cases, it is the business of science to find what objective fact corresponds to the subjective data of sensation. It is very difficult to realize the fact, certain as it is, that light (in the sense of *brightness*) is a mere sensation or subjective impression, and has no objective existence. Yet we know that, beside those radiations which give us the sensation of light, there are others, in endless series both higher and lower in their refrangibility, to which our eyes are absolutely blind. And the only difference between these and the former is one of mere wave-length or of period of vibration. Similarly, it is very hard to realize the fact that sound (in the sense of *noise*) is only a sensation; and that outside us there is merely a series of alternate compressions and dilatations of the air, the great majority of which produce no sensible effect upon our ears. Thus because we know that we should seek in vain for brightness or noise in the external world, familiar as our senses have rendered us with these conceptions, we are driven to inquire whether the idea of *force* may not also be a mere suggestion of sense, corresponding (no doubt) to some process going on outside us, but quite as different from the sensation which suggests it as is a periodic shearing of the ether from brightness, or a periodic change of density of air from noise.

Stress.

§ 289. So far, we have treated of force as acting on a body without inquiring whence or why; we have referred to the first and second laws of motion only, and have thus seen only one half of the phenomenon. As soon, however, as we turn to the third law, we find a new light cast on the question. Force is always dual. To *every* action there is *always* an equal and contrary reaction. Thus the weight which we lift or try to lift, and the massive gate which we open or try to open, both as truly exert force upon our hands as we do upon them. This looking to the other side of the account, as it were, puts matters in a very different aspect. "Do you mean to tell me," said a medical man of the old school, "that, if I pull a 'subject' by the hand, it will pull me with an equal and opposite force?" When he was convinced of the truth of this statement, he gave up the objectivity of force at once.

Tension and pressure.

§ 290. The third law, in modern phraseology, is merely this:—

Every action between two bodies is a stress.

When we pull one end of a string, the other end being fixed, we produce what is called *tension* in the string. When we push one end of a beam, of which the other end is fixed, we produce what is called *pressure* throughout the beam. Leaving out of account, for the moment, the effects of gravity, this merely amounts to saying that there is stress across every transverse section of the string or beam. But, in the case of the string, the part of the stress which every portion exerts on the adjoining portion is a *pull*; in the case of the beam it is a *push*. And all this distribution of stress, though exerted across every one of the infinitely numerous cross sections of the string or beam, disappears the moment we let go the end. We can thus, by a touch, call into action at will an infinite number of stresses, and put them out of existence again as easily. This, of itself, is a very strong argument against the supposition that force, in any form, can have objective reality.

Objective physical realities.

§ 291. We must now say a word or two on the question of the objective realities in the physical world. If we inquire carefully into the grounds we have for believing that matter (whatever it may be) has objective existence, we find that by far the most convincing of them is what may be called the "conservation of matter." This means that, do what we will, we cannot alter the mass or quantity of a portion of matter. We may change its form, dimensions, state of aggregation, &c., or (by chemical processes) we may entirely alter its appearance and properties, but its quantity remains unchanged. It is this experimental result which has led, by the aid of the balance, to the immense developments of modern chemistry. If we receive this as evidence of the objective reality of matter, we must allow objective reality to anything else which we find to be conserved *in the same sense* as matter is conserved. Now there is no such thing as negative mass; mass is, in mathematical language, a signless quantity. Hence the conservation of matter does not contemplate the simultaneous production of equal quantities of positive and negative mass, thus leaving the (algebraic) sum unchanged. But this is the nature of conservation of momentum (§ 165) and of moment of momentum. The only other known thing in the physical universe, which is conserved in the same sense as matter is conserved, is energy. Hence we naturally consider energy as the other objective reality in the physical universe, and look to it for information as to the true nature of what we call force.

True nature of force.

§ 292. When we do so, the answer is easily obtained, and in a completely satisfactory form. We give only a very simple instance. When a stone, whose mass is M and weight W, has fallen through a space h towards the earth, it has acquired a speed v, which (§ 28) is given by the equation

$$\tfrac{1}{2}Mv^2 = Wh.$$

This is a particular case of the conservation of energy, but the terms in which it is expressed are those suggested by Newton's laws of motion, and are therefore based on the recognition of "force." The first member of the equation represents the kinetic energy acquired; the second the potential energy lost, or the work done by gravity upon the stone during its fall. Both members therefore express real things, having objective existence.

Space-rate of transformation of energy.

But the "force" (so-called) which is said to have produced the motion, has the value

$$W = \tfrac{1}{2}Mv^2/h,$$

i.e., it is the *rate per unit of length*, at which potential energy is converted into kinetic energy during the fall. In other words, it is merely an expression for the *space-rate at which energy is transformed.*

§ 293. Another mode of presenting the case will make this still more clear. The average speed with which the stone falls is (§ 28) $v/2$. Divide both sides of the equation above by this quantity, remembering that $2h/v$ is the time of falling, which we call t. We have thus, as another perfectly legitimate deduction from our premises,

Time-rate of change of momentum.

$$W = Mv/t.$$

Here the (so-called) force appears in a new light. It is now the *time-rate at which momentum is generated* in the falling stone.

§ 294. The statements in the last two sections are, in fact, merely particular cases of Newton's two interpretations of action in the third law, which have already been discussed (§§ 165, 167).

Analytically, the whole affair is merely this: if s be the space described, v the speed of a particle,

$$\ddot{s}=\dot{v}=\frac{dv}{dt}=\frac{dv}{ds}\cdot\frac{ds}{dt}=v\frac{dv}{ds}.$$

Hence the equation of motion (formed by the second law)

$$m\ddot{s}=m\dot{v}=f,$$

which gives f as the time-rate of increase of momentum, may be written in the new form

$$mv\frac{dv}{ds}=\frac{d}{ds}(\tfrac{1}{2}mv^2)=f,$$

giving f as the space-rate of increase of kinetic energy.

Rate. § 295. But a mere *rate*, be it a space-rate or a time-rate, is not a thing which has objective existence. No one would confound the bank rate of interest with a sum of money, nor the birth or death rate of a country with a group of individual human beings. These rates are, in fact, mere abstract numbers, by the help of which a man may compute interest per annum from the amount of capital, or the number of infants per annum from the amount of the population. The gradient of temperature, in an irregularly heated body, is a mere vector-rate, by the help of which we can calculate how much energy (in the form of heat) passes in a given time across any assigned surface in the body. To attribute objectivity to a rate is even more ridiculous than it would be to attribute it to a sensation, or to a thought, or to a word or phrase which we find useful in characterizing some material object.

§ 296. On the other hand, all these different kinds of rates have been introduced and continue to be employed, because they have been found to be useful. There is no harm done by retaining them, provided those who use them know that they are introduced for convenience of expression, and not because there are objective realities corresponding to them. Even such a term as "centrifugal force" is sometimes useful; but always under the proviso that he who employs it shall remember that it is only one side of the stress under which a particle of matter is compelled, in spite of its inertia, to move in a curved line. But the term must be taken, like "algebra," "theodolite," "Abracadabra," or any other combination of letters whose derivation is uncertain or unknown, as one and indivisible, to which a certain definite meaning is attached, and as having nothing whatever to do with the meaning or derivation of the word centrifugal, whose embodiment in it is a perennial monument to the memory of an old error.

Potential energy kinetic. § 297. The main characteristics of energy, especially from the experimental point of view, have already been discussed under Dynamics (*q.v.*) and Energy (*q.v.*). But there is one point of importance connected with it which comes more naturally here than in either of the articles referred to.

When two measurable quantities, of any kind, are equivalent to one another, their numerical expressions must involve the same fundamental units, and in the same manner. This is obvious from the fact that an alteration of any unit alters in the inverse ratio the numerical measure of any quantity which is a mere multiple of it. And equivalent quantities must always be expressed by equal numbers when both are measured in terms of the same system of units. It appears, therefore, from the conservation of energy directly, as well as from the special data in §§ 111, 113, that potential energy must, like kinetic energy, be of dimensions $[ML^2T^{-2}]$.

Now it is impossible to conceive of a truly dormant form of energy whose magnitude should depend in any way on the unit of time; and we are therefore forced to the conclusion that potential energy, like kinetic energy, depends (in some as yet unexplained, or rather unimagined, way) upon motion. For the immediate purposes of this article the question is not one of importance. We have been dealing with the more direct consequences of a very compact set of laws, exceedingly simple in themselves, originally based upon observation and experiment, and, most certainly, true. But reason cannot content itself with the mere consequences of a series of observed facts, however elegantly and concisely these may be stated by the help of new terms and their definitions. We are forced to inquire into what may underlie these definitions, and the laws which are observed to regulate the things signified by them. And the conclusion which appears inevitable is that, whatever matter may be, the other reality in the physical universe, energy, which is never found unassociated with matter, depends in all its widely varied forms upon motion of matter. In some cases we are sure, in others we can as yet only suspect, that it depends upon motions in a medium which, unlike ordinary matter, has not yet been subjected to the scrutiny of the chemist. But the question, in its generality, is one of the most obscure in the whole range of physics. In the articles Atom, Attraction, Ether, will be found nearly all that is yet known on this profoundly difficult subject. But to what is there said must be added the remark that a state of strain of the ether, whether associated with the propagation of light and radiant heat or with a statical distribution of electricity, represents so much "potential" energy, and must in its turn in some way depend on motion.

§ 298. The remarks of Clerk Maxwell on the nature of the evidence for Newton's *first* law of motion raise a question, in some respects novel, but in all respects well worthy of careful study. He says:— Maxwell on inertia.

"Our conviction of the truth of this law may be greatly strengthened by considering what is involved in a denial of it. Given a body in motion. At a given instant let it be left to itself and not acted on by any force. What will happen? According to Newton's law it will persevere in moving uniformly in a straight line; that is, its velocity will remain constant both in direction and magnitude.

"If the velocity does not remain constant let us suppose it to vary. The change of velocity must have a definite direction and magnitude. By the maxim that *the same causes will always produce the same effects*, this variation must be the same whatever be the time or place of the experiment. The direction of the change of motion must therefore be determined either by the direction of the motion itself, or by some direction fixed in the body. Let us, in the first place, suppose the law to be that the velocity diminishes at a certain rate, which, for the sake of the argument, we may suppose so slow that by no experiments on moving bodies could we have detected the diminution of velocity in hundreds of years. The velocity referred to in this hypothetical law can only be the velocity referred to a point absolutely at rest. For if it is a relative velocity, its direction as well as its magnitude depends on the velocity of the point of reference. If, when referred to a certain point, the body appears to be moving northward with diminishing velocity, we have only to refer it to another point moving northward with a uniform velocity greater than that of the body, and it will appear to be moving southward with increasing velocity. Hence the hypothetical law is without meaning, unless we admit the possibility of defining absolute rest and absolute velocity. . . . .

"It may thus be shown that the denial of Newton's law is in contradiction to the only system of consistent doctrine about space and time which the human mind has been able to form."

This is a good example of a valuable application of a principle which, in its widest scope, is inconsistent with the true foundations of physical science. It is, in fact, the exceedingly dangerous "principle of sufficient reason"—which requires for its legitimate use the utmost talent and knowledge on the part of the user. Principle of sufficient reason.

§ 299. But in all methods and systems which involve the idea of force there is the leaven of artificiality. *The* true laws of motion, based entirely on experiments of the most extensive and most varied kinds, are those of the conservation and of the transformation of energy. With the help True laws of motion.

of kinematical ideas, it is easy to base the whole science of dynamics on these principles; and there is no necessity for the introduction of the word "force" nor of the sense-suggested ideas on which it was originally based.

§ 300. Nothing beyond a mere mention has been made above of virtual velocities, and of the so-called elementary machines. These belong to the subject of Applied Mechanics, separately treated below.

§ 301. The references which have been made to various grand theories, such as action, impulse in general, &c., have been illustrated by simple cases only. For a detailed examination of these theories the reader is referred to Thomson and Tait's *Natural Philosophy*, chap. ii. To the same work he is referred for the general "theory of small oscillations," the "dissipative function," the "ignoration of coordinates," the treatment of "gyrostatic systems" and of "kinetic stability." All of these have been exhibited, though in mere particular instances, in the preceding pages.

Treatises on Mechanics.

§ 302. The following works on Mechanics are indispensable:—

1. Newton's *Principia* (1st ed., 1687; latest ed., Glasgow, 1871). Here, for the first time, the fundamental principles were systematized, extended (as we have seen) in a most vital particular, and applied, by the aid of a new mathematical method of immense power (based entirely on kinematical considerations), to many of the most important questions of cosmical and terrestrial dynamics.

Newton's system was first *taught* in the university of Edinburgh; and, with brief intervals, his methods also have been habitually kept before the students there. From the time of Maclaurin to that of Forbes the value of the quasi-geometrical methods in giving a clear insight into the problems treated has rarely been overlooked. In Cambridge these methods were of later introduction, but they still deservedly figure as a necessary part of the reading of candidates for "mathematical honours." It is to be feared, however, that in some other British universities the study of Newton's methods is not prosecuted to anything like the same extent. But the very reverse seems to be the case in America, where, probably to a considerable extent on this account, mathematical physics is advancing in a most remarkable manner.

2. Lagrange's *Mécanique Analytique* (1st ed., 1788). Though objections may fairly be taken to the fundamental method of this work, there can be no question as to the immense power and originality of its author. His "generalized coordinates," and the equations of motion of a system in terms of these, form one of the most important contributions to the science since the days of Newton. The method of Lagrange, though he was not aware of the fact, is really based upon the consideration of energy; and when, in quite recent times, experiment had shown what are the grand laws of energy, Lagrange's magnificent mathematical methods and results were ready for translation into the new language of science.

3. Hamilton's papers in the *Philosophical Transactions* for 1833 and 1834. Here the principle of varying action, and the characteristic function, were first applied to mechanics;—though they had been given, some years before, to the Royal Irish Academy, in their optical applications. Grand as have been the extensions of these new ideas made by Hamilton himself, and by many others, among whom Jacobi and Liouville may be especially mentioned, they have been mainly in a purely mathematical direction. We wait for what cannot now be long delayed, the coming of the philosopher who is to tell us the true *dynamical* bearings of varying action and of the characteristic function.

4. If to these we add some of the works of Galileo, Huygens, Euler, Maclaurin, and D'Alembert, we have the great landmarks in the history of the subject, as distinguished from its development.

5. The mere enumeration of the more important developments which the subject has received, as distinguished from the absolutely new grand ideas and methods introduced, would require a long article. Brilliant examples of what may be done in this direction are furnished by Stokes's "Report on Recent Researches in Hydrodynamics" and by Cayley's "Reports on Theoretical Dynamics" (printed in the *British Association Reports* for 1846, and for 1857 and 1862). These should be consulted by every student who desires to trace the growth of the subject. They have been succeeded, in the same *Reports* (1880, 1881) by two excellent summaries, by Hicks, of "Recent Progress in Hydrodynamics."

But Laplace's *Mécanique Celeste*, Poisson's *Mécanique*, Poinsot's *Théorie Nouvelle de la Rotation*, &c., more or less parts of the immediate outcome of the period when France intellectually dwarfed the rest of the world, are still of far more than mere historic value.

For the English-reading student of modern times, the work of Thomson and Tait will be found suitable. The authors of this work claim the position of "restorers," not of innovators; and they have (since 1863, when the first short sketch of their work was published) striven with success to re-establish in Britain Newton's grand yet simple foundations of the subject. But these foundations, as stated above, are only temporarily the best. We have not, *as yet*, anything nearly so good.

Other modern works of value are the *Analytic Mechanics* of the late Professor Peirce (Boston, 1855) and Kirchhoff's *Vorlesungen über Mathematische Physik* (Leipsic, 1876). Both are rather of the nature of collections of short treatises on special questions than organized wholes, but both will well repay careful reading. This, in the case of Peirce's work, is rendered extremely puzzling and laborious by the peculiar notations and modes of reference adopted by the author. It is particularly interesting to study the ways in which the fundamental principles are introduced in these works, and to compare them with the corresponding parts of the works of Newton and Lagrange. Lagrange, Peirce, and Kirchhoff construct each a system as free from anything but analysis as possible. In fact Lagrange prefaces his work by the characteristic statement, "On ne trouvera point de Figures dans cet ouvrage. Les méthodes que j'y expose ne demandent ni constructions, ni raisonnemens géométriques ou méchaniques, mais seulement des opérations algébriques, assujetties à une marche réguliere et uniforme. Ceux qui aiment l'Analyse verront avec plaisir la Méchanique en devenir une nouvelle branche." . . . . How far we have considered it expedient to differ from such an authority, a glance at the preceding pages will show.

A part of the detailed work of several of the examples above given in *Dynamics of a Particle* has been taken from the elementary treatise (with that title) of Tait and Steele. The English reader who wishes to pursue elementary Statics may profitably consult the treatise of Minchin. The higher parts are discussed in the work of Somoff, *Theoretische Mechanik* (Leipsic, 1879). An excellent introduction to the use of Generalized Coordinates has been published by Watson and Burbury (1879). On Lagrange's Generalized Equations the student should also read in Maxwell's *Treatise on Electricity and Magnetism*, part iv. chap. v. And Maxwell's brief treatise on *Matter and Motion* should be in the hands of every one commencing the subject.

Analysis of the Preceding Article.

(P. G. T.)

APPLIED MECHANICS.

1. The practical applications of mechanics may be divided into two classes, according as the assemblages of material objects to which they relate are intended to remain fixed or to move relatively to each other,—the former class being comprehended under the term "Theory of Structures," and the latter under the term "Theory of Machines." As the details of the theory of structures are dealt with in other articles, it will be treated of here to such extent only as may be necessary in order to state certain general principles applicable to all these subjects. The greater part of the article will relate to machines.

PART I. OUTLINE OF THE THEORY OF STRUCTURES.

2. *Support of Structures.*—Every structure, as a whole, is maintained in equilibrium by the joint action of its own *weight*, of the *external load* or pressure applied to it from without and tending to displace it, and of the *resistance* of the material which supports it. A structure is supported either by resting on the solid crust of the earth, as buildings do, or by floating in a fluid, as ships do in water and balloons in air. The principles of the support of a floating structure form an important part of HYDROMECHANICS (*q.v.*). The principles of the support, as a whole, of a structure resting on the land, are so far identical with those which regulate the equilibrium and stability of the several parts of that structure, and of which a summary will presently be given, that the only principle which seems to require special mention here is one which comprehends in one statement the power both of liquids and of loose earth to support structures, and which was first demonstrated in a paper "On the Stability of Loose Earth," read to the Royal Society on the 19th of June 1856, and published in the *Philosophical Transactions* for that year, viz. :—

Let E represent the weight of the portion of a horizontal stratum of earth which is displaced by the foundation of a structure, S the utmost weight of that structure consistently with the power of the earth to resist displacement, ϕ the angle of repose of the earth; then

$$\frac{S}{E}=\left(\frac{1+\sin\phi}{1-\sin\phi}\right)^2.$$

To apply this to liquids, ϕ must be made $=0$, and then $\frac{S}{E}=1$, as is well known.

3. *Composition of a Structure, and Connexion of its Pieces.*—A structure is composed of *pieces*,—such as the stones of a building in masonry, the beams of a timber frame-work, the bars, plates, and bolts of an iron bridge. Those pieces are connected at their *joints* or surfaces of mutual contact, either by simple pressure and friction (as in masonry with moist mortar or without mortar), by pressure and adhesion (as in masonry with cement or with hardened mortar, and timber with glue), or by the resistance of *fastenings* of different kinds, whether made by means of the form of the joint (as dovetails, notches, mortises, and tenons) or by separate fastening pieces (as trenails, pins, spikes, nails, holdfasts, screws, bolts, rivets, hoops, straps, and sockets).

4. *Stability, Stiffness, and Strength.*—A structure may be damaged or destroyed in three ways :—first, by *displacement* of its pieces from their proper positions relatively to each other or to the earth; secondly, by *disfigurement* of one or more of those pieces, owing to their being unable to preserve their proper shapes under the pressures to which they are subjected; thirdly, by *breaking* of one or more of those pieces. The power of resisting displacement constitutes *stability*; the power of each piece to resist disfigurement is its *stiffness*; and its power to resist breaking, its *strength.*

5. *Conditions of Stability.*—The principles of the stability of a structure can be to a certain extent investigated independently of the stiffness and strength, by assuming, in the first instance, that each piece has strength sufficient to be safe against being broken, and stiffness sufficient to prevent its being disfigured to an extent inconsistent with the purposes of the structure, by the greatest forces which are to be applied to it. The condition that each piece of the structure is to be maintained in equilibrium by having its gross load, consisting of its own weight and of the external pressure applied to it, balanced by the *resistances* or pressures exerted between it and the contiguous pieces, furnishes the means of determining the magnitude, position, and direction of the resistances required at each joint in order to produce equilibrium; and the *conditions of stability* are, first, that the *position*, and, secondly, that the *direction*, of the resistance required at each joint shall, under all the variations to which the load is subject, be such as the joint is capable of exerting,—conditions which are fulfilled by suitably adjusting the figures and positions of the joints, and the *ratios* of the gross loads of the pieces. As for the *magnitude* of the resistance, it is limited by conditions, not of stability, but of strength and stiffness.

6. *Principle of Least Resistance.*—Where more than one system of resistances are alike capable of balancing the same system of loads applied to a given structure, it has been demonstrated by Moseley that the *smallest* of those alternative systems is that which will actually be exerted,—because the resistances to displacement are the effect of a strained state of the pieces, which strained state is the effect of the load, and when the load is applied the strained state and the resistances produced by it increase until the resistances acquire just those magnitudes which are sufficient to balance the load, after which they increase no further.

This principle of least resistance renders determinate many problems in the statics of structures which were formerly considered indeterminate.

7. *Relations between Polygons of Loads and of Resistances.*—In a structure in which each piece is supported at two joints only, the well-known laws of statics show that the directions of the gross load on each piece and of the two resistances by which it is supported must lie in one plane, must either be parallel or meet in one point, and must bear to each other, if not parallel, the proportions of the sides of a triangle respectively parallel to their directions, and, if parallel, such proportions that each of the three forces shall be proportional to the distance between the other two,—all the three distances being measured along one direction.

Considering, in the first place, the case in which the load and the two resistances by which each piece is balanced meet in one point, which may be called the *centre of load*, there will be as many such points of intersection, or centres of load, as there are pieces in the structure; and the directions and positions of the resistances or mutual pressures exerted between the pieces will be represented by the sides of a polygon joining those points, as in fig. 1, where P_1, P_2, P_3, P_4 represent the centres of load in a structure of four pieces, and the sides of the *polygon of resistances* $P_1P_2P_3P_4$ represent respectively the directions and positions of the resistances exerted at the joints.

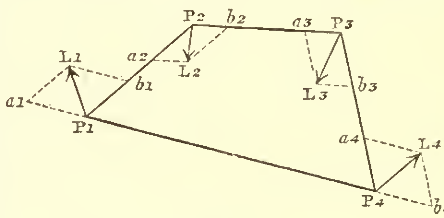

Fig. 1.

Further, at any one of the centres of load let PL represent the magnitude and direction of the gross load, and P*a*, P*b* the two resistances by which the piece to which that load is applied is supported; then will those three lines be respectively the diagonal and sides of a parallelogram; or, what is the same thing, they will be equal to the three sides of a triangle; and they must be in the same plane, although the sides of the polygon of resistances may be in different planes.

According to a well-known principle of statics, because the loads or external pressures P_1L_1, &c., balance each other, they must be proportional to the sides of a closed polygon drawn respectively parallel to their directions. In fig. 2 construct such a *polygon of loads* by drawing the lines L_1, &c., parallel and proportional to, and joined end to end in the order of, the gross loads on the pieces of the structure. Then from the proportionality and parallelism of the load and the two resistances applied to each piece of the structure to the three sides of a triangle, there results the following theorem [originally due to Rankine] :—

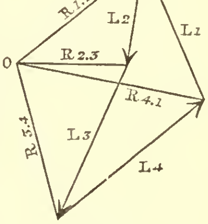

Fig. 2.

If from the angles of the polygon of loads there be drawn lines (R_1, R_2, &c.), *each of which is parallel to the resistance* (*as* P_1P_2, &c.) *exerted at the joint between the pieces to which the two loads represented by the contiguous sides of the polygon of loads* (*such as* L_1, L_2, &c.) *are applied; then will all those lines meet in one point* (O), *and their lengths, measured from that point to the angles of the polygon, will represent the magnitudes of the resistances to which they are respectively parallel.*

When the load on one of the pieces is parallel to the resistances which balance it, the polygon of resistances ceases to be closed, two of the sides becoming parallel to each other and to the load in question, and extending indefinitely. In the polygon of loads the direction of a load sustained by parallel resistances traverses the point O.

8. *How the Earth's Resistance is to be treated.*—When the pressure exerted by a structure on the earth (to which the earth's resistance is equal and opposite) consists either of one pressure, which is necessarily the resultant of the weight of the structure and of all the other forces applied to it, or of two or more parallel vertical forces, whose amount can be determined at the outset of the

investigation, the resistance of the earth can be treated as one or more *upward loads* applied to the structure. But in other cases the earth is to be treated as *one of the pieces of the structure*, loaded with a force equal and opposite in direction and position to the resultant of the weight of the structure and of the other pressures applied to it.

9. *Partial Polygons of Resistance.*—In a structure in which there are pieces supported at more than two joints, let a polygon be constructed of lines connecting the centres of load of any continuous series of pieces. This may be called a *partial polygon of resistances.* In considering its properties, the *load* at each centre of load is to be held to *include* the resistances of those joints which are *not* comprehended in the partial polygon of resistances, to which the theorem of section 7 will then apply in every respect. By constructing several partial polygons, and computing the relations between the loads and resistances which are determined by the application of that theorem to each of them, with the aid, if necessary, of Moseley's principle of the least resistance, the whole of the relations amongst the loads and resistances may be found.

10. *Line of Pressures—Centres and Line of Resistance.*—The *line of pressures* is a line to which the directions of all the resistances in one polygon are tangents. The *centre of resistance* at any joint is the point where the line representing the total resistance exerted at that joint intersects the joint. The *line of resistance* is a line traversing all the centres of resistance of a series of joints,—its form, in the positions intermediate between the actual joints of the structure, being determined by supposing the pieces and their loads to be subdivided by the introduction of intermediate joints *ad infinitum*, and finding the continuous line, curved or straight, in which the intermediate centres of resistance are all situated, however great their number. The difference between the line of resistance and the line of pressures was first pointed out by Moseley.

11. *Stability of Position, and Stability of Friction.*—The resistances at the several joints having been determined by the principles set forth in sections 6, 7, 8, 9, and 10, not only under the ordinary load of the structure, but under all the variations to which the load is subject as to amount and distribution, the joints are now to be placed and shaped so that the pieces shall not suffer relative displacement under any of those loads. The relative displacement of the two pieces which abut against each other at a joint may take place either by turning or by sliding. Safety against displacement by turning is called *stability of position*; safety against displacement by sliding, *stability of friction.*

12. *Condition of Stability of Position.*—If the materials of a structure were infinitely stiff and strong, stability of position at any joint would be insured simply by making the centre of resistance fall within the joint under all possible variations of load. In order to allow for the finite stiffness and strength of materials, the least distance of the centre of resistance inward from the nearest edge of the joint is made to bear a definite proportion to the depth of the joint measured in the same direction, which proportion is fixed, sometimes empirically, sometimes by theoretical deduction from the laws of the strength of materials. That least distance is called by Moseley the *modulus of stability.* The following are some of the ratios of the modulus of stability to the depth of the joint which occur in practice :—

Retaining walls, as designed by British engineers	1 : 8
Retaining walls, as designed by French engineers	1 : 5
Rectangular piers of bridges and other buildings, and arch-stones	1 : 3
Rectangular foundations, firm ground	1 : 3
Rectangular foundations, very soft ground	1 : 2
Rectangular foundations, intermediate kinds of ground	1 : 3 to 1 : 2
Thin, hollow towers (such as furnace chimneys exposed to high winds), square	1 : 6
Thin, hollow towers, circular	1 : 4
Frames of timber or metal, under their ordinary or average distribution of load	1 : 3
Frames of timber or metal, under the greatest irregularities of load	1 : 3

In the case of the towers, the *depth of the joint* is to be understood to mean the *diameter of the tower.*

13. *Condition of Stability of Friction.*—If the resistance to be exerted at a joint is always perpendicular to the surfaces which abut at and form that joint, there is no tendency of the pieces to be displaced by sliding. If the resistance be oblique, let JK (fig. 3) be the joint, C its centre of resistance, CR a line representing the resistance, CN a perpendicular to the joint at the centre of resistance. The angle NCR is the *obliquity* of the resistance. From R draw RP parallel and RQ perpendicular to the joint; then, by the principles of statics, the component of the resistance *normal* to the joint is—

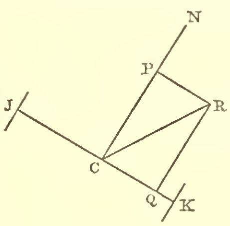

Fig. 3.

$$CP = CR \cdot \cos \angle PRC \,;$$

and the component *tangential* to the joint is—

$$CQ = CR \cdot \sin \angle PCR = CP \cdot \tan \angle PCR \,.$$

If the joint be provided either with projections and recesses, such as mortises and tenons, or with fastenings, such as pins or bolts, so as to resist displacement by sliding, the question of the utmost amount of the tangential resistance CQ which it is capable of exerting depends on the *strength* of such projections, recesses, or fastenings, and belongs to the subject of strength, and not to that of stability. In other cases the safety of the joint against displacement by sliding depends on its power of exerting friction, and that power depends on the law, known by experiment, that the friction between two surfaces bears a constant ratio, depending on the nature of the surfaces, to the force by which they are pressed together. In order that the surfaces which abut at the joint JK may be pressed together, the resistance required by the conditions of equilibrium, CR, must be a *thrust* and not a *pull*; and in that case the force by which the surfaces are pressed together is equal and opposite to the normal component CP of the resistance. The condition of stability of friction is that the tangential component CQ of the resistance required shall not exceed the friction due to the normal component; that is, that

$$CQ \not> f \cdot CP,$$

where f denotes the *coefficient of friction* for the surfaces in question. The angle whose tangent is the coefficient of friction is called *the angle of repose*, and is expressed symbolically by—

$$\phi = \tan^{-1} f.$$

$$\text{Now } CQ = CP \cdot \tan \angle PCR \,;$$

consequently the condition of stability of friction is fulfilled if

$$\angle PCR \not> \phi \,;$$

that is to say, if *the obliquity of the resistance required at the joint does not exceed the angle of repose*; and this condition ought to be fulfilled under all possible variations of the load.

It is chiefly in masonry and earthwork that stability of friction is relied on.

14. *Stability of Friction in Earth.*—The grains of a mass of loose earth are to be regarded as so many separate pieces abutting against each other at joints in all possible positions, and depending for their stability on friction. To determine whether a mass of earth is stable at a given point, conceive that point to be traversed by planes in all possible positions, and determine which position gives the greatest obliquity to the total pressure exerted between the portions of the mass which abut against each other at the plane. The condition of stability is that this obliquity shall not exceed the angle of repose of the earth. The consequences of this principle are developed in a paper "On the Stability of Loose Earth," already cited in sect. 2.

15. *Parallel Projections of Figures.*—If any figure be referred to a system of coordinates, rectangular or oblique, and if a second figure be constructed by means of a second system of coordinates, rectangular or oblique, and either agreeing with or differing from the first system in rectangularity or obliquity, but so related to the coordinates of the first figure that for each point in the first figure there shall be a corresponding point in the second figure, the lengths of whose coordinates shall bear respectively to the three corresponding coordinates of the corresponding point in the first figure three ratios which are the same for every pair of corresponding points in the two figures, these corresponding figures are called *parallel projections* of each other. The properties of parallel projections of most importance to the subject of the present article are the following :—

(1) A parallel projection of a straight line is a straight line.

(2) A parallel projection of a plane is a plane.

(3) A parallel projection of a straight line or a plane surface divided in a given ratio is a straight line or a plane surface divided in the same ratio.

(4) A parallel projection of a pair of equal and parallel straight lines, or plain surfaces, is a pair of equal and parallel straight lines, or plane surfaces; whence it follows

(5) That a parallel projection of a parallelogram is a parallelogram, and

(6) That a parallel projection of a parallelepiped is a parallelepiped.

(7) A parallel projection of a pair of solids having a given ratio is a pair of solids having the same ratio.

Though not essential for the purposes of the present article, the following consequence will serve to illustrate the principle of parallel projections :—

(8) A parallel projection of a curve, or of a surface of a given algebraical order, is a curve or a surface of the same order.

For example, all ellipsoids referred to coordinates parallel to any three conjugate diameters are parallel projections of each other and of a sphere referred to rectangular coordinates.

16. *Parallel Projections of Systems of Forces.*—If a balanced system of forces be represented by a system of lines, then will every parallel projection of that system of lines represent a balanced system of forces.

For the condition of equilibrium of forces not parallel is that they shall be represented in direction and magnitude by the sides and diagonals of certain parallelograms, and of parallel forces that they shall divide certain straight lines in certain ratios; and the parallel projection of a parallelogram is a parallelogram, and that of a straight line divided in a given ratio is a straight line divided in the same ratio.

The resultant of a parallel projection of any system of forces is the projection of their resultant; and the centre of gravity of a parallel projection of a solid is the projection of the centre of gravity of the first solid.

17. *Principle of the Transformation of Structures.*—Here we have the following theorem:—If a structure of a given figure have stability of position under a system of forces represented by a given system of lines, then will any structure whose figure is a parallel projection of that of the first structure have stability of position under a system of forces represented by the corresponding projection of the first system of lines.

For in the second structure the weights, external pressures, and resistances will balance each other as in the first structure; the weights of the pieces and all other parallel systems of forces will have the same ratios as in the first structure; and the several centres of resistance will divide the depths of the joints in the same proportions as in the first structure.

If the first structure have stability of friction, the second structure will have stability of friction also, so long as the effect of the projection is not to increase the obliquity of the resistance at any joint beyond the angle of repose.

The lines representing the forces in the second figure show their *relative* directions and magnitudes. To find their *absolute* directions and magnitudes, a vertical line is to be drawn in the first figure, of such a length as to represent the weight of a particular portion of the structure. Then will the projection of that line in the projected figure indicate the vertical direction, and represent the weight of the part of the second structure corresponding to the before-mentioned portion of the first structure.

The foregoing "principle of the transformation of structures" was first announced, though in a somewhat less comprehensive form, to the Royal Society on the 6th of March 1856. It is useful in practice, by enabling the engineer easily to deduce the conditions of equilibrium and stability of structures of complex and unsymmetrical figures from those of structures of simple and symmetrical figures. By its aid, for example, the whole of the properties of elliptical arches, whether square or skew, whether level or sloping in their span, are at once deduced by projection from those of symmetrical circular arches, and the properties of ellipsoidal and elliptic-conoidal domes from those of hemispherical and circular-conoidal domes; and the figures of arches fitted to resist the thrust of earth, which is less horizontally than vertically in a certain given ratio, can be deduced by a projection from those of arches fitted to resist the thrust of a liquid, which is of equal intensity, horizontally and vertically.

18. *Conditions of Stiffness and Strength.*—After the arrangement of the pieces of a structure and the size and figure of their joints or surfaces of contact have been determined so as to fulfil the conditions of *stability*,—conditions which depend mainly on the position and direction of the *resultant* or *total* load on each piece, and the *relative* magnitude of the loads on the different pieces,—the dimensions of each piece singly have to be adjusted so as to fulfil the conditions of *stiffness* and *strength*,—conditions which depend not only on the *absolute* magnitude of the load on each piece, and of the resistances by which it is balanced, but also on the *mode of distribution* of the load over the piece, and of the resistances over the joints.

The effect of the pressures applied to a piece, consisting of the load and the supporting resistances, is to force the piece into a state of *strain* or disfigurement, which increases until the elasticity, or resistance to strain, of the material causes it to exert a *stress*, or effort to recover its figure, equal and opposite to the system of applied pressures. The condition of *stiffness* is that the strain or disfigurement shall not be greater than is consistent with the purposes of the structure; and the condition of *strength* is that the stress shall be within the limits of that which the material can bear with safety against breaking. The ratio in which the utmost stress before breaking exceeds the safe working stress is called the *factor of safety*, and is determined empirically. It varies from three to twelve for various materials and structures.

The Strength of Materials forms the subject of a special article, to which the reader is referred.

PART II. THEORY OF MACHINES.

19. *Parts of a Machine—Frame and Mechanism.*—The parts of a machine may be distinguished into two principal divisions,—the *frame*, or fixed parts, and the *mechanism*, or moving parts. The frame is a structure which supports the pieces of the mechanism, and to a certain extent determines the nature of their motions. The form and arrangement of the pieces of the frame depend upon the arrangement and the motions of the mechanism; the dimensions of the pieces of the frame required in order to give it stability and strength are determined from the pressures applied to it by means of the mechanism. It appears therefore that in general the mechanism is to be designed first and the frame afterwards, and that the designing of the frame is regulated by the principles of the stability of structures and of the strength and stiffness of materials,—care being taken to adapt the frame to the most severe load which can be thrown upon it at any period of the action of the mechanism.

Each independent piece of the mechanism also is a structure, and its dimensions are to be adapted, according to the principles of the strength and stiffness of materials, to the most severe load to which it can be subjected during the action of the machine.

20. *Definition and Division of the Theory of Machines.*—From what has been said in the last section it appears that the department of the art of designing machines which has reference to the stability of the frame and to the stiffness and strength of the frame and mechanism is a branch of the art of construction. It is therefore to be separated from the *theory of machines*, properly speaking, which has reference to the action of machines considered as moving. In the action of a machine the following three things take place:—

First, Some natural source of energy communicates motion and force to a piece or pieces of the mechanism, called the *receiver of power* or *prime mover*.

Secondly, The motion and force are transmitted from the prime mover through the *train of mechanism* to the *working piece* or *pieces*, and during that transmission the motion and force are modified in amount and direction, so as to be rendered suitable for the purpose to which they are to be applied.

Thirdly, The working piece or pieces by their motion, or by their motion and force combined, produce some useful effect.

Such are the phenomena of the action of a machine, arranged in the order of *causation*. But in studying or treating of the theory of machines, the order of *simplicity* is the best; and in this order the first branch of the subject is the modification of motion and force by the train of mechanism; the next is the effect or purpose of the machine; and the last, or most complex, is the action of the prime mover.

The modification of motion and the modification of force take place together, and are connected by certain laws; but in the study of the theory of machines, as well as in that of pure mechanics, much advantage has been gained in point of clearness and simplicity by first considering alone the principles of the modification of motion, which are founded upon what is now known as Kinematics, and afterwards considering the principles of the combined modification of motion and force, which are founded both on geometry and on the laws of dynamics. The separation of kinematics from dynamics is due mainly to Monge, Ampère, and Willis.

The theory of machines in the present article will be considered under the following four heads:—

I. Pure Mechanism, or Applied Kinematics; being the theory of machines considered simply as modifying motion.
II. Applied Dynamics; being the theory of machines considered as modifying both motion and force.
III. Purposes and Effects of Machines.
IV. Applied Energetics; being the theory of prime movers and sources of power.

Chap. I. On Pure Mechanism.

21. *Division of the Subject.*—Proceeding in the order of simplicity, the subject of Pure Mechanism, or Applied Kinematics, may be thus divided:—

Division 1.—Motion of a point.
Division 2.—Motion of the surface of a fluid.
Division 3.—Motion of a rigid solid.
Division 4.—Motions of a pair of connected pieces, or of an "elementary combination" in mechanism.
Division 5.—Motions of trains of pieces of mechanism.
Division 6.—Motions of sets of more than two connected pieces, or of "aggregate combinations."

A point is the boundary of a line, which is the boundary of a surface, which is the boundary of a volume. Points, lines, and surfaces have no independent existence, and consequently those divisions of this chapter which relate to their motions are only preliminary to the subsequent divisions, which relate to the motions of bodies.

Division 1. *Motion of a Point.*

22. *Path and Direction.*—See above, p. 679, § 21.
23. *Uniform Velocity.*—See p. 680, § 25.
24. *Varied Velocity.*—See p. 680, § 25.
25. *Direct Deviation, or Acceleration and Retardation.*—See pp. 680, 681, §§ 27–29.

26. *Lateral Deviation or Deflexion—Angular Velocity of Deviation—Revolution.*—See pp. 681, 682, §§ 31–38.

27. *Comparative Motion.*—The comparative motion of two points is the relation which exists between their motions, without having regard to their absolute amounts. It consists of two elements,—the *velocity ratio*, which is the ratio of any two magnitudes bearing to each other the proportions of the respective velocities of the two points at a given instant, and the *directional relation*, which is the relation borne to each other by the respective directions of the motions of the two points at the same given instant.

It is obvious that the motions of a pair of points may be varied in any manner, whether by direct or by lateral deviation, and yet that their *comparative motion* may remain constant, in consequence of the deviations taking place in the same proportions, in the same directions, and at the same instants for both points.

Willis has the merit of having been the first to simplify considerably the theory of pure mechanism, by pointing out that that branch of mechanics relates wholly to comparative motions.

The comparative motion of two points at a given instant is capable of being completely expressed by one of Sir William Hamilton's Quaternions,—the "tensor" expressing the velocity ratio, and the "versor" the directional relation.

28. *Resolution and Composition of Motion.*—See p. 681, §§ 30, 31.

29. *Rectangular Projection, Resolution, and Composition.*—See p. 681, § 31.

30. *Resolution and Composition of Deviations.*—See p. 681, § 31.

Division 2. Motion of the Surface of a Fluid Mass.

31. *General Principle.*—A mass of fluid is used in mechanism to transmit motion and force between two or more movable portions (called *pistons* or *plungers*) of the solid envelope or vessel in which the fluid is contained; and, when such transmission is the sole action, or the only appreciable action of the fluid mass, its volume is either absolutely constant, by reason of its temperature and pressure being maintained constant, or not sensibly varied.

Let a represent the area of the section of a piston made by a plane perpendicular to its direction of motion, and v its velocity, which is to be considered as positive when outward, and negative when inward. Then the variation of the cubic contents of the vessel in a unit of time by reason of the motion of one piston is va. The condition that the volume of the fluid mass shall remain unchanged requires that there shall be more than one piston, and that the velocities and areas of the pistons shall be connected by the equation—

$$\Sigma \,.\, va = 0 \quad \ldots\ldots\ldots \quad (1).$$

32. *Comparative Motion of two Pistons.*—If there be but two pistons, whose areas are a_1 and a_2, and their velocities v_1 and v_2, their comparative motion is expressed by the equation—

$$\frac{v_2}{v_1} = -\frac{a_1}{a_2} \quad \ldots\ldots\ldots \quad (2);$$

that is to say, their velocities are opposite as to inwardness and outwardness, and inversely proportional to their areas.

33. *Applications—Hydraulic Press—Pneumatic Power-Transmitter.*—In the hydraulic press the vessel consists of two cylinders, viz., the pump-barrel and the press-barrel, each having its piston, and of a passage connecting them having a valve opening towards the press-barrel. The action of the enclosed water in transmitting motion takes place during the inward stroke of the pump-plunger, when the above-mentioned valve is open; and at that time the press-plunger moves outwards with a velocity which is less than the inward velocity of the pump-plunger, in the same ratio that the area of the pump-plunger is less than the area of the press-plunger. (See HYDROMECHANICS.)

In the pneumatic power-transmitter the motion of one piston is transmitted to another at a distance by means of a mass of air contained in two cylinders and an intervening tube. When the pressure and temperature of the air can be maintained constant, this machine fulfils equation 2, like the hydraulic press. The amount and effect of the variations of pressure and temperature undergone by the air depend on the principles of the mechanical action of heat, or THERMODYNAMICS (*q.v.*), and are foreign to the subject of pure mechanism.

Division 3. Motion of a Rigid Solid.

34. *Motions Classed.*—In problems of mechanism, each solid piece of the machine is supposed to be so stiff and strong as not to undergo any sensible change of figure or dimensions by the forces applied to it,—a supposition which is realized in practice if the machine is skilfully designed.

This being the case, the various possible motions of a rigid solid body may all be classed under the following heads:—(1) *Shifting or Translation*; (2) *Turning or Rotation*; (3) *Motions compounded of Shifting and Turning.*

The most common forms for the paths of the points of a piece of mechanism, whose motion is simple shifting, are the straight line and the circle.

Shifting in a straight line is regulated either by straight fixed guides, in contact with which the moving piece slides, or by combinations of link-work, called *parallel motions*, which will be described in the sequel. Shifting in a straight line is usually *reciprocating*; that is to say, the piece, after shifting through a certain distance, returns to its original position by reversing its motion.

Circular shifting is regulated by attaching two or more points of the shifting piece to ends of equal and parallel rotating cranks, or by combinations of wheel-work to be afterwards described. As an example of circular shifting may be cited the motion of the coupling rod, by which the parallel and equal cranks upon two or more axles of a locomotive engine are connected and made to rotate simultaneously. The coupling rod remains always parallel to itself, and all its points describe equal and similar circles relatively to the frame of the engine, and move in parallel directions with equal velocities at the same instant.

35. *Rotation about a Fixed Axis—Lever, Wheel, and Axle.*—The fixed axis of a turning body is a line fixed relatively to the body and relatively to the fixed space in which the body turns. In mechanism it is usually the central line either of a rotating shaft or axle having journals, gudgeons, or pivots turning in fixed bearings, or of a fixed spindle or dead centre round which a rotating bush turns; but it may sometimes be entirely beyond the limits of the turning body. For example, if a sliding piece moves in circular fixed guides, that piece rotates about an ideal fixed axis traversing the centre of those guides.

Let the angular velocity of the rotation be denoted by $a = \frac{d\theta}{dt}$, then the linear velocity of any point A at the distance r from the axis is ar; and the path of that point is a circle of the radius r described about the axis.

This is the principle of the modification of motion by the lever, which consists of a rigid body turning about a fixed axis called a fulcrum, and having two points at the same or different distances from that axis, and in the same or different directions, one of which receives motion and the other transmits motion, modified in direction and velocity according to the above law.

In the wheel and axle, motion is received and transmitted by two cylindrical surfaces of different radii described about their common fixed axis of turning, their velocity-ratio being that of their radii.

36. *Velocity Ratio of Components of Motion.*—As the distance between any two points in a rigid body is invariable, the projections of their velocities upon the line joining them must be equal. Hence it follows that, if A in fig. 4 be a point in a rigid body CD, rotating round the fixed axis F, the component of the velocity of A in any direction AP parallel to the plane of rotation is equal to the total velocity of the point m, found by letting fall Fm perpendicular to AP; that is to say, is equal to

$$a \,.\, \mathrm{F}m.$$

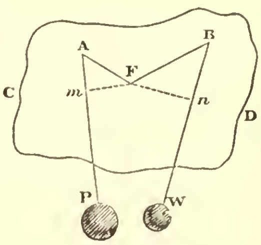

Fig. 4.

Hence also the ratio of the components of the velocities of two points A and B in the directions AP and BW respectively, both in the plane of rotation, is equal to the ratio of the perpendiculars Fm and Fn.

37. *Instantaneous Axis of a Cylinder rolling on a Cylinder.*—Let a cylinder bbb, whose axis of figure is B and angular velocity γ, roll on a fixed cylinder aaa, whose axis of figure is A, either outside (as in fig. 5), when the rolling will be towards the same hand as the

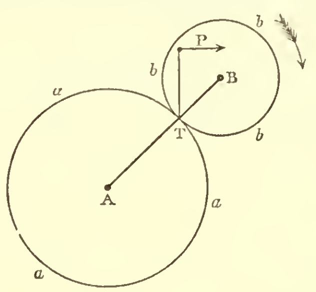

Fig. 5.

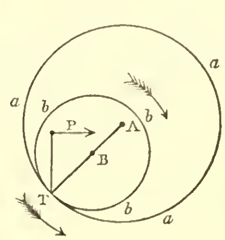

Fig. 6.

rotation, or inside (as in fig. 6), when the rolling will be towards the opposite hand; and at a given instant let T be the line of contact of the two cylindrical surfaces, which is at their common intersection with the plane AB traversing the two axes of figure.

The line T on the surface bbb has for the instant no velocity in a direction perpendicular to AB; because for the instant it touches, without sliding, the line T on the fixed surface *aaa*.

The line T on the surface *bbb* has also for the instant no velocity in the plane AB; for it has just ceased to move towards the fixed surface *aaa*, and is just about to begin to move away from that surface.

The line of contact T, therefore, on the surface of the cylinder *bbb*, is *for the instant* at rest, and is the "instantaneous axis" about which the cylinder *bbb* turns, together with any body rigidly attached to that cylinder.

To find, then, the direction and velocity at the given instant of any point P, either in or rigidly attached to the rolling cylinder T, draw the plane PT; the direction of motion of P will be perpendicular to that plane, and towards the right or left hand according to the direction of the rotation of *bbb*; and the velocity of P will be

$$v_P = \gamma \cdot PT \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3),$$

PT denoting the perpendicular distance of P from T. The path of P is a curve of the kind called *epitrochoids*. If P is in the circumference of *bbb*, that path becomes an *epicycloid*.

The velocity of any point in the axis of figure B is

$$v_B = \gamma \cdot TB \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad 4);$$

and the path of such a point is a circle described about A with the radius AB, being for outside rolling the sum, and for inside rolling the difference, of the radii of the cylinders.

Let α denote the angular velocity with which the *plane of axes* AB rotates about the fixed axis A. Then it is evident that

$$v_B = \alpha \cdot AB \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (5),$$

and consequently that $\alpha = \gamma \cdot \frac{TB}{AB}$ . . . . (6).

For internal rolling, as in fig. 6, AB is to be treated as negative, which will give a negative value to α, indicating that in this case the rotation of AB round A is contrary to that of the cylinder *bbb*.

The angular velocity of the rolling cylinder, *relatively to the plane of axes* AB, is obviously given by the equation—

$$\left.\begin{aligned} \beta &= \gamma - \alpha ; \\ \text{whence } \beta &= \gamma \cdot \frac{TA}{AB} \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (7);$$

care being taken to attend to the sign of α, so that when that is negative the arithmetical values of γ and α are to be added in order to give that of β.

The whole of the foregoing reasonings are applicable, not merely when *aaa* and *bbb* are actual cylinders, but also when they are the osculating cylinders of a pair of cylindroidal surfaces of varying curvature, A and B being the axes of curvature of the parts of those surfaces which are in contact for the instant under consideration.

38. *Composition and Resolution of Rotations about Parallel Axes.*—See above, p. 691, § 73.

39. *Instantaneous Axis of a Cone rolling on a Cone.*—Let O*aa* (fig. 7) be a fixed cone, OA its axis, O*bb* a cone rolling on it, OB the axis of the rolling cone, OT the line of contact of the two cones at the instant under consideration. By reasoning similar to that of sect. 37, it appears that OT is the instantaneous axis of rotation of the rolling cone.

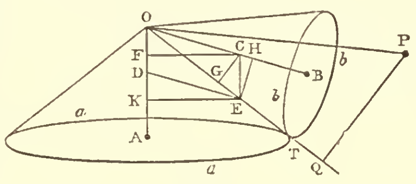

Fig. 7.

Let γ denote the total angular velocity of the rotation of the cone B about the instantaneous axis, β its angular velocity about the axis OB *relatively* to the plane AOB, and α the angular velocity with which the plane AOB turns round the axis OA. It is required to find the ratios of those angular velocities.

Solution.—In OT take any point E, from which draw EC parallel to OA, and ED parallel to OB, so as to construct the parallelogram OCED. Then

$$\left.\begin{matrix} OD : OC : OE \\ :: \alpha : \beta : \gamma \end{matrix}\right\} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (8).$$

Or because of the proportionality of the sides of triangles to the sines of the opposite angles,

$$\left.\begin{matrix} \sin\angle TOB : \sin\angle TOA : \sin\angle AOB \\ :: \quad \alpha \quad : \quad \beta \quad : \quad \gamma \end{matrix}\right\} \quad . \quad . \quad . \quad (8, \text{A});$$

that is to say, the angular velocity about each axis is proportional to the sine of the angle between the other two.

Demonstration.—From C draw CF perpendicular to OA, and CG perpendicular to OE.

$$\text{Then } CF = 2 \times \frac{\text{area ECO}}{CE},$$

$$\text{and } CG = 2 \times \frac{\text{area ECO}}{OE};$$

$$\therefore CG : CF :: CE = OD : OE.$$

Let v_C denote the linear velocity of the point C. Then

$$v_C = \alpha \cdot CF = \gamma \cdot CG$$

$$\therefore \gamma : \alpha :: CF : CG :: OE : OD;$$

which is one part of the solution above stated. From E draw EH perpendicular to OB, and EK to OA. Then it can be shown as before that

$$EK : EH :: OC : OD.$$

Let v_E be the linear velocity of the point E *fixed in the plane of axes* AOB. Then

$$v_E = \alpha \cdot EK.$$

Now, as the line of contact OT is for the instant at rest on the rolling cone as well as on the fixed cone, the linear velocity of the point E fixed to the plane AOB relatively to the rolling cone is the same with its velocity relatively to the fixed cone. That is to say,

$$\beta \cdot EH = v_E = \alpha \cdot EK;$$

therefore $\alpha : \beta :: EH : EK :: OD : OC$,

which is the remainder of the solution.

The path of a point P in or attached to the rolling cone is a spherical epitrochoid traced on the surface of a sphere of the radius OP. From P draw PQ perpendicular to the instantaneous axis. Then the motion of P is perpendicular to the plane OPQ, and its velocity is

$$v_P = \gamma \cdot PQ \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (9).$$

The whole of the foregoing reasonings are applicable, not merely when A and B are actual regular cones, but also when they are the osculating regular cones of a pair of irregular conical surfaces, having a common apex at O.

40. *Composition of Rotations about Two Axes meeting in a Point.*—See p. 691, § 76.

41. *Screw-like or Helical Motion.*—Since (see p. 690, §§ 71, 72) any displacement in a plane can be represented in general by a rotation, it follows that the only combination of translation and rotation, in which a complex movement which is not a mere rotation is produced, occurs when there is a translation *perpendicular to the plane and parallel to the axis* of rotation.

Such a complex motion is called *screw-like* or *helical* motion; for each point in the body describes a *helix* or *screw* round the axis of rotation, fixed or instantaneous as the case may be. To cause a body to move in this manner it is usually made of a helical or screw-like figure, and moves in a guide of a corresponding figure. Helical motion and screws adapted to it are said to be right- or left-handed according to the appearance presented by the rotation to an observer looking towards the direction of the translation. Thus the screw G in fig. 8 is right-handed.

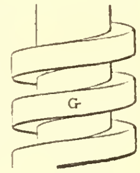

Fig. 8.

The translation of a body in helical motion is called its *advance*. Let v_x denote the velocity of advance at a given instant, which of course is common to all the particles of the body; α the angular velocity of the rotation at the same instant; $2\pi = 6{\cdot}2832$ nearly, the circumference of a circle of the radius unity. Then

$$T = \frac{2\pi}{\alpha} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (10)$$

is the time of one turn at the rate α; and

$$p = v_x T = \frac{2\pi v_x}{\alpha} \quad . \quad . \quad . \quad . \quad . \quad . \quad (11)$$

is the *pitch* or *advance per turn*,—a length which expresses the *comparative motion* of the translation and the rotation.

The pitch of a screw is the distance, measured parallel to its axis, between two successive turns of the same *thread* or helical projection.

Let r denote the perpendicular distance of a point in a body moving helically from the axis. Then

$$v_r = \alpha r \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (12)$$

is the component of the velocity of that point in a plane perpendicular to the axis, and its total velocity is

$$v = \sqrt{\{v_x^2 + v_r^2\}} \quad . \quad . \quad . \quad . \quad . \quad . \quad (13).$$

The ratio of the two components of that velocity is

$$\frac{v_x}{v_r} = \frac{p}{2\pi r} = \tan\theta \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (14);$$

where θ denotes the angle made by the helical path of the point with a plane perpendicular to the axis.

42. *To find the Motion of a Rigid Body from the Motions of Three Points in it.*—See p. 690, § 71, and p. 692, § 78.

Division 4. Elementary Combinations in Mechanism.

43. *Definitions.*—An *elementary combination* in mechanism consists of two pieces whose kinds of motion are determined by their connexion with the frame, and their comparative motion by their connexion with each other,—that connexion being effected either by direct contact of the pieces, or by a connecting piece, which is not connected with the frame, and whose motion depends entirely on the motions of the pieces which it connects.

The piece whose motion is the cause is called the *driver*; the piece whose motion is the effect, the *follower*.

The connexion of each of those two pieces with the frame is in general such as to determine the path of every point in it. In the investigation, therefore, of the comparative motion of the driver and follower, in an elementary combination, it is unnecessary to consider relations of angular direction, which are already fixed by the connexion of each piece with the frame; so that the inquiry is confined to the determination of the velocity ratio, and of the directional relation, so far only as it expresses the connexion between *forward* and *backward* movements of the driver and follower. When a continuous motion of the driver produces a continuous motion of the follower, forward or backward, and a reciprocating motion a motion reciprocating at the same instant, the directional relation is said to be *constant.* When a continuous motion produces a reciprocating motion, or *vice versa*, or when a reciprocating motion produces a motion not reciprocating at the same instant, the directional relation is said to be *variable.*

The *line of action* or *of connexion* of the driver and follower is a line traversing a pair of points in the driver and follower respectively, which are so connected that the component of their velocity relatively to each other, resolved along the line of connexion, is null. There may be several or an indefinite number of lines of connexion, or there may be but one; and a line of connexion may connect either the same pair of points or a succession of different pairs.

44. *General Principle.*—From the definition of a line of connexion it follows that *the components of the velocities of a pair of connected points along their line of connexion are equal.* And from this, and from the property of a rigid body, already stated in sect. 36, it follows, that *the components along a line of connexion of all the points traversed by that line, whether in the driver or in the follower, are equal*; and consequently, *that the velocities of any pair of points traversed by a line of connexion are to each other inversely as the cosines, or directly as the secants, of the angles made by the paths of those points with the line of connexion.*

The general principle stated above in different forms serves to solve every problem in which—the mode of connexion of a pair of pieces being given—it is required to find their comparative motion at a given instant, or *vice versa.*

45. *Application to a Pair of Shifting Pieces.*—In fig. 9, let P_1P_2 be the line of connexion of a pair of pieces, each of which has a motion of translation or shifting. Through any point T in that line draw TV_1, TV_2, respectively parallel to the simultaneous direction of motion of the pieces; through any other point A in the line of connexion draw a plane perpendicular to that line, cutting TV_1, TV_2 in V_1, V_2; then, velocity of piece 1 : velocity of piece 2 :: $TV_1 : TV_2$. Also TA represents the equal components of the velocities of the pieces parallel to their line of connexion, and the line V_1V_2 represents their velocity relatively to each other.

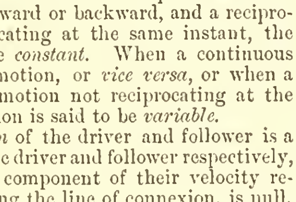

Fig. 9.

46. *Application to a Pair of Turning Pieces.*—Let α_1, α_2 be the angular velocities of a pair of turning pieces; θ_1, θ_2 the angles which their line of connexion makes with their respective planes of rotation; r_1, r_2 the common perpendiculars let fall from the line of connexion upon the respective axes of rotation of the pieces. Then the equal components, along the line of connexion, of the velocities of the points where those perpendiculars meet that line are—

$$\alpha_1 r_1 \cos\theta_1 = \alpha_2 r_2 \cos\theta_2 ;$$

consequently, the comparative motion of the pieces is given by the equation

$$\frac{\alpha_2}{\alpha_1} = \frac{r_1 \cos\theta_1}{r_2 \cos\theta_2} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (15).$$

47. *Application to a Shifting Piece and a Turning Piece.*—Let a shifting piece be connected with a turning piece, and at a given instant let α_1 be the angular velocity of the turning peice, r_1 the common perpendicular of its axis of rotation and the line of connexion, θ_1 the angle made by the line of connexion with the plane of rotation, θ_2 the angle made by the line of connexion with the direction of motion of the shifting piece, v_2 the linear velocity of that piece. Then

$$\alpha_1 r_1 \cos\theta_1 = v_2 \cos\theta_2 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (16);$$

which equation expresses the comparative motion of the two pieces.

48. *Classification of Elementary Combinations in Mechanism.*—The first systematic classification of elementary combinations in mechanism was that founded by Monge, and fully developed by Lanz and Bétancourt, which has been generally received, and has been adopted in most treatises on applied mechanics. But that classification is founded on the absolute instead of the comparative motions of the pieces, and is, for that reason, defective, as Willis has pointed out in his admirable treatise *On the Principles of Mechanism.*

Willis's classification is founded, in the first place, on comparative motion, as expressed by velocity ratio and directional relation, and in the second place, on the mode of connexion of the driver and follower. He divides the elementary combinations in mechanism into three classes, of which the characters are as follows:—

Class A: Directional relation constant; velocity ratio constant.
Class B: Directional relation constant; velocity ratio varying.
Class C: Directional relation changing periodically; velocity ratio constant or varying.

Each of those classes is subdivided by Willis into five divisions, of which the characters are as follows:—

Division A:	Connexion	by	rolling contact.
,, B:	,,	,,	sliding contact.
,, C:	,,	,,	wrapping connectors.
,, D:	,,	,,	link-work.
,, E:	,,	,,	reduplication.

In the present article the principle of Willis's classification is followed; but the arrangement is modified by taking the *mode of connexion* as the basis of the primary classification, and by removing the subject of connexion by reduplication to the section of aggregate combinations. This modified arrangement is adopted as being better suited than the original arrangement to the limits of an article in an encyclopædia; but it is not disputed that the original arrangement may be the best for a separate treatise.

49. *Rolling Contact—Smooth Wheels and Racks.*—In order that two pieces may move in *rolling contact*, it is necessary that each pair of points in the two pieces which touch each other should at the instant of contact be moving in the same direction with the same velocity. In the case of two *shifting* pieces this would involve equal and parallel velocities for all the points of each piece, so that there could be no rolling, and, in fact, the two pieces would move like one; hence, in the case of rolling contact, either one or both of the pieces must rotate.

The direction of motion of a point in a turning piece being perpendicular to a plane passing through its axis, the condition that each pair of points in contact with each other must move in the same direction leads to the following consequences:—

I. That, when both pieces rotate, their axes, and all their points of contact, lie in the same plane.

II. That, when one piece rotates and the other shifts, the axis of the rotating piece, and all the points of contact, lie in a plane perpendicular to the direction of motion of the shifting piece.

The condition that the velocity of each pair of points of contact must be equal leads to the following consequences:—

III. That the angular velocities of a pair of turning pieces in rolling contact must be inversely as the perpendicular distances of any pair of points of contact from the respective axes.

IV. That the linear velocity of a shifting piece in rolling contact with a turning piece is equal to the product of the angular velocity of the turning piece by the perpendicular distance from its axis to a pair of points of contact.

The *line of contact* is that line in which the points of contact are all situated. Respecting this line, the above principles III. and IV. lead to the following conclusions:—

V. That for a pair of turning pieces with parallel axes, and for a turning piece and a shifting piece, the line of contact is straight, and parallel to the axes or axis; and hence that the rolling surfaces are either plane or cylindrical (the term "cylindrical" including all surfaces generated by the motion of a straight line parallel to itself).

VI. That for a pair of turning pieces with intersecting axes the line of contact is also straight, and traverses the point of intersection of the axes; and hence that the rolling surfaces are conical, with a common apex (the term "conical" including all surfaces generated by the motion of a straight line which traverses a fixed point).

Turning pieces in rolling contact are called *smooth* or *toothless wheels.* Shifting pieces in rolling contact with turning pieces may be called *smooth* or *toothless racks.*

VII. In a pair of pieces in rolling contact every straight line traversing the line of contact is a line of connexion.

50. *Cylindrical Wheels and Smooth Racks.*—In designing cylindrical wheels and smooth racks, and determining their comparative motion, it is sufficient to consider a section of the pair of pieces made by a plane perpendicular to the axis or axes.

The points where axes intersect the plane of section are called *centres*; the point where the line of contact intersects it, the *point of contact*, or *pitch-point*; and the wheels are described as *circular*, *elliptical*, &c., according to the forms of their sections made by that plane.

When the point of contact of two wheels lies between their centres, they are said to be in *outside gearing*; when beyond their centres, in *inside gearing*, because the rolling surface of the larger wheel must in this case be turned inward or towards its centre.

From Principle III. of sect. 49 it appears that the angular velocity-ratio of a pair of wheels is the inverse ratio of the distances of the point of contact from the centres respectively.

For outside gearing that ratio is *negative*, because the wheels turn contrary ways; for inside gearing it is *positive*, because they turn the same way.

If the velocity ratio is to be constant, as in Willis's Class A, the wheels must be circular; and this is the most common form for wheels.

If the velocity ratio is to be variable, as in Willis's Class B, the figures of the wheels are a pair of *rolling curves*, subject to the condition that the distance between their *poles* (which are the centres of rotation) shall be constant.

The following is the geometrical relation which must exist between such a pair of curves. See fig. 10.

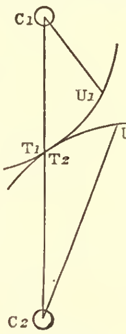

Fig. 10.

Let C_1, C_2 be the poles of a pair of rolling curves; T_1, T_2 any pair of points of contact; U_1, U_2 any other pair of points of contact. Then, for every possible pair of points of contact, the two following equations must be simultaneously fulfilled:—

$$\text{Sum of radii, } C_1U_1 + C_2U_2 = C_1T_1 + C_2T_2 = \text{constant};$$
$$\text{arc, } T_2U_2 = T_1U_1 \quad \ldots\ldots\ldots \quad (17).$$

A condition equivalent to the above, and necessarily connected with it, is, that at each pair of points of contact the inclinations of the curves to their radii-vectores shall be equal and contrary; or, denoting by r_1, r_2 the radii-vectores at any given pair of points of contact, and s the length of the equal arcs measured from a certain fixed pair of points of contact—

$$\frac{dr_2}{ds} = -\frac{dr_1}{ds} \quad \ldots\ldots\ldots \quad (18);$$

which is the differential equation of a pair of rolling curves whose poles are at a constant distance apart.

For full details as to rolling curves, see Willis's work, already mentioned, and Clerk Maxwell's paper on Rolling Curves in the *Transactions of the Royal Society of Edinburgh*, 1849.

A rack, to work with a circular wheel, must be straight. To work with a wheel of any other figure, its section must be a rolling curve, subject to the condition that the perpendicular distance from the pole or centre of the wheel to a straight line parallel to the direction of the motion of the rack shall be constant. Let r_1 be the radius-vector of a point of contact on the wheel, x_2 the ordinate from the straight line before mentioned to the corresponding point of contact on the rack. Then

$$\frac{dx_2}{ds} = -\frac{dr_1}{ds} \quad \ldots\ldots\ldots \quad (19)$$

is the differential equation of the pair of rolling curves.

To illustrate this subject, it may be mentioned that an ellipse rotating about one focus rolls completely round in outside gearing with an equal and similar ellipse also rotating about one focus, the distance between the axes of rotation being equal to the major axis of the ellipses, and the velocity ratio varying from $\frac{1 + \text{eccentricity}}{1 - \text{eccentricity}}$ to $\frac{1 - \text{eccentricity}}{1 + \text{eccentricity}}$; an hyperbola rotating about its further focus rolls in inside gearing, through a limited arc, with an equal and similar hyperbola rotating about its nearer focus, the distance between the axes of rotation being equal to the axis of the hyperbolas, and the velocity ratio varying between $\frac{\text{eccentricity} + 1}{\text{eccentricity} - 1}$ and unity; and a parabola rotating about its focus rolls with an equal and similar parabola, shifting parallel to its directrix.

51. *Conical or Bevel and Disk Wheels.*—From Principles III. and VI. of sect. 49 it appears that the angular velocities of a pair of wheels whose axes meet in a point are to each other inversely as the sines of the angles which the axes of the wheels make with the line of contact. Hence follows the following construction (figs. 11 and 12).—Let O be the apex or point of meeting of the two axes OC_1, OC_2. The angular velocity ratio being given, it is required to find the line of contact. On OC_1, OC_2 take lengths OA_1, OA_2, respectively proportional to the angular velocities of the pieces on whose axes they are taken. Complete the parallelogram OA_1EA_2; the diagonal OET will be the line of contact required.

When the velocity ratio is variable, the line of contact will shift its position in the plane C_1OC_2, and the wheels will be cones, with eccentric or irregular bases. In every case which occurs in practice, however, the velocity ratio is constant; the line of contact is constant in position, and the rolling surfaces of the wheels are regular circular cones (when they are called *bevel wheels*); or one of a pair of wheels may have a flat disk for its rolling surface, as W_2 in fig. 12, in which case it is a *disk wheel*. The rolling surfaces of actual wheels consist of frusta or zones of the complete cones or disks, as shown by W_1, W_2 in figs. 11 and 12.

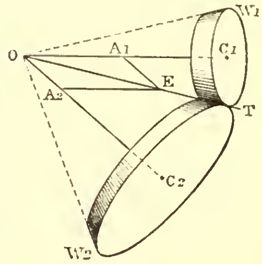

Fig. 11.

52. *Sliding Contact (lateral): Skew-Bevel Wheels.*—An hyperboloid of revolution is a surface resembling a sheaf or a dice box, generated by the rotation of a straight line round an axis from which it is at a constant distance, and to which it is inclined at a constant angle. If two such hyperboloids, equal or unequal, be placed in the closest possible contact, as in fig. 13, they will touch each other along one of the generating straight lines of each, which will form their line of contact, and will be inclined to the axes AG, BH in opposite directions. The axes will not be parallel, nor will they intersect each other.

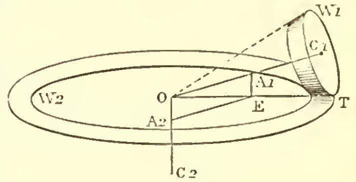

Fig. 12.

The motion of two such hyperboloids, turning in contact with each other, has hitherto been classed amongst cases of rolling contact; but that classification is not strictly correct, for, although the component velocities of a pair of points of contact in a direction at right angles to the line of contact are equal, still, as the axes are neither parallel to each other nor to the line of contact, the velocities of a pair of points of contact have components along the line of contact which are unequal, and their difference constitutes a *lateral sliding*.

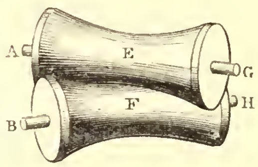

Fig. 13.

The directions and positions of the axes being given, and the required angular velocity ratio, the following construction serves to determine the line of contact, by whose rotation round the two axes respectively the hyperboloids are generated:—

In fig. 14, let B_1C_1, B_2C_2 be the two axes; B_1B_2 their common perpendicular. Through any point O in this common perpendicular draw OA_1 parallel to B_1C_1 and OA_2 parallel to B_2C_2; make those lines proportional to the angular velocities about the axes to which they are respectively parallel; complete the parallelogram OA_1EA_2, and draw the diagonal OE; divide B_1B_2 in D into two parts, *inversely* proportional to the angular velocities about the axes which they respectively adjoin; through D parallel to OE draw DT. This will be the line of contact.

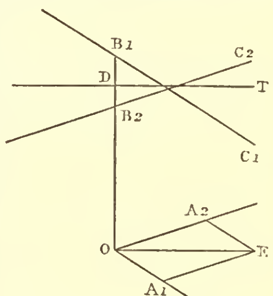

Fig. 14.

A pair of thin frusta of a pair of hyperboloids are used in practice to communicate motion between a pair of axes neither parallel nor intersecting, and are called *skew-bevel wheels*.

In skew-bevel wheels the properties of a line of connexion are not possessed by every line traversing the line of contact, but only by every line traversing the line of contact at right angles.

If the velocity ratio to be communicated were variable, the point D would alter its position, and the line DT its direction, at different periods of the motion, and the wheels would be hyperboloids of an eccentric or irregular cross-section; but forms of this kind are not used in practice.

53. *Sliding Contact (circular): Grooved Wheels.*—As the adhesion or friction between a pair of smooth wheels is seldom sufficient to prevent their slipping on each other, contrivances are used to increase their mutual hold. One of those consists in forming the rim of each wheel into a series of alternate ridges and grooves

parallel to the plane of rotation; it is applicable to cylindrical and bevel wheels, but not to skew-bevel wheels. The comparative motion of a pair of wheels so ridged and grooved is the same with that of a pair of smooth wheels in rolling contact, whose cylindrical or conical surfaces lie midway between the tops of the ridges and bottoms of the grooves, and those ideal smooth surfaces are called the *pitch surfaces* of the wheels.

The relative motion of the faces of contact of the ridges and grooves is a *rotatory sliding* or *grinding* motion, about the line of contact of the pitch-surfaces as an instantaneous axis.

Grooved wheels have hitherto been but little used.

54. *Sliding Contact (direct): Teeth of Wheels, their Number and Pitch.*—The ordinary method of connecting a pair of wheels, or a wheel and a rack, and the only method which insures the exact maintenance of a given numerical velocity ratio, is by means of a series of alternate ridges and hollows parallel or nearly parallel to the successive lines of contact of the ideal smooth wheels whose velocity ratio would be the same with that of the toothed wheels. The ridges are called *teeth*; the hollows, *spaces*. The teeth of the driver push those of the follower before them, and in so doing sliding takes place between them in a direction across their lines of contact.

The *pitch-surfaces* of a pair of toothed wheels are the ideal smooth surfaces which would have the same comparative motion by rolling contact that the actual wheels have by the sliding contact of their teeth. The *pitch-circles* of a pair of circular toothed wheels are sections of their pitch-surfaces, made for *spur-wheels* (that is, for wheels whose axes are parallel) by a plane at right angles to the axes, and for bevel wheels by a sphere described about the common apex. For a pair of skew-bevel wheels the pitch-circles are a pair of contiguous rectangular sections of the pitch-surfaces. The *pitch-point* is the point of contact of the pitch-circles.

The pitch-surface of a wheel lies intermediate between the points of the teeth and the bottoms of the hollows between them. That part of the acting surface of a tooth which projects beyond the pitch-surface is called the *face*; that part which lies within the pitch-surface, the *flank*.

Teeth, when not otherwise specified, are understood to be made in one piece with the wheel,—the material being generally cast-iron, brass, or bronze. Separate teeth, fixed into mortises in the rim of the wheel, are called *cogs*. A *pinion* is a small toothed wheel; a *trundle* is a pinion with cylindrical *staves* for teeth.

The radius of the pitch-circle of a wheel is called the *geometrical radius*; a circle touching the ends of the teeth is called the *addendum circle*, and its radius the *real radius*; the difference between these radii, being the projection of the teeth beyond the pitch-surface, is called the *addendum*.

The distance, measured along the pitch-circle, from the face of one tooth to the face of the next, is called the *pitch*. The pitch and the number of teeth in wheels are regulated by the following principles:—

I. In wheels which rotate continuously for one revolution or more, it is obviously necessary *that the pitch should be an aliquot part of the circumference.*

In wheels which reciprocate without performing a complete revolution this condition is not necessary. Such wheels are called *sectors*.

II. In order that a pair of wheels, or a wheel and a rack, may work correctly together, it is in all cases essential *that the pitch should be the same in each.*

III. Hence, in any pair of circular wheels which work together, the numbers of teeth in a complete circumference are directly as the radii and inversely as the angular velocities.

IV. Hence also, in any pair of circular wheels which rotate continuously for one revolution or more, the ratio of the numbers of teeth and its reciprocal the angular velocity ratio must be expressible in whole numbers.

From this principle arise problems of a kind which will be referred to in treating of *Trains of Mechanism*.

V. Let n, N be the respective numbers of teeth in a pair of wheels, N being the greater. Let t, T be a pair of teeth in the smaller and larger wheel respectively, which at a particular instant work together. It is required to find, first, how many pairs of teeth must pass the line of contact of the pitch-surfaces before t and T work together again (let this number be called a); and, secondly, with how many different teeth of the larger wheel the tooth t will work at different times (let this number be called b); thirdly, with how many different teeth of the smaller wheel the tooth T will work at different times (let this be called c).

CASE 1. If n is a divisor of N,

$$a = \mathrm{N}\,;\; b = \frac{\mathrm{N}}{n}\,;\; c = 1 \quad . \quad . \quad . \quad . \quad . \quad (20).$$

CASE 2. If the greatest common divisor of N and n be d, a number less than n, so that $n = md$, $\mathrm{N} = \mathrm{M}d$; then

$$a = m\mathrm{N} = \mathrm{M}n = \mathrm{M}md\,;\; b = \mathrm{M}\,;\; c = m \quad . \quad . \quad . \quad (21).$$

CASE 3 If N and n be prime to each other,

$$a = n\mathrm{N}\,;\; b = \mathrm{N}\,;\; c = n \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (22).$$

It is considered desirable by millwrights, with a view to the preservation of the uniformity of shape of the teeth of a pair of wheels, that each given tooth in one wheel should work with as many different teeth in the other wheel as possible. They therefore study that the numbers of teeth in each pair of wheels which work together shall either be prime to each other, or shall have their greatest common divisor as small as is consistent with a velocity ratio suited for the purposes of the machine.

55. *Sliding Contact—Forms of the Teeth of Spur-wheels and Racks.*—A line of connexion of two pieces in sliding contact is a line perpendicular to their surfaces at a point where they touch. Bearing this in mind, the principle of the comparative motion of a pair of teeth belonging to a pair of spur-wheels, or to a spur-wheel and a rack, is found by applying the principles stated generally in sects. 46 and 47 to the case of parallel axes for a pair of spur-wheels, and to the case of an axis perpendicular to the direction of shifting for a wheel and a rack.

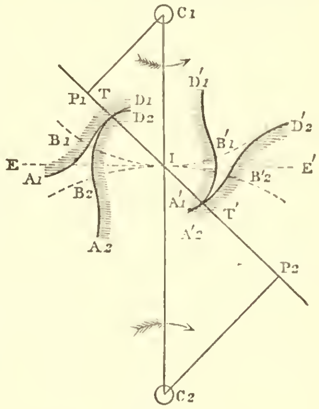

Fig. 15.

In fig. 15, let C_1, C_2 be the centres of a pair of spur-wheels; $B_1IB'_1$, $B_2IB'_2$ portions of their pitch-circles, touching at I, the pitch-point. Let the wheel 1 be the driver, and the wheel 2 the follower.

Let $D_1TB_1A_1$, $D_2TB_2A_2$ be the positions, at a given instant, of the acting surfaces of a pair of teeth in the driver and follower respectively, touching each other at T; the line of connexion of those teeth is P_1P_2, perpendicular to their surfaces at T. Let C_1P_1, C_2P_2 be perpendiculars let fall from the centres of the wheels on the line of contact. Then, by sect. 46, the angular velocity-ratio is

$$\frac{\alpha_2}{\alpha_1} = \frac{C_1P_1}{C_2P_2} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (23).$$

The following principles regulate the forms of the teeth and their relative motions:—

I. The angular velocity ratio due to the sliding contact of the teeth will be the same with that due to the rolling contact of the pitch-circles, if the line of connexion of the teeth cuts the line of centres at the pitch-point.

For, let P_1P_2 cut the line of centres at I; then, by similar triangles,

$$\alpha_1 : \alpha_2 :: C_2P_2 : C_1P_1 :: IC_2 :: IC_1 \quad . \quad . \quad . \quad (24);$$

which is also the angular velocity ratio due to the rolling contact of the circles $B_1IB'_1$, $B_2IB'_2$.

This principle determines the *forms* of all teeth of spur-wheels. It also determines the forms of the teeth of straight racks, if one of the centres be removed, and a straight line EIE′, parallel to the direction of motion of the rack, and perpendicular to C_1IC_2, be substituted for a pitch-circle.

II. The component of the velocity of the point of contact of the teeth T along the line of connexion is

$$\alpha_1 \,.\, C_1P_1 = \alpha_2 \,.\, C_2P_2 \quad . \quad . \quad . \quad . \quad . \quad . \quad (25).$$

III. The relative velocity perpendicular to P_1P_2 of the teeth at their point of contact,—that is, their *velocity of sliding* on each other,—is found by supposing one of the wheels, such as 1, to be fixed, the line of centres C_1C_2 to rotate backwards round C_1 with the angular velocity α_1, and the wheel 2 to rotate round C_2 as before, with the angular velocity α_2 relatively to the line of centres C_1C_2, so as to have the same motion as if its pitch-circle *rolled* on the pitch-circle of the first wheel. Thus the *relative* motion of the wheels is unchanged; but 1 is considered as fixed, and 2 has the *total motion* given by the principles of sects. 37 and 38,—that is, a rotation about the instantaneous axis I, with the angular velocity $\alpha_1 + \alpha_2$. Hence the *velocity of sliding* is that due to this rotation about I, with the radius IT; that is to say, its value is

$$(\alpha_1 + \alpha_2) \,.\, \mathrm{IT} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (26);$$

so that it is greater the farther the point of contact is from the line of centres; and at the instant when that point passes the line of centres, and coincides with the *pitch-point*, the velocity of sliding is null, and the action of the teeth is, for the instant, that of rolling contact.

IV. The *path of contact* is the line traversing the various positions of the point T. If the line of connexion preserves always the same position, the path of contact coincides with it, and is straight; in other cases the path of contact is curved.

It is divided by the pitch-point I into two parts,—the *arc* or *line of approach* described by T in approaching the line of centres, and the *arc* or *line of recess* described by T after having passed the line of centres.

During the *approach*, the *flank* D_1B_1 of the driving tooth drives the *face* D_2B_2 of the following tooth, and the teeth are sliding *towards* each other. During the *recess* (in which the position of the teeth is exemplified in the figure by curves marked with accented letters), the *face* $B'_1A'_1$ of the driving tooth drives the *flank* $B'_2A'_2$ of the following tooth, and the teeth are sliding *from* each other.

The path of contact is bounded where the approach commences by the addendum-circle of the follower, and where the recess terminates by the addendum-circle of the driver. The length of the path of contact should be such that there shall always be at least one pair of teeth in contact; and it is better still to make it so long that there shall always be at least two pairs of teeth in contact.

V. The *obliquity* of the action of the teeth is the angle $EIT = IC_1P_1 = IC_2P_2$.

In practice it is found desirable that the mean value of the obliquity of action during the contact of teeth should not exceed 15°, nor the maximum value 30°.

It is unnecessary to give separate figures and demonstrations for inside gearing. The only modification required in the formulæ is, that in equation 26 the *difference* of the angular velocities should be substituted for their sum.

56. *Involute Teeth.*—The simplest form of tooth which fulfils the conditions of sect. 55 is obtained in the following manner (see fig. 16). Let C_1, C_2 be the centres of two wheels, $B_1IB'_1$, $B_2IB'_2$ their pitch-circles, I the pitch-point; let the obliquity of action of the teeth be constant, so that the same straight line P_1IP_2 shall represent at once the constant line of connexion of teeth and the path of contact. Draw C_1P_1, C_2P_2 perpendicular to P_1IP_2, and with those lines as radii describe about the centres of the wheels the circles $D_1D'_1$, $D_2D'_2$, called *base-circles*. It is evident that the radii of the base-circles bear to each other the same proportions as the radii of the pitch-circles, and also that

$$\left.\begin{array}{l} C_1P_1 = IC_1 \,.\, \cos \text{obliquity} \\ C_2P_2 = IC_2 \,.\, \cos \text{obliquity} \end{array}\right\} \quad . \quad . \quad . \quad . \quad . \quad (27).$$

(The obliquity which is found to answer best in practice is about $14\frac{1}{2}°$; its cosine is about $\frac{3\,1}{3\,2}$, and its sine about $\frac{1}{4}$. These values, though not absolutely exact, are near enough to the truth for practical purposes.)

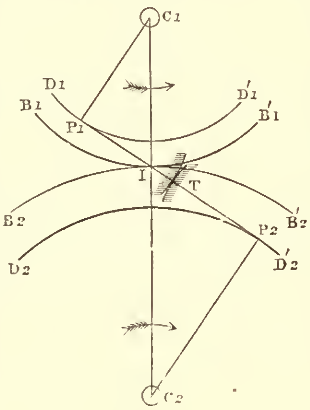

Fig. 16.

Suppose the base-circles to be a pair of circular pulleys connected by means of a cord whose course from pulley to pulley is P_1IP_2. As the line of connexion of those pulleys is the same with that of the proposed teeth, they will rotate with the required velocity ratio. Now, suppose a tracing point T to be fixed to the cord, so as to be carried along the path of contact P_1IP_2, that point will trace on a plane rotating along with the wheel 1 part of the involute of the base-circle $D_1D'_1$, and on a plane rotating along with the wheel 2 part of the involute of the base-circle $D_2D'_2$; and the two curves so traced will always touch each other in the required point of contact T, and will therefore fulfil the condition required by Principle I. of sect. 55.

Consequently, one of the forms suitable for the teeth of wheels is the involute of a circle; and the obliquity of the action of such teeth is the angle whose cosine is the ratio of the radius of their base-circle to that of the pitch-circle of the wheel.

All involute teeth of the same pitch work smoothly together.

To find the length of the path of contact on either side of the pitch-point I, it is to be observed that the distance between the fronts of two successive teeth, as measured along P_1IP_2, is less than the pitch in the ratio of cos obliquity : 1; and consequently that, if distances equal to the pitch be marked off either way from I towards P_1 and P_2 respectively, as the extremities of the path of contact, and if, according to Principle IV. of sect. 55, the addendum-circles be described through the points so found, there will always be at least two pairs of teeth in action at once. In practice it is usual to make the path of contact somewhat longer, viz., about $2\frac{1}{5}$th times the pitch; and with this length of path, and the obliquity already mentioned of $14\frac{1}{2}°$, the addendum is about $\frac{3}{10}$ths of the pitch.

The teeth of a *rack*, to work correctly with wheels having involute teeth, should have plane surfaces perpendicular to the line of connexion, and consequently making with the direction of motion of the rack angles equal to the complement of the obliquity of action.

57. *Teeth for a given Path of Contact—Mr Sang's Method.*—In the preceding section the form of the teeth is found by assuming a figure for the path of contact, viz., the straight line. Any other convenient figure may be assumed for the path of contact, and the corresponding forms of the teeth found by determining what curves a point T, moving along the assumed path of contact, will trace on two disks rotating round the centres of the wheels with angular velocities bearing that relation to the component velocity of T along TI, which is given by Principle II. of sect. 55, and by equation 25. This method of finding the forms of the teeth of wheels forms the subject of an elaborate and most interesting treatise by Mr Edward Sang.

All wheels having teeth of the same pitch, traced from the same path of contact, work correctly together, and are said to belong to the *same set*.

58. *Teeth traced by Rolling Curves.*—If any curve R (fig. 17) be rolled on the inside of the pitch-circle BB of a wheel, it appears, from sect. 37, that the instantaneous axis of the rolling curve at any instant will be at the point I, where it touches the pitch-circle for the moment, and that consequently the line AT, traced by a tracing-point T, fixed to the rolling curve upon the plane of the wheel, will be everywhere perpendicular to the straight line TI; so that the traced curve AT will be suitable for the flank of a tooth, in which T is the point of contact corresponding to the position I of the pitch-point. If the same rolling curve R, with the same tracing-point T, be rolled on the *outside* of any other pitch-circle, it will have the *face* of a tooth suitable to work with the *flank* AT.

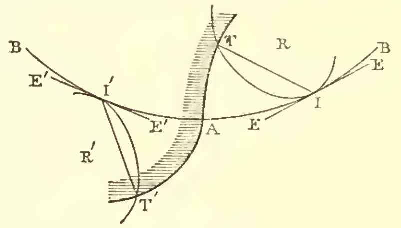

Fig. 17.

In like manner, if either the same or any other rolling curve R' be rolled the opposite way, on the *outside* of the pitch-circle BB, so that the tracing point T' shall start from A, it will trace the *face* AT' of a tooth suitable to work with a *flank* traced by rolling the same curve R' with the same tracing-point T' *inside* any other pitch-circle.

The figure of the *path of contact* is that traced on a fixed plane by the tracing-point, when the rolling curve is rotated in such a manner as always to touch a fixed straight line EIE (or E'I'E', as the case may be) at a fixed point I (or I').

If the same rolling curve and tracing point be used to trace both the faces and the flanks of the teeth of a number of wheels of different sizes but of the same pitch, all those wheels will work correctly together, and will form a *set*. The teeth of a *rack*, of the same set, are traced by rolling the rolling curve on both sides of a straight line.

The teeth of wheels of any figure, as well as of circular wheels, may be traced by rolling curves on their pitch-surfaces; and all teeth of the same pitch, traced by the same rolling curve with the same tracing-point, will work together correctly if their pitch-surfaces are in rolling contact.

59. *Epicycloidal Teeth.*—The most convenient rolling curve is the circle. The path of contact which it traces is identical with itself; and the flanks of the teeth are internal and their faces external epicycloids for wheels, and both flanks and faces are cycloids for a rack.

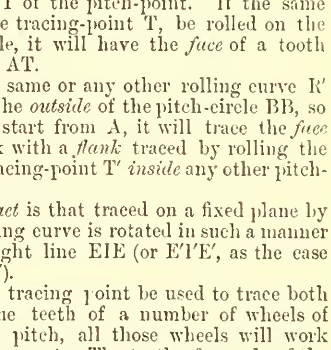

Fig. 18.

For a pitch-circle of twice the radius of the rolling or *describing* circle (as it is called) the internal epicycloid is a straight line, being, in fact, a diameter of the pitch circle, so that the flanks of the teeth for such a pitch-circle are planes radiating from the axis. For a smaller pitch-circle the flanks would be convex and *incurved* or *under-cut*, which would be inconvenient: therefore the smallest wheel of a set should have its pitch-circle of twice the radius of the describing circle, so that the flanks may be either straight or concave.

In fig. 18, let BB' be part of the pitch-circle of a wheel with epicycloidal teeth; CIC' the line of centres; I the pitch-point; EIE' a straight tangent to the pitch-circle at that point; R the internal and R′ the equal external describing circles, so placed as to touch the pitch-circle and each other at I. Let DID′ be the path of contact, consisting of the arc of approach DI and the arc of recess ID′. In order that there may always be at least two pairs of teeth in action, each of those arcs should be equal to the pitch.

The obliquity of the action in passing the line of centres is nothing; the maximum obliquity is the angle EID = E′ID; and the mean obliquity is one-half of that angle.

It appears from experience that the mean obliquity should not exceed 15°; therefore the maximum obliquity should be about 30°; therefore the equal arcs DI and ID′ should each be one-sixth of a circumference; therefore the circumference of the describing circle should be *six times the pitch.*

It follows that the smallest pinion of a set in which pinion the flanks are straight should have twelve teeth.

60. *Nearly Epicycloidal Teeth—Willis's Method.*—To facilitate the drawing of epicycloidal teeth in practice, Willis has shown how to approximate to their figure by means of two circular arcs,—one concave, for the flank, and the other convex, for the face,—and each having for its radius the *mean* radius of curvature of the epicycloidal arc. Willis's formulæ are founded on the following properties of epicycloids:—

Let R be the radius of the pitch-circle; r that of the describing circle; θ the angle made by the normal TI to the epicycloid at a given point T, with a tangent to the circle at I; that is, the obliquity of the action at T.

Then the radius of curvature of the epicycloid at T is—

$$\left.\begin{aligned}&\text{For an internal epicycloid, } \rho = 4r\sin\theta\,\frac{R-r}{R-2r}\\&\text{For an external epicycloid, } \rho' = 4r\sin\theta\,\frac{R+r}{R+2r}\end{aligned}\right\} \quad . \quad . \quad . \quad . \quad (28).$$

Also, to find the position of the centres of curvature relatively to the pitch-circle, we have, denoting the chord of the describing circle TI by c, $c = 2r\sin\theta$; and therefore

$$\left.\begin{aligned}&\text{For the flank, } \rho - c = 2r\sin\theta\,\frac{R}{R-2r}\\&\text{For the face, } \rho' - c = 2r\sin\theta\,\frac{R}{R+2r}\end{aligned}\right\} \quad . \quad . \quad (29).$$

For the proportions approved of by Willis, $\sin\theta = \frac{1}{4}$ nearly; $r = p$ (the pitch) nearly; $c = \frac{1}{2}p$ nearly; and, if N be the number of teeth in the wheel, $\frac{r}{R} = \frac{6}{N}$ nearly; therefore, approximately,

$$\left.\begin{aligned}\rho - c &= \frac{p}{2}\cdot\frac{N}{N-12}\\ \rho' - c &= \frac{p}{2}\cdot\frac{N}{N+12}\end{aligned}\right\} \quad . \quad . \quad . \quad . \quad . \quad (30).$$

Hence the following construction (fig. 19). Let BB be part of the pitch-circle, and a the point where a tooth is to cross it. Set off $ab = ac = \frac{1}{2}p$. Draw radii bd, ce; draw fb, cg, making angles of $75\frac{1}{2}$° with those radii. Make $bf = \rho' - c$, $cg = \rho - c$. From f, with the radius fa, draw the circular arc ah; from g, with the radius ga, draw the circular arc ak. Then ah is the face and ak the flank of the tooth required.

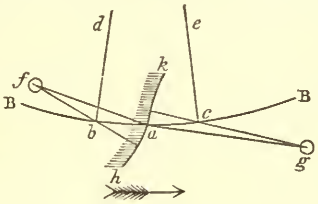

Fig. 19.

To facilitate the application of this rule, Willis published tables of $\rho - c$ and $\rho' - c$, and invented an instrument called the "odontograph."

61. *Trundles and Pin-Wheels.*—If a wheel or trundle have cylindrical pins or staves for teeth, the faces of the teeth of a wheel suitable for driving it are described by first tracing external epicycloids, by rolling the pitch-circle of the pin-wheel or trundle on the pitch-circle of the driving-wheel, with the centre of a stave for a tracing-point, and then drawing curves parallel to, and within the epicycloids, at a distance from them equal to the radius of a stave. Trundles having only six staves will work with large wheels.

62. *Backs of Teeth and Spaces.*—Toothed wheels being in general intended to rotate either way, the *backs* of the teeth are made similar to the fronts. The *space* between two teeth, measured on the pitch-circle, is made about $\frac{1}{11}$th part wider than the thickness of the tooth on the pitch-circle; that is to say,

Thickness of tooth = $\frac{5}{11}$ pitch;
Width of space = $\frac{6}{11}$ pitch.

The difference of $\frac{1}{11}$ of the pitch is called the *back-lash.* The clearance allowed between the points of teeth and the bottoms of the spaces between the teeth of the other wheel is about $\frac{1}{10}$th of the pitch.

63. *Stepped and Helical Teeth.*—Hooke invented the making of the fronts of teeth in a series of steps with a view to increase the smoothness of action. A wheel thus formed resembles in shape a series of equal and similar toothed disks placed side by side, with the teeth of each a little behind those of the preceding disk. He also invented, with the same object, teeth whose fronts, instead of being parallel to the line of contact of the pitch-circles, cross it obliquely, so as to be of a screw-like or helical form. In wheelwork of this kind the contact of each pair of teeth commences at the foremost end of the helical front, and terminates at the aftermost end; and the helix is of such a pitch that the contact of one pair of teeth shall not terminate until that of the next pair has commenced.

Stepped and helical teeth have the desired effect of increasing the smoothness of motion, but they require more difficult and expensive workmanship than common teeth; and helical teeth are, besides, open to the objection that they exert a laterally oblique pressure, which tends to increase resistance, and unduly strain the machinery.

64. *Teeth of Bevel-Wheels.*—The acting surfaces of the teeth of bevel-wheels are of the conical kind, generated by the motion of a line passing through the common apex of the pitch-cones, while its extremity is carried round the outlines of the cross section of the teeth made by a sphere described about that apex.

The operations of describing the exact figures of the teeth of bevel-wheels, whether by involutes or by rolling curves, are in every respect analogous to those for describing the figures of the teeth of spur-wheels, except that in the case of bevel-wheels all those operations are to be performed on the surface of a sphere described about the apex instead of on a plane, substituting *poles* for *centres*, and *great circles* for *straight lines.*

In consideration of the practical difficulty, especially in the case of large wheels, of obtaining an accurate spherical surface, and of drawing upon it when obtained, the following approximate method, proposed originally by Tredgold, is generally used:—

Let O (fig. 20) be the common apex of a pair of bevel-wheels; OB_1I, OB_2I their pitch cones; OC_1, OC_2 their axes; OI their line of contact. Perpendicular to OI draw A_1IA_2, cutting the axes in A_1, A_2; make the outer rims of the patterns and of the wheels portions of the cones A_1B_1I, A_2B_2I, of which the narrow zones occupied by the teeth will be sufficiently near to a spherical surface described about O for practical purposes. To find the figures of the teeth, draw on a flat surface circular arcs ID_1, ID_2, with the radii A_1I, A_2I; those arcs will be the *developments* of arcs of the pitch-circles B_1I, B_2I, when the conical surfaces A_1B_1I, A_2B_2I are spread out flat. Describe the figures of teeth for the developed arcs as for a pair of spur-wheels; then wrap the developed arcs on the cones, so as to make them coincide with the pitch-circles, and trace the teeth on the conical surfaces.

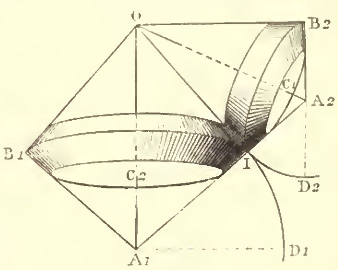

Fig. 20.

65. *Teeth of Skew-Bevel Wheels.*—The crests of the teeth of a skew-bevel wheel are parallel to the generating straight line of the hyperboloidal pitch-surface; and the transverse sections of the teeth at a given pitch-circle are similar to those of the teeth of a bevel-wheel whose pitch-surface is a cone touching the hyperboloidal surface at the given circle.

66. *Cams.*—A *cam* is a single tooth, either rotating continuously or oscillating, and driving a sliding or turning piece either constantly or at intervals. All the principles which have been stated in sect. 55 as being applicable to teeth are applicable to cams; but in designing cams it is not usual to determine or take into consideration the form of the ideal pitch-surface, which would give the same comparative motion by rolling contact that the cam gives by sliding contact.

67. *Screws.*—The figure of a screw is that of a convex or concave cylinder, with one or more helical projections, called *threads*, winding round it. Convex and concave screws are distinguished technically by the respective names of *male* and *female*; a short concave screw is called a *nut*; and when a *screw* is spoken of without qualification a *convex* screw is usually understood.

The relation between the *advance* and the *rotation*, which compose the motion of a screw working in contact with a fixed screw or helical guide, has already been demonstrated in sect. 41; and the same relation exists between the magnitudes of the rotation of a screw about a fixed axis and the advance of a shifting nut in which it rotates. The advance of the nut takes place in the opposite direction to that of the advance of the screw in the case in which the nut is fixed. The *pitch* or *axial pitch* of a screw has the meaning assigned to it in that section, viz., the distance, measured parallel to the axis, between the corresponding points in two successive turns of the *same thread*. If, therefore, the screw has several equidistant threads, the true pitch is equal to the *divided axial pitch*, as measured between two adjacent threads, multiplied by the number of threads.

If a helix be described round the screw, crossing each turn of the thread at right angles, the distance between two corresponding points on two successive turns of the same thread, measured along this *normal helix*, may be called the *normal pitch*; and when the screw has more than one thread the normal pitch from thread to thread may be called the *normal divided pitch*.

The distance from thread to thread, measured on a circle described about the axis of the screw, called the pitch-circle, may be called the *circumferential pitch*; for a screw of one thread it is one circumference; for a screw of n threads, $\frac{\text{one circumference}}{n}$.

Let r denote the radius of the pitch circle;
n the number of threads;
θ the obliquity of the threads to the pitch circle, and of the normal helix to the axis;

P_a, $\frac{P_a}{n}=p_a$ } the axial { pitch, divided pitch;

P_n, $\frac{P_n}{n}=p_n$ } the normal { pitch, divided pitch;

P_c the circumferential pitch;

then

$$\left.\begin{aligned} p_c &= p_a\ \cot\theta = p_n\ \cos\theta = \frac{2\pi r}{n} \\ p_a &= p_n\ \sec\theta = p_c\ \tan\theta = \frac{2\pi r\ \tan\theta}{n} \\ p_n &= p_c\ \sin\theta = p_a\ \cos\theta = \frac{2\pi r\ \sin\theta}{n} \end{aligned}\right\} \quad (31).$$

If a screw rotates, the number of threads which pass a fixed point in one revolution is the number of threads in the screw.

A pair of convex screws, each rotating about its axis, are used as an elementary combination to transmit motion by the sliding contact of their threads. Such screws are commonly called *endless screws*. At the point of contact of the screws their threads must be parallel; and their line of connexion is the common perpendicular to the acting surfaces of the threads at their point of contact. Hence the following principles:—

I. If the screws are both right-handed or both left-handed, the angle between the directions of their axes is the sum of their obliquities; if one is right-handed and the other left-handed, that angle is the difference of their obliquities.

II. The normal pitch for a screw of one thread, and the normal divided pitch for a screw of more than one thread, must be the same in each screw.

III. The angular velocities of the screws are inversely as their numbers of threads.

Hooke's wheels with oblique or helical teeth are in fact screws of many threads, and of large diameters as compared with their lengths.

The ordinary position of a pair of endless screws is with their axes at right angles to each other. When one is of considerably greater diameter than the other, the larger is commonly called in practice a *wheel*, the name *screw* being applied to the smaller only; but they are nevertheless both screws in fact.

To make the teeth of a pair of endless screws fit correctly and work smoothly, a hardened steel screw is made of the figure of the smaller screw, with its thread or threads notched so as to form a cutting tool; the larger screw, or "wheel," is cast approximately of the required figure; the larger screw and the steel screw are fitted up in their proper relative position, and made to rotate in contact with each other by turning the steel screw, which cuts the threads of the larger screw to their true figure.

68. *Coupling of Parallel Axes—Oldham's Coupling.*—A *coupling* is a mode of connecting a pair of shafts so that they shall rotate in the same direction with the same mean angular velocity. If the axes of the shafts are in the same straight line, the coupling consists in so connecting their contiguous ends that they shall rotate as one piece; but if the axes are not in the same straight line combinations of mechanism are required. A coupling for parallel shafts which acts by *sliding contact* was invented by Oldham, and is represented in fig. 21. C_1, C_2 are the axes of the two parallel shafts; D_1, D_2 two disks facing each other, fixed on the

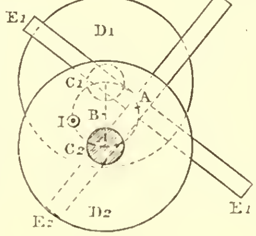

Fig. 21.

ends of the two shafts respectively; E_1E_1 a bar sliding in a diametral groove in the face of D_1; E_2E_2 a bar sliding in a diametral groove in the face of D_2: those bars are fixed together at A, so as to form a rigid cross. The angular velocities of the two disks and of the cross are all equal at every instant; the middle point of the cross, at A, revolves in the dotted circle described upon the line of centres C_1C_2 as a diameter twice for each turn of the disks and cross; the instantaneous axis of rotation of the cross at any instant is at I, the point in the circle C_1C_2 diametrically opposite to A.

Oldham's coupling may be used with advantage where the axes of the shafts are intended to be as nearly in the same straight line as is possible, but where there is some doubt as to the practicability or permanency of their exact continuity.

69. *Wrapping Connectors—Belts, Cords, and Chains.*—Flat belts of leather or of gutta percha, round cords of catgut, hemp, or other material, and metal chains are used as wrapping connectors to transmit rotatory motion between pairs of pulleys and drums.

Belts (the most frequently used of all wrapping connectors) require nearly cylindrical pulleys. A belt tends to move towards that part of a pulley whose radius is greatest; pulleys for belts, therefore, are slightly swelled in the middle, in order that the belt may remain on a pulley, unless forcibly shifted. A belt when in motion is shifted off a pulley, or from one pulley on to another of equal size alongside of it, by pressing against that part of the belt which is moving *towards* the pulley.

Cords require either cylindrical drums with ledges or grooved pulleys.

Chains require pulleys or drums, grooved, notched, and toothed, so as to fit the links of the chain.

Wrapping connectors for communicating continuous motion are endless.

Wrapping connectors for communicating reciprocating motion have usually their ends made fast to the pulleys or drums which they connect, and which in this case may be sectors.

The line of connexion of two pieces connected by a wrapping connector is the centre line of the belt, cord, or chain; and the comparative motions of the pieces are determined by the principles of sect. 46 if both pieces turn, and of sect. 47 if one turns and the other shifts, in which latter case the motion must be reciprocating.

The *pitch-line* of a pulley or drum is a curve to which the line of connexion is always a tangent; that is to say, it is a curve parallel to the acting surface of the pulley or drum, and distant from it by half the thickness of the wrapping connector.

Pulleys and drums for communicating a constant velocity ratio are circular. The *effective radius*, or radius of the pitch-circle of a circular pulley or drum, is equal to the real radius added to half the thickness of the connector. The angular velocities of a pair of connected circular pulleys or drums are inversely as the effective radii.

A *crossed* belt, as in fig. 22, A, reverses the direction of the rotation communicated; an *uncrossed* belt, as in fig. 22, B, preserves that direction.

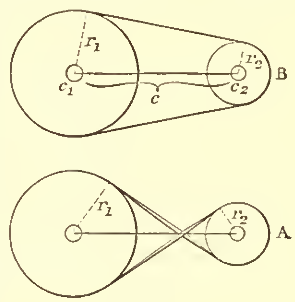

Fig. 22.

The *length* L of an endless belt connecting a pair of pulleys whose effective radii are r_1, r_2, with parallel axes whose distance apart is C, is given by the following formulæ, in each of which the first term, containing the radical, expresses the length of the straight parts of the belt, and the remainder of the formula the length of the curved parts.

For a crossed belt,—

$$L=2\sqrt{c^2-(r_1+r_2)^2}+(r_1+r_2)\left(\pi-2\sin^{-1}\frac{r_1+r_2}{c}\right) \quad (32,\ A);$$

and for an uncrossed belt,—

$$L=2\sqrt{\{c^2-(r_1-r_2)^2\}}+\pi(r_1+r_2)+2(r_1-r_2)\sin^{-1}\frac{r_1-r_2}{c} \quad (32,B);$$

in which r_1 is the greater radius, and r_2 the less.

When the axes of a pair of pulleys are not parallel, the pulleys should be so placed that the part of the belt which is *approaching* each pulley shall be in the plane of the pulley.

70. *Speed-Cones* (see fig. 23).—A pair of speed-cones is a contrivance for varying and adjusting the velocity ratio communicated between a pair of parallel shafts by means of a belt. The speed-cones are either continuous cones or conoids, as A, B, whose velocity ratio can be varied gradually while they are in motion by shifting the belt, or sets of pulleys whose radii vary by steps, as C, D, in which case the velocity ratio can be changed by shifting the belt from one pair of pulleys to another.

In order that the belt may fit accurately in every possible position on a pair of speed-cones, the quantity L must be constant, in equations 32, A, or 32, B, according as the belt is crossed or uncrossed.

For a *crossed* belt, as in A and C, fig. 23, L depends solely on c and on $r_1 + r_2$. Now c is constant because the axes are parallel; therefore the *sum of the radii* of the pitch-circles connected in every position of the belt is to be constant. That condition is fulfilled by a pair of continuous cones generated by the revolution of two straight lines inclined opposite ways to their respective axes at equal angles.

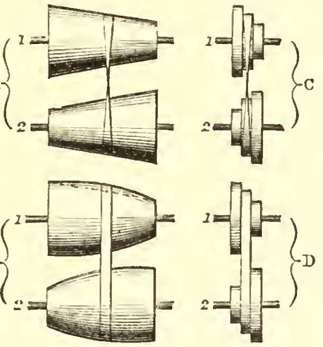

Fig. 23.

For an uncrossed belt, the quantity L in equation 32, B is to be made constant. The exact fulfilment of this condition requires the solution of a transcendental equation; but it may be fulfilled with accuracy sufficient for practical purposes by using, instead of 32, B, the following *approximate* equation:—

$$L \text{ nearly} = 2c + \pi(r_1 + r_2) + \frac{(r_1 - r_2)^2}{c} \quad . \quad . \quad . \quad (33).$$

The following is the most convenient practical rule for the application of this equation:—

Let the speed-cones be equal and similar conoids, as in B, fig. 23, but with their large and small ends turned opposite ways. Let r_1 be the radius of the large end of each, r_2 that of the small end, r_0 that of the middle; and let v be the *sagitta*, measured perpendicular to the axes, of the arc by whose revolution each of the conoids is generated, or, in other words, the *bulging* of the conoids in the middle of their length. Then

$$v = r_0 - \frac{r_1 + r_2}{2} = \frac{(r_1 - r_2)^2}{2\pi c} \quad . \quad . \quad . \quad . \quad . \quad (34).$$

$2\pi = 6{\cdot}2832$; but 6 may be used in most practical cases without sensible error.

The radii at the middle and end being thus determined, make the generating curve an arc either of a circle or of a parabola.

71. *Linkwork in General.*—The pieces which are connected by linkwork, if they rotate or oscillate, are usually called *cranks, beams,* and *levers.* The *link* by which they are connected is a rigid rod or bar, which may be straight or of any other figure; the straight figure, being the most favourable to strength, is always used when there is no special reason to the contrary. The link is known by various names under various circumstances, such as *coupling-rod, connecting-rod, crank-rod, eccentric-rod,* &c. It is attached to the pieces which it connects by two pins, about which it is free to turn. The effect of the link is to maintain the distance between the axes of those pins invariable; hence the common perpendicular of the axes of the pins is *the line of connexion,* and its extremities may be called the *connected points.* In a turning piece, the perpendicular let fall from its connected point upon its axis of rotation is the *arm* or *crank-arm.*

The axes of rotation of a pair of turning pieces connected by a link are almost always parallel, and perpendicular to the line of connexion; in which case the angular velocity ratio at any instant is the reciprocal of the ratio of the common perpendiculars let fall from the line of connexion upon the respective axes of rotation.

If at any instant the direction of one of the crank-arms coincides with the line of connexion, the common perpendicular of the line of connexion and the axis of that crank-arm vanishes, and the directional relation of the motions becomes indeterminate. The position of the connected point of the crank-arm in question at such an instant is called a *dead-point.* The velocity of the other connected point at such an instant is null, unless it also reaches a dead-point at the same instant, so that the line of connexion is in the plane of the two axes of rotation, in which case the velocity ratio is indeterminate. Examples of dead-points, and of the means of preventing the inconvenience which they tend to occasion, will appear in the sequel.

72. *Coupling of Parallel Axes.*—Two or more parallel shafts (such as those of a locomotive engine, with two or more pairs of driving wheels) are made to rotate with constantly equal angular velocities by having equal cranks, which are maintained parallel by a coupling-rod of such a length that the line of connexion is equal to the distance between the axes. The cranks pass their dead-points simultaneously. To obviate the unsteadiness of motion which this tends to cause, the shafts are provided with a second set of cranks at right angles to the first, connected by means of a similar coupling-rod, so that one set of cranks pass their dead points at the instant when the other set are farthest from theirs.

73. *Comparative Motion of Connected Points.*—As the link is a rigid body, it is obvious that its action in communicating motion may be determined by finding the comparative motion of the connected points, according to the principles laid down in §§ 71, 78, pp. 690, 692, and this is often the most convenient method of proceeding.

If a connected point belongs to a turning piece, the direction of its motion at a given instant is perpendicular to the plane containing the axis and crank-arm of the piece. If a connected point belongs to a shifting piece, the direction of its motion at any instant is given, and a plane can be drawn perpendicular to that direction.

The line of intersection of the planes perpendicular to the paths of the two connected points at a given instant is the *instantaneous axis of the link* at that instant; and the *velocities of the connected points are directly as their distances from that axis.*

In drawing on a plane surface, the two planes perpendicular to the paths of the connected points are represented by two lines (being their sections by a plane normal to them), and the instantaneous axis by a point (fig. 24); and, should the length of the two lines render it impracticable to produce them until they actually intersect, the velocity ratio of the connected points may be found by the principle that it is equal to the ratio of the segments which a line parallel to the line of connexion cuts off from any two lines drawn from a given point, perpendicular respectively to the paths of the connected points.

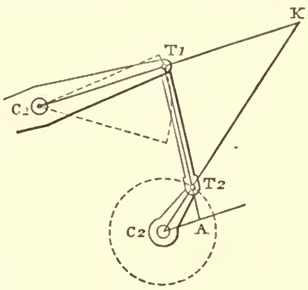

Fig. 24.

To illustrate this by one example. Let C_1 be the axis, and T_1 the connected point of the beam of a steam-engine; T_1T_2 the connecting or crank-rod; T_2 the other connected point, and the centre of the crank-pin; C_2 the axis of the crank and its shaft. Let v_1 denote the velocity of T_1 at any given instant; v_2 that of T_2. To find the ratio of these velocities, produce C_1T_1, C_2T_2, till they intersect in K; K is the instantaneous axis of the connecting rod, and the velocity ratio is

$$v_1 : v_2 :: KT_1 : KT_2 . \quad . \quad . \quad . \quad . \quad . \quad (35).$$

Should K be inconveniently far off, draw any triangle with its sides respectively parallel to C_1T_1, C_2T_2, and T_1T_2; the ratio of the two sides first mentioned will be the velocity ratio required. For example, draw C_2A parallel to C_1T_1, cutting T_1T_2 in A; then

$$v_1 : v_2 :: C_2A : C_2T_2 \quad . \quad . \quad . \quad . \quad . \quad . \quad (36).$$

74. *Eccentric.*—An eccentric circular disk fixed on a shaft, and used to give a reciprocating motion to a rod, is in effect a crank-pin of sufficiently large diameter to surround the shaft, and so to avoid the weakening of the shaft which would arise from bending it so as to form an ordinary crank. The centre of the eccentric is its connected point; and its eccentricity, or the distance from that centre to the axis of the shaft, is its crank-arm.

An eccentric may be made capable of having its eccentricity altered by means of an adjusting screw, so as to vary the extent of the reciprocating motion which it communicates.

75. *Reciprocating Pieces—Stroke—Dead-Points.*—The distance between the extremities of the path of the connected point in a reciprocating piece (such as the piston of a steam-engine) is called the *stroke* or *length of stroke* of that piece. When it is connected with a continuously turning piece (such as the crank of a steam-engine) the ends of the stroke of the reciprocating piece correspond to the *dead-points* of the path of the connected point of the turning piece, where the line of connexion is continuous with or coincides with the crank-arm.

Let S be the length of stroke of the reciprocating piece, L the length of the line of connexion, and R the crank-arm of the continuously turning piece. Then, if the two ends of the stroke be in one straight line with the axis of the crank,

$$S = 2R \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (37);$$

and if these ends be not in one straight line with that axis, then S, L − R, and L + R, are the three sides of a triangle, having the angle opposite S at that axis; so that, if θ be the supplement of the arc between the dead-points,

$$\left.\begin{aligned} S^2 &= 2(L^2 + R^2) - 2(L^2 - R^2)\cos\theta \\ \cos\theta &= \frac{2L^2 + 2R^2 - S^2}{2(L^2 - R^2)} \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad (38).$$

76. *Coupling of Intersecting Axes—Hooke's Universal Joint.*—Intersecting axes are coupled by a contrivance of Hooke's, known as the "universal joint," which belongs to the class of linkwork (see fig. 25). Let O be the point of intersection of the axes OC_1, OC_2, and θ their angle of inclination to each other. The pair of shafts C_1, C_2 terminate in a pair of forks F_1, F_2, in bearings at the extremi-

ties of which turn the gudgeons at the ends of the arms of a rectangular cross, having its centre at O. This cross is the link; the connected points are the centres of the bearings F_1, F_2. At each instant each of those points moves at right angles to the central plane of its shaft and fork; therefore the line of intersection of the central planes of the two forks at any instant is the instantaneous axis of the cross, and the *velocity ratio* of the points F_1, F_2 (which, as the forks are equal, is also the *angular velocity ratio* of the shafts) is equal to the ratio of the distances of those points from that instantaneous axis. The *mean* value of that velocity ratio is that of equality, for each successive *quarter-turn* is made by both shafts in the same time; but its actual value fluctuates between the limits—

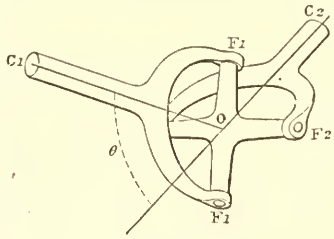

Fig. 25.

$$\left.\begin{array}{l}\dfrac{a_2}{a_1}=\dfrac{1}{\cos\theta}\text{ when }F_1\text{ is the plane }OC_1C_2\\ \text{and }\dfrac{a_2}{a_1}=\cos\theta\text{ when }F_2\text{ is in that plane}\end{array}\right\}\quad . \quad . \quad . \quad (39).$$

Its value at intermediate instants is given by the following equations:—let ϕ_1, ϕ_2 be the angles respectively made by the central planes of the forks and shafts with the plane OC_1C_2 at a given instant; then

$$\left.\begin{array}{l}\cos\theta=\tan\phi_1\tan\phi_2\\ \dfrac{a_2}{a_1}=-\dfrac{d\phi_2}{d\phi_1}=\dfrac{\tan\phi_1+\cot\phi_1}{\tan\phi_2+\cot\phi_2}\end{array}\right\}\quad . \quad . \quad . \quad . \quad (40).$$

77. *Intermittent Linkwork—Click and Ratchet.*—A *click* acting upon a ratchet-wheel or rack, which it pushes or pulls through a certain arc at each forward stroke and leaves at rest at each backward stroke, is an example of intermittent linkwork. During the forward stroke the action of the click is governed by the principles of linkwork; during the backward stroke that action ceases. A *catch* or *pall*, turning on a fixed axis, prevents the ratchet-wheel or rack from reversing its motion.

Division 5. Trains of Mechanism.

78. *General Principles.*—A *train of mechanism* consists of a series of pieces each of which is follower to that which drives it and driver to that which follows it.

The comparative motion of the first driver and last follower is obtained by combining the proportions expressing by their terms the velocity ratios and by their signs the directional relations of the several elementary combinations of which the train consists.

79. *Trains of Wheelwork.*—Let A_1, A_2, A_3, &c., A_{m-1}, A_m denote a series of axes, and a_1, a_2, a_3, &c., a_{m-1}, a_m their angular velocities. Let the axis A_1 carry a wheel of N_1 teeth, driving a wheel of n_2 teeth on the axis A_2, which carries also a wheel of N_2 teeth, driving a wheel of n_3 teeth on the axis A_3, and so on; the numbers of teeth in drivers being denoted by N's, and in followers by n's, and the axes to which the wheels are fixed being denoted by numbers. Then the resulting velocity ratio is denoted by

$$\frac{a_m}{a_1}=\frac{a_2}{a_1}\cdot\frac{a_3}{a_2}\cdot\ \&c.\ .\ .\ \frac{a_m}{a_{m-1}}=\frac{N_1\cdot N_2\ .\ .\ \&c.\ .\ .\ .\ N_{m-1}}{n_2\cdot n_3\ .\ .\ \&c.\ .\ .\ .\ n_m}\quad(41);$$

that is to say, the velocity ratio of the last and first axes is the ratio of the product of the numbers of teeth in the drivers to the product of the numbers of teeth in the followers.

Supposing all the wheels to be in outside gearing, then, as each elementary combination reverses the direction of rotation, and as the number of elementary combinations $m-1$ is one less than the number of axes m, it is evident that if m is odd the direction of rotation is preserved, and if even reversed.

It is often a question of importance to determine the number of teeth in a train of wheels best suited for giving a determinate velocity ratio to two axes. It was shown by Young that, to do this with the *least total number of teeth*, the velocity ratio of each elementary combination should approximate as nearly as possible to 3·59. This would in many cases give too many axes; and, as a useful practical rule, it may be laid down that from 3 to 6 ought to be the limit of the velocity ratio of an elementary combination in wheelwork. The smallest number of teeth in a pinion for epicycloidal teeth ought to be *twelve* (see sect. 59),—but it is better, for smoothness of motion, not to go below *fifteen*; and for involute teeth the smallest number is about *twenty-four*.

Let $\frac{B}{C}$ be the velocity ratio required, reduced to its least terms, and let B be greater than C. If $\frac{B}{C}$ is not greater than 6, and C lies between the prescribed minimum number of teeth (which may be called t) and its double $2t$, then one pair of wheels will answer the purpose, and B and C will themselves be the numbers required. Should B and C be inconveniently large, they are, if possible, to be resolved into factors, and those factors (or if they are too small, multiples of them) used for the number of teeth. Should B or C, or both, be at once inconveniently large and prime, then, instead of the exact ratio $\frac{B}{C}$, some ratio approximating to that ratio, and capable of resolution into convenient factors, is to be found by the method of continued fractions.

Should $\frac{B}{C}$ be greater than 6, the best number of elementary combinations $m-1$ will lie between

$$\frac{\log B-\log C}{\log 6}\text{ and }\frac{\log B-\log C}{\log 3}.$$

Then, if possible, B and C themselves are to be resolved each into $m-1$ factors (counting 1 as a factor), which factors, or multiples of them, shall be not less than t nor greater than $6t$; or if B and C contain inconveniently-large prime factors, an approximate velocity ratio, found by the method of continued fractions, is to be substituted for $\frac{B}{C}$ as before.

So far as the resultant velocity ratio is concerned, the *order* of the drivers N and of the followers n is immaterial; but to secure equable wear of the teeth, as explained in sect. 54, the wheels ought to be so arranged that, for each elementary combination, the greatest common divisor of N and n shall be either 1, or as small as possible.

80. *Double Hooke's Coupling.*—It has been shown in section 76 that the velocity ratio of a pair of shafts coupled by a universal joint fluctuates between the limits $\cos\theta$ and $\frac{1}{\cos\theta}$. Hence one or both of the shafts must have a vibratory and unsteady motion, injurious to the mechanism and framework. To obviate this evil a short intermediate shaft is introduced, making equal angles with the first and last shaft, coupled with each of them by a Hooke's joint, and having its own two forks in the same plane. Let a_1, a_2, a_3 be the angular velocities of the first, intermediate, and last shaft in this *train of two Hooke's couplings*. Then, from the principles of sect. 76 it is evident that at each instant $\frac{a_2}{a_1}=\frac{a_2}{a_3}$, and consequently that $a_3=a_1$; so that the fluctuations of angular velocity ratio caused by the first coupling are exactly neutralized by the second, and the first and last shafts have equal angular velocities at each instant.

81. *Converging and Diverging Trains of Mechanism.*—Two or more trains of mechanism may *converge* into one,—as when the two pistons of a pair of steam-engines, each through its own connecting-rod, act upon one crank-shaft. One train of mechanism may *diverge* into two or more,—as when a single shaft, driven by a prime mover, carries several pulleys, each of which drives a different machine. The principles of comparative motion in such converging and diverging trains are the same as in simple trains.

Division 6. Aggregate Combinations.

82. *General Principles.*—Willis has designated as "aggregate combinations" those assemblages of pieces of mechanism in which the motion of one follower is the *resultant* of component motions impressed on it by more than one driver. Two classes of aggregate combinations may be distinguished which, though not different in their actual nature, differ in the *data* which they present to the designer, and in the method of solution to be followed in questions respecting them.

Class I. comprises those cases in which a piece A is not carried directly by the frame C, but by another piece B, *relatively* to which the motion of A is given,—the motion of the piece B relatively to the frame C being also given. Then the motion of A relatively to the frame C is the *resultant* of the motion of A relatively to B and of B relatively to C; and that resultant is to be found by the principles already explained in division 3 of this chapter, sects. 34 to 41.

Class II. comprises those cases in which the motions of three points in one follower are determined by their connexions with two or with three different drivers, so that the motion of the follower, as a whole, is to be determined by the principles of §§ 71, 78, pp. 690, 692.

This classification is founded on the kinds of problems arising from the combinations. Willis adopts another classification, founded on the *objects* of the combinations, which objects he divides into two classes, viz., (1) to produce *aggregate velocity*, or a velocity which is the resultant of two or more components in the same path, and (2) to produce *an aggregate path*, that is, to make a given point in a rigid body move in an assigned path by communicating certain motions to other points in that body.

It is seldom that one of these effects is produced without at the same time producing the other; but the classification of Willis depends upon which of those two effects, even supposing them to occur together, is the practical object of the mechanism.

83. *Reduplication of Cords—Differential Windlass—Blocks, Sheaves, and Tackle.*—The axis C (fig. 26) carries a larger barrel AE and a smaller barrel DB, rotating as one piece with the angular velocity a_1 in the direction AE. The pulley or *sheave* FG has a weight W hung to its centre. A cord has one end made fast to and wrapped round the barrel AE; it passes from A under the sheave FG, and has the other end wrapped round and made fast to the barrel BD. Required the relation between the velocity of translation v_2 of W and the angular velocity a_1 of the *differential barrel.*

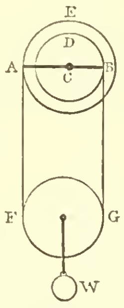

Fig. 26.

In this case v_2 is an *aggregate velocity,* produced by the joint action of the two drivers AE and BD, transmitted by wrapping connectors to FG, and combined by that sheave so as to act on the follower W, whose motion is the same with that of the centre of FG.

The velocity of the point F is $a_1 . AC$, *upward* motion being considered positive. The velocity of the point G is $-a_1 . CB$, *downward* motion being negative. Hence (p. 690, §§ 71, 72) the instantaneous axis of the sheave FG is in the diameter FG, at the distance

$$\frac{FG}{2} \cdot \frac{AC - BC}{AC + BC}$$

from the centre towards G; the angular velocity of the sheave is

$$a_2 = a_1 \cdot \frac{AC + BC}{FG} ;$$

and, consequently, the velocity of its centre is

$$v_2 = a_2 \cdot \frac{FG}{2} \cdot \frac{AC - BC}{AC + BC} = \frac{a_1(AC - BC)}{2} \quad . \quad . \quad (42),$$

or the *mean between the velocities of the two vertical parts of the cord.*

If the cord be fixed to the frame-work at the point B, instead of being wound on a barrel, the velocity of W is half that of AF.

A case containing several sheaves is called a *block.* A *fall-block* is attached to a fixed point; a *running-block* is movable to and from a fall-block, with which it is connected by two or more plies of a rope. The whole combination constitutes a *tackle* or *purchase.*

The two plies of a rope at opposite sides of a sheave in the fall-block have equal and opposite velocities. The two plies at opposite sides of a sheave in the running-block have velocities (as in the case of the sheave FG) differing equally in opposite directions from the velocity of the running-block.

One end of the rope is fastened either to the fall-block or the running-block The other, or free end, is called the *fall.* Let v_1 be the velocity of the fall, v_2 that of the running-block; and let it be required to find their ratio; and let velocities towards the fall-block be positive, and from it negative.

CASE 1. If the fastened end of the rope be attached to the fall-block its velocity is 0, and this also is the velocity of the first ply. The rope passes under a sheave in the running-block, so that the velocity of the second ply is $2v_2$. It then passes over a sheave in the fall-block; the velocity of the third ply is $-2v_2$; then under a sheave in the running-block; the velocity of the fourth ply is $4v_2$; and so on,—the general law being this:—let n be an *even* number, then

$$\left.\begin{array}{l} \text{the velocity of the } n^{\text{th}} \text{ ply} = nv_2 \\ \quad ,, \quad (n+1)^{\text{th}} \text{ ply} = -nv_2 \\ = v_1, \text{ if the fall be the } (n+1)^{\text{th}} \text{ ply} \end{array}\right\} \quad . \quad . \quad . \quad (43).$$

CASE 2. If the fastened end of the rope be attached to the running-block, the velocity of the first ply is v_2; of the second, $-v_2$; of the third, $3v_2$; of the fourth, $-3v_2$; and, generally, if n be an *odd* number,

$$\left.\begin{array}{l} \text{velocity of the } n^{\text{th}} \text{ ply} = nv_2 \\ \quad ,, \quad (n+1)^{\text{th}} \text{ ply} = -nv_2 \\ = v_1, \text{ if the fall be the } (n+1)^{\text{th}} \text{ ply} \end{array}\right\} \quad . \quad . \quad . \quad (44).$$

Generally,—

$$\frac{v_1}{v_2} = -n \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (45),$$

where n is the *number of plies of rope by which the running-block hangs.*

The sheaves in a block are usually made all of the same diameter, and turn on a fixed pin, and they have, consequently, different angular velocities. But by making the diameter of each sheave proportional to the velocity, relatively to the block, of the ply of rope which it is to carry, the angular velocities of the sheaves in one block may be rendered equal, so that the sheaves may be made all in one piece, and may have journals turning in fixed bearings. This is called *White's tackle,* from the inventor.

For details and technical terms see SHIPBUILDING.

84. *Differential Screw.*—On the same axis let there be two screws of the respective pitches p_1 and p_2, made in one piece, and rotating with the angular velocity a. Let this piece be called B. Let the first screw turn in a fixed nut C, and the second in a sliding nut A. The velocity of advance of B relatively to C is (according to sect. 41) ap_1, and of A relatively to B (according to sect. 67) $-ap_2$; hence the velocity of A relatively to C is

$$a(p_1 - p_2) \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (46),$$

being the same with the velocity of advance of a screw of the pitch $p_1 - p_2$. This combination, called *Hunter's* or the *differential screw,* combines the strength of a large thread with the slowness of motion due to a small one.

85. *Epicyclic Trains.*—The term *epicyclic train* is used by Willis to denote a train of wheels carried by an arm, and having certain rotations relatively to that arm, which itself rotates. The arm may either be driven by the wheels or assist in driving them. The comparative motions of the wheels and of the arm, and the *aggregate paths* traced by points in the wheels, are determined by the principles of the composition of rotations, and of the description of rolling curves, explained in sects. 37 to 40.

86. *Link Motion.*—Let S (fig. 27) be the shaft of a steam-engine, O its axis, E_f the *forward eccentric,* suitably placed for moving the slide-valve when the shaft rotates forwards, F its centre, OF its crank-arm, C_f its rod, E_b the *backward eccentric,* suitably placed for moving the slide-valve when the shaft rotates backwards, B its centre, OB its crank-arm, C_b its rod. L is a long narrow box called the *link,* jointed at T_f and T_b to the eccentric rods; R is the valve-rod which works the slide-valve, jointed to P, a slider, which, by moving either L or R, or both, can be adjusted to any required position in the link.

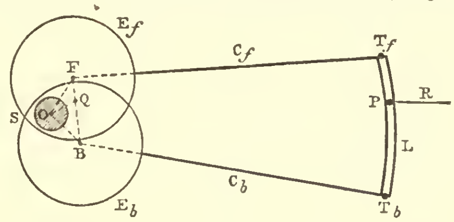

Fig. 27.

When P is at T_f the valve is said to be in *full forward gearing,* being acted upon by E_f alone. When P is at T_b the valve is said to be in *full backward gearing,* being acted upon by E_b alone. When P is placed in an intermediate position, the valve has an aggregate motion due to the joint action of E_f and E_b. The most exact mode of determining that motion is to make a skeleton drawing of the apparatus in various positions; but an *approximation* to the motion of the valve may be obtained by joining FB, and taking Q so that

$$T_fP : T_bP : : FQ : BQ ;$$

then the valve will move nearly as if it were worked by one eccentric, having its centre at Q.

87. *Parallel Motions (exact).*—A *parallel motion* is a combination of turning pieces in mechanism designed to guide the motion of a reciprocating piece either exactly or approximately in a straight line, so as to avoid the friction which arises from the use of straight guides for that purpose.

Fig. 28 represents an exact parallel motion, first proposed, it is believed, by Mr Scott Russell.

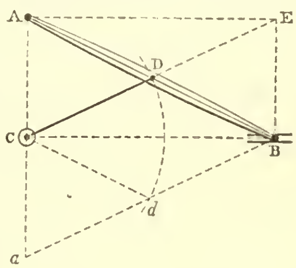

Fig. 28.

The arm CD turns on the axis C, and is jointed at D to the middle of the bar ADB, whose length is double of that of CD, and one of whose ends B is jointed to a slider, sliding in straight guides along the line CB. Draw BE perpendicular to CB, cutting CD produced in E, then E is the instantaneous axis of the bar ADB; and the direction of motion of A is at every instant perpendicular to EA, that is, along the straight line AC*a*. While the stroke of A is AC*a*, extending to equal distances on either side of C, and equal to twice the chord of the arc D*d*, the stroke of B is only equal to twice the sagitta; and thus A is guided through a comparatively long stroke by the sliding of B through a comparatively short stroke, and by rotatory motions at the joints C, D, B. (For details, see STEAM-ENGINE.)

88. *Parallel Motion—Watt's Approximate* (see fig. 29).—Let CT, *ct* be a pair of levers connected by a link T*t*, and oscillating about the axes C*c* between the positions marked 1 and 3. Let the middle positions of the levers CT_2, ct_2 be parallel to each other. It is required to find a point P in the link T*t* such that its middle

position P_2 and its extreme positions P_1, P_3 shall be in the same straight line SS, perpendicular to CT_2, ct_2, and so to place the axes C, c on the lines CT_2, ct_2 that the path of P between the positions P_1, P_2, P_3 shall be as near as possible to a straight line.

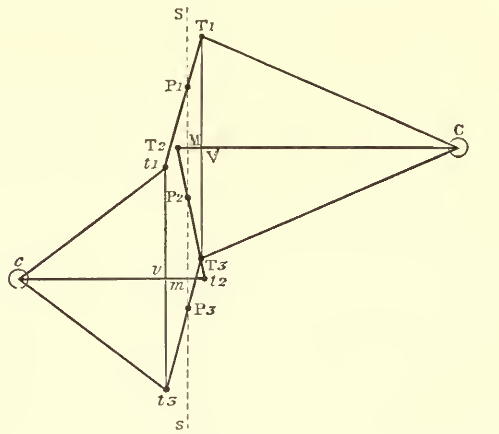

Fig. 29.

The axes C, c are to be so placed that the middle M of the versed sine VT_2, and the middle m of the versed sine vt_2, of the respective arcs whose equal chords T_1T_3, t_1t_3 represent the stroke, may each be in the line SS. Then T_1 and T_3 will be as far to one side of SS as T_2 is to the other, and t_1 and t_3 will be as far to the latter side of SS as t_2 is to the former; consequently, the two extreme positions of the links T_1t_1, T_3t_3 are parallel to each other, and inclined to SS at the same angle in one direction that the middle position of the link T_2t_2 is inclined to that line in the other direction, and the three intersections P_1, P_2, P_3 are at the same point on the link.

The position of the point P on the link is found by the following proportional equation:—

$$\left.\begin{aligned} Tt &: PT : Pt \\ :: TV + tv &: TV : tv \\ :: CM + cm &: cm \ : CM \end{aligned}\right\} \quad \ldots\ldots \quad (47).$$

Suppose the axes C, c to be given, the line of stroke SS, and the length of stroke $L = T_1T_3 = t_1t_3$, and that it is required to find the dimensions of the levers and link. Let fall CM and *cm* perpendicular to SS; then

$$\left.\begin{aligned} TV &= \frac{L^2}{8CM};\ tv = \frac{L^2}{8cm}; \\ CT &= CM + \tfrac{1}{2}TV;\ ct = cm + \tfrac{1}{2}tv; \\ Tt &= \sqrt{\{Mm^2 + \tfrac{1}{4}(TV + tv)^2\}} \end{aligned}\right\} \quad \ldots \quad (48).$$

If C and c are at the same side of SS, the smaller of the two perpendiculars is to be treated as negative in the formulæ, and the difference of the versed sines used instead of their sum; and the point P will lie in the *prolongation* of the link beyond Tt to the side of the longer lever. When the arcs of oscillation of the levers on either side of their middle positions do not exceed 20°, the intermediate portions of the path of P between P_1, P_2, and P_3 are near enough to a straight line for practical purposes; and that point may be used to guide a sliding piece, such as the piston-rod of a steam-engine, for which purpose this parallel motion was originally invented by Watt.

Chapter II. On Applied Dynamics.

89. *Laws of Motion.*—The action of a machine in transmitting *force* and *motion* simultaneously, or performing *work*, is governed, in common with the phenomena of moving bodies in general, by two "laws of motion," for which see pp. 676 *sq.*

90. *Comparison of Deviating Force with Gravity.*—See pp. 698, 699, §§ 104–106.

91. *Deviating Forces Classed—Deflecting Force—Accelerating and Retarding Forces.*—See p. 701, §§ 114–119.

92. *Division of the Subject.*—On this classification of the deviating forces in machines is founded the following division of the subject of dynamics as applied to machines:—

Division 1.—Balanced forces in machines of uniform velocity.
Division 2.—Deflecting forces in such machines.
Division 3.—Working of machines of varying velocity.

Division 1. *Balanced Forces in Machines of Uniform Velocity.*

93. *Application of Force to Mechanism.*—Forces are applied in units of weight; and the unit most commonly employed in Britain is the *pound avoirdupois.* The action of a force applied to a body is always in reality distributed over some definite space, either a volume of three dimensions or a surface of two. An example of a force distributed throughout a volume is the *weight* of the body itself, which acts on every particle, however small. The *pressure* exerted between two bodies at their surface of contact, or between the two parts of one body on either side of an ideal surface of separation, is an example of a force distributed over a surface. The mode of distribution of a force applied to a solid body requires to be considered when its stiffness and strength are treated of; but, in questions respecting the action of a force upon a rigid body considered as a whole, the *resultant* of the distributed force, determined according to the principles of statics, and considered as acting in a *single line* and applied at a *single point*, may, for the occasion, be substituted for the force as really distributed. Thus, the weight of each separate piece in a machine is treated as acting wholly at its *centre of gravity*, and each pressure applied to it as acting at a point called the *centre of pressure* of the surface to which the pressure is really applied.

94. *Forces applied to Mechanism Classed.*—If θ be the *obliquity* of a force F applied to a piece of a machine,—that is, the angle made by the direction of the force with the direction of motion of its point of application,—then by the principles of Statics, F may be resolved into two rectangular components, viz.:—

$$\left.\begin{aligned} &\text{Along the direction of motion, } P = F\cos\theta \\ &\text{Across the direction of motion, } Q = F\sin\theta \end{aligned}\right\} \quad \ldots \quad (49).$$

If the component along the direction of motion acts *with* the motion, it is called an *effort*; if *against* the motion, a *resistance.* The component *across* the direction of motion is a *lateral pressure*; the unbalanced lateral pressure on any piece, or part of a piece, is *deflecting force.* A lateral pressure may increase resistance by causing friction; the friction so caused acts against the motion, and is a resistance, but the lateral pressure causing it is not a resistance. Resistances are distinguished into *useful* and *prejudicial*, according as they arise from the useful effect produced by the machine or from other causes.

95. *Work.*—*Work* consists in moving against resistance. The work is said to be *performed*, and the resistance *overcome.* Work is measured by the product of the resistance into the distance through which its point of application is moved. The *unit of work* commonly used in Britain is a resistance of one pound overcome through a distance of one foot, and is called a *foot-pound.*

Work is distinguished into *useful work* and *prejudicial* or *lost work*, according as it is performed in producing the useful effect of the machine, or in overcoming prejudicial resistance.

96. *Energy—Potential Energy.*—*Energy* means *capacity for performing work.* The *energy of an effort*, or *potential energy*, is measured by the product of the effort into the distance through which its point of application is *capable* of being moved. The unit of energy is the same with the unit of work.

When the point of application of an effort *has been moved* through a given distance, energy is said to have been *exerted* to an amount expressed by the product of the effort into the distance through which its point of application has been moved.

97. *Variable Effort and Resistance.*—If an effort has different magnitudes during different portions of the motion of its point of application through a given distance, let each different magnitude of the effort P be multiplied by the length Δs of the corresponding portion of the path of the point of application; the sum

$$\Sigma . P\Delta s \quad \ldots\ldots\ldots \quad (50)$$

is the whole energy exerted. If the effort varies by insensible gradations, the energy exerted is the integral or limit towards which that sum approaches continually as the divisions of the path are made smaller and more numerous, and is expressed by

$$\int P ds \quad \ldots\ldots\ldots \quad (51).$$

Similar processes are applicable to the finding of the work performed in overcoming a varying resistance.

98. *Dynamometer or Indicator.*—A dynamometer or indicator is an instrument which measures and records the energy exerted by an effort. It usually consists essentially, first, of a piece of paper moving with a velocity proportional to that of the point of application of the effort, and having a straight line marked on it parallel to its direction of motion, called the zero line; and, secondly, of a spring acted upon and bent by the effort, and carrying a pencil whose perpendicular distance from the zero line, as regulated by the bending of the spring, is proportional to the effort. The pencil traces on the piece of paper a line such that its *ordinate* perpendicular to the zero line at a given point represents the effort P for the corresponding point in the path of the point of effort, and the *area between two ordinates* represents the energy exerted, $\int P ds$, for the corresponding portion of the path of the point of effort.

99. *Principle of the Equality of Energy and Work.*—From the first law of motion it follows that in a machine whose pieces move with uniform velocities the efforts and resistances must balance each

other. Now from the laws of statics (see above) it is known that, in order that a system of forces applied to a system of connected points may be in equilibrium, it is necessary that the sum formed by putting together the products of the forces by the respective distances through which their points of application are capable of moving simultaneously, each along the direction of the force applied to it, shall be zero,—products being considered positive or negative according as the direction of the forces and the possible motions of their points of application are the same or opposite.

In other words, the sum of the negative products is equal to the sum of the positive products. This principle, applied to a machine whose parts move with uniform velocities, is equivalent to saying that in any given interval of time *the energy exerted is equal to the work performed.*

The symbolical expression of this law is as follows:—let efforts be applied to one or any number of points of a machine; let any one of these efforts be represented by P, and the distance traversed by its point of application in a given interval of time by ds; let resistances be overcome at one or any number of points of the same machine; let any one of these resistances be denoted by R, and the distance traversed by its point of application in the given interval of time by ds'; then

$$\Sigma . \mathrm{P}ds = \Sigma . \mathrm{R}ds' \quad \ldots \ldots \quad (52).$$

The lengths ds, ds' are proportional to the velocities of the points to whose paths they belong, and the proportions of those velocities to each other are deducible from the construction of the machine by the principles of pure mechanism explained in Chapter I.

100. *Efficiency.*—The *efficiency* of a machine is the ratio of the *useful* work to the *total* work,—that is, to the energy exerted,—and is represented by

$$\frac{\Sigma . \mathrm{R}_u ds'}{\Sigma . \mathrm{R}ds'} = \frac{\Sigma . \mathrm{R}_u ds'}{\Sigma . \mathrm{R}_u ds' + \Sigma . \mathrm{R}_p ds'} = \frac{\Sigma . \mathrm{R}_u ds'}{\Sigma . \mathrm{P}ds} = \frac{\mathrm{U}}{\mathrm{E}} \quad . \quad . \quad (53),$$

R_u being taken to represent useful and R_p prejudicial resistances.

The more nearly the efficiency of a machine approaches to unity the better is the machine.

101. *Power and Effect.*—The *power* of a machine is the energy exerted, and the *effect* the useful work performed, in some interval of time of definite length, such as a second, an hour, or a day.

The unit of power, called conventionally a *horse-power*, is 550 foot-pounds per second, or 33,000 foot-pounds per minute, or 1,980,000 foot-pounds per hour.

102. *Modulus of a Machine.*—In the investigation of the properties of a machine, the useful resistances to be overcome and the useful work to be performed are usually given. The prejudicial resistances are generally functions of the useful resistances of the weights of the pieces of the mechanism, and of their form and arrangement; and, having been determined, they serve for the computation of the *lost* work, which, being added to the useful work, gives the expenditure of energy required. The result of this investigation, expressed in the form of an equation between this energy and the useful work, is called by Moseley the *modulus* of the machine. The general form of the modulus may be expressed thus—

$$\mathrm{E} = \mathrm{U} + \phi(\mathrm{U}, \mathrm{A}) + \psi(\mathrm{A}) \quad . \quad . \quad . \quad . \quad . \quad (54),$$

where A denotes some quantity or set of quantities depending on the form, arrangement, weight, and other properties of the mechanism. Moseley, however, has pointed out that in most cases this equation takes the much more simple form of

$$\mathrm{E} = (1 + \mathrm{A})\mathrm{U} + \mathrm{B}, \quad . \quad . \quad . \quad . \quad . \quad . \quad (55),$$

where A and B are *constants*, depending on the form, arrangement, and weight of the mechanism. The efficiency corresponding to the last equation is

$$\frac{\mathrm{U}}{\mathrm{E}} = \frac{1}{1 + \mathrm{A} + \mathrm{B}/\mathrm{U}} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (56).$$

103. *Trains of Mechanism.*—In applying the preceding principles to a train of mechanism, it may either be treated as a whole, or it may be considered in sections consisting of single pieces, or of any convenient portion of the train,—each section being treated as a machine driven by the effort applied to it and energy exerted upon it through its line of connexion with the preceding section, performing useful work by driving the following section, and losing work by overcoming its own prejudicial resistances.

It is evident that *the efficiency of the whole train is the product of the efficiencies of its sections.*

104. *Rotating Pieces—Couples of Forces.*—It is often convenient to express the energy exerted upon and the work performed by a turning piece in a machine in terms of the *moment* of the *couples of forces* acting on it, and of the angular velocity. See p. 728, § 219.

The ordinary British unit of moment is a *foot-pound*; but it is to be remembered that this is a foot-pound of a different sort from the unit of energy and work.

If a force be applied to a turning piece in a line not passing through its axis, the axis will press against its bearings with an equal and parallel force, and the equal and opposite reaction of the bearings will constitute, together with the first-mentioned force, a couple whose arm is the perpendicular distance from the axis to the line of action of the first force.

A couple is said to be *right* or *left handed* with reference to the observer, according to the direction in which it tends to turn the body, and is a *driving* couple or a *resisting* couple according as its tendency is with or against that of the actual rotation.

Let dt be an interval of time, α the angular velocity of the piece; then αdt is the angle through which it turns in the interval dt, and $ds = vdt = r\alpha dt$ is the distance through which the point of application of the force moves. Let P represent an effort, so that $\mathrm{P}r$ is a driving couple, then

$$\mathrm{P}ds = \mathrm{P}vdt = \mathrm{P}r\alpha dt = \mathrm{M}\alpha dt \quad . \quad . \quad . \quad . \quad . \quad (57)$$

is the energy exerted by the couple M in the interval dt; and a similar equation gives the work performed in overcoming a resisting couple. When several couples act on one piece, the resultant of their moments is to be multiplied by the common angular velocity of the whole piece.

105. *Reduction of Forces to a given Point, and of Couples to the Axis of a given Piece.*—In computations respecting machines it is often convenient to substitute for a force applied to a given point, or a couple applied to a given piece, the *equivalent* force or couple applied to some other point or piece; that is to say, the force or couple, which, if applied to the other point or piece, would exert equal energy or employ equal work. The principles of this reduction are that the ratio of the given to the equivalent force is the reciprocal of the ratio of the velocities of their points of application, and the ratio of the given to the equivalent couple is the reciprocal of the ratio of the angular velocities of the pieces to which they are applied.

These velocity ratios are known by the construction of the mechanism, and are independent of the absolute speed.

106. *Balanced Lateral Pressure of Guides and Bearings.*—The most important part of the lateral pressure on a piece of mechanism is the reaction of its guides, if it is a sliding piece, or of the bearings of its axis, if it is a turning piece; and the balanced portion of this reaction is equal and opposite to the resultant of all the other forces applied to the piece, its own weight included. There may be or may not be an unbalanced component in this pressure, due to the deviated motion. Its laws will be considered in the sequel.

107. *Friction—Unguents.*—The most important kind of resistance in machines is the *friction* or *rubbing resistance* of surfaces which slide over each other. The *direction* of the resistance of friction is opposite to that in which the sliding takes place. Its *magnitude* is the product of the *normal pressure* or force which presses the rubbing surfaces together in a direction perpendicular to themselves into a specific constant already mentioned in Part I., sect. 13, as the *coefficient of friction*, which depends on the nature and condition of the surfaces of the unguent, if any, with which they are covered. The *total pressure* exerted between the rubbing surfaces is the resultant of the normal pressure and of the friction, and its *obliquity*, or inclination to the common perpendicular of the surfaces, is the *angle of repose* formerly mentioned in sect. 13, whose tangent is the coefficient of friction. Thus, let N be the normal pressure, R the friction, T the total pressure, f the coefficient of friction, and ϕ the angle of repose; then

$$\left.\begin{aligned} f &= \tan\phi \quad . \quad . \quad . \\ \mathrm{R} = f\mathrm{N} &= \mathrm{N}\tan\phi = \mathrm{T}\sin\phi \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad . \quad (58).$$

Experiments on friction have been made by Coulomb, Vince, Rennie, Wood, D. Rankine, and others. The most complete and elaborate experiments are those of Morin, published in his *Notions Fondamentales de Mécanique*, and republished in Britain in the works of Moseley and Gordon. The following is an exceedingly condensed abstract of the most important results, as regards machines, of these experiments:—

Surfaces.	f.
Wood on wood, dry	0·25 to 0·5
Do., soaped	0·2
Metals on oak, dry	0·5 to 0·6
Do., wet	0·24 to 0·26
Do., soaped	0·2
Do., elm, dry	0·2 to 0·25
Hemp on oak, dry	0·53
Do., wet	0·33
Leather on oak, wet or dry	0·27 to 0·35
Leather on metals, dry	0·56
Do., wet	0·36
Do., greasy	0·23
Do., oiled	0·15
Metals on metals, dry	0·15 to 0·2
Do., wet	0·30
Smooth surfaces with ungents, occasionally greased	0·07 to 0·08
Do. do., well greased	0·05
Do. do., do., best results	0·03 to 0·036

It is to be understood that the above-stated law of friction is only true for dry surfaces when the pressure is not sufficient to indent or abrade the surfaces, and for greased surfaces when the pressure is not sufficient to force out the unguent from between the surfaces. If the proper limit be exceeded, the friction increases more rapidly than in the simple ratio of the normal pressure.

The limit of pressure for unguents diminishes as the speed increases. The following are some of its approximate values as inferred from experience in railway locomotive and carriage axles :—

Velocity of rubbing in feet per second	1	$2\frac{1}{3}$	5
Intensity of normal pressure per lb per square inch of surface	392	224	140

In pivots, the intensity of the pressure is usually fixed at about one ton per square inch.

Unguents should be comparatively thick for heavy pressures, that they may resist being forced out, and comparatively thin for light pressures, that their viscidity may not add to the resistance.

Unguents are of three classes, viz. :—

1. *Fatty*: consisting of animal or vegetable fixed oils, such as tallow, lard, lard-oil, seal-oil, whale-oil, olive-oil. *Drying* oils, which absorb oxygen and harden, are obviously unfit for unguents.

2. *Soapy*: composed of fatty oil, alkali, and water. The best grease of this class should not contain more than about 25 or 30 per cent. of water ; bad kinds contain 40 or 50 per cent. The additional water diminishes the cost, but spoils the unguent.

3. *Bituminous*: composed of solid and liquid mineral compounds of hydrogen and carbon.

108. *Work of Friction—Moment of Friction.*—The work performed in a unit of time in overcoming the friction of a pair of surfaces is the product of the friction by the velocity of sliding of the surfaces over each other, if that is the same throughout the whole extent of the rubbing surfaces. If that velocity is different for different portions of the rubbing surfaces, the velocity of each portion is to be multiplied by the friction of that portion, and the results summed or integrated.

When the relative motion of the rubbing surfaces is one of rotation, the work of friction in a unit of time, for a portion of the rubbing surfaces at a given distance from the axis of rotation, may be found by multiplying together the friction of that portion, its distance from the axis, and the angular velocity. The product of the force of friction by the distance at which it acts from the axis of rotation is called the *moment of friction*. The total moment of friction of a pair of rotating rubbing surfaces is the sum or integral of the moments of friction of their several portions.

To express this symbolically, let du represent the area of a portion of a pair of rubbing surfaces at a distance r from the axis of their relative rotation ; p the intensity of the normal pressure at du per unit of area ; and f the coefficient of friction. Then the moment of friction of du is

$$fprdu\,;$$

the total moment of friction is

$$f\!\int pr.du\,;$$

and the work performed in a unit of time in overcoming friction, when the angular velocity is a, is

$$af\!\int pr.du. \qquad \cdots\cdots\cdots (59).$$

It is evident that the moment of friction, and the work lost by being performed in overcoming friction, are less in a rotating piece as the bearings are of smaller radius. But a limit is put to the diminution of the radii of journals and pivots by the conditions of durability and of proper lubrication stated in sect. 107, and also by conditions of strength and stiffness.

109. *Total Pressure between Journal and Bearing.*—A single piece rotating with an uniform velocity has four mutually balanced forces applied to it :—(1) the effort exerted on it by the piece which drives it ; (2) the resistance of the piece which follows it,—which may be considered for the purposes of the present question as useful resistance ; (3) its weight ; and (4) the reaction of its own cylindrical bearings. There are given the following data :—

The direction of the effort.
The direction of the useful resistance.
The weight of the piece and the direction in which it acts.
The magnitude of the useful resistance.
The radius of the bearing r.
The angle of repose ϕ, corresponding to the friction of the journal on the bearing.

And there are required the following:—

The direction of the reaction of the bearing.
The magnitude of that reaction.
The magnitude of the effort.

Let the useful resistance and the weight of the piece be compounded by the principles of statics into one force, and let this be called *the given force*.

The directions of the effort and of the given force are either parallel or meet in a point. If they are parallel, the direction of the reaction of the bearing is also parallel to them ; if they meet in a point, the direction of the reaction traverses the same point.

Also, let AAA, fig. 30, be a section of the bearing, and C its axis ; then the direction of the reaction, at the point where it intersects the circle AAA, must make the angle ϕ with the radius of that circle ; that is to say, it must be a line such as PT touching the smaller circle BB, whose radius is $r . \sin \phi$. The side on which it touches that circle is determined by the fact that the obliquity of the reaction is such as to oppose the rotation.

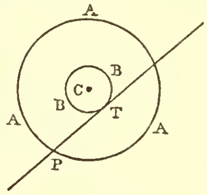

Fig. 30.

Thus is determined the direction of the reaction of the bearing ; and the magnitude of that reaction and of the effort are then found by the principles of the equilibrium of three forces already stated in Part I., sect. 7 (see also p. 702, § 124).

The work lost in overcoming the friction of the bearing is the same with that which would be performed in overcoming at the circumference of the small circle BB a resistance equal to the whole pressure between the journal and bearing.

In order to diminish that pressure to the smallest possible amount, the effort, and the resultant of the useful resistance, and the weight of the piece (called above the "given force") ought to be opposed to each other as directly as is practicable consistently with the purposes of the machine.

110. *Friction of Pivots and Collars.*—When a shaft is acted upon by a force tending to shift it lengthways, that force must be balanced by the reaction of a bearing against a *pivot* at the end of the shaft ; or, if that be impossible, against one or more *collars*, or rings *projecting* from the body of the shaft. The bearing of the pivot is called a *step* or *footstep*. Pivots require great hardness, and are usually made of steel. The *flat* pivot is a cylinder of steel having a plane circular end as a rubbing surface. Let N be the total pressure sustained by a flat pivot of the radius r ; if that pressure be uniformly distributed, which is the case when the rubbing surfaces of the pivot and its step are both true planes, the *intensity* of the pressure is

$$p = \frac{N}{\pi r^2} \quad \cdots\cdots\cdots \quad (60);$$

and, introducing this value into equation 59, the *moment of friction of the flat pivot* is found to be

$$\tfrac{2}{3} f N r \quad \cdots\cdots\cdots \quad (61),$$

or two-thirds of that of a cylindrical journal of the same radius under the same normal pressure.

The friction of a *conical* pivot exceeds that of a flat pivot of the same radius, and under the same pressure, in the proportion of the side of the cone to the radius of its base.

The moment of friction of a *collar* is given by the formula—

$$\tfrac{2}{3} f N \frac{r^3 - r'^3}{r^2 - r'^2} \quad \cdots\cdots\cdots \quad (62),$$

where r is the external and r' the internal radius.

In the *cup and ball* pivot the end of the shaft and the step present two recesses facing each other, into which are fitted two shallow cups of steel or hard bronze. Between the concave spherical surfaces of those cups is placed a steel ball, being either a complete sphere or a lens having convex surfaces of a somewhat less radius than the concave surfaces of the cups. The moment of friction of this pivot is at first almost inappreciable from the extreme smallness of the radius of the circles of contact of the ball and cups, but, as they wear, that radius and the moment of friction increase.

It appears that the rapidity with which a rubbing surface wears away is proportional to the friction and to the velocity jointly, or nearly so. Hence the pivots already mentioned wear unequally at different points, and tend to alter their figures. Schiele has invented a pivot which preserves its original figure by wearing equally at all points in a direction parallel to its axis. The following are the principles on which this equality of wear depends :—

The rapidity of wear of a surface measured in an *oblique* direction is to the rapidity of wear measured normally as the secant of the obliquity is to unity. Let OX (fig. 31) be the axis of a pivot, and let RPC be a portion of a curve such that at any point P the secant of the obliquity to the normal of the curve of a line parallel to the axis is inversely proportional to the ordinate PY, to which the velocity of P is proportional. The rotation of that curve round OX will generate the form of pivot required. Now let PT be a tangent to the

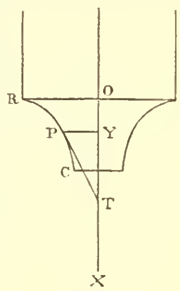

Fig 31.

curve at P, cutting OX in T; PT = PY × *secant obliquity*, and this is to be a constant quantity; hence the curve is that known as the *tractory* of the straight line OX, in which PT = OR = constant. This curve is described by having a fixed straight edge parallel to OX, along which slides a slider carrying a pin whose centre is T. On that pin turns an arm, carrying at a point P a tracing-point, pencil, or pen. Should the pen have a nib of two jaws, like those of an ordinary drawing-pen, the plane of the jaws must pass through PT. Then, while T is slid along the axis from O towards X, P will be drawn after it from R towards C along the tractory. This curve, being an asymptote to its axis, is capable of being indefinitely prolonged towards X; but in designing pivots it should stop before the angle PTY becomes less than the angle of repose of the rubbing surfaces, otherwise the pivot will be liable to stick in its bearing.

The moment of friction of "Schiele's anti-friction pivot," as it is called, is equal to that of a cylindrical journal of the radius OR = PT the constant tangent, under the same pressure.

111. *Friction of Teeth.*—Let N be the normal pressure exerted between a pair of teeth of a pair of wheels; s the total distance through which they slide upon each other; n the number of pairs of teeth which pass the plane of axis in a unit of time; then

$$nfNs \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (63)$$

is the work lost in unity of time by the friction of the teeth. The sliding s is composed of two parts, which take place during the approach and recess respectively. Let those be denoted by s_1 and s_2, so that $s = s_1 + s_2$. In sect. 55 the *velocity* of sliding at any instant has been given, viz., $u = c(\alpha_1 + \alpha_2)$, where u is that velocity, c the distance TI at any instant from the point of contact of the teeth to the pitch-point, and α_1, α_2 the respective angular velocities of the wheels.

Let v be the common velocity of the two pitch-circles, r_1, r_2 their radii; then the above equation becomes

$$u = cv\left(\frac{1}{r_1} + \frac{1}{r_2}\right).$$

To apply this to involute teeth, let c_1 be the length of the approach, c_2 that of the recess, u_1 the *mean* velocity of sliding during the approach, u_2 that during the recess; then

$$u_1 = \frac{c_1 v}{2}\left(\frac{1}{r_1} + \frac{1}{r_2}\right); \quad u_2 = \frac{c_2 v}{2}\left(\frac{1}{r_1} + \frac{1}{r_2}\right)$$

also, let θ be the obliquity of the action; then the times occupied by the approach and recess are respectively

$$\frac{c_1}{v\cos\theta}, \qquad \frac{c_2}{v\cos\theta};$$

giving, finally, for the length of sliding between each pair of teeth,

$$s = s_1 + s_2 = \frac{c_1^2 + c_2^2}{2\cos\theta}\left(\frac{1}{r_1} + \frac{1}{r_2}\right) \quad . \quad . \quad . \quad . \quad (64),$$

which, substituted in equation 63, gives the work lost in a unit of time by the friction of involute teeth. This result, which is exact for involute teeth, is approximately true for teeth of any figure.

For inside gearing, if r_1 be the less radius and r_2 the greater, $\frac{1}{r_1} - \frac{1}{r_2}$ is to be substituted for $\frac{1}{r_1} + \frac{1}{r_2}$.

112. *Friction of Cords and Belts.*—A flexible band, such as a cord, rope, belt, or strap, may be used either to exert an effort or a resistance upon a pulley round which it wraps. In either case the tangential force, whether effort or resistance, exerted between the band and the pulley is their mutual friction, caused by and proportional to the normal pressure between them.

Let T_1 be the tension of the free part of the band at that side *towards* which it tends to draw the pulley, or *from* which the pulley tends to draw it; T_2 the tension of the free part at the other side; T the tension of the band at any intermediate point of its arc of contact with the pulley; θ the ratio of the length of that arc to the radius of the pulley; $d\theta$ the ratio of an indefinitely small element of that arc to the radius; $F = T_1 - T_2$ the total friction between the band and the pulley; dF the elementary portion of that friction due to the elementary arc $d\theta$; f the coefficient of friction between the materials of the band and pulley.

Then, according to a well-known principle in statics, the normal pressure at the elementary arc $d\theta$ is $Td\theta$, T being the mean tension of the band at that elementary arc; consequently the friction on that arc is $dF = fTd\theta$. Now that friction is also the difference between the tensions of the band at the two ends of the elementary arc, or $dT = dF = fTd\theta$; which equation, being integrated throughout the entire arc of contact, gives the following formulæ:—

$$\left.\begin{aligned} &\text{hyp. log}\frac{T_1}{T_2} = f\theta \\ &\frac{T_1}{T_2} = e^{f\theta} \\ &F = T_1 - T_2 = T_1(1 - e^{-f\theta}) = T_2(e^{f\theta} - 1) \end{aligned}\right\} \quad . \quad . \quad (65).$$

When a belt connecting a pair of pulleys has the tensions of its two sides originally equal, the pulleys being at rest, and when the pulleys are next set in motion, so that one of them drives the other by means of the belt, it is found that the advancing side of the belt is exactly as much tightened as the returning side is slackened, so that the *mean* tension remains unchanged. Its value is given by this formula—

$$\frac{T_1 + T_2}{2} = \frac{e^{f\theta} + 1}{2(e^{f\theta} - 1)} \quad . \quad . \quad . \quad . \quad . \quad (66),$$

which is useful in determining the original tension required to enable a belt to transmit a given force between two pulleys.

The equations 65 and 66 are applicable to a kind of *brake* called a *friction-strap*, used to stop or moderate the velocity of machines by being tightened round a pulley. The strap is usually of iron, and the pulley of hard wood.

Let a denote the arc of contact expressed in *turns and fractions of a turn*; then

$$\left.\begin{aligned} &\theta = 6\cdot2832a \\ &e^{f\theta} = \text{number whose common logarithm is } 2\cdot7288fa \end{aligned}\right\} \quad (67).$$

113. *Stiffness of Ropes.*—Ropes offer a resistance to being bent, and, when bent, to being straightened again, which arises from the mutual friction of their fibres. It increases with the sectional area of the rope, and is inversely proportional to the radius of the curve into which it is bent.

The *work lost* in pulling a given length of rope over a pulley is found by multiplying the length of the rope in feet by its stiffness in pounds, that stiffness being the excess of the tension at the leading side of the rope above that at the following side, which is necessary to bend it into a curve fitting the pulley, and then to straighten it again.

The following empirical formulæ for the stiffness of hempen ropes have been deduced by Morin from the experiments of Coulomb:—

Let F be the stiffness in pounds avoirdupois; d the diameter of the rope in inches, $n = 48d^2$ for white ropes and $35d^2$ for tarred ropes; r the *effective* radius of the pulley in inches; T the tension in pounds. Then

$$\left.\begin{aligned} &\text{For white ropes, } F = \frac{n}{r}(0\cdot0012 + 0\cdot001026n + 0\cdot0012T) \\ &\text{For tarred ropes, } F = \frac{n}{r}(0\cdot006 + 0\cdot001392n + 0\cdot00168T) \end{aligned}\right\} (68).$$

114. *Friction-Couplings.*—Friction is useful as a means of communicating motion where sudden changes either of force or velocity take place, because, being limited in amount, it may be so adjusted as to limit the forces which strain the pieces of the mechanism within the bounds of safety. Amongst contrivances for effecting this object are *friction-cones*. A rotating shaft carries upon a cylindrical portion of its figure a wheel or pulley turning loosely on it, and consequently capable of remaining at rest when the shaft is in motion. This pulley has fixed to one side, and concentric with it, a short frustum of a hollow cone. At a small distance from the pulley the shaft carries a short frustum of a solid cone accurately turned to fit the hollow cone. This frustum is made always to turn along with the shaft by being fitted on a square portion of it, or by means of a rib and groove, or otherwise, but is capable of a slight longitudinal motion, so as to be pressed into, or withdrawn from, the hollow cone by means of a lever. When the cones are pressed together or engaged, their friction causes the pulley to rotate along with the shaft; when they are disengaged, the pulley is free to stand still. The angle made by the sides of the cones with the axis should not be less than the angle of repose. In the *friction-clutch*, a pulley loose on a shaft has a hoop or gland made to embrace it more or less tightly by means of a screw; this hoop has short projecting arms or ears. A fork or *clutch* rotates along with the shaft, and is capable of being moved longitudinally by a handle. When the clutch is moved towards the hoop, its arms catch those of the hoop, and cause the hoop to rotate and to communicate its rotation to the pulley by friction. There are many other contrivances of the same class, but the two just mentioned may serve for examples.

115. *Heat of Friction—Unguents.*—The work lost in friction is employed in producing heat. This fact is very obvious, and has been known from a remote period; but the *exact* determination of the proportion of the work lost to the heat produced, and the experimental proof that that proportion is the same under all circumstances, and with all materials, solid, liquid, and gaseous, are comparatively recent achievements of Joule. The quantity of work which produces a British unit of heat (or so much heat as elevates the temperature of one pound of pure water, at or near ordinary atmospheric temperatures, by one degree of Fahrenheit) is 772 foot-pounds. This constant, now designated as "Joule's equivalent," is the principal experimental datum of the science of thermodynamics.

The heat produced by friction, when moderate in amount, is useful in softening and liquefying thick unguents; but when excessive it is prejudicial, by decomposing the unguents, and sometimes even by softening the metal of the bearings, and raising their temperature so high as to set fire to neighbouring combustible matters.

Excessive heating is prevented by a constant and copious supply of a good unguent. The elevation of temperature produced by the friction of a journal is sometimes used as an experimental test of the quality of unguents. When the velocity of rubbing is about 4 or 5 feet per second, the elevation of temperature has been found by some recent experiments to be, with good fatty and soapy unguents, 40° to 50° Fahr.; with good mineral unguents, about 30°.

116. *Rolling Resistance.*—By the rolling of two surfaces over each other without sliding a resistance is caused which is called sometimes "rolling friction," but more correctly *rolling resistance.* It is of the nature of a *couple*, resisting rotation. Its *moment* is found by multiplying the normal pressure between the rolling surfaces by an *arm*, whose length depends on the nature of the rolling surfaces, and the work lost in a unit of time in overcoming it is the product of its moment by the *angular velocity* of the rolling surfaces relatively to each other. The following are approximate values of the arm in decimals of a foot:—

Oak upon oak	0·006	(Coulomb).
Lignum vitæ on oak	0·004	,,
Cast iron on cast iron	0·002	(Tredgold).

117. *Reciprocating Forces—Stored and Restored Energy.*—When a force acts on a machine alternately as an effort and as a resistance, it may be called a *reciprocating force.* Of this kind is the weight of any piece in the mechanism whose centre of gravity alternately rises and falls; for during the rise of the centre of gravity that weight acts as a resistance, and energy is employed in lifting it to an amount expressed by the product of the weight into the vertical height of its rise; and during the fall of the centre of gravity the weight acts as an effort, and exerts in assisting to perform the work of the machine an amount of energy exactly equal to that which had previously been employed in lifting it. Thus that amount of energy is not lost, but has its operation deferred; and it is said to be *stored* when the weight is lifted, and *restored* when it falls.

In a machine of which each piece is to move with a uniform velocity, if the effort and the resistance be constant, the weight of each piece must be balanced on its axis, so that it may produce lateral pressure only, and not act as a reciprocating force. But if the effort and the resistance be alternately in excess, the uniformity of speed may still be preserved by so adjusting some moving weight in the mechanism that when the effort is in excess it may be lifted, and so balance and employ the excess of effort, and that when the resistance is in excess it may fall, and so balance and overcome the excess of resistance,—thus *storing* the periodical excess of energy, and *restoring* that energy to perform the periodical excess of work.

Other forces besides gravity may be used as reciprocating forces for storing and restoring energy,—for example, the elasticity of a spring or of a mass of air.

In most of the delusive machines commonly called "perpetual motions," of which so many are patented in each year, and which are expected by their inventors to perform work without receiving energy, the fundamental fallacy consists in an expectation that some reciprocating force shall restore more energy than it has been the means of storing.

Division 2. *Deflecting Forces.*

118. *Deflecting Force for Translation in a Curved Path.*—In machinery, deflecting force is supplied by the tenacity of some piece, such as a crank, which guides the deflected body in its curved path, and is *unbalanced*, being employed in producing deflexion, and not in balancing another force.

119. *Centrifugal Force.*—See p. 682, § 35, and p. 701, § 119.

120. *Rectangular Resolution of Centrifugal Force.*—See p. 701, §§ 117 and 119.

121. *Centrifugal Force of a Rotating Body.* — *The centrifugal force exerted by a rotating body on its axis of rotation is the same in magnitude as if the mass of the body were concentrated at its centre of gravity, and acts in a plane passing through the axis of rotation and the centre of gravity of the body.*

The particles of a rotating body exert centrifugal forces on each other, which strain the body, and tend to tear it asunder; but these forces balance each other, and do not affect the resultant centrifugal force exerted on the axis of rotation.[1]

If the axis of rotation traverses the centre of gravity of the body, the centrifugal force exerted on that axis is nothing.

Hence, unless there be some reason to the contrary, each piece of a machine should be balanced on its axis of rotation; otherwise the centrifugal force will cause strains, vibration, and increased friction, and a tendency of the shafts to jump out of their bearings.

122. *Centrifugal Couples of a Rotating Body.*—Besides the tendency (if any) of the combined centrifugal forces of the particles of a rotating body to *shift* the axis of rotation, they may also tend to *turn* it out of its original direction. The latter tendency is called a *centrifugal couple*, and vanishes for rotation about a principal axis (see p. 732, § 237).

It is essential to the steady motion of every rapidly rotating piece in a machine that its axis of rotation should not merely traverse its centre of gravity, but should be a permanent axis; for otherwise the centrifugal couples will increase friction, produce oscillation of the shaft, and tend to make it leave its bearings.

The principles of this and the preceding section are those which regulate the adjustment of the weight and position of the *counterpoises* which are placed between the spokes of the driving-wheels of locomotive engines.

123. *Revolving Pendulum—Governors.*—In fig. 32 AO represents an upright axis or spindle; B a weight called a *bob*, suspended by rod OB from a horizontal axis at O, carried by the vertical axis. When the spindle is at rest the bob hangs close to it; when the spindle rotates, the bob, being made to revolve round it, diverges until the resultant of the centrifugal force and the weight of the bob is a force acting at O in the direction OB, and then it revolves steadily in a circle. This combination is called a *revolving, centrifugal*, or *conical pendulum.* Revolving pendulums are usually constructed with *pairs* of rods and bobs, as OB, O*b*, hung at opposite sides of the spindle, that the centrifugal forces exerted at the point O may balance each other.

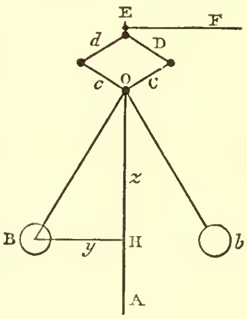

Fig. 32.

In finding the position in which the bob will revolve with a given angular velocity α, for most practical cases connected with machinery the mass of the rod may be considered as insensible compared with that of the bob. Let the bob be a sphere, and from the centre of that sphere draw $BH = y$ perpendicular to OA. Let $OH = z$; let W be the weight of the bob, F its centrifugal force. Then the condition of its steady revolution is $W : F :: z : y$; that is to say, $\frac{y}{z} = \frac{F}{W} = \frac{y\alpha^2}{g}$; consequently

$$z = \frac{g}{\alpha^2} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (69).$$

Or, if $n = \frac{\alpha}{2\pi} = \frac{\alpha}{6 \cdot 2832}$ be the number of turns or fractions of a turn in a second,

$$z = \frac{g}{4\pi^2 n^2} = \frac{0 \cdot 8165 \text{ foot}}{n^2} = \frac{9 \cdot 79771 \text{ inches}}{n^2} \Bigg\} \quad . \quad . \quad (70);$$

z is called the *altitude of the pendulum.*

If the rod of a revolving pendulum be jointed, as in fig. 33, not to a point in the vertical axis, but to the end of a projecting arm C, the position in which the bob will revolve will be the same as if the rod were jointed to the point O, where its prolongation cuts the vertical axis.

A revolving pendulum is an essential part of most of the contrivances called *governors*, for regulating the speed of prime movers.

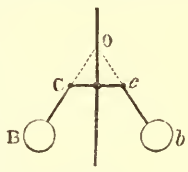

Fig. 33.

The earlier kinds of governors act on the prime mover by the variations of their altitude. Thus in Watt's steam-engine governor the rods, through a combination of levers and linkwork C, *c*, D, *d* (fig. 32), act on a lever EF, which acts upon the throttle-valve for the admission of steam so as to enlarge or contract its opening when the speed becomes too small or too great.

In a more recent kind of governors invented by the Messrs Siemens, which may be called *differential governors*, the regulation of the prime mover is effected by means of the difference between the velocity of a wheel driven by it and that of a wheel regulated by a revolving pendulum. Fig. 34 illustrates this class of governors. A is a vertical dead-centre or fixed shaft, about which the after-mentioned pieces turn; C is a pulley driven by the prime mover, and fixed to a bevel-wheel, which is seen below it; E is a bevel-wheel similar to the first, and having the same apex. To this wheel are hung the bobs B, of which there are

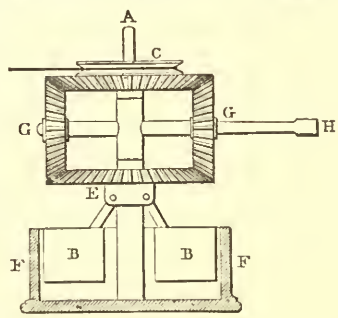

Fig. 34.

[1] This is a particular case of a more general principle, that *the motion of the centre of gravity of a body is not affected by the mutual actions of its parts*, for the proof of which see p. 718, § 179.

usually four, although two only are shown. Those bobs form sectors of a ring, and are surrounded by a cylindrical casing F. When the bobs revolve with their proper velocity, they are adjusted so as nearly to touch this casing; should they exceed that velocity, they fly outwards and touch the casing, and are retarded by the friction. For practical purposes their velocity of rotation about the vertical axis may be considered constant. G, G are horizontal arms projecting from a socket which is capable of rotation about A, and carrying vertical bevel wheels which rest on E and support C, and transmit motion from C to E. There are usually four of the arms G, G with their wheels, though two only are shown. H is one of those arms which projects, and has a rod attached to its extremity to act on the throttle-valve of a steam-engine, the sluice of a water-wheel, or the regulator of the prime mover, of whatever sort it may be.

When C rotates with an angular velocity equal and contrary to that of E with its revolving pendulums, the arms G, G remain at rest; but should C deviate from that velocity, those arms rotate in one direction or the other, as the case may be, with an angular velocity equal to one half of the difference between the angular velocity of C and that of E, and continue in motion until the regulator is adjusted so that the prime mover shall impart to C an angular velocity exactly equal to that of the revolving pendulums.

There are various modifications of the differential governor, but they all act on the same principle.

Division 3. Working of Machines of Varying Velocity.

124. *General Principles.*—In order that the velocity of every piece of a machine may be uniform, it is necessary that the forces acting on each piece should be always exactly balanced. Also, in order that the forces acting on each piece of a machine may be always exactly balanced, it is necessary that the velocity of that piece should be uniform.

An excess of the effort exerted on any piece, above that which is necessary to balance the resistance, is accompanied with acceleration; a deficiency of the effort, with retardation.

When a machine is being started from a state of rest, and brought by degrees up to its proper speed, the effort must be in excess; when it is being retarded for the purpose of stopping it, the resistance must be in excess.

An excess of effort above resistance involves an excess of energy exerted above work performed; that excess of energy is employed in producing acceleration.

An excess of resistance above effort involves an excess of work performed above energy expended; that excess of work is performed by means of the retardation of the machinery.

When a machine undergoes alternate acceleration and retardation, so that at certain instants of time, occurring at the end of intervals called *periods* or *cycles*, it returns to its original speed, then in each of those periods or cycles the alternate excesses of energy and of work neutralize each other; and at the end of each cycle the principle of the equality of energy and work stated in sect. 96, with all its consequences, is verified exactly as in the case of machines of uniform speed.

At intermediate instants, however, other principles have also to be taken into account, which are deduced from the second law of motion, sect. 89, as applied by the aid of the principles of sect. 90, to *direct deviation*, or acceleration and retardation.

125. *Energy of Acceleration and Work of Retardation for a Shifting Body.*—Let w be the weight of a body which has a motion of translation in any path, and in the course of the interval of time Δt let its velocity be increased at a uniform rate of acceleration from v_1 to v_2. The rate of acceleration will be

$$\frac{dv}{dt} = \text{constant} = \frac{v_2 - v_1}{\Delta t};$$

and (p. 698, § 104) to produce this acceleration a uniform effort will be required, expressed by

$$P = \frac{w \cdot (v_2 - v_1)}{g \Delta t} \quad . \quad . \quad . \quad . \quad . \quad . \quad (71).$$

(The product $\frac{wv}{g}$ of the mass of a body by its velocity is called its *momentum*; so that the effort required is found by dividing the increase of momentum by the time in which it is produced.)

To find the *energy* which has to be exerted to produce the acceleration from v_1 to v_2, it is to be observed that the *distance* through which the effort P acts during the acceleration is

$$\Delta s = \frac{v_2 + v_1}{2} \Delta t;$$

consequently, the *energy of acceleration* is

$$P \Delta s = \frac{w(v_2 - v_1)(v_2 + v_1)}{2g} = \frac{w(v_2^2 - v_1^2)}{2g} \quad . \quad . \quad . \quad (72),$$

being proportional to the increase in the square of the velocity, and *independent of the time*.

In order to produce a *retardation* from the greater velocity v_2 to the less velocity v_1, it is necessary to apply to the body a *resistance*, connected with the retardation and the time by an equation identical in every respect with equation 71, except by the substitution of a resistance for an effort; and in overcoming that resistance the body *performs work* to an amount determined by equation 72, putting Rds for Pds.

126. *Energy Stored and Restored by Deviations of Velocity.*—Thus a body alternately accelerated and retarded, so as to be brought back to its original speed, performs work during its retardation exactly equal in amount to the energy exerted upon it during its acceleration; so that that energy may be considered as *stored* during the acceleration, and *restored* during the retardation, in a manner analogous to the operation of a reciprocating force (sect. 117).

Let there be given the mean velocity $V = \frac{1}{2}(v_2 + v_1)$ of a body whose weight is w, and let it be required to determine the fluctuation of velocity $v_2 - v_1$, and the extreme velocities v_1, v_2, which that body must have, in order alternately to store and restore an amount of energy E. By equation 72 we have

$$E = \frac{w(v_2^2 - v_1^2)}{2g}$$

which, being divided by $V = \frac{1}{2}(v_2 + v_1)$, gives

$$\frac{E}{V} = \frac{w(v_2 - v_1)}{g};$$

and consequently

$$v_2 - v_1 = \frac{gE}{Vw} \quad . \quad . \quad . \quad . \quad . \quad . \quad (73).$$

The ratio of this fluctuation to the mean velocity, sometimes called the *unsteadiness* of the motion of the body, is

$$\frac{v_2 - v_1}{V} = \frac{gE}{V^2 w} \quad . \quad . \quad . \quad . \quad . \quad . \quad (74).$$

127. *Actual Energy of a Shifting Body.*—The energy which must be exerted on a body of the weight w, to accelerate it from a state of rest up to a given velocity of translation v, and the equal amount of work which that body is capable of performing by overcoming resistance while being retarded from the same velocity of translation v to a state of rest, is

$$\frac{wv^2}{2g} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (75).$$

This is called the *actual energy* of the motion of the body, and is half the quantity which in some treatises is called *vis viva*.

The energy stored or restored, as the case may be, by the deviations of velocity of a body or a system of bodies, is the amount by which the actual energy is increased or diminished.

128. *Principle of the Conservation of Energy in Machines.*—The following principle, expressing the general law of the action of machines with a velocity uniform or varying, includes the law of the equality of energy and work stated in sect. 99 for machines of uniform speed.

In any given interval during the working of a machine, the energy exerted added to the energy restored is equal to the energy stored added to the work performed.

129. *Actual Energy of Circular Translation—Moment of Inertia.*—Let a body of the weight w undergo translation in a circular path of the radius ρ, with the angular velocity of deflexion α, so that the common linear velocity of all its particles is $v = \alpha\rho$. Then the actual energy of that body is

$$\frac{wv^2}{2g} = \frac{w\alpha^2\rho^2}{2g} \quad . \quad . \quad . \quad . \quad . \quad . \quad (76).$$

By comparing this with the expression for the centrifugal force $(w\alpha^2/\rho g)$, it appears that the actual energy of a revolving body is equal to the potential energy $F\rho/2$ due to the action of the deflecting force along one-half of the radius of curvature of the path of the body.

The product $w\rho^2/g$, by which the half-square of the angular velocity is multiplied, is called the *moment of inertia* of the revolving body.

130. *Actual Energy and Moment of Inertia of Rotation—Radius of Gyration.*—See p. 732, §§ 234–237.

131. *Examples of Radii of Gyration.*—See p. 733, § 238.

132. *Fly-wheels.*—A fly-wheel is a rotating piece in a machine, generally shaped like a wheel (that is to say, consisting of a rim with spokes), and suited to store and restore energy by the periodical variations in its angular velocity.

The principles according to which variations of angular velocity store and restore energy are the same with those of sect. 126, only substituting *moment of inertia* for *mass*, and *angular* for *linear* velocity.

Let W be the weight of a fly-wheel, R its radius of gyration, α_2 its maximum, α_1 its minimum, and $A = \frac{1}{2}(\alpha_2 + \alpha_1)$ its mean angular velocity. Let

$$\frac{1}{S} = \frac{\alpha_2 - \alpha_1}{A}$$

denote the *unsteadiness* of the motion of the fly-wheel; the denominator S of this fraction is called the *steadiness*. Let e denote the quantity by which the energy exerted in each cycle of the working of the machine alternately exceeds and falls short of the work performed, and which has consequently to be alternately stored by acceleration and restored by retardation of the fly-wheel. The value of this *periodical excess* is—

$$e = \frac{R^2 W(a_2^2 - a_1^2)}{2g} \quad \ldots \ldots \quad (77),$$

from which, dividing both sides by A^2, we obtain the following equations:—

$$\left.\begin{aligned} \frac{e}{A^2} &= \frac{R^2 W}{gS} \\ \frac{R^2 W A^2}{2g} &= \frac{Se}{2} \end{aligned}\right\} \quad \ldots \ldots \quad (78).$$

The latter of these equations may be thus expressed in words:—*The actual energy due to the rotation of the fly, with its mean angular velocity, is equal to one-half of the periodical excess of energy multiplied by the steadiness.*

In ordinary machinery S = about 32; in machinery for fine purposes S = from 50 to 60.

The periodical excess e may arise either from variations in the effort exerted by the prime mover, or from variations in the resistance of the work, or from both these causes combined. When but one fly-wheel is used, it should be placed in as direct connexion as possible with that part of the mechanism where the greatest amount of the periodical excess originates; but when it originates at two or more points, it is best to have a fly-wheel in connexion with each of those points. For example, in a machine-work, the steam-engine, which is the prime mover of the various tools, has a fly-wheel on the crank-shaft to store and restore the periodical excess of energy arising from the variations in the effort exerted by the connecting-rod upon the crank; and each of the slotting machines, punching machines, rivetting machines, and other tools has a fly-wheel of its own to store and restore energy, so as to enable the very different resistances opposed to those tools at different times to be overcome without too great unsteadiness of motion.

According to the computation of General Morin, the periodical excess e in steam-engines with single cranks is from $\frac{1}{10}$th to nearly $\frac{1}{4}$th of the energy exerted during one revolution of the crank. For a pair of steam-engines driving one shaft, with a pair of cranks at right angles to each other, the value of e is one-fourth of its value for a single cranked engine of the same kind, and of the same power with the two combined.

The ordinary radius of gyration of a steam-engine fly-wheel is from three to five times the length of the crank-arm. (For further particulars on this subject, see STEAM-ENGINE.)

For tools performing useful work at intervals, and having only their own friction to overcome during the intermediate intervals, e should be assumed equal to the whole work performed at each separate operation.

133. *Brakes.*—A brake is an apparatus for stopping and diminishing the velocity of a machine by friction, such as the friction-strap already referred to in sect. 112. To find the distance s through which a brake, exerting the friction F, must rub in order to stop a machine having the total actual energy E at the moment when the brake begins to act, reduce, by the principles of sect. 105, the various efforts and other resistances of the machine which act at the same time with the friction of the brake to the rubbing surface of the brake, and let R be their resultant,—*positive* if resistance, *negative* if effort preponderates. Then

$$s = \frac{E}{F + R} \quad \ldots \ldots \quad (79).$$

134. *Energy distributed between two Bodies—Projection and Propulsion.*—Hitherto the effort by which a machine is moved has been treated as a force exerted between a movable body and a fixed body, so that the whole energy exerted by it is employed upon the movable body, and none upon the fixed body. This conception is sensibly realized in practice when one of the two bodies between which the effort acts is either so heavy as compared with the other, or has so great a resistance opposed to its motion, that it may, without sensible error, be treated as fixed. But there are cases in which the motions of both bodies are appreciable, and must be taken into account,—such as the projection of projectiles, where the velocity of the *recoil* or backward motion of the gun bears an appreciable proportion to the forward motion of the projectile; and such as the propulsion of vessels, where the velocity of the water thrown backward by the paddle, screw, or other propeller bears a very considerable proportion to the velocity of the water moved forwards and sideways by the ship. In cases of this kind the energy exerted by the effort is *distributed* between the two bodies between which the effort is exerted in shares proportional to the velocities of the two bodies during the action of the effort; and those velocities are to each other directly as the portions of the effort unbalanced by resistance on the respective bodies, and inversely as the weights of the bodies.

To express this symbolically, let W_1, W_2 be the weights of the bodies; P the effort exerted between them; S the distance through which it acts; R_1, R_2 the resistances opposed to the effort overcome by W_1, W_2 respectively; E_1, E_2 the shares of the whole energy E exerted upon W_1, W_2 respectively. Then

$$\left.\begin{aligned} &E : E_1 : E_2 \\ :: &\frac{W_2(P - R_1) + W_1(P - R_2)}{W_1 W_2} : \frac{P - R_1}{W_1} : \frac{P - R_2}{W_2} \end{aligned}\right\} \quad \ldots \quad (80).$$

If $R_1 = R_2$, which is the case when the resistance, as well as the effort, arises from the mutual actions of the two bodies, the above becomes,

$$\left.\begin{aligned} &E : E_1 : E_2 \\ :: &W_1 + W_2 : W_2 : W_1 \end{aligned}\right\} \quad \ldots \ldots \quad (81);$$

that is to say, the energy is exerted on the bodies in shares inversely proportional to their weights; and they receive accelerations inversely proportional to their weights, according to the principle of dynamics, already quoted in a note to sect. 121, that the mutual actions of a system of bodies do not affect the motion of their common centre of gravity.

For example, if the weight of a gun be 160 times that of its ball, $\frac{160}{161}$ of the energy exerted by the powder in exploding will be employed in propelling the ball, and $\frac{1}{161}$ in producing the recoil of the gun, provided the gun up to the instant of the ball's quitting the muzzle meets with no resistance to its recoil except the friction of the ball.

135. *Centre of Percussion.*—It is obviously desirable that the deviations or changes of motion of oscillating pieces in machinery should, as far as possible, be effected by forces applied at their centres of percussion.

If the deviation be a *translation*,—that is, an equal change of motion of all the particles of the body,—the centre of percussion is obviously the centre of gravity itself; and, according to the second law of motion, if dv be the deviation of velocity to be produced in the interval dt, and W the weight of the body, then

$$P = \frac{W}{g} \cdot \frac{dv}{dt} \quad \ldots \ldots \quad (82)$$

is the unbalanced effort required.

If the deviation be a rotation about an axis traversing the centre of gravity, there is no centre of percussion; for such a deviation can only be produced by a *couple* of forces, and not by any single force. Let da be the deviation of angular velocity to be produced in the interval dt, and I the moment of the inertia of the body; then $\frac{1}{2}Id(a^2) = Iada$ is the variation of the body's actual energy. Let M be the moment of the unbalanced couple required to produce the deviation; then, by equation 57, sect. 104, the energy exerted by this couple in the interval dt is $Madt$, which, being equated to the variation of energy, gives

$$M = I\frac{da}{dt} = \frac{R^2 W}{g} \cdot \frac{da}{dt} \quad \ldots \ldots \quad (83).$$

Now (fig. 35), let the required deviation be a rotation of the body BB about an axis O, not traversing the centre of gravity G, da being, as before, the deviation of angular velocity to be produced in the interval dt. A rotation with the angular velocity a about an axis O may be considered as compounded of a rotation with the same angular velocity about an axis drawn through G parallel to O and a translation with the velocity a. OG, OG being the perpendicular distance between the two axes. Hence the required deviation may be regarded as compounded of a deviation of translation $dv = OG \cdot da$, to produce which there would be required, according to equation 82, a force applied at G perpendicular to the plane OG—

$$P = \frac{W}{g} \cdot OG \cdot \frac{da}{dt} \quad \ldots \ldots \quad (84),$$

and a deviation da of rotation about an axis drawn through G parallel to O, to produce which there would be required a couple of the moment M given by equation 83. According to the principles of statics, the resultant of the force P, applied at G perpendicular to the plane OG, and the couple M is a force equal and parallel to P, but applied at a distance GC from G, in the prolongation of the perpendicular OG, whose value is

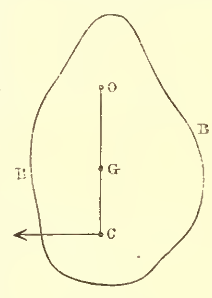

Fig. 35.

$$GC = \frac{M}{P} = \frac{R^2}{OG} \quad \ldots \ldots \quad (85).$$

Thus is determined the position of the centre of percussion C, corresponding to the axis of rotation O. It is obvious from this equation that, for an axis of rotation parallel to O traversing C, the centre of percussion is at the point where the perpendicular OG meets O.

136. *Impact.*—Impact or collision is a pressure of short duration exerted between two bodies. For the detailed investigation of its laws the reader is referred to MECHANICS, p. 719, § 180 *sq.*

The effects of impact are sometimes an alteration of the distribution of actual energy between the two bodies, and always a loss of a portion of that energy, depending on the imperfection of the elasticity of the bodies, in permanently altering their figures, and producing heat. The determination of the distribution of the actual energy after collision and of the loss of energy is effected by means of the following principles:—

I. The motion of the common centre of gravity of the two bodies is unchanged by the collision.

II. The loss of energy consists of a certain proportion of that part of the actual energy of the bodies which is due to their motion relatively to their common centre of gravity.

Unless there is some special reason for using impact in machines, it ought to be avoided, on account not only of the waste of energy which it causes, but from the damage which it occasions to the frame and mechanism.

CHAPTER III. PURPOSES AND EFFECTS OF MACHINES.

137. *Observing Machines and Working Machines.*—The present chapter must necessarily be limited to some very general observations on the principal classes into which machines may be divided, with reference to their purposes and effects, leaving details of particular examples for treatment under the respective special headings.

Machines may be divided, in the first instance, into two great divisions, viz.:—

I. *Observing Machines*, in which either the modification of motion alone, or the balancing of forces alone, is the object in view,—the performance of work being either null or incidental, and being limited to that which arises from the resistance of the machine.

II. *Working machines*, in which the performance of work is the main object.

138. *Classification of Observing Machines.*—Observing machines might very properly have been classed as *instruments*, being designed to aid the human senses and memory in obtaining and recording information. They may be divided, in the first instance, into four classes, according as the subject of observation by their aid is number, measure, or weight, into—

A. Counting machines.
B. Measuring machines.
C. Copying and drawing machines.
D. Weighing machines.

And to these may be added a fifth class, in which the functions of the first four are more or less combined, viz.:—

E. Recording machines.

139. (A.) *Counting Machines.*—The most important as well as the most common of counting machines are *time-keepers*, which count and indicate the numbers of oscillations of bodies which oscillate isochronously (viz., pendulums for clocks, balance-wheels for watches and marine chronometers) so as to measure time. In constructing such machines, the objects to be aimed at are the exact isochronism of the pendulum or balance, and the equable action of the motive power, so that it shall overcome the friction of the mechanism without affecting the rate.

Other counting machines count the oscillations of the beam of a steam-engine, or the revolutions of the cylinder of a gas-meter or of the wheel of a water-meter.

Others perform additions, subtractions, and multiplications, and of these the most elaborate kind (as, *e.g.*, that of Babbage) compute tables of functions by the addition of differences.

140. (B.) *Measuring Machines.*—Measuring machines are pieces of mechanism, by means of which the motion of some body of the nature of an index through some geometrical magnitude, such as a distance or an angle, is connected with some other motion, either equal or greater or smaller in some given ratio, and capable of being more readily compared with some standard of measure.

To this class belong all those astronomical and surveying instruments in which the motion of a line of sight (generally the line of collimation of a telescope) through a given angle is connected with the motion of an index or vernier round a corresponding arc of a graduated circle; also those micrometers in which the advance of the end of a screw of fine pitch is measured by observing the simultaneous arc of rotation of a graduated circle attached to it.

Such micrometers have attained increased importance by the discovery of Whitworth,—that the mechanical magnifying of small distances by a train of screws affords a more accurate means of measurement than optical magnifying by the microscope,—and by the perfection to which that engineer has brought that art of accurate workmanship which is necessary in order to render mechanical magnifying possible.

Amongst measuring machines are included the *platometers* or *planimeters* of Sang, Morin, and Clerk Maxwell, which measure areas by means of mechanism. The amount of resistance in a measuring machine should be perfectly uniform, and sufficiently great to prevent accidental forces from disturbing the machine, without being so great as to render it inconveniently stiff. To combine these objects requires great accuracy of workmanship, together with strength and rigidity in the structure of the frame and mechanism.

141. (C.) *Copying and Drawing Machines.*—In copying machines for enlarging or reducing drawings there is usually a combination of levers and linkwork connecting a tracing-point, which is moved over the lines of the original figure, with a drawing-point, which draws the copy in such a manner that the velocity ratio of their motions is a given constant quantity, and that the directions of their motions make a constant angle.

Mechanism depending for its principle on the theory of the composition of rotations is used to draw ellipses, epicycloids, epitrochoids, and other curves.

142. (D.) *Weighing Machines.*—In weighing machines the motion of the mechanism is used only for the purpose that its cessation, or its becoming an oscillation about a certain position, may indicate the equilibrium of the forces applied to the machine. Those forces may either be weights, which are to be compared with each other, or forces of other kinds, to be compared directly or indirectly with weights.

The machine for comparing weights which is capable of the most minute accuracy is also the simplest, being the *balance*, in which the equality of two weights is ascertained by their balancing each other at the ends of a lever of equal arms. In the *steelyard*, consisting either of one lever or of a train of levers, the unknown weight has an unchangeable point of application, and is compared with a known weight by shifting the latter along the lever to which it is applied until the machine is balanced; the ratio of the weights is then the reciprocal of the velocity ratio of their points of application. The steelyard is more convenient for weighing very heavy loads than the balance, but is not capable of such minute accuracy.

It is essential to accuracy in balances and steelyards that the friction should be less than the smallest admissible amount of error. To diminish the friction as much as possible, the axes of motion are all *knife-edges*, as they are termed, of steel or hardened iron, resting on hard surfaces of hardened iron or steel for ordinary purposes, and of some hard mineral, such as agate, for scientific purposes.

The weight of a column of fluid is determined by balancing it against a column of fluid whose weight is known, as in the barometer, where the weight of a column of the atmosphere is balanced against that of a column of mercury.

Weights are compared with each other indirectly, and other forces compared with weights, by means of their effects in bending a spring,—a convenient method, but not susceptible of minute accuracy.

The elastic pressure exerted by a fluid may be compared with weight, either by balancing the pressure against the weight of a column of a liquid, or by maintaining a piston in equilibrium against that pressure, by means of a weight pressing it directly, or of a weight acting through a steelyard, or of the elasticity of a spring which has been compared with weights.

143. (E.) *Recording Machines.*—Recording machines may be divided into two classes:—*self-registering instruments*, which, by the aid of clockwork, record measurements either of space or of force, together with the instants of time at which these measurements were made; and *dynamometers*, already mentioned in Chap. II. of this article, which register measurements of force, together with the space through which it has acted, thus recording energy or work.

144. *Working Machines Classed.*—The object or purpose of working machines is to perform useful work; and their classification relatively to their objects and purposes is founded on the kind of useful work which they perform. In this point of view they may be classed as follows:—

A. Machines for lifting or lowering solid weights.
B. Machines for the horizontal transport of weights, either combined or not with lifting or lowering.
C. Machines for projecting solids.
D. Machines for lifting fluids.
E. Machines for propelling or projecting fluids.
F. Machines for dividing bodies.
G. Machines for shaping bodies by removing portions of them.
H. Machines for shaping bodies by pressure.
I. Machines for uniting bodies into fabrics.
J. Machines for printing.
K. Machines for producing sound.
L. Miscellaneous machines.

It is not pretended that the above classification (taken to a considerable extent from the writings of Young and of Babbage) exhausts all kinds of machines; it is brought forward merely as an attempt to introduce method to a certain extent into a subject which would otherwise be exceedingly confused.

145. (A.) *Machines for Lifting and Lowering Solids.*—The most common machines of this class are *capstans*, *cranes*, and *windlasses*.

They are usually worked by manual labour, but sometimes by hydraulic engines, or by steam-engines. The useful resistance, when a load is lifted, being the weight of that load, is in general greater than the effort exerted by the prime mover, so that the mechanism has to be adapted to giving the working-piece a less velocity than the piece to which the effort is applied. In lowering solid loads the weight of the load acts as the effort, and the energy exerted by it is expended in overcoming the friction of a brake in order that the speed of descent may not be excessive.

146. (B.) *Transporting Machines.*—The mechanism of transporting machines consists of two parts:—that by which the resistance is diminished, as the wheels and axles of vehicles; and that by which the resistance is overcome and the load propelled, comprising all kinds of locomotive and propelling machinery. In the present work transporting machines are treated of in the articles relating specially to the lines of conveyance to which they are applied.

147. (C.) *Machines for Projecting Solids.*—This class comprehends all kinds of artillery.

148. (D.) *Machines for Lifting Fluids.*—See HYDROMECHANICS.

149. (E.) *Machines for Propelling or Projecting Fluids.*—See the same article.

150. (F.) *Machines for Dividing Bodies.*—This class comprehends all machines for separating solid masses into parts, whether by digging, cutting, sawing, grinding, tearing, crushing, pounding, pressing out fluids, or otherwise; and whether applied to earth, stones, metals, timber, fruit, grain, fibres, or other materials.

151. (G.) *Machines for Shaping Bodies by Removing Portions of them.*—This class of machines to a certain extent resembles the preceding. It includes machines for cutting, grinding, and polishing blocks of stone into required figures, and for shaping pieces of wood, metal, or other material, whether by *turning*, to produce spherical, cylindrical, and other curved surfaces,—by *boring, punching, slotting*, or *gouging*, to produce cylindrical, rectangular, or other orifices and grooves,—by *screw-cutting*, by *planing*, by *grinding* and *polishing*, to produce curved or plane surfaces. The most difficult and important of all these operations is to produce a surface truly plane; and the perfecting of this operation by Whitworth is the most important step recently made in *Constructive Mechanics*, or the art of making machines and instruments. Next in point of difficulty may be placed the art of forming the concave reflecting surfaces of great specula for telescopes, such as those of the Herschels, of Lassell, and of Lord Rosse.

152. (H.) *Machines for Shaping Bodies by Pressure* comprehend, amongst others, *rolling-mills* for iron, *steam-hammers*, *wire-drawing* machines, *pinmaking* and *nailmaking* machines, *coining* and other *stamping* machinery, *brickmaking* machines, *presses* for packing and compressing, &c.

153. (I.) *Machines for Uniting Bodies into Fabrics* comprise *spinning* machinery, whether applied to ropes, yarn, or thread, *weaving* machinery of all kinds, *papermaking* machinery, *felting* machinery, and *sewing* machinery.

154. (J.) *Machines for Printing* are used to apply either colouring matters or matters for discharging colour to paper, cloth, and other materials.

155. (K.) *Machines for producing Sound.*—See ACOUSTICS and MUSIC.

156. (L.) *Miscellaneous Machines.*—There are numerous machines which perform processes, especially in the preparation of textile fabrics for the market, which it would be almost impossible to class. Examples of such machines will be found by referring to the articles relating to the various branches of manufacture.

CHAPTER IV. APPLIED ENERGETICS, OR THEORY OF PRIME MOVERS.

157. *Prime Movers in general—Their Efficiency.*—Prime movers, or receivers of power, are those pieces or combinations of pieces of mechanism which receive motion and force directly from some natural source of energy. The point where the mechanism belonging to the prime mover ends and that belonging to the train for modifying the force and motion begins is somewhat arbitrary; in general, however, the mechanism belonging to the prime mover may be held to include all pieces which regulate or assist in regulating the transmission of energy from the source of energy. Thus, in the ordinary rotative steam-engine, the crank-shaft belongs to the prime mover, because it carries the eccentric which moves the valves and the fly-wheel which stores and restores the periodical excess of energy of the engine, and drives the governor (when there is one) which regulates the admission of steam.

The *useful work* of the prime mover is the energy exerted by it upon that piece which it directly drives; and the ratio which this bears to the energy exerted by the source of energy is the *efficiency* of the prime mover.

It is often convenient to divide the prime mover into sections, and resolve its efficiency into factors, each factor being the efficiency of one of those sections. Thus the efficiency of a steam-engine may be resolved into the following factors:—

Efficiency of the furnace and boiler,—being the proportion of the total heat of combustion of the fuel which takes effect in heating and evaporating the water.

Efficiency of the steam in driving the piston,—being the proportion of the energy exerted by the steam on the piston (called the *indicated* energy or power, as being measured by an indicator) to the mechanical equivalent of the heat received by the water.

Efficiency of the mechanism from the piston to the crank-shaft inclusive,—being the proportion of the effective energy transmitted by the crank-shaft to the indicated energy.

The product of those three factors is the efficiency of the engine as a whole.

In all prime movers the loss of energy may be distinguished into two parts,—one being the unavoidable effect of the circumstances under which the machine necessarily works in the case under consideration; the other the effect of causes which are, or may be, capable of indefinite diminution by practical improvements. Those two parts may be distinguished as *necessary loss* and *waste*.

The efficiency which a prime mover would have under given circumstances if the *waste* of energy were altogether prevented, and the loss reduced to necessary loss alone, is called the *maximum* or the *theoretical* efficiency under the given circumstances.

For some prime movers there is a combination of circumstances which makes the theoretical efficiency greater than any other combination does. The theoretical efficiency under those circumstances is the *absolute maximum efficiency*.

The *duty* of a prime mover is its useful work in some given unit of time, as a second, a minute, an hour, a day. In some cases, such as that of the work of animals, the duty can be ascertained, while the efficiency can only be inferred indirectly or conjecturally from the want of precise data as to the whole energy expended.

158. *Sources of Energy Classed.*—The sources of energy used in practice may be classed as follows:—

A. Strength of men and animals.
B. Weight of liquids.
C. Motion of fluids.
D. Heat.
E. Electricity and magnetism.

159. (A.) *Strength of Men and Animals.*—The *mechanical daily duty* of a man or of a beast is the product of three quantities—the effort, the velocity, and the number of units of time per day during which work is continued. It is well known that for each individual man or animal there is a certain set of values of those three quantities which make their product, the daily duty, a maximum, and that any departure from those values diminishes the daily duty. Attempts have been made to represent by a formula the law of this diminution; but they have met with imperfect success. That which agrees on the whole best with the facts is the formula of Maschek, which is as follows:—let P_1 be the effort, V_1 the velocity, and T_1 the time of working per day, which give the maximum daily duty, and let P, V, T, be any other set of values of those quantities; then

$$\frac{P}{P_1} + \frac{V}{V_1} + \frac{T}{T_1} = 3 \quad \ldots \ldots \quad (86).$$

One consequence of this formula is, that the best time of working per day for men, and for all animals, is *one-third part of a day*, or eight hours,—a conclusion in accordance with experience.

The best effort P_1, and the best velocity V_1, are much less certain,—the difficulty of determining their true mean values for particular species being rendered very great by the differences, not only between individuals, but between races or varieties of the same species. The following table of values is proposed by Maschek as approximately true:—

Animals.	Weighing	P_1.	V_1.	$\frac{T_1}{3600}$.	P_1V_1.	$P_1V_1T_1$.
		lb.	Feet per second.	Hours per day.	Foot-lb per sec.	Foot-lb.
Man	150 lb	30	2·5	8	75	2,160,000
Horse (draught)	600 lb	120	4·0	8	480	13,824,000
Ox	600 lb	120	2·5	8	300	8,640,000
Ass	360 lb	72?	2·5	8	180	5,184,000?
Mule	500 lb	100?	3·5	8	350	10,080,000?

Of the numbers in this table those for the draught horse are probably the most accurate. For the thoroughbred horse it is certain that the value of V_1 is much greater, and that of P_1 much less, than for the draught horse,—the effect being probably that the *maximum* daily duty $P_1V_1T_1$ is nearly the same; but experimental data are wanting to determine these quantities with precision.

The following table, chiefly extracted from the works of Poncelet and Morin, with the addition of some results of experiments by Lieutenant David Rankine and by the author of this article, shows the daily duty of men and horses under certain specified circumstances:—

	P.	V.	$\frac{T}{3600}$.	PV.	PVT.
	lb.	Feet p. sec.	Hours p. day.	Foot-lb per sec.	Foot-lb per day.
MAN—					
1. Raising his own weight up stair or ladder	143	0·5	8	72·5	2,088,000
2. Do. do. do.	...	...	10	...	2,616,000
3. (Tread-wheel—see 1)					
4. Hauling up weight with rope	40	0·75	6	30	648,000
5. Lifting weights by hand	44	0·55	6	24·2	522,720
6. Carrying weights up stairs	143	0·13	6	18·5	399,600
7. Shovelling up earth to a height of 5 ft. 3 in.	6	1·3	10	7·8	280,800
8. Wheeling earth in barrow up slope of 1 in 12; ½ horiz. veloc. 0·9 ft. per sec. (returning empty)	132	0·075	10	9·9	356,400
9. Pushing or pulling horizontally (capstan or oar)	26·5	2·0	8	53	1,526,400
10. Turning a crank or winch	12·5 18·0 20·0	5·0 2·5 14·4	? 8 2 min.	62·5 45 288	1,296,000
11. Working pump	13·2	2·5	10	33	1,188,000
12. Hammering	15	?	8?	?	480,000
HORSE—					
13. (Thoroughbred) cantering and trotting, drawing a light railway carriage	min. 22·5 mean 30·5 max. 50	14·6	4	417·5	6,444,000
14. Horse (draught) drawing cart or boat, walking	120	3·6	8	432	12,441,600

160. *Horizontal Transport.*—When men and animals carry burdens, or draw or propel loads in certain vehicles, it is difficult, and sometimes impossible, to determine the duty performed in foot-pounds of work, because of the uncertainty of the amount in pounds of the resistance overcome. In this case, for the purpose of comparing performances of the same kind with each other, a unit is employed called a *foot-pound of horizontal transport*, meaning the conveying of a load of 1 pound 1 foot horizontally. The following table, compiled from the sources referred to in sect. 159, gives some examples of the daily duty of men and horses in units of horizontal transport, L denoting the load in lb, V the velocity in feet per second, and T the number of seconds per day of working:—

	L.	V.	$\frac{T}{3600}$.	LV.	LVT.
	lb.	Feet per second.	Hours per day.	lb conveyed 1 foot.	lb conveyed 1 foot.
MAN—					
15. Walking unloaded, transport of own weight	140	5	10	700	25,200,000
Do. do.	140	6	10	840	30,240,000
16. Wheeling load L in two-wheeled barrow, returning empty; V = ½ velocity	224	1·6	10	373	13,428,000
17. Do. one-wheeled barrow, do.	135	1·6	10	225	8,100,000
18. Travelling with burden	90	2.5	7	225	5,670,000
19. Conveying burden, returning unloaded	140	1·6	6	233	5,032,800
20. Carrying burden for 30 seconds only	252 126 0	... 11·7 23·1	... ...	... 1474·2 0	... ...
HORSE—					
21. Walking with cart always loaded	1500	3·6	10	5400	194,400,000
22. Trotting do. do.	750	7·2	4½	5400	87,480,000
23. Walking with cart, going loaded, returning empty; V = ½ mean velocity	1500	2·0	10	3000	108,000,000
24. Carrying burden, walking	270	3·6	10	972	34,992,000
25. Do. trotting	180	7·2	7	1296	32,659,200

161. (B.) *Weight of Liquids.*—(C.) *Motion of Fluids.*—In water-wheels and other hydraulic engines the weight and motion of a liquid usually act together as sources of energy.

To determine the necessary loss of energy and the theoretical efficiency, we have the following formulæ:—

The *power* or *energy* exerted per second is

$$Q\left(H + \frac{V_1^2}{2g}\right);$$

the *necessary loss* —

$$Q \cdot \frac{V_2^2}{2g};$$

the *theoretical effect* or *useful work* per second—

$$Q\left(H + \frac{V_1^2 - V_2^2}{2g}\right);$$

the *theoretical efficiency*—

$$\left(H + \frac{V_1^2 - V_2^2}{2g}\right) \div \left(H + \frac{V_1^2}{2g}\right) \qquad (87);$$

where Q denotes the weight of liquid which acts on the wheel or other engine per second; H the vertical fall from the point where the liquid first begins to act directly or indirectly on the wheel or other engine to the point where it ceases to act; V_1 the velocity of the liquid when it begins to act; and V_2 the least velocity, when it ceases to act, which will properly discharge the liquid, and prevent its accumulating so as to impede the wheel or engine.

(For details as to the actual efficiency and duty and the construction of hydraulic engines, see HYDROMECHANICS.)

In *windmills*, the air, being in motion, presses against and moves four or five radiating vanes or *sails*, whose surfaces are approximately helical, their axis of rotation being parallel, or slightly inclined in a vertical plane, to the direction of the wind. The best form and proportions for windmill sails, as determined experimentally by Smeaton, are as follows (see fig. 36):—

Angle of each sail with the plane of rotation—at DE = 18°;
Do. do. do. at BC = 7°;
OD = ⅙ of *whip* OA; bar DE = ⅕OA; bar BC = ⅓OA; AC = DE.

162. (D.) *Heat.*—In sect. 157 the three factors into which the efficiency of an engine moved by heat can be resolved have already been stated. The efficiency of the furnace and boiler in steam-engines varies from 0·4 to 0·85. It may be considered that the loss of heat to the extent of 0·15 by the chimney is necessary in order to produce a sufficient draught; any loss beyond this is *waste.* The theoretical efficiency of the *steam,* or *other elastic fluid,* which serves as the mechanism for converting heat into mechanical energy, is regulated by a law which will now be explained.

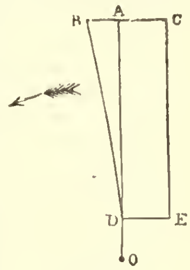

Fig. 36.

Heat acts on bodies in two ways—to elevate temperature and make the bodies hotter, and to produce mechanical changes. Heat employed in producing mechanical changes disappears or becomes *latent,* as it is termed, and can be reproduced by reversing those mechanical changes. When a cycle of mechanical changes, ending by the restoration of the body to its original condition, produces mechanical energy, heat disappears to an amount equal to that which would be generated by employing the mechanical energy in overcoming friction,—that is to say, a British unit of heat (or one degree Fahr. in one lb of liquid water) for every 772 foot-pounds of energy (being the constant already mentioned in sect. 115 as *Joule's equivalent*). This is called the *conversion of heat into mechanical energy.*

The *efficiency of the fluid* in a heat-engine is the proportion which the heat converted into mechanical energy bears to the whole heat received by the water or other fluid; and the *theoretical* or *maximum* value of that efficiency depends solely upon the respective temperatures at which the fluid receives heat and rejects the unconverted heat, according to the following law:—let t_1 represent the temperature at which the fluid receives heat, and t_2 the temperature at which it rejects the unconverted heat, as measured from the *absolute zero,*—that is, from a point 493°·2 Fahr. or 274° C. below the temperature of melting ice (temperatures so measured are called *absolute temperatures*); then the *maximum theoretical efficiency of the water or other fluid in a steam-engine or other heat-engine is*

$$\frac{t_1 - t_2}{t_1} \qquad (88).$$

The necessary loss of heat by the fluid is t_2/t_1 of the whole heat received by it; and any loss beyond this is *waste.*

The theoretical efficiency of the steam in ordinary steam-engines seldom exceeds ⅕th; the greatest actual efficiency is about ⅛th; the efficiency in good ordinary engines is about 0·1 or 0·08, and in bad and wasteful engines 0·04, or even less. (For details see STEAM-ENGINE.)

163. (E.) *Electricity and Magnetism.*—Electricity developed by chemical action in a galvanic battery has been to a small extent used to produce mechanical energy by alternately magnetizing and unmagnetizing soft-iron bars.

The data for determining the actual efficiency of such engines are deficient. Their theoretical efficiency depends on the following law demonstrated by Joule:—

Let γ_1 denote the strength of the electric current which would be developed in the conducting wire of the battery if there were no iron bar to be magnetized; γ_2 the strength to which the current is reduced by the reaction of the iron bar, tending to induce a contrary current. Then the theoretical efficiency of the engine is

$$\frac{\gamma_1 - \gamma_2}{\gamma_1} \qquad (89).$$

The proportion of the energy expended which is *necessarily lost* is γ_2/γ_1, and is employed in producing heat in the conducting circuit.

This law is exactly analogous to that of the theoretical efficiency of heat-engines given in equation 88.

There is reason to believe that electromagnetic engines are capable of a higher efficiency than heat-engines; but the greater cost of the materials consumed renders them much less economical commercially.

(W. J. M. R.)

MECHITHARISTS, a congregation of Armenian monks, in communion with the church of Rome, which has enjoyed papal recognition since 1712. Its founder Mechithar, or Mechitar da Pietro, a native of Sebaste (Sivas) in Armenia, was born on February 7, 1676; his original name was Manuk, which he exchanged for that by which he was subsequently known ("Comforter") when he entered the cloister of the Holy Cross in his native town. In the pursuit of knowledge he visited various seats of learning in Armenia, and in the years 1691, 1696, and 1699 respectively he attained the office of deacon, priest, and vartabed or doctor in theology. Having removed to Constantinople, he founded there in 1701 a religious institute for the intellectual, moral, and spiritual elevation of his countrymen, and for the cultivation of their language and literature. In 1703 sectarian jealousy obliged him to retire to the Morea, where he ultimately found a settlement at Modon, and built a cloister and church (1706-8). The outbreak of hostilities between the Turks and Venetians in 1715 compelled him to take refuge in Venice, where in 1717 he received from the senate the island of San Lazzaro, which ever since has been the home of his order. Mechithar, who died on April 27, 1749, was the author of a *Grammatica Armena*, printed in 1770, of an Armenian *Lexicon*, printed in 1744, of an Armenian translation of the Bible, printed in 1734, and of several commentaries on Biblical books. The order of Mechitharists, which, as already mentioned, received formal recognition (from Clement XI.) in 1712, uses the Armenian language and the Syrian rite; its rule resembles the Benedictine, prominent among the duties of its members being the proclamation of the gospel and the diffusion of good literature. They have accumulated at San Lazzaro a large library, specially rich in Armenian MSS.; and their linguistic attainments are considerable. Among their services to the cause of learning may be mentioned, in addition to the preparation of critical texts of the Armenian classics and of the Armenian version of the Bible, the publication in old translations of various works of Ephraem Syrus, Philo, and Eusebius, of which the originals have been lost. There are establishments belonging to the order elsewhere in Italy (Padua), as well as in Russia and Turkey, in Paris, in Austria-Hungary, and in Germany. Of these the most important is that of Vienna, which has existed since 1810, and has become a sort of learned "academy," receiving honorary members even from beyond the pale of the Roman Catholic Church.

MECHLIN, or MALINES, a city of Belgium, in the province of Antwerp, on the river Dyle, about 14 miles north of Brussels. The general aspect of the town, belted by a fine avenue of trees, with well-built houses, extensive gardens, and broad airy streets and squares of proverbial cleanliness, is pleasing to the eye; there is, however, a lack of life and motion, a repose bordering on stagnation; and the area occupied by the town is much too extensive for the population. Mechlin was for many centuries, and is to this day, the religious metropolis of Flanders, and its monuments and curiosities are in general of a sacred description. Among the most remarkable is the cathedral church of St Rombold or Rombaut, mainly built in the latter half of the 14th century; the square massive tower, rising 300 feet high and bearing four dials, each 48 feet in diameter, is visible from all the country round. The interior proportions of the edifice are grand, and it contains some fine works of art—statues of the apostles, standing against the pillars of the nave, Vandyck's picture of the Crucifixion, the Adoration of the Shepherds, by Erasmus Quellin, and others. The church of St John possesses a celebrated triptych of Rubens, and another by the same master is to be seen at Notre Dame. The "Halle" or market still retains some vestiges of the splendid palace raised on the site by Charles V. in 1530, and on the chief market-place is a monument erected to Margaret of Austria, daughter of the emperor Maximilian. Mechlin is an archiepiscopal see, occupied by a cardinal, primate of Belgium, deriving his spiritual power from Rome, and quite independent of (at times even openly opposed to) the civil Government. His palace is the headquarters of the Catholic party, and the seat of considerable moral and political influence extending over every parish in the land; the university of Louvain, the Catholic schools, more than four thousand in number, and the great seminary of Mechlin, the nursery of the Belgian priesthood, are entirely under the direction of the archbishop. The industrial activity of the town, formerly very great, has constantly decreased in the present century, and is now almost extinct. The important corporation of weavers was scattered by the political troubles of the 15th and 16th centuries; and the lace trade has gradually been transferred to Brussels and other towns. There still exist a few special manufactures, those of carved oak furniture, straw chairs, and wool and linen tissues being among the foremost; some tanyards and breweries are also to be found, and the means of communication furnished by the Dyle supply a tolerably brisk market in corn, oils, flax, hemp, and hops. As a railway station Mechlin possesses peculiar importance, being a junction of the chief Belgian Government lines and the great central workshop for constructing and repairing the rolling-stock. The population of Mechlin in 1880 was 42,381.

Mechlin appears to have been about the 8th century a mere group of cabins surrounding a noted monastery where St Rombaut, now the patron saint of the town, suffered martyrdom on the 24th of June 775. After having belonged to the first Frankish monarchs, it was given by Pippin the Little to his relative Adon, and passed, at the commencement of the 10th century, under the dominion of the bishops of Liége, in whose name it was governed by the powerful house of Berthold until the year 1333. When this family became extinct, Mechlin and the surrounding district were divided in two portions and sold by the bishops to the duke of Brabant and the count of Flanders, the former of whom, ten years later, once more united the whole territory under his own sway. By the marriage of Margaret of Brabant with Philip the Bold, Mechlin was brought under the sceptre of the house of Burgundy, whose fate it shared from that time. Stormed by the French in 1572, by the prince of Orange in 1578, by the English in 1580, the town suffered much during the wars of the 17th and 18th centuries. Napoleon I. had its fortifications razed in 1804, and made it the capital of the French "Département des deux Nèthes" until 1814, when it was comprised in the kingdom of the Netherlands, and it finally became part of Belgium in 1830.

MECKLENBURG, a territory in North Germany, on the Baltic Sea, extending from 53° 4′ to 54° 24′ N. lat., and from 10° 35′ to 13° 57′ E. long., corresponds with tolerable closeness to the old lower Saxon province of the same name, and is now unequally divided into the two grand-duchies of Mecklenburg-Schwerin and Mecklenburg-Strelitz. These are so closely related in history, political organization, natural features, and general development that it is convenient to treat them in a single article.

MECKLENBURG-SCHWERIN, the seventh state of the German empire in size and the eighth in population, is bounded on the N. by the Baltic Sea, on the W. by the principality of Ratzeburg and Lauenburg, on the S. by Brandenburg and Hanover, and on the E. by Pomerania and Mecklenburg-Strelitz. It embraces the duchies of Schwerin and Güstrow, the district of Rostock, the principality of Schwerin, and the barony of Wismar, besides several small "enclaves" in the adjacent territories. Its total area is about 5117 square miles.

MECKLENBURG-STRELITZ, the eleventh state of the German empire in area and the nineteenth in population, consists of two detached parts, the duchy of Strelitz on the east of Mecklenburg-Schwerin and the principality of

Ratzeburg on the west. The first of these is bounded by Mecklenburg-Schwerin, Pomerania, and Brandenburg, the second by Mecklenburg-Schwerin, Lauenburg, and the territory of the free town of Lübeck. Their joint area is 1126 square miles.

Mecklenburg lies wholly within the great North-European plain, and its flat surface is interrupted only by one range of low hills, intersecting the country from south-east to north-west, and forming the watershed between the Baltic Sea and the Elbe. Its highest point, the Helpter Berg, is 580 feet above the sea-level. The coast-line runs for 65 miles along the Baltic (without including indentations), for the most part in flat sandy stretches covered with dunes. The chief inlets are the bays of Wismar, Grosse Wiek, Salzhaff, and Kroy, and the roads of Warnemünde. The rivers are numerous though small; most of them are affluents of the Elbe, which itself traverses a small portion of Mecklenburg. Several of the streams are navigable, and the facilities for inland water traffic are increased by a tolerably extensive system of canals. Lakes are very numerous; about four hundred of fair size, covering an area of 500 square miles, are reckoned in the two duchies. The largest is Lake Müritz, 52 square miles in extent. The climate on the whole resembles that of Great Britain, but the winters are generally more severe; the mean annual temperature is 48° F., and the annual rainfall is about 28 inches. Although there are long stretches of marshy moorland along the coast, the soil is on the whole productive. According to the official returns of 1878, about 57 per cent. of the total area of Mecklenburg-Schwerin consisted of cultivated land, 17 per cent. of forest, and 13 per cent. of heath and pasture. In Mecklenburg-Strelitz the corresponding figures were 48, 20, and 9 per cent. Agriculture is by far the most important industry in both duchies. The following table shows the areas and products of the chief crops in 1880:—

Crops.	Mecklenburg-Schwerin.		Mecklenburg-Strelitz.	
	Acres.	Tons.	Acres.	Tons.
Rye	411,627	243,818	68,530	29,619
Oats	285,257	188,166	49,422	26,743
Wheat	108,550	43,420	26,240	93,378
Barley	44,687	33,487	10,722	7,244
Potatoes	92,942	345,233	16,440	70,537
Hay	259,497	333,737	46,805	93,464
Totals	1,202,560	1,187,861	218,159	320,985

Besides these, smaller areas are devoted to maize, buckwheat, pease, rape, hemp, flax, hops, and tobacco. The extensive pastures support large herds of sheep and cattle, including a noteworthy breed of merino sheep. The horses of Mecklenburg are of a fine sturdy quality, and are highly esteemed in Germany. In 1878 the two duchies contained 100,651 horses, 315,712 cattle, and 1,321,916 sheep. Red deer, wild swine, and various other kinds of game are found in the forests. The manufactures of Mecklenburg are of little importance. Its industrial establishments include a few iron foundries, wool-spinning mills, carriage and machine factories, dye-works, tanneries, brick-fields, soap-works, breweries, distilleries, numerous limekilns and tar-boiling works, tobacco and cigar factories, and about eight hundred mills of various kinds. Mining is also insignificant, though a fair variety of minerals is represented in the district. Amber is found on and near the Baltic coast. Trade, mainly confined to the larger duchy, is tolerably active. Rostock, Warnemünde, and Wismar are the principal commercial centres. The chief exports are grain and other agricultural produce, live stock, spirits, wood, and wool; the chief imports are colonial produce, iron, coal, salt, wine, beer, and tobacco. The horse and wool markets of Mecklenburg are largely attended by buyers from various parts of Germany. Fishing is carried on extensively in the numerous inland lakes. Within the last decade the mercantile fleet of Mecklenburg-Schwerin has doubled the number and quadrupled the tonnage of its ships, these consisting in 1881 of 370 sailing vessels and 11 steamers, with an aggregate burden of 112,388 tons. Mecklenburg-Strelitz has no seaboard.

Mecklenburg-Schwerin and Mecklenburg-Strelitz are both limited monarchies under grand-dukes, who are hereditary in the male line. The reigning families are closely related, and possess mutual rights of succession; should both families become extinct, their possessions pass to Prussia. The constitution, which is common to both the duchies, exhibits few traces of the liberal tendency of modern politics. The temporary modifications brought about by the agitation of 1848 were quickly rescinded, and matters returned to the old semi-feudal arrangements, which deprive the bulk of the people of all share in the government. The constitution as it now exists is based upon an agreement made between the duke of Mecklenburg-Schwerin and his estates in 1755, and adopted in the same year by Mecklenburg-Strelitz. The Landes-Union, or common assembly of the two duchies, consists of representatives of the Ritterschaft, or landed proprietors, and of the Landschaft, which embraces forty-seven towns. The peasantry is unrepresented, and the principality of Ratzeburg, in Mecklenburg-Strelitz, is governed directly by the grand-duke. The Landes-Union meets once annually, alternating between Sternberg and Malchin. When not sitting it is represented by a committee of nine members. Distinct from the Landes-Union are the convocation diet and the deputation diet, which are assemblies of the estates of one or other duchy for special business. In Mecklenburg-Schwerin the executive is placed in the hands of four ministers, holding the portfolios of foreign affairs, domestic affairs, finance, and justice (including education and religion). In Mecklenburg-Strelitz there is one minister, who is aided by a small council. In both duchies the military administration is in the hands of the crown. Mecklenburg-Schwerin has two votes in the federal council of the German empire, and sends six members to the imperial diet, while the smaller duchy has one representative in each assembly. As no official budget is published in either duchy, it is impossible to give accurate details of their financial position. In Mecklenburg-Schwerin it is usual to distinguish three branches of revenue, one under the control of the sovereign, one under the joint control of the sovereign and estates, and the third (of small amount) under the sole management of the estates. The income under the first heading is derived from the royal domains, the ordinary taxes, and special votes for special purposes, and amounts to about £600,000. With this sum are defrayed the ordinary expenses of government, including the annual contribution to the imperial treasury. The revenue under the second head is about £100,000. The public debt in 1880 amounted to £1,100,000. The revenues of Mecklenburg-Strelitz are unknown; its debt is estimated at about £300,000. The private income of the duke, derived from the royal domains, makes him one of the richest princes in Germany. The duchies of Mecklenburg contribute three regiments of infantry, a battalion of rifles, two regiments of dragoons, and four batteries of field artillery to the imperial army.

The educational institutions partake of the high character common to those of the German empire. The two duchies contain nine gymnasia, seven "Realschulen," three normal schools, and an adequate number of schools of a lower grade. There is a university at Rostock, which in 1882 had a teaching staff of 36 professors and an attendance of about 250 students. In 1880–81 only 0·56 per cent. of the recruits in Mecklenburg-Schwerin were unable to read and write their names, while all the recruits in Mecklenburg-Strelitz were able to do both. The predominant confession in Mecklenburg is the Lutheran, which is professed by both the grand-dukes. The proportion of Roman Catholics, Jews, and members of the Reformed Church is insignificant. The ultimate spiritual authority is exercised by consistories at Schwerin and Strelitz. Mecklenburg also contains a fair share of learned societies and benevolent institutions. The supreme court of appeal for both duchies, in all criminal and civil cases, is at Rostock.

The population of Mecklenburg-Schwerin in 1861 was 548,449; in 1871, 557,707; in 1875, 553,785; and in 1880, 577,055. The capital is Schwerin (30,146 inhabitants), but the most important town is Rostock (36,967 inhabitants). The population of Mecklenburg-Strelitz in 1861 was 99,060; in 1871, 96,982; in 1875, 95,673; in 1880, 100,269. The chief town is Neu-Strelitz. About 71 per cent. of the inhabitants are engaged in agricultural pursuits. The proportion of the rural to the urban population is as 3 to 1, or exactly the reverse ratio to that in the neighbouring Prussia. The peasantry of Mecklenburg still retain numerous traces of their Slavonic origin, especially in their speech, but their peculiarities have been much modified by amalgamation with the German colonists who settled within this district at various times. The townspeople and nobility are almost wholly of Saxon strain. The slow rate of increase in the population of Mecklenburg is chiefly accounted for by the constant stream of emigration. Between 1870 and 1880 the two duchies contributed in the highest proportion to the emigration from Germany. Out of 595,151 German emigrants who sailed from Bremen, Hamburg, Stettin, and Antwerp within that period, 24,870 came from Mecklenburg-Schwerin and 2481 from Mecklenburg-Strelitz, representing respectively 4·38 and 2·52 per 1000 inhabitants as the yearly average. Probably another cause of the slow growth of population is to be sought for in the difficulties thrown in the way of the marriage of the peasants by the semi-feudal character of their tenure. It is a significant fact that in 1880 the proportion of illegitimate births in the two duchies amounted to 14 per cent. as compared with 9 per cent. in the entire German empire.

History.—The Vandals, who in the time of Tacitus occupied the region now known as Mecklenburg, were succeeded in the 6th century by a Slavonic race. Though partly conquered by Charlemagne in 789, this people soon regained their independence, and long offered a successful resistance to all attempts on the part of the German emperors to overcome and Christianize them. At last, in 1160, Duke Henry of Saxony made himself master of the country. The native prince was, however, permitted to retain his sovereignty, and has transmitted to his descendants and successors of the present day the distinction of being the only ruling princes of Slavonic origin in Germany. In 1160 he was raised by the emperor Frederick I. to the dignity of a prince of the empire. From 1202 till 1227 Mecklenburg was under Danish supremacy; and in 1229, two years after its restoration to Germany, there occurred the first of a long series of divisions of the territory, which, with subsequent reunions, constitute so much of its complicated history. In 1348 Charles IV. made Mecklenburg a duchy. In 1523 the trials and commotions springing from the rivalry and jealousy of two joint rulers incited the prelates, nobility, and burghers to form a union among themselves, the effects of which are visible to the present day,—most prominently in the existence of the common Landes-Union. The Reformation was welcomed by the inhabitants of Mecklenburg in 1524; and about 1555 nearly all the monasteries were suppressed. In 1621, when a new partition took place, the town of Rostock "with its university and high court" was declared to be held in common. The diet also retained its joint character, and henceforth alternated between Sternberg and Malchin.

In the Thirty Years' War both Mecklenburg-Schwerin and Mecklenburg-Güstrow—as the parts were then called—incurred the suspicion of the emperor, who secretly sold them to Wallenstein, and expelled the dukes in his behalf. They were reinstated, however, by Gustavus Adolphus, and at the peace of Prague in 1635 they both made their peace with the emperor. At the peace of Westphalia Rostock and some other parts of Mecklenburg territory were given in pledge to Sweden, and they were not redeemed till 1803. The sufferings of the Mecklenburg peasantry during the Thirty Years' War were exceeded in no other part of sorely-tried Germany. Most were reduced to serfdom through poverty; in some cases whole villages utterly vanished. In 1695 the Mecklenburg-Güstrow line became extinct; and, after some contention between the brother and the nephew of the last duke of Mecklenburg-Schwerin for the vacant succession, the "Hamburg Division" (March 8, 1701) apportioned to each shares that are represented by the present duchies. The affixes Schwerin and Strelitz are derived from the capital towns of the two dukes.

Mecklenburg-Schwerin began its new independent existence by a series of constitutional struggles between its nobility and its rulers. The heavy debt incurred by Charles Leopold, who had joined Russia in a war against Sweden, brought matters to such a pitch that in 1728 the emperor Charles VI. deposed the duke in favour of his brother Christian Louis. Under this prince, the "Rostock Contract," which is still the basis of the constitution, was framed in 1755. During the Seven Years' War Mecklenburg-Schwerin assumed a hostile attitude towards Frederick the Great, and was in consequence occupied by Prussian troops. In 1806 it was overrun by the French, and in 1808 it joined the confederation of the Rhine. The duke, however, though he assisted Napoleon in 1812, was the first member of the confederation to renounce it, and in the following year his troops fought against France and Denmark. On joining the Germanic confederation he assumed the title of grand-duke, with the style of royal highness. In and after 1818 the duchy witnessed a considerable agitation in favour of a new and more liberal constitution, but the subsequent reaction rescinded all the concessions that had been made, and reduced matters to their former feudal condition. In 1819 and 1820 serfdom and personal bondage were abolished, and various slight ameliorations of the state of the peasantry have since been introduced.

Mecklenburg-Strelitz adopted the constitution of the sister duchy by an "Agnitions-Act" in 1755. In 1806 it was spared the infliction of a French occupation through the interest of the king of Bavaria; but in 1813 it was mulcted in the sum of two million thalers for the French army. In 1808 it entered the Rhenish confederation, but repudiated it in 1813 and joined the alliance against Napoleon. In 1815 the duke assumed the title of grand-duke.

MEDALS. See NUMISMATICS.

MEDEA, the daughter of Æetes, king of the Colchians, who were believed to be of Egyptian descent (Herod., ii. 104), and are said to have found a settlement on the east of the Euxine and to the south of the Caucasus. Medea was one of the "wise women" (witches or sorceresses) of antiquity, and perhaps, like Helen, was a human embodiment of some goddess connected with Eastern element-worship, possibly with Hera. For the story of her love for Jason the Argonaut, and of the revenge she took for his desertion of her for another bride, a Corinthian princess, Glauce, daughter of Creon, see ARGONAUTS and JASON. A more interesting inquiry is the origin of the tale, and its connexion with solar myths.

The legend of the Argonautic expedition is a very ancient one. It is alluded to in the *Odyssey* (xii. 70), in more than one passage of Æschylus,[1] and is given at some length in the fourth Pythian ode of Pindar, the close agreement of which with the Alexandrine compilation by Apollonius Rhodius, entitled *Argonautica*, in four books, shows that, according to the general law of mythology, the main features of the legend differed but little. The original story, it is probable, was contained in a still older epic poem called ἡ Ναυπακτία ποίησις...

The "Golden Fleece," in quest of which the adventurers

[1] He alludes to Phineus and the *Lemnia facinora* (*Eum.* 50; *Cho.* 620), and there were plays composed by him on both these subjects.

[2] Pausan., iv. 33, 7. He quotes from it two hexameter verses in x. 28, 2.

made a voyage from the home of Jason, Iolchus in the Thessalian Magnesia, is virtually identical with the fiery robe which Medea prepared for her rival Glauce, the new bride, with the Homeric "ægis," and with the garment smeared with phosphorus which was sent by Deianira to Hercules, and burst into a flame when brought near to a sacrificial fire.[1] Jason, as the story went, was not allowed by the guardian of the fleece, King Æetes, to approach it till he had performed a certain task in putting to the yoke fire-breathing bulls, which he effected by the aid of Medea. The bull is a well-known symbol of the sun, and it occurs in the bull-slaying group representing the Persian sun-god Mithras. Again, the slaying of a father by a son (the old sun killed by the new one) is seen alike in Œdipus having caused the death of his father Laius, in Æson, the father of Jason, having been restored to life by the magic arts of Medea, and in Pelias having been killed and boiled in a caldron by his own daughters at the instigation of the sorceress. Lastly, the legend that Medea was herself the granddaughter of the Sun, and that she escaped in a car drawn by flying dragons, given to her for safety by her grandsire,[2] equally tends to prove that the whole story is of solar origin, and can be explained on that theory alone.

This, indeed, has been well stated by Sir G. W. Cox.[3] The "dragon chariot is simply the chariot of Indra, Helios, and Achilles; and it is drawn by dragons because the word denoted simply beings of keen sight, and was naturally applied to the creatures which may be supposed to bear the sun across the heaven."

In all these legends about the sun the performance of certain imposed "toils" or labours is included, the idea expressed being the hard necessity of the sun going his daily course in the appointed time in spite of thickening storm-clouds and opposing powers of darkness, through which he has to fight his way, both visibly above and invisibly underneath the earth. Thus Hercules has his twelve labours (the number corresponding to the lunar months), while Jason is not only required by his uncle King Pelias to bring the golden fleece, but is commanded by Æetes to tame the bulls as a condition of obtaining it. The name Μήδεια may possibly be referred to *μήδεσθαι*, "to care for," as Jason may contain the root *ἰᾶσθαι*, "to heal," which is the meaning that Pindar attaches to it,[4] or to *ἴον*, the violet-coloured dawn, as in Iocaste, Iamos, and Iolaus.[5] In his relation to the snake, which guarded the fleece, and to the dragons' teeth which he sowed on the ground ploughed by the fiery bulls, compared with the serpent entwining the staff of the healing god Asclepius, we see that almost invariable connexion that subsists between solar and phallic worship.[6] This view is confirmed by the "ship Argo," one of the many sexual symbols of cup-shaped and boat-like form.[7] It is the "ship" which was the Teutonic symbol of the goddess Isis.[8]

The existing literature on the love of Medea for Jason shows how popular was the story in antiquity for its pathos and its sentimentality. Thus the *Medea* of Euripides was rendered by Ennius; Neophron of Sicyon and Melanthius[9] wrote plays of the same name; we have the long and fine Pythian ode of Pindar, already referred to, the touching epistle "Medea Jasoni" in the *Heroides* of Ovid, and the interesting, beautiful, and too little read *Argonautica* of Apollonius.

Of course, the similarity of the names Μῆδοι and Μήδεια led to etymological speculations on the identity of the nomenclature, and one Medus, a son of Medea, was believed to have been an eponym hero.[10] The author of the compilation known as Hesiod's *Theogony* says that Medeus was a son of Medea by Jason,[11] and was brought up, as Jason himself had been, by Chiron in the mountains. Euripides assigns but two children to Medea and Jason,[12] and Apollodorus[13] gives their names as Mermerus and Pheres.

MEDELLIN, a town of Colombia, South America, capital of the state of Antioquia, is situated at a height of 4845 feet above the sea, in the valley of the Rio Porce, a right-hand tributary of the Rio Cauca, and, though 100 miles from the confluence, not more than 16 miles east from the valley of the larger stream. It is a clean and well-built place, but has no public buildings of note. Though the population is estimated at 14,000, there is no great activity except on the market days, twice a week, when the buyers and sellers flock in from the country. See Fr. von Schenck in *Petermann's Mittheil.*, 1880.

MEDFORD, a town of the United States, in Middlesex county, Massachusetts, at the head of navigation on Mystic river, and 5 miles north-west of Boston by a branch of the Boston and Maine Railroad. It is a busy place, with a considerable variety of manufactures—woollens, carpets, buttons, bricks, leather, &c. Tufts College, situated near the town on Walnut Hill, was founded by the Universalists in 1853, and named in honour of Charles Tufts, the donor of the 70 acres occupied by the building and its grounds. The endowment amounts to more than $1,000,000. The population of Medford was 5717 in 1870 and 7537 in 1880.

MEDHURST, WALTER HENRY (1796–1857), one of the most distinguished Protestant missionaries to the Chinese, was born in London in 1796. His education began at St Paul's Cathedral school. As he grew up, he learned the business of a printer; and, having become interested in missions to the heathen, he sailed in 1816 for the London Missionary Society's station at Malacca, which was likely to be a great printing-centre. His linguistic powers soon showed themselves. He became proficient in Malay, in a knowledge of the written characters of Chinese, and in the colloquial use of more than one of its dialects. He was ordained at Malacca in 1819, and was in all missionary labours "more abundant,"—first at Penang, then at Batavia, and finally at Shanghai. To give only the names of his various works, some in English, some in Chinese, would take a considerable space. A dictionary of one of the Fuh-Kien dialects is still valuable; and his Chinese-English and English-Chinese dictionaries (Batavia, 1842) are more complete and reliable than any earlier or later works of the same kind. After the conclusion of the first English war with China he removed to Shanghai in 1843, and there he continued till 1856, laying the foundations, broad and deep, of a successful mission. His principal labour for several years, as one of a committee of delegates of whom he was *facile princeps*, was in the revision of existing Chinese versions of the Sacred Scriptures. The result was what should be called a new version of the Bible, marvellously correct in idiom, and faithful to the meaning of the original. The university of New York conferred upon him in 1843 the degree of D.D. Medhurst left Shanghai in 1856, with several members of his family, to try the effect of a visit to England for his failing health. He died, however, two days after reaching London, on the 24th January next year. Strong, sprightly, versatile, and genial, he was a man of extraordinary gifts and generous soul. No efforts (and many were made) could draw him from his devotion to the work of missions.

[13] *Bibl.*, i. 9, 28.

MEDICAL JURISPRUDENCE, or, as it is now more usually termed, Forensic Medicine, is that branch of state medicine which treats of the application of medical knowledge to the purposes of the law. The term medical jurisprudence, though sanctioned by long usage, is not an appropriate one; since the subject is, strictly speaking, a branch of medicine rather than of jurisprudence; it does not properly include sanitation or Hygiene (*q.v.*), both this and medical jurisprudence proper being distinct branches of state medicine. The connexion between medicine and the law was perceived long before medical jurisprudence was recognized, or had obtained a distinct appellation. It first took its rise in Germany, and subsequently, but more tardily, received recognition in Great Britain.

Forensic medicine, or medical jurisprudence proper as distinguished from hygiene, embraces all those questions which bring the medical man into contact with the law, and embraces (1) questions affecting the civil rights of individuals, and (2) injuries to the person.

I. Questions Affecting the Civil or Social Rights of Individuals.

1. *Development of the Human Frame.*—The development of the physical and mental powers of the human being is a matter of the highest importance, and is a factor of great consequence in determining criminal responsibility, civil responsibility, or the power of giving validity to civil contracts, and in determining the personal identity of a living person or of a corpse. Human life is usually divided into the five periods of *infancy*, *childhood*, *youth*, *manhood*, and *old age*. Some writers increase the number of these, unnecessarily, to seven periods, without any practical advantage.

Infancy is the period from birth till the first or milk set of teeth begin to be shed—usually about the seventh year. During this period the body increases in size and stature more, relatively, than at any other period of existence; and the mental faculties undergo great development. The milk teeth, twenty in number, are evolved in a definite order, beginning with the central incisors at about six months, and ending with the second molars about the termination of the second year. From the size and stature of the body, the development of the teeth, and the more or less advanced state of ossification or solidification of the bony skeleton, conclusions may be drawn as to the probable age of the infant.

Childhood extends from the commencement of the shedding of the milk teeth to the age of puberty—usually from the seventh to the fourteenth or fifteenth year. During this period the body expands, as well as the bony structures, without any clearly marked difference in structure being observable between the sexes except as regards the genitals, so that it is impossible to distinguish absolutely between the male and the female skeleton during this period. The milk-teeth are shed, and are replaced by the second or permanent set, thirty-two in number, though these do not usually all make their appearance during childhood. Marked differences between the proclivities of the sexes are noticeable even at an early period of childhood, and long before the characteristic functions begin to be developed.

Youth is marked at its commencement by the changes which occur at puberty—the development of the genitals in both sexes, the appearance of hair on the genitals, the appearance of a beard in the male, the development of the breasts in the female, the appearance of the monthly flow in the female, and the ability to secrete semen in the male. Marked mental changes now occur, and the generative functions are perfected. Youth terminates at the age of legal majority, twenty-one years; or perhaps the period ought to be extended to twenty-five years of age, as it is with some nations.

Manhood (or *Womanhood*) is the period of perfection of all the bodily and mental powers. It ceases in woman with the cessation of the monthly flow at about forty-five years of age; but in man it often extends to a much later period of life.

Old Age begins with the decay of the bodily and mental faculties, and is characterized by wrinkling of the skin, loss of the teeth, whitening of the hair, and feebleness of the limbs. In its later stages decay of the mental faculties, deafness, obscurity or loss of vision, and bowing of the spine are added.

2. *Duration of Human Life.*—The chances of human life form an important subject of inquiry, which has been elucidated by the labours of Price, Milne, Farr, and others; and on deductions from comparisons of birth and death rates is founded the system of annuities, insurance against loss in sickness, and the insurance of lives. Since the establishment of compulsory registration of deaths, our knowledge of the ordinary and extraordinary chances of human life has been much extended, and surer data are now available for calculations of probabilities of life, of survivorships, and of the payments which ought to be made in benefit clubs. See Insurance and Longevity.

3. *Personal Identity.*—It might be imagined that there is little danger, with the exercise of ordinary care, of mistaking one person for another; but the remarkable case of the Tichborne claimant, and some other less-known but perhaps equally singular instances, have demonstrated that mistakes as to the identity of individuals are easily made, and are more frequent than is commonly supposed. Where the identity has to be established or disproved after long absence, exposure to foreign climates and great hardships, wounds, &c., the problem is often one of extreme difficulty. The data for identifying a person are individual and family likeness, stature, the colour of the eyes, peculiarities of garb and manner, recollection of antecedent events, but more especially marks on the person either congenital or acquired. Such are *nævi* or mother's marks, scars, and disunited or badly united fractures, known to have existed upon the missing person. An accurate solution of the question is, nevertheless, often a matter of the greatest difficulty.

4. *Marriage.*—Under this head the medical jurist has to deal principally with the nubile age, viewed in the light of nature and according to legislative enactments, and with such physical circumstances as affect the legality of marriages, or justify divorce.

In Great Britain the age at which the sexes are first capable of propagating the species is later than in more southern climes. Ordinarily it does not occur before fifteen years of age for the male and fourteen for the female; exceptionally, however, it occurs at the ages of thirteen and of twelve (or even less) respectively in the male and female. By legislative enactment, nevertheless, parents and guardians may, in England at all events, forbid the marriage of young people till the age of legal majority. The only physical circumstances which in Great Britain form a bar to marriage are physical inability to consummate, and the insanity of one of the parties at the time of marriage. Both those circumstances have been pleaded and sustained in the law courts. In other countries minor physical circumstances, as disease, are held to invalidate marriage.

5. *Impotence and Sterility.*—These may arise from organic or from functional causes,—the former being alone irremediable, and as such taken cognizance of by the law courts. On this subject it is unnecessary to enlarge here.

6. *Pregnancy.*—This subject presents one of the widest fields for medico-legal evidence. The limits of age between which it is possible, the limits of utero-gestation, and the signs of pregnancy may all in turn be the subjects of investigation.

The limits of age between which pregnancy is possible are usually fixed by the appearance and cessation of the monthly flow; and these ordinarily begin about fourteen and cease at forty-five years of age. Exceptionally they appear as early as the tenth year, and may not cease till the end of the fifth decade of life. Cases, however, have occurred where a woman has conceived before menstruating; and a few doubtful cases of conception are recorded in women upwards of fifty, or even sixty, years of age. The general fact of pregnancy being limited by the age of puberty on the one hand and the cessation of the monthly flow—or fifty years as the extreme limit of age—must be accepted as the safest guide in practice.

The limits of utero-gestation are not in England fixed by legislation. The French code fixes the extreme limit of three hundred days. The ordinary period is forty weeks and a half, or two hundred and eighty-three days from the cessation of the last monthly flux. The limit of three hundred days, as fixed by the French code, is perhaps never exceeded, if ever reached. The uncertainty of females in fixing the exact date of conception has given rise to the discrepant opinions of physiologists on the subject. It is well known, however, that among the higher animals the period is not a precise one; and impregnation and conception are doubtless not necessarily coincident.

The signs of pregnancy are of the utmost importance to the medical jurist. He may be called upon to pronounce upon the virtue of a female, to sustain or rebut a plea for divorce, to determine whether a capital sentence shall be carried out, or to determine whether it is probable that an heir will be born to an estate. Should he err in his judgment—and mistakes are very possible in the earlier months of utero-gestation—he may commit a grievous wrong. Medical jurists are in the habit of classifying the signs of pregnancy as uncertain or certain; it is the former which are most regarded by the public, but the latter are alone of probative value to the jurist. The usual and uncertain signs are the cessation of the monthly flow, nausea, sickness, a darkening of the areola and the formation of a secondary areola around the nipple, enlargement of the breasts, increased size of the abdomen, the formation of a tumour in the womb, quickening, and the motions of the fœtus. There are also other minor signs of less importance. The certain signs are the uterine souffle, which is a peculiar soft sound heard over the abdomen, and synchronous with the maternal pulse; ballottement, or the examination for a floating tumour in the abdomen between the fifth and eighth months of pregnancy; and the pulsations of the fœtal heart, heard by means of the stethoscope. These pulsations are much quicker than, and not synchronous with, the maternal pulse. This is the only indubitable sign of pregnancy. It is inapplicable before the fourth month of gestation.

7. *Parturition.*—The *imminence* of the process of parturition is of comparatively little interest to the medical jurist; but the *signs of recent delivery* are all-important. These signs are the bruised, swollen, and lacerated state of the external genitals, relaxation and dilatation of the vagina and womb, the existence of a peculiar vaginal discharge known as the lochia, a relaxed and fissured condition of the abdominal walls, a peculiar aspect of the countenance, and the distended state of the breasts due to the secretion of milk. The lochial discharge is the most characteristic sign. All the signs may disappear within ten days of delivery, though this is not usual.

Connected with parturition, the question of *viability* of the child is not unimportant. After the intra-uterine age of seven months is reached a child is certainly viable. The period at which the fœtus becomes viable cannot be stated with certainty; but five calendar months, or one hundred and fifty days, is perhaps the nearest approximation which can be made. The viability of a child is judged by its size and weight, its general state of development, the state of the skin, hair, and nails, its strength or feebleness, the ability to cry, and its power of taking maternal nourishment. The question of viability has important bearings upon the crime of infanticide, and the succession to property.

The subject of *superfœtation*, or the possibility of two conceptions having occurred resulting in the birth of twins with a considerable intervening interval, is a very obscure one, and has given rise to much controversy,—its existence being affirmed by some medical jurists, and denied by others. There is much, however (*e.g.*, the existence of a double or bifid womb), to countenance the view that a double conception is possible.

In the curious case of a man marrying a woman having possession of an estate of inheritance, and by her having issue born alive and capable of inheriting her estate, the man on the death of his wife holds her lands for life as a tenant by the "curtesy" of England. Here the meaning of "born alive" is different from the meaning of the same expression as used respecting infanticide. In questions of tenancy by the curtesy it has been decided that any kind of motion of the child, as a twitching and tremulous motion of the lips, is sufficient evidence of live-birth. As regards infanticide, proof of a conclusive separate existence of the child is demanded before live-birth is admitted.

8. *Monsters and Hermaphrodites.*—To destroy any living human birth, however unlike a human creature it may be, is to commit a crime. Blackstone states that a monster which hath not the shape of mankind hath no inheritable blood; but the law has not defined a monster, nor what constitutes a human form. The same author states that if, in spite of deformity, the product of birth has human shape, it may be an heir. Hermaphrodites are beings with malformations of the sexual organs, simulating a double sex. Physiologists do not admit, however, the existence of true hermaphrodites with double perfect organs, capable of performing the functions of both sexes.

9. *Paternity and Affiliation.*—These are often matters of great doubt. A considerable time may elapse between the absence or death of a father and the birth of his reputed child. As has already been said, three hundred days is the utmost limit to which physiologists would extend the period of utero-gestation. This subject involves questions respecting children born during a second marriage of the mother, posthumous children, bastardy, and alleged cases of posthumous children.

10. *Presumption of Survivorship.*—When two or more persons perish by a common accident, when a mother and her new-born child are found dead, and in a few analogous cases, important civil rights may depend upon the question which lived the longest; and great ingenuity has been displayed in elucidating the disputes which have arisen in the law courts in such cases.

11. *Maladies Exempting from Discharge of Public Duties* frequently demand the attention of the medical man. He may be called upon to decide whether a man is able to undertake military or naval service, to act as a juryman without serious risk to life or health, or to attend as a witness at a trial. An endeavour to give a fearless and honest certificate should animate the medical man in the discharge of this delicate duty.

12. *Feigned and Simulated Diseases* often require much

skill and acuteness in order to detect the imposture. Where there is reason to suppose that a disease is simulated, much caution as to procedure is also required.

13. *Insanity or Mental Alienation.*—This subject presents an enormous field to the medical jurist. A medical man may be required to give evidence in any of the law courts, civil, criminal, or ecclesiastical, before commissions *de lunatico inquirendo*, or before a magistrate, as to the sanity or insanity of an individual; and he may have to sign certificates of unsoundness of mind with the view of providing for the safe custody and proper treatment of a lunatic. Hence he must be familiar with the chief forms of insanity (see INSANITY), and be able to distinguish and treat each of these. He will also be required to detect feigned insanity, and to examine persons charged with crime with the view of preventing real lunatics from being treated as criminals.

The terms "unsoundness of mind," applied to the condition of the mind itself, and "*non compos mentis*" to the person whose mind is affected, are legal terms applied to insanity. Lawyers have disputed as to whether imbecility should or should not be included under the head of insanity; but medical men include under this category all disorders or defects of the mind which disqualify a person for managing his affairs, and entering into a binding contract, or which render the individual morally irresponsible for his or her otherwise criminal actions. There is good legal authority for recognizing four forms of unsoundness of mind—*idiocy*, *dementia*, *mania*, and *monomania*.

The chief questions respecting unsoundness of mind which present themselves to the medical jurist are—is the person of sound or unsound mind; if unsound, are there real lucid intervals; is he fit to manage his affairs, to contract a marriage, or to execute a will; is he dangerous to others?

As grounds for restraint, the law recognizes only these conditions—danger to himself, inability to manage his own affairs and property, and danger to the person of others. Before an individual can be placed under restraint in an asylum the certificates of two medical men must be obtained, and the formal order of a relation or friend. The certificates to be valid must be signed by legally qualified medical practitioners having no interest, direct or indirect, in the patient, or in the asylum to which he is to be sent. The medical examiners must pay separate visits, each medical man examining the patient separately. The certificates, which remain valid for seven days only, must bear the exact address of the lunatic, his occupation, and the date of the examination; they must also set forth distinctly the grounds of the opinion they express, under the separate heads of facts observed by the examiner, and facts (to be specified) communicated by others. In the case of pauper lunatics one medical certificate only is required, which is supplemented by an order from a justice of the peace. In urgent cases also one medical certificate suffices for incarceration in an asylum, provided that within three days of the patient's reception two other such certificates are signed by two other medical practitioners, not being connected with the asylum, upon a like examination. The superintendent or proprietor of the asylum must in all cases forward to the commissioners of lunacy a notice of admission within one clear day from the patient's admission. Any infringement of the statutory regulations subjects the person who commits it to a heavy penalty.

II. INJURIES TO THE PERSON.

1. *Defloration.*—The signs of defloration are obscure and uncertain; and it is rather by the coexistence of several of the usual marks than the existence of any one sign, that any just conclusion can be arrived at.

2. *Rape.*—This crime consists in the carnal knowledge of a woman forcibly and against her will. The resistance must be to the utmost, else the crime of rape has not been committed in the legal sense of the word. The proofs of rape, accordingly, apart from the consistency of the woman's story, mainly depend on the presence of the signs of defloration, and on marks of injury on the man.

3. *Mutilation.*—This may consist in the cutting or maiming of any member; castration is the most important, and perhaps but rarely effected as a crime. Self-mutilation, giving rise to false accusations, is occasionally resorted to.

4. *Criminal Abortion.*—The crime of abortion consists in unlawfully administering to a woman, or causing to be taken by her (whether she be with child or not), with intent to procure her miscarriage, any poison or noxious thing, or using for the same purpose any instrument or other means whatsoever; also in the use of the same means, with the same intent, by any woman being with child.

5. *Homicide.*—The legal sense of the term homicide excludes such injuries as are the result of either accident or of suicide. It embraces murder or wilful homicide, manslaughter or culpable homicide, casual homicide, and justifiable homicide.

As a preliminary in all cases of homicide, it is the duty of the medical jurist in the first place to ascertain the fact of death, and to distinguish between real and apparent death; and then to determine, if possible, the period at which death took place.

Infanticide or child murder is by the British law treated with the same severity as the murder of an adult. Indeed infanticide as a crime distinct from murder has no legal recognition. Practically this severity defeats itself, and offences which are really cases of child murder are often treated simply as cases of concealment of birth. The iniquity of the old law which threw the onus of proof of still-birth on the mother now no longer exists, and the law demands strict proof of live-birth at the hands of the prosecution. Hence the subject involves very nice points of forensic medicine. The child must be proved to have arrived at the period when there was a probability of its living (proof of viability); and as the establishment of respiration is necessary to prove live-birth the evidences of this act must be carefully investigated. The size and position of the lungs, and the state of the vessels concerned in fœtal circulation, must be carefully noted. The fœtal lungs are dark, dense, and liver-like in appearance and consistence, and sink when immersed in water; whilst the fully respired lungs are rosy, marbled, and soft and crepitant when handled. Minor degrees of respiration are recognized by the appearance of little groups of dilated air-vesicles, and by the fact that, although the lungs as a whole may sink in water, certain portions of them, into which respired air has penetrated, float in water even after subjection to firm pressure in the hand. Care must be taken, nevertheless, to exclude buoyancy of the lung due to putrefaction; in this case the air may be expelled by gentle pressure, and the previously buoyant portion of lung now sinks in water. It is impossible, however, to distinguish certainly between a lung naturally inflated and one artificially insufflated.

It must be borne in mind that, although live-birth cannot be affirmed in the absence of signs of respiration, the presence of these signs is not proof of live-birth in the legal sense of the term. The law demands for live-birth a separate existence of the child after delivery; and breathing may take place whilst the child is still either wholly or partially within the maternal passages, and in some special cases whilst still within the womb itself.

When proofs of respiration—it may be to such an extent as to leave no doubt as to live-birth—have been found, the cause of death is then to be investigated. Wounds, and other forms of injury, must be sought for. There may be signs of strangulation, suffocation, puncture of the fontanelles, and consequent injury to the brain, the administration of a poison, or other means of procuring death. It must be borne in mind that some of these causes may be brought about by omission, or even by accident. Thus strangulation may arise from natural and unrelieved pressure of the navel string on the neck of the child; suffocation from immersion of the face of the child in the maternal discharges, or by pressure of clothes on the mouth. Death may result from hæmorrhage through neglect to tie the navel string, or the infant may perish from exposure to cold.

In the case of exposed infants it is very important to ascertain the real mother. As such exposure usually takes place soon after birth, comparison of the age of the infant with the signs of recent delivery in the suspected mother is the best method of proving the relation.

Ordinary *homicide* may be accomplished by several modes that may sometimes be ascertained by examination of the body. Of one of the most important of these consideration is deferred to the article POISONS.

Death by *asphyxia* is a common mode of accomplishing homicide, as by suffocation, drowning, hanging, strangulation, or by exposure to mephitic air. Suicide and accidental death from these causes are still more common. (1) *Drowning* is thought to produce death occasionally by the suddenness of the shock causing suspension of the functions of circulation and respiration—by shock without a struggle. The usual mode of death appears, however, to be by the circulation of unoxygenated blood through the brain acting as a poison upon that organ; and this is attended with all the phenomena of asphyxia, as in suffocation. The phenomena attending asphyxia are as follows. As soon as the oxygen in the arterial blood, through exclusion of air, sinks below the normal, the respiratory movements grow deeper and at the same time more frequent; both the inspiratory and expiratory phases are exaggerated, the supplementary respiratory muscles are brought into play, and the breathing becomes hurried. As the blood becomes more and more venous, the respiratory movements continue to increase both in force and frequency. Very soon the expiratory movements become more marked than the inspiratory, and every muscle which can in any way assist in expiration is brought into play. The orderly expiratory movements culminate in expiratory convulsions; these violent efforts speedily exhaust the nervous system, and the convulsions suddenly cease and are followed by a period of calm. The calm is one of exhaustion; all expiratory active movements have ceased, and all the muscles of the body are flaccid and quiet. But at long intervals lengthened deep inspiratory movements take place; then these movements become less frequent; the rhythm becomes irregular, so that each breath becomes a more and more prolonged gasp, which becomes at last a convulsive stretching of the whole body; and with extended limbs and a straightened trunk, with the head thrown back, the mouth widely open, the face drawn, and the nostrils dilated, the last breath is taken. The above phenomena are not all observed except in cases of sudden and entire exclusion of air from the lungs. In slow asphyxia, where the supply of air is gradually diminished (*e.g.*, in drowning), the phenomena are fundamentally the same, but with minor differences. The appearances of the body after death from drowning are various. There may be pallor of the countenance, or this may be livid and swollen. The air passages are filled with frothy mucus, and there may be water in the stomach. The ends of the fingers are often excoriated from grasping at objects; and weeds, &c., are sometimes found grasped in the hands. The distinction between murder and suicide by drowning can rarely be made out by examination of the body alone, and is usually decided from collateral circumstances or marks of a struggle. Attention must also be paid to the existence of wounds on the body, marks of strangulation on the neck, and the like. (2) *Hanging* may result in death from asphyxia, or, as is more particularly the case in judicial hanging, some injury is inflicted on the upper portion of the spinal cord, resulting in instant death. The ordinary appearances of death from asphyxia may be found: dark fluid blood, congestion of the brain, intensely congested lungs, the right cavities of the heart full, and the left comparatively empty of blood, and general engorgement of the viscera. Ecchymosis may be found beneath the site of the cord, or a mere parchmenty appearance. There may even be no mark of the cord visible. The mark, when present, usually follows an oblique course, and is high up the neck. The fact that a body may be suspended after death, and that if this be done speedily whilst the body is still warm there may be a *post-mortem* mark undistinguishable from the mark observed in death from hanging, must not be forgotten. (3) *Suffocation* may occur from the impaction of any substance in the glottis, or by covering up the mouth and nose. It is frequently of accidental origin, as when substances become accidentally impacted in the throat, and when infants are overlaid. The phenomena are those of pure asphyxia, which have already been detailed. On *post-mortem* examination the surface of the lungs is found covered with minute extravasations of blood, known as punctated ecchymosis. (4) *Strangulation* may be accomplished by drawing a cord tightly round the neck, or by forcibly compressing the windpipe (throttling). Hence there may be either a circular mark round the neck, not so oblique as after hanging, or the marks of the fingers may be found about the region of the larynx. The cartilaginous structures of the larynx and windpipe may be broken. The mark of the ligature is often low down in the neck. The signs of asphyxia are present in a marked degree. (5) *Mephitism.*—Death from the inhalation of irrespirable gases is a mode of assassination seldom employed, but is frequently resorted to on the Continent by suicides, charcoal fumes being commonly used for the purpose (see POISONS).

6. *Death from Starvation.*—Cases occur in which it is important to distinguish this from other modes of death. In such cases the skin becomes harsh and dry, and may acquire a peculiar odour; the subcutaneous fat disappears; the gums shrink away from the teeth; the tongue and mouth become dark-coloured and dry; the eyes are bloodshot; the intestines become thin and their coats translucent; the gall-bladder is distended. The period of total abstinence from food required to kill an adult is unknown, and greatly depends upon whether there be access to liquid. In some cases persons have been able to subsist on little or no nourishment for long periods, the body being in a state of quasi-hibernation.

7. *Death from Extremes of Temperature.*—(1) Death from cold is not often observed in the British Isles. A portion only of the body, as the extremity of a limb, may perish from extreme cold. After the first sensation of tingling experienced on exposure to severe cold, loss of sensation supervenes, with languor and an irresistible propensity to sleep. The tendency to this forms an extreme danger in such cases. (2) Death from extreme heat usually occurs in the form of burning and scalding, attended with destruction of a large portion of the cutaneous structures. Here the cause of death is obvious. The human body is capable of exposure to very hot air—as is seen in Turkish baths—for a considerable period with impunity. Sun-stroke is a cerebral affection brought on by too great exposure to a hot atmosphere, especially whilst undergoing fatigue.

8. *Death by Lightning.*—Lightning or an artificial electric current may cause instant death. No visible marks of the effects of the electric current may be left, or the body may be singed or discoloured, or the skin may be perforated at one or two spots.

9. *Wounds.*—The examination of wounds, whether fatal or not, often becomes an important branch of forensic medicine. Wounds are usually divided into *contused*, *lacerated*, *incised*, *punctured*, and *gunshot* wounds. For poisoned wounds see POISONS. Each kind of wound requires to be minutely examined and described, as they are in approved works on surgery. The degree of danger from each should be familiar to the medical jurist; and he should recollect that there is no wound which may not become incidentally fatal from improper treatment, peculiarities of constitution, or accidental inoculation with septic material. Punctured wounds or stabs require minute attention; for there have been instances in which death has been produced by an instrument so small as a pin thrust into a vital part. *Wounds of the head* are always dangerous, especially if the blow has been severe. The person so wounded may die without division of the skin, or fracture of the bones, as happens in what is known as *concussion* of the brain. Contusions which do not divide the skin may fracture the skull; or the inner table of the skull may be fractured without the outer being broken or depressed. Even wounds of the scalp may prove fatal, from inflammation extending towards the brain. Punctured wounds of the head are more dangerous than cuts, as more likely to excite fatal inflammation. When the brain and its membranes are injured, all such wounds are generally fatal. Wounds of the face or organs of sense are often dangerous, always disfiguring, and productive of serious inconvenience. *Wounds of the neck* are always very serious wherever more than the skin is divided. The danger of opening large blood-vessels, or wounding important nerves, is imminent; even the division of a large vein in the neck has proved immediately fatal, from the entrance of air into the vessel, and its speedy conveyance to the heart. A blow on the neck has instantly proved fatal, from injury to an important nerve, generally the pneumogastric or the sympathetic. Dislocations and fractures of the bones of the neck prove instantly fatal. *Wounds of the chest* are always serious when the cavity is penetrated, though persons may recover from wounds of the lungs, and have even survived for some time considerable wounds of the heart. This last is an important fact; because we are not always to consider the spot where the body of a person killed by a wound of the heart, and apparently remaining where he fell, is found as that in which the fatal wound was inflicted. Instances have occurred of persons surviving severe wounds of the heart for several days. Broken ribs are never without danger; and the same may be said of severe contusions of the chest, from the chance of inflammation extending inwards. Wounds penetrating both sides of the chest are generally considered as fatal; but possibly there may be recovery from such. *Wounds of the abdomen*, when they do not completely penetrate, may be considered as simple wounds, unless when inflicted with great force, so as to bruise the contents of the abdominal cavity; in that case they may produce death without breach of surface, from rupture of some viscus, as sometimes happens from blows or kicks upon the belly. Wounds injuring the peritoneum are highly perilous, from the risk of severe inflammation. Wounds of the stomach or intestines, or of the gall-bladder, generally prove mortal, from the effusion of their contents into the peritoneal cavity producing fatal inflammation. Wounds of the liver, spleen, or kidneys are generally soon mortal, from the great vascularity of those organs. Wounds of the extremities, when fatal, may generally be considered so from excessive hæmorrhage, from the consequences of inflammation and gangrene, or from the shock to the system when large portions of the limb are forcibly removed, as in accidents from machinery, and in wounds from firearms.

10. *Poisonous Food.*—Under certain conditions, various articles of diet, especially butcher meat, eggs, milk, butter, cheese, and honey, may become possessed of poisonous properties, and this may arise from a variety of causes besides the introduction of known and specific poisons. Moreover, certain kinds of animal food—fish chiefly—may have definite toxic properties. Food may be more or less poisonous—(1) from unsoundness, either from putridity or decomposition or disease; (2) from the presence of parasites; (3) from mouldiness, or presence of deleterious microscopic fungi; and (4) where the flesh is that of animals which have fed on noxious plants,—and under this head may also be classed poisonous honey, which bees have gathered from poisonous plants. (5) It may be of the nature of poisonous fish, using the term fish in the popular sense. (6) Certain fungi or mushrooms are poisonous. Parasitic diseases would, strictly speaking, come under the first head; but the pre-

ventive measures to be adopted in the use of food infested with parasites will alone be treated of in this place.

(1) *Poisonous Vegetables.*—Unsound or even rotten vegetables and fruits may be consumed, and become fertile sources of varied forms of poisoning, especially in hot summers. The symptoms produced by the ingestion of large quantities of unsound fruit or vegetables are of a diarrhœal character, not often of an alarming severity, except in the cases of the young and feeble. They may, however, sometimes attain a fatal severity. The cause is usually obvious, and the treatment is simple; mild purgatives, as rhubarb or castor oil, with or followed by opiates, to remove peccant matters from the intestines; and stimulants, as ammonia or alcohol, if there be much collapse. Certain fungi or mushrooms are known to be specifically poisonous, such as the *Amanita muscaria*, or fly-fungus, and others. Certain kinds of mushrooms, usually innocuous, are occasionally poisonous or deleterious; and the cause of this is not always clear. Poisonous fungi produce narcotic and irritant symptoms.

(2) *Poisonous, Tainted, or Putrid Meat.*—The obvious characteristics of good sound flesh meat are that its colour is red—neither pale pink nor deep purple; that it is marbled in appearance; firm and elastic to the touch, scarcely moistening the fingers; having a slight and not unpleasant odour; and that when exposed to the air for a day or two it should neither become dry on the surface nor wet and sodden. Sound meat is acid to litmus paper; unsound meat may be neutral or alkaline. Meat may be tainted with physic administered to the animal. It is a common practice, when a fat and valuable animal is unwell, to physic it, and if its recovery be not speedy to slaughter it. The meat of such animals may often be met with in our markets, and may induce illness from the physic with which it is contaminated. The effects of simple putridity are most varied. It is well known that some nations habitually eat putrid meat, and even prefer it to fresh; and the development of rottenness in eggs for the epicure is an art in China. There is no doubt that habit has much to do with the tolerance by the stomach of putrid meat, whether cooked or uncooked. But tainted game, and indeed all kinds of meat in which putrefaction has commenced, may indubitably produce disease. This is chiefly of a diarrhœal character, preceded by rigors, and attended with collapse and, it may be, convulsions and other signs of a profound affection of the nervous system. The effects of such tainted meat are slight as compared with those which are produced by the sausage-poison, developed by a sort of modified putrefaction in certain German sausages. These sausages, when they become musty and soft in their interior, nauseous in odour and flavour, and strongly acid to test paper, acquire a highly poisonous character, and are frequently fatal in their effects. The symptoms produced by the use of poisonous flesh are gastric pain, vomiting, diarrhœa, depression, coldness of the limbs, and weak irregular action of the heart. Fatal cases end in convulsions and oppressed respiration, death ensuing from the third to the eighth day. The nature of the sausage-poison, which is probably akin to that of putrid and indeed all non-specifically tainted meats, has been a matter of considerable controversy. Some have held that the poisonous action is due to the development of rancid fatty acids; others believe that a so-called catalytic body is produced, capable of setting up by contact a similar catalytic action. Others have regarded the sausage-poison as due to the formation of pyrogeneous acids during the drying or smoking of the sausages. The recent discovery by Selmi of a class of poisonous alkaloids or amides, termed *ptomaines*, developed during putrefaction of animal matters, on the one hand, and the discovery by Ballard and Klein, still more recently, that the fatally poisonous properties of hams prepared according to the American method may be due to the presence of a parasitic bacillus, point to one or other of these two latter causes as that of the effects of sausage-poison. Others again have referred the effects to the presence of a microscopic fungus—*Sarcina botulina.*

The poisonous nature of the flesh of animals which have fed on certain plants—for example, hares which have fed on certain species of rhododendron, pheasants on the kalmia shrub, &c.—has been abundantly demonstrated, and need only be referred to here. The honey from bees which have garnered on poisonous plants, as the azalea, may likewise be deleterious; and the fact is of classic interest. The milk even of goats which have browsed on poisonous herbs has also proved poisonous.

(3) *Diseased Meat.*—The poisonous effects of meat affected with certain parasites—trichinæ, cysticerci, trematodes, &c., is an undoubted fact. Great quantities of meat pass through our markets which is undoubtedly the flesh of animals affected with disease, such as foot-and-mouth disease, pleuro-pneumonia, pig typhoid, the so-called scarlatina of swine, sheep-pox, &c.; and the question is quite undecided as to whether such flesh produces any injurious effects. To stop the sale of such meat would be to cut off large sources of our meat supplies. The evils attending the use of such diseased meat, when well cooked, have undoubtedly been exaggerated; but, on the other hand, there is enough evidence to show that the use of certain kinds of diseased meat may be followed by serious results. Thus it is generally admitted that the flesh of animals which have suffered from pleuro-pneumonia and murrain will give rise to boils and carbuncles. Braxy mutton may also produce disease when eaten. Trichinæ will produce trichinosis, flukes, the tape-worm, &c. Hams are occasionally fatally poisonous; and this has been traced to the presence of certain low organisms known as *bacilli.*

(4) *Poisonous Fish.*—Fish is sometimes a poisonous article of food. Cases of poisoning by the so-called shell-fish of the British islands are not unfrequently met with. Generally it is the eating of crabs, lobsters, and mussels which produces such results. These are usually of a distressing rather than of a serious character, nettle-rash being a common symptom. Occasionally, however, fatal results have ensued from the use of mussels. In tropical seas poisonous fish are more plentiful—the golden sardine, the bladder fish, the grey snapper, &c.; and, these being eaten by larger fish, as the barracuda, perch, globe-fish, conger eel, &c., the latter may in turn become poisonous.

Good cookery, that is, exposure to a sufficiently high temperature for a sufficiently lengthened time, is undoubtedly the best measure to adopt short of absolute destruction of unsound and diseased meat. So long as meat is high-priced, and the effects of diseased meat so little understood and so undefined, it will be impossible to induce medical officers of health and sanitary inspectors to seize all the diseased and unsound meat which is daily offered for sale. Notwithstanding all that has been said to the contrary, experienced observers are pretty well agreed that thorough exposure of the meat throughout to the temperature at which albumen is coagulated is destructive to the parasites of flesh. Smoking is less effective. Salting is more effective than smoking; but there is some evidence to show that salting may merely hold the life of organisms in suspense without entirely destroying their vitality; and thus in the conversion of salted pork into hams—a process of re-salting and subsequent drying—the specific germ (a bacillus) has been known to be again rendered harmful. It is not known whether efficient cooking entirely removes the deleterious effects of flesh affected with other than parasitic disease, as for example pleuro-pneumonia.

The curative measures for the results of eating poisonous food cannot be specifically described. They are those which must be arrived at on general principles. Symptoms are to be treated, and the powers of the patient sustained until the deleterious matter is removed by the ordinary channels, or the trichinæ have become encysted.

History of Forensic Medicine.

The true origin of medical jurisprudence is of comparatively recent date, although traces of its principles may be perceived in remote times. Among the ancient Greeks the principles of medical science appear only to have been applied to legislation in certain questions relating to legitimacy. In the writings of Galen we find, however, remarks on the differences between the fœtal and the adult lungs; he also treats of the legitimacy of seven months' children, and discusses feigned diseases. Turning to Rome, we find that the laws of the Twelve Tables fix three hundred days as the extreme duration of utero-gestation. It is doubtful whether the Roman law authorized medical inspections of dead bodies. In the code of Justinian we find *De Statu Hominum*; *De Pœnis et Manumissis*; *De Sicariis*; *De Inspiciendo Ventre Custodiendoque Partu*; *De Muliere quæ peperit undecimo mense*; *De Impotentia*; *De Hermaphroditis*,—titles which show obvious traces of a recognized connexion between medicine and law. It was not, however, by the testimony of living medical witnesses that such questions were to be settled, but on the authority of Hippocrates.

Medical jurisprudence, as a science, dates only from the 16th century. In 1507 the bishop of Bamberg introduced a penal code in which the necessity of medical evidence in certain cases was recognized; and in 1532 the emperor Charles V. persuaded the diet of Ratisbon to adopt an uniform code of German penal jurisprudence, in which the civil magistrate was enjoined in all cases of doubt or difficulty to obtain the evidence of medical witnesses,—as in cases of personal injuries, infanticide, pretended pregnancy, simulated diseases, and poisoning. The true dawn of forensic medicine dates, however, from the publication in 1553 of the *Constitutio Criminalis Carolina* in Germany. A few years later Weiher, a physician, having undertaken to prove that witches and demoniacs are, in fact, persons subject to hypochondriasis and hysteria, and should not be punished, aroused popular indignation, and was with difficulty rescued from the flames by his patron, William duke of Cleves.

At the close of the 16th century Ambrose Paré wrote on monsters, on simulated diseases, and on the art of drawing up medico-legal reports; Pineau also published his treatise on virginity and defloration. About the same time as these stimuli to the study of forensic medicine were being made known in Paris, the first systematic treatise on the science appeared in Sicily in the form of a treatise *De Relationibus Medicorum* by Fidele. Paulo Zacchia, the illustrious Roman medical jurist, moreover, published from 1621 to 1635 a work entitled *Quæstiones Medico-Legales*, which marks a new era in the history of the science,—a work which displays an immense amount of learning and sagacity in an age when chemistry was in its infancy, and physiology very imperfectly understood. The discovery of the circulation of the blood by Harvey soon followed, and gave a new impetus to the study of those branches of forensic medicine having direct relations to physiology; and to Harvey we owe the idea how to apply Galen's observations on the differences between the fœtal and the adult lungs to the elucidation of cases of supposed infanticide. About this time, too, Sebiz published two treatises, on the signs of virginity and on the examination of wounds respectively. In the former he contended that the hymen was the real mark of virginity; but this was denied by Augenio and Gassendi. In 1663 Bartholin, a Danish physician, investigated the period of human uterine gestation, a subject which had engaged the attention of Aristotle. He also proposed the "hydrostatic test" for the determination of live-birth—a test still in use, and applied by observing whether the lungs of an infant float or sink in water. Swammerdam explained the rationale of the process in 1677; but it was not till 1682 that it was first practically applied by Jan Schreyer.

Germany, ever the leader in questions of forensic medicine, introduced the first public lectures on medical jurisprudence. Michaelis gave the first course about the middle of the 17th century in the university of Leipsic; and these were followed by the lectures of Bohn, who also published *De Renunciatione Vulnerum; cui accesserunt Dissertationes binæ de partu enecato, et an quis vivus mortuusve aquis submersus, strangulatus, aut vulneratus fuerit*, and *De Officiis Medici Duplicis, Clinici et Forensis*. Welsch and Amman wrote on the fatality of wounds, and Licetus on monsters.

From the time of Ambrose Paré the mode of conducting investigations in forensic medicine had attracted attention in France; and in 1603 Henry IV. authorized his physician to appoint persons skilled in medicine and surgery to make medico-legal inspections and reports in all cities and royal jurisdictions; in 1692, difficulties having arisen, Louis XIV. created hereditary royal physicians and surgeons for the performance of like duties. These, having become a corrupt and venal body, were suppressed in 1790. The only works on forensic medicine which appeared in France during the 17th century, however, were Gendry's *Sur les Moyens de bien rapporter à Justice*, and Blégny's *Doctrine des Rapports en Chirurgie*. At the beginning of the 18th century the latter was superseded as a text-book by Devaux's *L'art de faire des rapports en Chirurgie*. Valentini followed with two works, which were finally incorporated in his *Corpus Juris Medico-Legale* which appeared in 1722. This work is a vast storehouse of medico-legal information, and a summary of the knowledge of the time.

Professorships for teaching the subject were founded in the German universities early in the 18th century, and numerous treatises on forensic medicine were published. Teichmeyer's *Institutiones Medicinæ Legalis* long formed the text-book of the subject; and Alberti, professor of legal medicine at Halle, in his *Systema* gave to the world a most complete and laborious treatise on the science. His industrious collection of facts renders his works a precious mine of information. Indeed towards the close of last century the Germans were almost the only cultivators of legal medicine. But in France the celebrated case of Villeblanche attracted attention to the subject, and called forth Louis, who in a memoir on utero-gestation attacked with powerful arguments the pretended instances of protracted pregnancy, and paved the way for the adoption in the *Code Napoléon* of three hundred days as the limit of utero-gestation, a period in precise accordance with the ancient Roman law of the Twelve Tables. Louis also wrote on death from hanging, and pointed out the mode by which we may distinguish murder from suicide under such circumstances. It is he who is credited with having been the first in France to publicly teach the just application of medical knowledge to jurisprudence. Foderé's celebrated *Traité de Médecine Légale* appeared in 1798, and marks a new era in the annals of legal medicine.

No British author wrote systematically on forensic medicine till 1788, when Dr Samuel Farr published a short treatise on the *Elements of Medical Jurisprudence*; but this was merely an abridgment of an earlier work of Fazelius. Previous writers, as Mead, Munro, Denman, Percival, and the two Hunters, had, however, dealt with fragments of the subject; nevertheless the science as a whole was little appreciated or recognized in this country during the last century.

In the present century France took the lead; and the institution of three professorships of forensic medicine at the end of the 18th century produced excellent fruits. In 1814 Orfila, a Spaniard by birth, but naturalized in France, published his *Toxicologie*, a work which revolutionized this branch of medical jurisprudence, and first placed the knowledge of poisons upon a scientific basis. Since the time of Orfila, France has never ceased to have one or more living medical jurists, among the most recent of whom we must enumerate Tardieu, whose treatises on abortion, on poisons, on wounds, &c., are justly celebrated. Germany too has industriously pursued the subject, and Casper's great work on forensic medicine will ever remain a classic in the science. In Russia Dragendorff has greatly contributed to our knowledge of poisons.

Though forensic medicine may be said to have been entirely neglected in England till the beginning of the present century, its progress has since been by no means slow or unimportant; and the subject now forms a recognized and obligatory portion of medical study. The first lectures delivered in Great Britain were given in the university of Edinburgh in 1801 by the elder Dr Duncan; and the first professorship was held by his son in 1803. Dr Alfred Swaine Taylor gave the first course of lectures delivered in England, at Guy's Hospital in 1831; and in 1863 the university of London made forensic medicine a separate subject for examination and honours for medical graduates. In 1822 there was not in the English language any treatise of authority either on medical jurisprudence or on any important division of the subject; for it was not till the following year that the useful compendium of Paris and Fonblanque was published; and even half a century ago medical jurisprudence may be said to have been almost in its infancy as compared with what it is now. Since 1829 Great Britain has produced an abundant crop of literature on forensic medicine. Sir Robert Christison's admirable treatise on *Toxicology*, Dr A. S. Taylor's *Principles and Practice of Medical Jurisprudence*, the same author's *Elements of Medical Jurisprudence*, Dr Guy's *Forensic Medicine*, and Ogston's *Lectures on Medical Jurisprudence* are well-known and widely circulated works. The separate memoirs of Taylor, Christison, Guy, and others are also storehouses of facts and deductions in the science.

America, too, has not been behind hand in the race. Wharton and Stillé's *Manual* and Wormley's *Toxicology* are the best-known works of American authors. (T. S.*)

MEDICI. This family is renowned in Italian history for the extraordinary number of statesmen to whom it gave birth, and for its magnificent patronage of letters and art. It emerged from private life and rose to power by means of a very subtle policy that was persistently pursued from generation to generation. The origin of the family is buried in obscurity. Some court historians indeed declare it to have been founded by Perseus, and assert that Benvenuto Cellini's bronze Perseus holding on high the head of Medusa was executed and placed in the Loggia dei Lanzi to symbolize the victory of the Medici over the republic. But this only proves that the real origin of the family is unknown, and equally unknown is the precise signification of the Medicean arms—six red balls on a field of gold.

Early bearers of the name.

The name appears in Florentine chronicles as early as the close of the 12th century, although only casually mentioned in connexion with various offices of the republic. The first of the family to be a distinct figure in history was Salvestro dei Medici, who, in the year 1378, took an active part in the revolt of the Ciompi—so-called because it was led by a wool-carder (*ciompo*), one Michele di Lando, and because the chief share in it was taken by the populace, who held the reins of government for some time, and sought to obtain extended political rights. But, although Michele di Lando was the nominal chief of the revolt, Salvestro dei Medici was its real leader. The latter, although a member of the greater guilds, had joined the lesser and sought to be at their head, in order to lay the foundation of his own power and that of his kindred by attacking the Albizzi, who were the leading men of the greater guilds. The victory of the Ciompi, however, was brief, for the excesses of the lower classes brought about a reaction, in which they were crushed, and Michele di Lando sent into banishment. Nevertheless the lesser guilds had gained some ground by this riot, and Salvestro dei Medici the great popularity at which he had aimed. His policy during that period had traced the sole possible road to power in liberty-loving Florence. And this was the road henceforth pursued by the Medici.

Salvestro.

On Salvestro's death in 1388 the Albizzi repossessed themselves of the government, and conducted the wars of the republic. Vieri dei Medici, who seems to have been the next head of the family, understanding the temper of the times, abstained from becoming a popular leader, and left it to his successors to prosecute the task under easier conditions. Then, in the person of Giovanni, son of Bicci dei Medici (1360–1429), another branch of the family arose, and became from that time forward its representative branch. Indeed this Giovanni may be considered the actual founder of Medicean greatness. He took little part in political affairs, but realized an immense fortune by trade,—establishing banks in Italy and abroad, which in his successors' hands became the most efficient engines of political power. The council of Constance (1414–1418) enabled Giovanni dei Medici to realize enormous profits. Besides, like his ancestor Salvestro, he was a constant supporter of the lesser guilds in Florence. Historians record his frequent resistance to the Albizzi when they sought to oppress the people with heavier taxation, and his endeavours to cause the chief weight to fall upon the richer classes. For this reason he was in favour of the so-called law of *catasto*, which, by assessing the property of every citizen, prevented those in power from arbitrarily imposing taxes that unjustly burdened the people. In this way, and by liberal loans of money to all who were in need of it, he gained a reputation that was practically the foundation-stone of the grand family edifice. Giovanni dei Medici died in 1429 leaving two sons, Cosimo (1389–1464) and Lorenzo (1395–1440). From the former proceeded the branch that held absolute sway for many generations over the nominal republic of Florence, and gave to Italy popes like Leo X. and Clement VII. On the extinction of this elder line in the 16th century, the younger branch derived from Lorenzo, Cosimo's brother, seemed to acquire new life, and for two centuries supplied grand-dukes to Tuscany. Cosimo, surnamed Cosimo the Elder, to distinguish him from the many others bearing the same name, and honoured after his death by the title of *Pater patriæ*, first succeeded in solving the strange problem of becoming absolute ruler of a republic that was keenly jealous of its liberty, without holding any fixed office, without suppressing any previous form of government, and always preserving the appearance and demeanour of a private citizen. Born in 1389, he had already reached the age of forty at the time of his father's death. He had a certain amount of literary culture, and throughout his life showed much taste and an earnest love both for letters and art. But his father had mainly trained him to commerce, for which he had a special liking and aptitude. In fact he was devoted to business to the day of his death, and like his forefathers derived pecuniary advantage from his friendly relations with the papal court. He accompanied Pope John XXIII. to the council of Constance, transacted a vast amount of business in that city, and made very large gains. He then travelled in Germany, and after his return to Florence discharged several ambassadorial missions. At the death of his father he was possessed of a vast fortune and an extended experience, and inherited the leadership of the opposition to the then dominant party of the greater guilds headed by Rinaldo degli Albizzi, Palla Strozzi, and Niccolò da Uzzano. Of gentle and kindly manners, generous in lending and even in giving money whenever he could gain popularity by that means, at critical moments he frequently came to the succour of the Government itself. He was very dexterous in turning his private liberalities to account for the increase of his political prestige, and showed no less acumen and still fewer scruples in making use of his political prestige for purposes of pecuniary profit. Indeed, whenever his own interests were at stake, he showed himself capable of positive villainy, although this was always tempered by calculation. Cosimo proved his skill in these knavish arts during the war between Florence and Lucca. He had joined the Albizzi in urging on this war, and many writers assert that he turned it to much pecuniary advantage by means of loans to the Government and other banking operations. When, however, military affairs went badly, Cosimo joined the discontented populace in invectives against the war and those who had conducted it. This won him an enormous increase of popularity, but the hatred of the Albizzi and their friends augmented in equal degree, and a conflict became inevitable. The Albizzi, who were far more impetuous and impatient than Cosimo, were now bent upon revenge. In 1433 one of their own friends, Bernardo Guadagni, was elected gonfalonier, and thereupon Cosimo dei Medici was called to the palace and summarily imprisoned in the tower. A general assembly of the people was convoked and a "balía" chosen, which changed the Government and sent Cosimo into exile. Undoubtedly the Albizzi party would have preferred a heavier sentence, but they did not dare to attempt their enemy's life, being well aware of the great number of his adherents. Cosimo had some apprehension that he might be poisoned in prison, but Federigo dei Malavolti, captain of the palace guard, showed him the utmost kindness, and, in order to soothe his fears, voluntarily shared his meals. On the 3d October the prisoner was sent to Padua, his allotted place of exile.

Giovanni.

Cosimo the Elder.

The Albizzi speedily saw that they had done either too much or too little. While seeking to keep the government entirely in their own hands, they beheld the continual growth of the Medici party. When it was necessary to make a campaign in Romagna against the mercenary captains commanding the forces of the duke of Milan, it was plainly seen that in banishing Cosimo the republic had lost the only citizen banker in a position to assist it with considerable loans. The Florentines were defeated by Piccinino in 1434, and this event greatly increased the public exasperation against the Albizzi. Meanwhile Cosimo, who had gone to Padua as a private individual, was entertained there like a prince. Then, being permitted to transfer his residence to Venice, he entered on a course of lavish expenditure. He was overwhelmed with letters and appeals from Florence. Finally, on the 1st of September 1434, a signory was elected composed of his friends, and his recall was decreed. Rinaldo degli Albizzi determined to oppose it by force, and rushed to the Piazza with a band of armed men; but his attempt failed, and he left the country to return no more. The Medici were now reinstated in all their former dignities and honours, and Cosimo, on the evening of September 6th, rode past the deserted mansions of the Albizzi and re-entered his own dwelling after an exile of a year. For three centuries, dating from that moment, the whole history of Florence was connected with that of the house of Medici.

Cosimo's first thought was to secure himself against all future risk of removal from Florence, and accordingly he drove the most powerful citizens into exile to all parts of Italy. Nor did he spare even his former political adversary, Palla Strozzi, although the latter had been favourable to him during the recent changes. His rigour in this particular case was universally censured, but Cosimo would tolerate no rivals in the city, and was resolved to abase the great families and establish his power by the support of the lower classes. He was accustomed to say that states could not be ruled by paternosters. Still, when cruelty seemed requisite, he always contrived that the chief odium of it should fall upon others. When Neri Capponi, the valiant soldier and able diplomatist, gained great public favour by his military prowess, and his influence was further increased by the friendship of Baldaccio d'Anghiari, captain of the infantry, Cosimo resolved to weaken his position by indirect means. Accordingly, when in 1441 a partisan of the Medici was elected gonfalonier, Baldaccio was instantly summoned to the palace, imprisoned, murdered, and his body hurled from the window. No one could actually fix this crime upon Cosimo, but the majority believed that he had thus contrived to rid himself of one enemy and cripple another without showing his hand. It was impossible for Cosimo openly to assume the position of tyrant of Florence, nor was it worth his while to become gonfalonier, since the term of office only lasted two months. It was necessary to discover some other way without resorting to violence; he accordingly employed what were then designated "civil methods." He managed to attain his object by means of the "balíe." These magistracies, which were generally renewed every five years, placed in the ballot bags the names of the candidates from whom the signory and other chief magistrates were to be chosen. As soon as a "balía" favourable to Cosimo was formed, he was assured for five years of having the government in the hands of men devoted to his interests. He had comprehended that the art of politics depended rather upon individuals than institutions, and that he who ruled men could also dictate laws. His foreign policy was no less astute. His great wealth enabled him to supply money not only to private individuals, but even to foreign potentates. Philippe de Comines tells us that Cosimo frequently furnished Edward IV. of England with sums amounting to many hundred thousand florins. When Tommaso Parentucelli was still a cardinal, and in needy circumstances, Cosimo made him considerable loans without demanding guarantees of payment. On the cardinal's accession to the tiara as Nicholas V. he was naturally very well disposed towards Cosimo, and employed the Medici bank in Rome in all the affairs of the curia, which brought immense profits to the house. At the time when Francesco Sforza was striving for the lordship of Milan, Cosimo foresaw his approaching triumph, showed him great friendship, and aided him with large sums of money. Accordingly, when Sforza became lord of Milan, Cosimo's power was doubled. Without the title of prince, this merchant showed royal generosity in his expenditure for the promotion of letters and the fine arts. Numerous edifices were raised and public works accomplished with his purse. Besides his palace in the city, he constructed noble villas at Careggi, Fiesole, and other places. He built the basilica of Fiesole, and that of St Lorenzo in Florence, and enlarged the church and monastery of St Mark. Even in distant Jerusalem he endowed a hospice for the use of pilgrims. The artists of the day comprised men like Donatello, Brunelleschi, Ghiberti, Luca della Robbia, and many others, and Cosimo's magnificent commissions not only developed their powers but stimulated other men of wealth to the patronage of art. Without being a scholar, Cosimo had a genuine taste for letters, and gave them much and efficient patronage. He purchased many Greek and Latin manuscripts; he opened the first public library at St Mark's at his own expense, and founded another in the abbey of Fiesole. The Greek refugees from Constantinople found a constant welcome in his palace. During the council of Florence (1439–1442), Gemisthus Pletho spoke to him with enthusiasm of the Platonic philosophy. Cosimo was so deeply attracted by the theme that he decided to have the young Marsilio Ficino trained in philosophy and Greek learning in order to make a Latin translation of the complete works of Plato. And thus a version was produced that is still considered one of the best extant, and that Platonic academy was founded which led to such important results in the history of Italian philosophy and letters. On the 1st of August 1464 Cosimo breathed his last, at the age of seventy-five, while engaged in listening to one of Plato's dialogues.

The concluding years of his life had been years of little happiness for Florence. Being old and infirm, he had left the government to the management of his friends, among whom Luca Pitti was one of the more powerful, and they had ruled with disorder, corruption, and cruelty. The lordship of Florence accordingly did not pass without some difficulty and danger into the hands of Piero, surnamed the Gouty, Cosimo's only surviving legitimate son. Afflicted by gout, and so terribly crippled that he was often only able to use his tongue, the new ruler soon discovered that a plot was on foot to overthrow his power. However, showing far more courage than he was supposed to possess, he had himself borne on a litter from his villa to Florence, defeated his enemies' designs, and firmly re-established his authority. But his success may be mainly attributed to the enormous prestige bequeathed by Cosimo to his posterity. Piero died at the end of five years' reign, on the 3d December 1469, leaving two sons, Lorenzo (1449–92) and Giuliano (1453–78). The younger, the gentler and less ambitious of the pair, was, as we shall presently see, quickly removed from the world. Lorenzo, on the contrary, at once seized the reins of state with a firm grasp, and was, chronologically, the second of the great men bestowed upon Italy by the house of Medici. In literary talent he was immensely superior to Cosimo, but greatly his inferior in the conduct of the commercial affairs of the house, for which he had neither aptitude nor inclination. In politics he had nobler conceptions and higher ambitions, but he was more easily carried away by his passions, less prudent in his revenge, and more disposed to tyranny. He had studied letters from his earliest years under the guidance of Ficino and other leading literati of the day, who were constant habitués of the Medici palace. At the age of eighteen he visited the different courts of Italy in order to gain experience of the world and mankind. At his father's death he was only twenty-one years old, but instantly showed his determination to govern Florence with greater despotism than his father or grandfather. He speedily resorted to the system of the "balíe," and was very dexterous in causing the first to be chosen to suit his purpose. He then proceeded to humiliate the great families and exalt those of little account, and this was the policy he constantly pursued. His younger brother Giuliano, being of a mild and yielding disposition, had only a nominal share in the government.

Piero the Gouty.

Lorenzo the Magnificent.

Lorenzo's policy was not exempt from danger, but, although prosecuted with less caution, it was still the old astute and fortunate policy initiated by Cosimo. But the grandson bestowed no care upon his commercial interests, although squandering his fortune with far greater lavishness. Accordingly he was sometimes driven to help himself from the public purse without ever being able to assist it as Cosimo had done. All this excited blame and enmity against him, while his greed in the matter of the alum mines of Volterra, and the subsequent sack of that unhappy city, were crimes for which there was no excuse. Among his worst enemies were the Pazzi, and, as they formed a very powerful clan, he sought their ruin by competing with them even in business transactions. They were just on the point of inheriting the large property of Giovanni Borromeo when, in order to prevent this, Lorenzo hurriedly caused a law to be passed that altered the right of succession. The hatred of the Pazzi was thereby exasperated to fury. And in addition to these things there ensued a desperate quarrel with Pope Sixtus IV., a man of very impetuous temper, who, on endeavouring to erect a state on the frontiers of the Florentine republic for the benefit of his nephews, found a determined and successful opponent in Lorenzo. Consequently the Pazzi and Archbishop Salviati, another enemy of Lorenzo, aided by the nephews of the pontiff, who was himself acquainted with the whole matter, determined to put an end to the family.

On the 26th April 1478, while Giuliano and Lorenzo were attending high mass in the cathedral of Florence, the former was mortally stabbed by conspirators, but the latter was able to beat back his assailants and escape into the sacristy. His life saved; and, no longer having to share the government with a brother, Lorenzo profited by the opportunity to wreak cruel vengeance upon his foes. Several of the Pazzi and their followers were hanged from the palace windows; others were hacked to pieces, dragged through the streets, and cast into the Arno, while a great many more were condemned to death or sent into exile. Lorenzo seemed willing and able to become a tyrant. But he stopped short of this point. He knew the temper of the city, and had also to look to fresh dangers threatening him from without. The pope had excommunicated him, put Florence under an interdict, and, being seconded by the Neapolitan king, made furious war against the republic. These hostilities speedily assumed alarming proportions, and the Florentines began to tire of submitting to so many hardships in order to support the yoke of a fellow-citizen. Lorenzo's hold over Florence seemed endangered. But he did not lose heart, and, on the contrary, rose superior to the difficulties by which he was encompassed. He boldly journeyed to Naples, to the court of King Ferdinand of Aragon, who was reputed to be as treacherous as he was cruel, and succeeded in obtaining from him an honourable peace, that soon led to a reconciliation with Sixtus. Thus at last Lorenzo found himself complete master of Florence, and was in a position to turn his power to account. But, as the "balíe" changed every five years, it was always requisite, in order to retain his supremacy, that he should be prepared to renew the usual manœuvre at the close of that term and have another elected equally favourable to his aims. This was often a difficult achievement, and Lorenzo showed much dexterity in overcoming all obstacles. In 1480 he compassed the institution of a new council of seventy, which was practically a permanent "balía" with extended powers, inasmuch as it not only elected the chief magistrates, but had also the administration of numerous state affairs. But, this permanent council of his own devoted adherents once formed, his security was firmly established. By this means, the chroniclers tell us, "liberty was buried," but the chief affairs of the state were always conducted by intelligent and experienced men, who promoted the public prosperity. Florence was still called a republic; the old institutions were still preserved, if only in name. Lorenzo was absolute lord of all, and virtually a tyrant. His immorality was scandalous; he kept an army of spies, and frequently meddled in the citizens' most private affairs, and exalted men of the lowest condition to important offices of the state. Yet, as Guicciardini remarks, "if Florence was to have a tyrant, she could never have found a better or more pleasant one." In fact all industry, commerce, and public works made enormous progress. The civil equality of modern states, which was quite unknown to the Middle Ages, was more developed in Florence than in any other city of the world. Even the condition of the peasantry was far more prosperous than elsewhere. And Lorenzo's authority was not confined to Tuscany, but was also very great throughout the whole of Italy. He was on the friendliest terms with Pope Innocent VIII., from whom he obtained the exaltation of his son Giovanni to the cardinalate at the age of fourteen. This boy cardinal was afterwards Pope Leo X. From the moment of the decease of Sixtus IV., the union of Florence and Rome became the basis of Lorenzo's foreign policy. By its means he was able to prevent the hatreds and jealousies of the Sforzas of Milan and the Aragonese of Naples from bursting into the open conflict that long threatened, and after his death actually caused, the beginning of new and irreparable calamities. Hence Lorenzo was styled the needle of the Italian compass.

But the events we have narrated cannot suffice for the full comprehension of this complex character, unless we add the record of his deeds as a patron of letters and his achievements as a writer. His palace was the school and resort of illustrious men. Within its walls were trained the two young Medici afterwards known to the world as Leo X. and Clement VII. Ficino, Poliziano, Pico della Mirandola, and all members of the Platonic academy were its constant habitués. It was here that Pulci gave readings of his *Morgante*, and Michelangelo essayed the first strokes of his chisel. Lorenzo's intellectual powers were of exceptional strength and versatility. He could speak with equal fluency on painting, sculpture, music, philosophy, and poetry. But his crowning superiority over every other Mæcenas known to history lay in his active participation in the intellectual labours that he promoted. Indeed at certain moments he was positively the leading spirit among the literati of his time. He was an elegant prose writer, and was likewise a poet of real originality. At that period Italians were forsaking erudition in order to forward the revival of the national literature by recurring to the primitive sources of the spoken tongue and popular verse. It is Lorenzo's lasting glory to have been the initiator of this movement. Without being—as some have maintained—a poet of genius, he was certainly a writer of much finish and eloquence, and one of the first to raise popular poetry to the dignity of art. In his *Ambra*, his *Caccia del Falcone*, and his *Nencia da Barberino*, he gives descriptions of nature and of the rural life that he loved, with the graphic power of an acute and tasteful observer, joined to an ease of style that occasionally sins by excess of homeliness. Both in his art and in his politics he leant upon the people. The more oppressive his government, the more did he seek in his verses to incite the public to festivities and lull it to slumber by sensual enjoyments. In his *Ballate*, or songs for dancing, and more especially in his carnival songs, a kind of verse invented by himself, Lorenzo displayed all the best qualities and worst defects of his muse. Marvellously and spontaneously elegant, very truthful and fresh in style, fertile in fancy and rich in colour, they are often of a most revolting indecency. And these compositions of one filling a princely station in the city were often sung by their author in the public streets, in the midst of the populace.

Lorenzo left three sons,—Pietro (1471–1503), Giovanni (1475–1521), and Giuliano (1479–1516). He was succeeded by Pietro, whose rule lasted but for two years. Pietro. During this brief term he performed no good deeds, and only displayed inordinate vanity and frivolity. His conduct greatly helped to foment the hatred between Lodovico Sforza and Ferdinand of Naples, which hastened the coming of the French under Charles VIII., and the renewal of foreign invasions. No sooner did the French approach the frontiers of Tuscany than Pietro, crazed with fear, hastened to meet them, and, basely yielding to every demand, accepted terms equally humiliating to himself and the state. But, returning to Florence, he found that the enraged citizens had already decreed his deposition, in order to reconstitute the republic, and was therefore compelled to escape to Venice. His various plots to reinstate himself in Florence were all unsuccessful. At last he went to the south of Italy with the French, was drowned at the passage of the Garigliano in 1503, and was buried in the cloister of Monte Cassino.

The ensuing period was adverse to the Medici, for a republican government was maintained in Florence from 1494 to 1512, and the city remained faithful to its alliance with the French, who were all-powerful in Italy. Cardinal

Giovanni, the head of the family, resided in Rome, playing the patron to a circle of literati, artists, and friends, seeking to increase his popularity, and calmly waiting for better days. The battle of Ravenna wrought the downfall of the fortunes of France in Italy, and led to the rise of those of Spain, whose troops entered Florence to destroy the republic and reinstate the Medici. Pietro had now been dead for some time, leaving a young son, Lorenzo (1492–1519), who was afterwards duke of Urbino. The following year (1513) Cardinal Giovanni was elected pope, and assumed the name of Leo X. He accordingly removed to Rome, leaving his brother Giuliano with his nephew Lorenzo in Florence, and accompanied by his cousin Giulio, who was a natural son of the Giuliano murdered in the conspiracy of the Pazzi, and was soon destined to be a cardinal and ultimately a pope. Meanwhile his kinsmen in Florence continued to govern that city by means of a "balía," although preserving an empty show of republican institutions. And thus, being masters of the whole of central Italy, the Medici enjoyed great authority throughout the country, and their ambition plumed itself for still higher flights. This was the moment when Niccolò Machiavelli, in his treatise *The Prince*, counselled them to accomplish the unity of Italy by arming the whole country, and expelling its foregin invaders.

Cardinal Giovanni (Leo X.). Giuliano. Lorenzo.

Leo X., who is only indirectly connected with the history of Florence, gave his name to the age in which he lived in consequence of his magnificent patronage of art and letters in Rome. But he was merely a clever amateur, and had not the literary gifts of his father Lorenzo. He surrounded himself with versifiers and inferior writers, who enlivened his board and accompanied him wherever he went. He liked to lead a gay and untroubled life, was fond of theatrical performances, satires, and other intellectual diversions. His patronage of the fine arts, his genuine affection for Raphael, and the numerous works he caused to be executed by him and other artists, have served to confer an exaggerated glory on his name. He failed to comprehend the significance of the great religious movement already stirring in Germany, and had not the remotest idea of the grave importance of the Reformation, which indeed he unconsciously promoted by his reckless and shameless sale of indulgences. The whole policy of Pope Leo X. consisted in oscillating between France and Spain, in always playing fast and loose, and deceiving both powers in turn. Yet the evil results of this contemptible policy never seemed to disturb his mind. He finally joined the side of the emperor Charles V., and in 1521, at the time of the defeat of the French by the Spanish troops on the river Adda, he ceased to breathe at his favourite villa of Magliana. Giuliano dei Medici had died during Leo's reign, in 1516, without having ever done anything worthy of record. He was the husband of Philiberta of Savoy, was duke of Nemours, and left a natural son, Ippolito dei Medici (1511–1535), who afterwards became a cardinal. Lorenzo, being of more ambitious temper, was by no means content to remain at the head of the Florence Government hampered by many restrictions imposed by republican institutions, and subject to the incessant control of the pope. In his eagerness to aggrandize his kinsmen, the latter had further decided to give Lorenzo the duchy of Urbino, and formally invested him in its rights, after expelling on false pretences its legitimate lord, Francesco Maria della Rovere. This prince, however, soon returned to Urbino, where he was joyously welcomed by his subjects, and Lorenzo regained possession only by a war of several months, in which he was wounded. In 1519 he also died, worn out by disease and excess. By his marriage with Madeleine de la Tour d'Auvergne, he had one daughter, Caterina dei Medici (1519–89), married in 1533 to Henry, duke of Orleans, afterwards king of France. She played a long and sinister part in the history of that country. Lorenzo also left a natural son named Alessandro, inheriting the frizzled hair and projecting lips of the negro or mulatto slave who had given him birth. His miserable death will be presently related. Thus the only three surviving representatives of the chief branch of the Medici, Cardinal Giulio, Ippolito, and Alessandro were all of illegitimate birth, and left no legitimate heirs.

Cardinal Giulio (Clement VII.).

Cardinal Giulio, who had laboured successfully for the reinstatement of his family in Florence in 1512, had been long attached to the person of Leo X. as his trusted factotum and companion. He had been generally regarded as the mentor of the pope, who had no liking for hard work. But in fact, his frivolity notwithstanding, Leo X. always followed his own inclinations. He had much aptitude for command, and pursued his shuffling policy without any mental anxiety. Giulio, on the contrary, shrank from all responsibility, muddled his brains in weighing the reasons for and against every possible decision, and was therefore a better tool of government in others' hands than he was fit to govern on his own account. When Giuliano and Lorenzo died, the pope appointed the cardinal to the government of Florence. In that post, restricted within the limits imposed by republican institutions, and acting under the continual direction of Rome, he performed his duties fairly well. He caressed the citizens with hopes of extended liberties, which, although never destined to be fulfilled, long served to keep men's minds in a pleasant flutter of expectation; and when the more impatient spirits attempted to raise a rebellion he speedily quenched it in blood. When, after the death of Leo X. and the very brief pontificate of Adrian VI., he was elected pope (1523) under the name of Clement VII., he entrusted the government of Florence to Cardinal Silvio Passerini conjointly with Alessandro and Ippolito, who were still too young to do much on their own account.

The pontificate of Leo X. had been a time of felicity to himself if of disaster to Italy and the church. The reign of Clement, on the contrary, was fatal to himself as well, a result chiefly due to his hesitating temper and continual uncertainty of mind. His policy, like that of Leo X., consisted in perpetual oscillation between France and Spain. By his endeavours to trick all the world, he frequently ended in being tricked himself. In 1525 he was the ally of the French, who then suffered a terrible defeat at Pavia, where their king Francis I. was taken prisoner. The armies of Charles V. triumphantly advanced, without Clement being able to oppose any effectual resistance. Both Rome and Florence were threatened with a fearful catastrophe.

Giovanni delle Bande Nere.

Thus far we have had no occasion to speak of the younger branch of the Medici, descended from Lorenzo, brother to Cosimo the Elder. Always in obscurity, and always held in check by the elder line, it now seemed to acquire new life, and first entered the arena of history when the other was on the point of extinction. In fact the most valiant captain of the papal forces was Giovanni dei Medici, afterwards known by the name of Giovanni delle Bande Nere. His father was Giovanni, son of Pier Francesco, who was the son of Lorenzo, the brother of Cosimo dei Medici. History has little to tell of the elder Giovanni; but his wife Caterina Sforza, of whom he was the third husband, was a woman of more than masculine vigour. Giovanni dei Medici married her in 1497, but died in 1498, leaving her with one son who was christened Lodovico, but afterwards took his father's name of Giovanni (1498–1526). Trained to arms from his earliest years, this youth inherited all the energy of his mother, whose Sforza blood seemed to infuse new life into the younger branch of the Medici. Notwithstanding his extreme youth, he had already achieved the title of the best captain in Italy. He always fought with immense dash and daring, and was devotedly loved and obeyed by his soldiery. He was the only leader who opposed a determined resistance to the imperial forces. He was seriously wounded at Pavia when fighting on the French side. On his recovery he joined the army of the League, and was much enraged by finding that the duke of Urbino, commander of the Venetian and papal forces, would never decide on attacking. When the imperial troops were struggling through the marshes of Mantua, surrounded on every side, and without stores or ammunition, Giovanni could not resign himself to inactivity like his colleagues in command. He was ignorant that the imperialists had just received supplies and artillery from the duke of Ferrara, and therefore daringly attacked them with a small body of men without taking any precautions for defence. One of the first shots fired by the enemy injured him so fatally that he died a few days after. He was married to Maria Salviati, by whom he had one son, Cosimo (1519–1574), born, as we shall see, to lofty fortunes, for he became the first grand-duke of Tuscany, and indeed the founder of the grand-duchy and the new dynasty.

Meanwhile the imperial army pursued its march upon Rome, captured the Eternal City after a few hours' combat, and cruelly sacked it during many days (1527). Thanks to his perpetual shuffling and excessive avarice, the pope found himself utterly forsaken, and, being unable to defend the city, was obliged to seek refuge in the castle of St Angelo, whence he only effected his escape after some months. He then signed a treaty of alliance with the emperor (1529), who sent an army to besiege Florence and restore the Medici, whom the people had expelled in 1527 on the re-establishment of the republic. After an heroic defence, the city was forced to surrender (1530); and, although it was expressly stipulated that the ancient liberties of Florence should be respected, every one foresaw that the conditions would be violated. In fact, pope and emperor immediately began to dispute as to which should be the new lord of the city. Clement VII. had inherited the traditional family dislike for the younger branch of his kin, and so the choice lay between the two bastards Ippolito and Alessandro. The former being a cardinal, the latter was chosen. Alessandro, who already bore the title of duke of Città di Penna, came to Florence in 1531, and by imperial patent was nominated head of the republic. According to the terms of this patent, the former liberty enjoyed under the Medicean rule was to remain intact. But no previous ruler of the city had enjoyed hereditary power confirmed by imperial patent, and such power was incompatible with the existence of a republic. Moreover, Clement VII. showed dissatisfaction with the uncertainty of the power conferred upon his kinsman, and finally succeeded in obtaining additional privileges. On the 4th of April 1532 a parliament was convoked for the last time in Florence, and, as usual, approved every measure proposed for acceptance. Accordingly a new council was formed of two hundred citizens elected for life, forty-eight of which number were to constitute a senate. Alessandro, as duke of the republic, filled the post of gonfalonier, and carried on the government with the assistance of three senators, changed every three months, who took the place of the suppressed signory.

Duke Alessandro.

The duke's chief advisers, and the contrivers of all these arrangements, were Baccio Valori, Francesco Vettori, and above all Francesco Guicciardini,—men, especially the two latter, of lofty political gifts and extensive influence. The mind and character of Duke Alessandro were as yet comparatively unknown. At first he seemed very anxious to win the favour of the people, and disposed to rule with justice and prudence. But soon encountering difficulties that he was unable to overcome, he began to neglect the business of the state, treated his new office as affording the means for increased indulgence in pleasure and vice, and acted as if the sole function of government consisted in lulling the people by festivities and corrupting it by the dissolute life of which he set the example. The question of the moment was the transformation of the old republican régime into a princedom; as an unavoidable result of this change it followed that Florence was no longer to be the ruling city to whose inhabitants alone belonged the monopoly of political office. When the leading Florentine families realized, not only that the republic was destroyed, but that they were reduced to equality with those whom they had hitherto regarded as their inferiors and subjects, their rage was indescribable, and hardly a day passed without the departure of influential citizens who were resolved to achieve the overthrow of their new ruler. They found a leader in Cardinal Ippolito dei Medici, who was then in Rome, embittered by the preference given to Alessandro, and anxious to become his successor with the least possible delay. Under the pressure of terror the duke at once became a tyrant. He garrisoned the different cities, and began the erection in Florence of the Fortezza da Basso, built chiefly at the expense of Filippo Strozzi, who afterwards met his death within its walls.

Cardinal Ippolito.

In 1534 Clement VII. died, and the election fell on Paul III., from whom Cardinal Ippolito hoped to obtain assistance for his designs. Accordingly the principal Florentine exiles were despatched on a mission to the emperor Charles V. with complaints of Alessandro's tyranny and his shameless violation of the terms upon which the city had surrendered. Cardinal Ippolito also represented his own willingness to carry on the government of Florence in a more equitable manner, and promised the emperor a large sum of money. Reply being delayed by the emperor's absence, he became so impatient that he set out, accompanied by several exiles, to meet Charles in Tunis, but on the 10th of August 1535 died suddenly by the way, at Itri, poisoned by order of Alessandro. Such at least was the general belief, and it was confirmed by the same fate befalling other enemies of the duke about the same time. On the emperor's return from Africa, the exiles presented themselves to him in Naples, and the venerable patriot Jacopo Nardi pleaded their cause. Duke Alessandro, being cited to appear, came to Naples accompanied by Francesco Guicciardini, who by speaking in his defence rendered himself odious to all friends of liberty, and irretrievably tarnished his illustrious name. The cardinal being dead, it was hard to find a successor to Alessandro. On this account, and perhaps to some extent through the emperor's personal liking for the duke, the latter rose higher than before in the imperial favour, married Margaret of Austria, the natural daughter of Charles, and returned to Florence with increased power. And now Alessandro indulged unchecked in the lowest excesses of tyranny, and although so recently a bridegroom gave way to increased libertinism. His whole time was passed in vicious haunts and in scandalous adventures. In order to conceal the obscurity of his birth, he left his mother to starve, and it was even asserted that he finally got rid of her by poison.

Lorenzino dei Medici.

His constant associate in this disgraceful routine was his distant kinsman Lorenzo, generally known as Lorenzino dei Medici. Of the younger branch of the Medici, the latter was second cousin of the Cosimo already mentioned as the son of Giovanni delle Bande Nere. He had much culture and literary talent, but led an irregular life, sometimes acting like a madman and sometimes like a villain. He was a writer of considerable elegance, the author of several plays, one of which, the *Aridosio*, was held to be among the best of the age, and he was a worshipper of antiquity. Notwithstanding these tastes, when in Rome he knocked off the heads of some of the finest statues of the age of Adrian, an act by which Clement VII. was so incensed that he threatened to have him hanged. Thereupon Lorenzino fled to Florence, where he became the friend of Duke Alessandro and his partner in the most licentious excesses. They went together to houses of ill-fame, and violated private dwellings and convents. They often showed themselves in public mounted on the same horse. All Florence eyed them with disgust, but no one foresaw the tragedy that was soon to take place.

Assassination of Alessandro. On the evening of January 5th, 1537, after a day passed in the usual excesses, Lorenzino led the duke to his own lodging, and left him there, promising shortly to return with the wife of Leonardo Ginori. Alessandro, worn out by the exertions of the day, fell asleep on the couch while awaiting Lorenzino's return. Before long the latter came accompanied by a desperado known as the Scoronconcolo, who aided him in falling on the sleeper. Roused by their first thrusts, the duke fought for his life, and was only despatched after a violent struggle. The murderers then lifted the body into bed, hid it beneath the clothes, and, Lorenzino having attached a paper to it bearing the words, *vincit amor patriæ, laudumque immensa cupido*, they both fled to Venice. In that city Lorenzino was assassinated some ten years later, in 1548, at the age of thirty-two, by order of Alessandro's successor. Thus he was only about twenty-two at the time he committed the murder. He wrote an *Apologia*, in which he defended himself with great skill and eloquence, saying that he had been urged to the deed solely by love of liberty. For this reason alone he had followed the example of Brutus and played the part of friend and courtier. The tone of this *Apologia* is so straightforward, sometimes even so eloquent and lofty, that we should be tempted to give it credence were it possible to believe the assertions of one who not only by his crime but by the infamy of his previous and subsequent career completely gave the lie to his vaunted nobility of purpose. By Alessandro's death the elder branch of the Medici became extinct, and thus the appearance of the younger line was heralded by a bloody crime.

When the duke's absence from his own palace was discovered on the morning of January 6th, he was at first supposed to have spent the night with one of his mistresses; but soon, some alarm being felt, search was made, and Cardinal Cybo was the first to discover the murder. Enjoining the strictest secrecy, he kept the corpse concealed for three days, and then had it interred in the sacristy of San Lorenzo. Meanwhile he had hastily summoned Alessandro Vitelli and the other captains, so that, by the time Alessandro's death was made public, the city was already filled with troops. The cardinal then convoked the council of forty-eight to decide upon a successor. Alessandro's only issue was a natural son named Giulio, aged five. The cardinal favoured his election, in the hope of keeping the real sovereignty in his own hands. But he speedily saw the impossibility of carrying out a design that was ridiculed by all. On the other hand, Guicciardini, Vettori, and others of the leading citizens favoured the choice of Cosimo, the son of Giovanni delle Bande Nere. He was already in Florence, was aged seventeen, was keen-witted and aspiring, strong and handsome in person, heir to the enormous wealth of the Medici, and, by the terms of the imperial patent, was Alessandro's lawful

Cosimo I. successor. Charles V. approved the nomination of Cosimo, who without delay seized the reins of government with a firm grasp. Like Alessandro, he was named head of the republic; and Guicciardini and others who had worked hardest in his cause hoped to direct him and keep him under their control. But Cosimo soon undeceived them by proving that, his youth notwithstanding, he had a will of his own, and was resolved to rule unshackled by republican forms and unhampered by advisers disposed to act as mentors. The Florentines had now an absolute prince who was likewise a statesman of eminent ability.

On learning the death of Alessandro and the election of Cosimo, the exiles appreciated the necessity for prompt action, as all delay would be fatal to the overthrow of the Medicean rule. They had received money and promises from France; they were strengthened by the adhesion of Filippo Strozzi and Baccio Valori, who had both become hostile to the Medici through the infamous conduct and mad tyranny of Alessandro; and Strozzi brought them the help of his enormous fortune and the prowess of that very distinguished captain, his son Piero. The exiles accordingly met, and assembled their forces at Mirandola. They had about four thousand infantry and three hundred horse; among them were members of all the principal Florentine families; and their leaders were Bernardo Salviati and Piero Strozzi. They marched rapidly, and entered Tuscany towards the end of July 1537. Cosimo on this occasion displayed signal capacity and presence of mind. Fully informed of the exiles' movements by means of his spies, he no sooner learned their approach than he ordered Alessandro Vitelli to collect the best German, Spanish, and Italian infantry at his disposal, and advance against the enemy without delay. On the evening of July 31 Vitelli marched towards Prato with seven hundred picked infantry and a band of one hundred horse, and on the way fell in with other Spanish foot soldiers who joined the expedition. At early dawn the following morning he made a sudden attack on the exiles' advanced guard close to Montemurlo, an old fortress converted into a villa belonging to the Nerli. Having utterly routed them, he proceeded to storm Montemurlo, where Filippo Strozzi and a few of his young comrades had taken refuge and barricaded the gates. Knowing that they must either conquer or die, they made a desperate resistance for some hours, and then, overwhelmed by superior numbers, were obliged to yield themselves prisoners. The main body of the army was still at some distance, having been detained in the mountains by heavy rains and difficult passes, and, on learning the defeat at Montemurlo, its leader refused to advance, and turned back by the way he had come. Alessandro Vitelli then re-entered Florence with his victorious army and his fettered captives. Cosimo had achieved his first triumph.

All the prisoners, who were members of great families, were brought before Cosimo, and were received by him with courteous coldness. Soon, however, a scaffold was erected in the Piazza, and on four mornings in succession four of the prisoners were beheaded. Then the duke saw fit to stay the executions. Baccio Valori, however, and his son and nephew were beheaded on the 20th of August in the courtyard of the Bargello. Filippo Strozzi still survived, confined in the Fortezza da Basso, that had been built at his expense. His family was illustrious, he had numerous adherents, and he enjoyed the protection of the French king. Nevertheless Cosimo only awaited some plausible pretext to rid himself of this dreaded enemy. He brought him to trial and had him put to the question. But this cruelty led to nothing, for Strozzi denied every accusation and bore the torture with much fortitude. On December 18th he was found dead in his prison, with a blood-stained sword by his side, and a slip of paper bearing these words: *exoriare aliquis nostris ex ossibus ultor.* It was believed that, having renounced all hope of his life being spared, Strozzi had preferred suicide to death at the hands of the executioner. Some, however, thought that Cosimo had caused him to be murdered, and adopted this mode of concealing the crime. The young prince's cold-blooded massacre of his captives cast an enduring shadow upon his reign and dynasty. But it was henceforward plain to all that he was a man of stern resolve, who went straight to his end without scruples or half measures. Before long he was regarded by many as the incarnation of Machiavelli's *Prince*, "inasmuch as he joined daring to talent and prudence, was capable of great cruelty, and yet could practise mercy in due season." Guicciardini, who still pretended to act as mentor, and who on account of his many services had a certain influence over him, was obliged to withdraw from public life and busy himself with writing his *History* at his villa of Arcetri. He died in this retreat in 1540, and it was immediately rumoured that the duke had caused him to be poisoned. This shows the estimation in which Cosimo was now held. It was true that he punished with death all who dared to resist his will. By 1540 sentence of death had been pronounced against four hundred and thirty contumacious fugitives, and during his reign one hundred and forty men and six women actually ascended the scaffold, without counting those who perished in foreign lands by the daggers of his assassins. He reduced the old republican institutions to empty forms, by making the magistrates mere creatures of his will. He issued the sternest edicts against the rebels, particularly by the law known as the "Polverina," from the name of its proposer Jacopo Polverini. This law decreed not only the confiscation of the property of exiles, but likewise that of their heirs, even if personally acquired by the latter. Cosimo ruled like the independent sovereign of a great state, and always showed the capacity, firmness, and courage demanded by that station. Only, his state being small and weak, he was forced to rely chiefly upon his personal talent and wealth. It was necessary for him to make heavy loans to the different European sovereigns, especially to Charles V., the most rapacious of them all, and to give enormous bribes to their ambassadors. Besides, he had to carry on wars for the extension of his dominions, and neither his inherited wealth nor the large sums gained by confiscating the estates of rebellious subjects sufficed for all this outlay. He was accordingly compelled to burden the people with taxes, and thus begin at once to diminish its strength.

Cosimo bore a special grudge against the neighbouring republics of Siena and Lucca. Although the latter was small and weak, and the former garrisoned by Spaniards, yet the spectacle of free institutions at the frontiers of his own state served as a continual incitement to subjects disaffected to the new régime. In fact Francesco Burlamacchi, a zealous Lucchese patriot, had conceived the design of re-establishing republican government in all the cities of Tuscany. Cosimo, with the emperor's help, succeeded in having him put to death. Lucca, however, was an insignificant state making no pretence of rivalry, whereas Siena was an old and formidable foe to Florence, and had always given protection to the Florentine exiles. It was now very reluctantly submitting to the presence of a Spanish garrison, and, being stimulated by promises of prompt and efficacious assistance from France, rose in rebellion and expelled the Spaniards in 1552. Cosimo instantly seized the opportunity, wrote to the emperor in terms that appealed to his pride, asked leave to attack Siena, and begged for troops to ensure the success of his enterprise. As no immediate answer arrived, he feigned to begin negotiations with Henry II. of France, and, by thus arousing the imperial jealousy, obtained a contingent of German and Spanish infantry. Then came a long and bloody war. Siena was besieged for fifteen months, and its inhabitants, aided by the valour of Piero Strozzi, who fought under the French flag, made a most heroic resistance, even women and children helping on the walls. But fortune was against them. Piero Strozzi sustained several defeats, and finally the Sienese, having exhausted their ammunition and being decimated by famine and the sword, were obliged to capitulate on honourable terms that were shamelessly violated. By the varied disasters of the siege and the number of fugitives the population was reduced from forty to eight thousand inhabitants. The republicans, still eager to resist, withdrew to Montalcino. Cosimo now ruled the city and territory of Siena in the name of Charles V., who always refused him its absolute possession. After the emperor's abdication, and the succession of Philip II. to the Spanish throne, Cosimo at last obtained Siena and Portoferra by giving up his claim to a sum of 200,000 ducats that he was to have received from Charles V. In 1559 he also captured Montalcino, and thus formed the grand-duchy of Tuscany, but he continued to govern the new state —*i.e.*, Siena and its territories—separately from the old. His rule was intelligent, skilful, and despotic; but his enormous expenses drove him to raise large sums of money by special contrivances unsuited to the country and the people. Hence, notwithstanding the genius of its founder, the grand-duchy held from the first the elements of its future decay. Cosimo preferred to confer office upon men of humble origin in order to have pliable tools, but he also liked to be surrounded by a courtier aristocracy on the Spanish and French pattern. As no Tuscan aristocracy any longer existed, he created new nobles, and tempted foreign ones to come by the concession of various feudal privileges; and, in order to turn this artificial aristocracy to some account, he founded the knightly order of St Stephen, charged with the defence of the coast against pirates, which in course of time won much honour by its prowess. He also established a small standing army for the protection of his frontiers; but, as we have seen, he generally employed German and Spanish troops for his wars, and always had a foreign bodyguard. At the commencement of his reign he opposed the popes in order to maintain the independence of his own state; but later, to obtain help, he truckled to them in many ways, even to the extent of giving up to the Inquisition his own confidant, Piero Carnesecchi, who, being accused of heresy, was beheaded and burnt in 1567. In reward for these acts of submission, the popes showed him friendship, and Pius V. granted him the title of grand-duke, conferring the patent and crown upon him in Rome, although the emperor had always withheld his consent. Finally, however, the latter confirmed the title to Cosimo's successor. The measure most injurious to Tuscany was the fiscal system of taxes, of which the sole aim was to extort the greatest possible amount of money. The consequent damage to industry, commerce, and agriculture was immense, and, added to the devastations caused by the Sienese war, led to their utter ruin. Otherwise Cosimo did not neglect useful measures for the interior prosperity of his state. He was no Mæcenas, but nevertheless restored the Pisan university, enlarged that of Siena, had the public records classified, and also executed public works like the Santa Trinità bridge. During the great inundations of 1557 he turned his whole energy to the relief of the sufferers.

Title of grand-duke.

In 1539 he had espoused Eleonora of Toledo, daughter of the viceroy of Naples, by whom he had several children. Two died in 1562, and their mother soon followed them to the grave. It was said that one of these boys, Don Garcia, had murdered the other, and then been killed by the enraged father. Indeed Cosimo was further accused of having put his own wife to death; but neither rumour had any foundation. He now showed signs of illness and failure of strength. He was not old, but worn by the cares of state and self-indulgence. Accordingly in 1564 he resigned the government to his eldest son, who was to act as his lieutenant, since he wished to remain the virtual head of the state and have power to resume the sceptre on any emergency. In 1570, by the advice of Pius V., he married Camilla Martelli, a young lady of whom he had been long enamoured. In 1574 he died, at the age of fifty-four years and ten months, after a reign of thirty-seven years, leaving three sons and one daughter besides natural children. These sons were Francesco, his successor, who was already at the head of the government, Cardinal Ferdinand, and Piero.

Francesco I.

Francesco I., born in 1541, began to govern as his father's lieutenant in 1564, and was married in 1565 to the archduchess Giovanna of Austria. On beginning to reign on his own account in 1574, he speedily manifested his real character. His training in the hands of a Spanish mother had made him suspicious, false, and despotic. Holding everyone aloof, he carried on the government with the assistance of a few devoted ministers. He compelled his stepmother to retire to a convent, and kept his brothers at a distance from Florence. He loved the privileges of power without its burdens. Cosimo had known how to maintain his independence, but Francesco cast himself like a vassal at Austria's feet. He reaped his reward by obtaining from Maximilian II. the title of grand-duke, for which Cosimo had never been able to win the imperial sanction, but he forfeited all independence. Towards Philip II. he showed even greater submissiveness, supplying him with large sums of money wrung from his over-taxed people. He held entirely aloof from France, in order not to awake the suspicions of his protectors. In short, under his rule the history of Tuscany was reduced to a mere record of local and municipal events. To increase his funds, he traded on his own account, thus creating a monopoly that was ruinous to the country at large, and led to an enormous number of failures. He raised the tax upon corn to so high a rate that few continued to find any profit in growing it, and thus the Maremme, already partly devastated during the war with Siena, were converted into a desert. Even industry declined under this system of government; and, although Francesco founded porcelain manufactories and pietra dura works, they did not rise to any prosperity until after his death. His love of science and letters was the only Medicean virtue that he possessed. He had an absolute passion for chemistry, and passed much of his time in his laboratory. Sometimes indeed he gave audience to his secretaries of state standing before a furnace, bellows in hand. He took some useful measures to promote the rise of a new city at Leghorn, which at that time had only a natural and ill-sheltered harbour. The improvement of Leghorn had been first projected by Cosimo I., and was carried on by all the succeeding Medici. Francesco was a slave to his passions, and was led by them to scandalous excesses and deeds of bloodshed. His example and neglect of the affairs of the state soon caused a vast increase of crime even among the people, and, during the first eighteen months of his reign, there occurred no less than one hundred and sixty-eight murders.

In default of public events, the historians of this period enlarge upon private incidents, generally of a scandalous or sanguinary kind. In 1575 Orazio Pucci, wishing to avenge his father, whom Cosimo had hanged, determined to get up a conspiracy, but, soon recognizing how firmly the Medicean rule had taken root in the country, desisted from the attempt. But the grand-duke, on hearing of the already abandoned plot, immediately caused Pucci to be hanged from the same window of the Palazzo Vecchio, and even from the same iron stanchion, from which his father before him had hung. His companions, who had fled to France and England, were pursued and murdered by the ducal emissaries. Their possessions were confiscated, and the "Polverina" law applied so that the conspirators' heirs were reduced to penury, and the grand-duke gained more than 300,000 ducats.

Next year Isabella dei Medici, Francesco's sister, was strangled in her nuptial bed by her husband, Paolo Giordano Orsini, whom she had betrayed. Piero dei Medici, Francesco's brother, murdered his wife Eleonora of Toledo from the same motive. Still louder scandal was caused by the duke's own conduct. He was already a married man, when, passing one day through the Piazza of St Mark in Florence, he saw an exceedingly beautiful woman at the window of a mean dwelling, and at once conceived a passion for her. She was the famous Bianca Cappello, a Venetian of noble birth, who had eloped with a young Florentine named Pietro Buonaventuri, to whom she was married at the time that she attracted the duke's gaze. He made her acquaintance, and, in order to see her frequently, nominated her husband to a post at court. Upon this, Buonaventuri behaved with so much insolence, even to the nobility, that one evening he was found murdered in the street. Thus the grand-duke, who was thought to have sanctioned the crime, was able to indulge his passion unchecked. On the death of the grand-duchess in 1578 he was privately united to Bianca, and afterwards married her publicly. But she had no children, and this served to poison her happiness, since the next in succession was her bitter enemy, the cardinal Ferdinand. The latter came to Florence in 1587, and was ostentatiously welcomed by Bianca, who was most anxious to conciliate him. On October 18th of the same year, the grand-duke died at his villa of Poggio a Caiano, of a fever caught on a shooting excursion in the Maremme, and the next day Bianca also expired, having ruined her health by drugs taken to cure her sterility. But rumour asserted that she had prepared a poisoned tart for the cardinal, and that, when he suspiciously insisted on the grand-duke tasting it first, Bianca desperately swallowed a slice and followed her husband to the tomb.

Such was the life of Francesco dei Medici, and all that can be said in his praise is that he gave liberal encouragement to a few artists, including Giovanni Bologna, who executed for him the group of the Rape of the Sabines. He was the founder of the Uffizi gallery, of the Medici theatre, and the villa of Pratolino; and during his reign the Della Cruscan academy was instituted.

Ferdinand I.

Ferdinand I. was thirty-eight years of age when, in 1587, he succeeded his brother on the throne. A cardinal from the age of fourteen, he had never taken holy orders. He showed much tact and experience in the management of ecclesiastical affairs. He was the founder of the Villa Medici at Rome, and the purchaser of many priceless works of art, such as the Niobe group and many other statues afterwards transported by him to Florence. After his accession he retained the cardinal's purple until the time of his marriage. He was in all respects his brother's opposite. Affable in his manners and generous with his purse, he chose a crest typical of the proposed mildness of his rule,—a swarm of bees with the motto *Majestate tantum*. He instantly pardoned all who had opposed him, and left his kinsmen at liberty to choose their own place of residence. Occasionally, for political reasons, he committed acts unworthy of his character; but he re-established the administration of justice, and sedulously attended to the business of the state and the welfare of his subjects. Accordingly Tuscany revived under his rule and regained the independence and political dignity that his brother had sacrificed to love of ease and personal indulgence. He favoured commerce, and effectually ensured the prosperity of Leghorn, by an edict enjoining toleration towards Jews and heretics, which led to the settlement of many foreigners in that city. He also improved the harbour and facilitated communication with Pisa by means of the Naviglio, a canal into which a portion of the water of the Arno was turned. He nevertheless retained the reprehensible custom of trading on his own account, keeping banks in many cities of Europe. He successfully accomplished the draining of the Val di Chiana, cultivated the plains of Pisa, Fucecchio, and Val di Nievole, and executed other works of public utility at Siena and Pisa. But his best energies were devoted to the foreign policy by which he sought to emancipate himself from subjection to Spain. On the assassination (1589) of Henry III. of France, Ferdinand supported the claims of the king of Navarre, undeterred by the opposition of Spain and the Catholic League, who were dismayed by the prospect of a Huguenot succeeding to the throne of France. He lent money to Henry IV., and strongly urged his conversion to Catholicism; he helped to persuade the pope to accept Henry's abjuration, and pursued this policy with marvellous persistence until his efforts were crowned with success. Subsequently, however, Henry IV. showed faint gratitude for the benefits conferred upon him, and paid no attention to the expostulations of the grand duke, who then began to slacken his relations with France, and showed that he could guard his independence by other alliances. He gave liberal assistance to Philip III. for the campaign of the latter in Algiers, and to the emperor for the war with the Turks. Hence he was compelled to burden his subjects with enormous taxes, forgetting that while guaranteeing the independence of Tuscany by his loans to foreign powers he was increasingly sapping the strength of future generations. He at last succeeded in obtaining the formal investiture of Siena, which Spain had always considered a fief of her own.

During this grand-duke's reign the Tuscan navy was notably increased, and did itself much honour on the Mediterranean. The war-galleys of the knights of St Stephen were despatched to the coast of Barbary to attack Bona, the headquarters of the corsairs, and they captured the town with much dash and bravery. And in the following year (1608) the same galleys achieved their most brilliant victory in the archipelago over the stronger fleet of the Turks, by taking nine of their vessels, seven hundred prisoners, and a store of jewels of the value of 2,000,000 ducats.

Cosimo II.

Ferdinand I. died in 1609, leaving four sons, of whom the eldest, Cosimo II., succeeded to the throne at the age of nineteen. He was at first assisted in the government by his mother and a council of regency. He had a good disposition, and the fortune to reign during a period when Europe was at peace and Tuscany blessed with abundant harvests. Of his rule there is little to relate. His chief care was given to the galleys of St Stephen, and he sent them to assist the Druses against the Porte. On one occasion he was involved in a quarrel with France. Concino Concini, the Marshal d'Ancre, being assassinated in 1617, Louis XIII. claimed the right of transferring the property of the murdered man to De Luynes. Cosimo opposed the decision, and, refusing to recognize the confiscation decreed by the French tribunals, demanded that Concini's son should be allowed to inherit. Hence followed much ill-feeling and mutual reprisals between the two countries, finally brought to an end by the intervention of the duke of Lorraine.

Like his predecessors, Cosimo II. studied to promote the prosperity of Leghorn, and he deserves honour for abandoning all commerce on his own account. But it was no praiseworthy act to pass a law depriving women of almost all rights of inheritance. By this means many daughters of the nobility were driven into convents against their will. He gave scanty attention to the general affairs of the state. He was fond of luxury, spent freely on public festivities, and detested trouble. Tuscany was apparently tranquil and prosperous; but the decay of which the seeds were sown under Cosimo I. and Ferdinand I. was rapidly spreading, and became before long patent to all and beyond all hope of remedy. The best deed done by Cosimo II. was the protection accorded by him to Galileo Galilei, who had removed to Padua, and there made some of his grandest discoveries. The grand-duke recalled him to Florence in 1610, and nominated him court mathematician and philosopher. Cosimo died in February 1621, after twelve years of a quiet reign marked by no great event. Feeling his end draw near, when he was only aged thirty and all his sons were still in their childhood, he hastened to arrange his family affairs. His mother, Cristina of Lorraine, and his wife, Maddalena of Austria, were nominated regents and guardians to his eldest son Ferdinand II., a boy of ten, and a council of four appointed, whose functions were regulated by law. Accordingly, after Cosimo's death, the young Ferdinand was sent to Rome and Vienna to complete his education, and the government of Tuscany remained in the hands of two jealous and quarrelsome women. Thus the administration of justice and finance speedily went to ruin. Out of submissiveness to the pope, the regents did not dare to maintain their legitimate right to inherit the duchy of Urbino, and in 1623 sanctioned the transfer of that right to the holy see. They conferred exaggerated privileges on the new Tuscan nobility, which became increasingly insolent and worthless. They resumed the practice of trading on their own account, and, without reaping much benefit thereby, did the utmost damage to private enterprise.

Ferdinand II.

In 1627 Ferdinand II., then aged seventeen, returned to Italy and assumed the reins of government; but, being of a very gentle disposition, he decided on sharing his power with the regents and his brothers, and arranged matters in such wise that each was almost independent of the other. He gained the love of his subjects by his great goodness; and, when Florence and Tuscany were cruelly ravaged by the plague in 1630, he showed admirable courage, and carried out many useful measures. But he was totally incapable of energy as a statesman. When the pope made bitter complaints because the board of health had dared to subject certain monks and priests to the necessary quarantine, the grand-duke insisted on his officers asking pardon on their knees for having done their duty. On the death in 1631 of the last duke of Urbino, the pope was allowed to seize the duchy without the slightest opposition on the part of Tuscany. As a natural consequence the pretensions of the Roman curia became increasingly exorbitant; ecclesiastics usurped the functions of the state; and the ancient laws of the republic, together with the regulations decreed by Cosimo I. as a check upon similar abuses, were allowed to become obsolete. On the extinction of the line of the Gonzagas at Mantua in 1627, war broke out between France on the one side and Spain, Germany, and Savoy on the other. The grand-duke, uncertain of his policy, trimmed his sails according to events. Fortunately peace was re-established in 1631. Mantua and Monferrato fell to the duke of Nevers, as France had always desired. But Europe was again in arms for the Thirty Years' War, and Italy was not at peace. Urban VIII. wished to aggrandize his nephews, the Barberini, by wresting Castro and Ronciglione from Odoardo Farnese, duke of Parma and brother-in-law to Ferdinand. Farnese determined to maintain his rights, and marched his army through Tuscany into the territories of the pope, who was greatly alarmed by the attack. Naturally the grand-duke was drawn into the war to defend his own state and his kinsman. His military operations, however, were of the feeblest and often the most laughable character. At last, by means of the French intervention, peace was made in 1644. But, although the pope was forced to yield, he resigned none of his ecclesiastical pretensions in Tuscany. It was during Ferdinand's reign that the septuagenarian Galileo was obliged to appear before the Inquisition in Rome, which treated him with infamous cruelty. On the death of this great and unfortunate man, the grand-duke wished to erect a monument to him, but was withheld by fear of the opposition of the clergy. The dynasty as well as the country now seemed on the brink of decay. Two of the grand duke's brothers had already died childless, and Ippolito, the sole survivor, was a cardinal. Accordingly the only remaining heir was Cosimo III., married to a wife who held him in detestation, and did her best to have her marriage annulled or at least obtain a separation.

Like nearly all his predecessors, Ferdinand II. gave liberal patronage to science and letters, greatly aided therein by his brother Leopold, who had been trained by Galileo Galilei, and who joined with men of learning in founding the celebrated academy *Del Cimento*, of which he was named president. This academy took for its motto the words *Provando e riprovando*, and followed the experimental method of Galileo. Formed in 1657, it was dissolved in 1667 in consequence of the jealousies and dissensions of its members, but during its brief existence won renown by the number and importance of its works.

Cosimo III. Cosimo III. succeeded his father in 1670. He was weak, vain, bigoted, and hypocritical. In 1661 he had espoused Louise d'Orléans, niece of Louis XIV., who, being enamoured of Duke Charles of Lorraine, was very reluctant to come to Italy, and speedily detested both her husband and his country, of which she refused to learn the language. She had two sons and one daughter, but after the birth of her third child, Giovan Gastone, her hatred for her husband increased almost to madness. She first withdrew to Poggio a Caiano, and then, being unable to get her marriage annulled, returned to France, where, although supposed to live in conventual seclusion, she passed the greater part of her time as a welcome visitor at court. Even her testamentary dispositions attested the violence of her dislike to her husband.

Cosimo's hypocritical zeal for religion compelled his subjects to multiply services and processions, that greatly infringed upon their working hours. He wasted enormous sums in pensioning converts—even those from other countries—and in giving rich endowments to sanctuaries. Meanwhile funds often failed for the payment of Government clerks and soldiers. His court was composed of bigots and parasites; he ransacked the world for dainties for his table, adorned his palace with costly foreign hangings, had foreign servants, and filled his gardens with exotic plants. He purchased from the emperor the title of "Highness" in order to be the equal of the duke of Savoy. He remained neutral during the Franco-Spanish war, and submitted to every humiliation and requisition exacted by the emperor. He had vague notions of promoting agriculture, but accomplished no results. At one time he caused eight hundred families to be brought over from the Morea for the cultivation of the Maremme, where all of them died of fever. But when, after the revocation of the edict of Nantes, French Huguenots offered to apply their labour and capital to the same purpose, the grand-duke's religious scruples refused them refuge. So ruin fell upon Tuscany. Crime and misery increased, and the poor, who only asked for work, were given alms and sent oftener to church. This period witnessed the rise of many charitable institutions of a religious character under the patronage of the grand duke, as for instance the congregation of San Giovanni Battista. But these could not remedy the general decay.

Cosimo's dominant anxiety regarded the succession to the throne. His eldest son Ferdinand died childless in 1713. The pleasure-loving Giovan Gastone was married to Anna Maria of Saxe-Lauenburg, widow of a German prince, a wealthy coarse woman wholly immersed in domestic occupations, and who seemed little likely to give birth to any children. After living with her for some time in a Bohemian village, Giovan Gastone yielded to his dislike to his wife and her country, withdrew to France, and ruined his health by his excesses. After a brief return to Bohemia he finally separated from his wife, by whom he had no family. Thus the dynasty was doomed to extinction. Cosimo had a passing idea of reconstituting the Florentine republic, but, this design being discountenanced by the European powers, he determined to transfer the succession, after the death of Giovan Gastone, to his sister Anna Maria Louisa, who in fact survived him. For this purpose he proposed to annul the patent of Charles V., but the powers objected to this arrangement also, and by the treaty of 1718 the quadruple alliance of Germany, France, England, and Holland decided that Parma and Tuscany should descend to the Spanish Infante Don Carlos. The grand-duke made energetic but fruitless protests.

Giovan Gastone. Cosimo III. had passed his eightieth year at the time of his decease in October 1723, and was succeeded by his son Giovan Gastone, then aged fifty-three. The new sovereign was in bad health, worn out by dissipation, and had neither ambition nor aptitude for rule. His throne was already at the disposal of foreign powers, and his only thought on ascending it was to regain strength enough to pass the remainder of his days in enjoyment. He dismissed the spies, parasites, and bigots that had formed his father's court, abolished the pensions given to converts, suppressed several taxes, and prohibited the organized espionage established in the family circle. He wished to live and let live, and liked the people to be amused. Everything in fact bore a freer and gayer aspect under his reign, and the Tuscans seemed to feel renewed attachment for the dynasty as the moment of its extinction drew near. But the grand-duke was too feeble and incapable to accomplish any real improvement. Surrounded by gay and dissipated young men, he entrusted all the cares of government to a certain Giuliano Dami, who drove a profitable trade by the sale of offices and privileges. In this way all things were in the hands of corrupt individuals; while the grand-duke, compelled to pass the greater part of his time in bed, vainly sought diversion in the company of buffoons, and was only tormented by perceiving that all the world disposed of his throne without even asking his advice. And when, after prolonged opposition, he had resigned himself to accept Don Carlos as his successor, the latter led a Spanish army to the conquest of Naples, an event afterwards leading to the peace of 1735, by which the Tuscan succession was transferred to Francesco II., duke of Lorraine, and husband of Maria Theresa. Giovan Gastone was finally obliged to submit even to this. Spain withdrew her garrisons from Tuscany, and Austrian soldiers took their place and swore fealty to the grand-duke on the 5th of February 1737. He expired on the 9th July of the same year. Such was the end of the younger branch of the Medici, which had found Tuscany a prosperous country, where art, letters, commerce, industry, and agriculture flourished, and left her poor and decayed in all ways, drained by taxation, and oppressed by laws contrary to every principle of sound economy, downtrodden by the clergy, and burdened by a weak and vicious aristocracy.

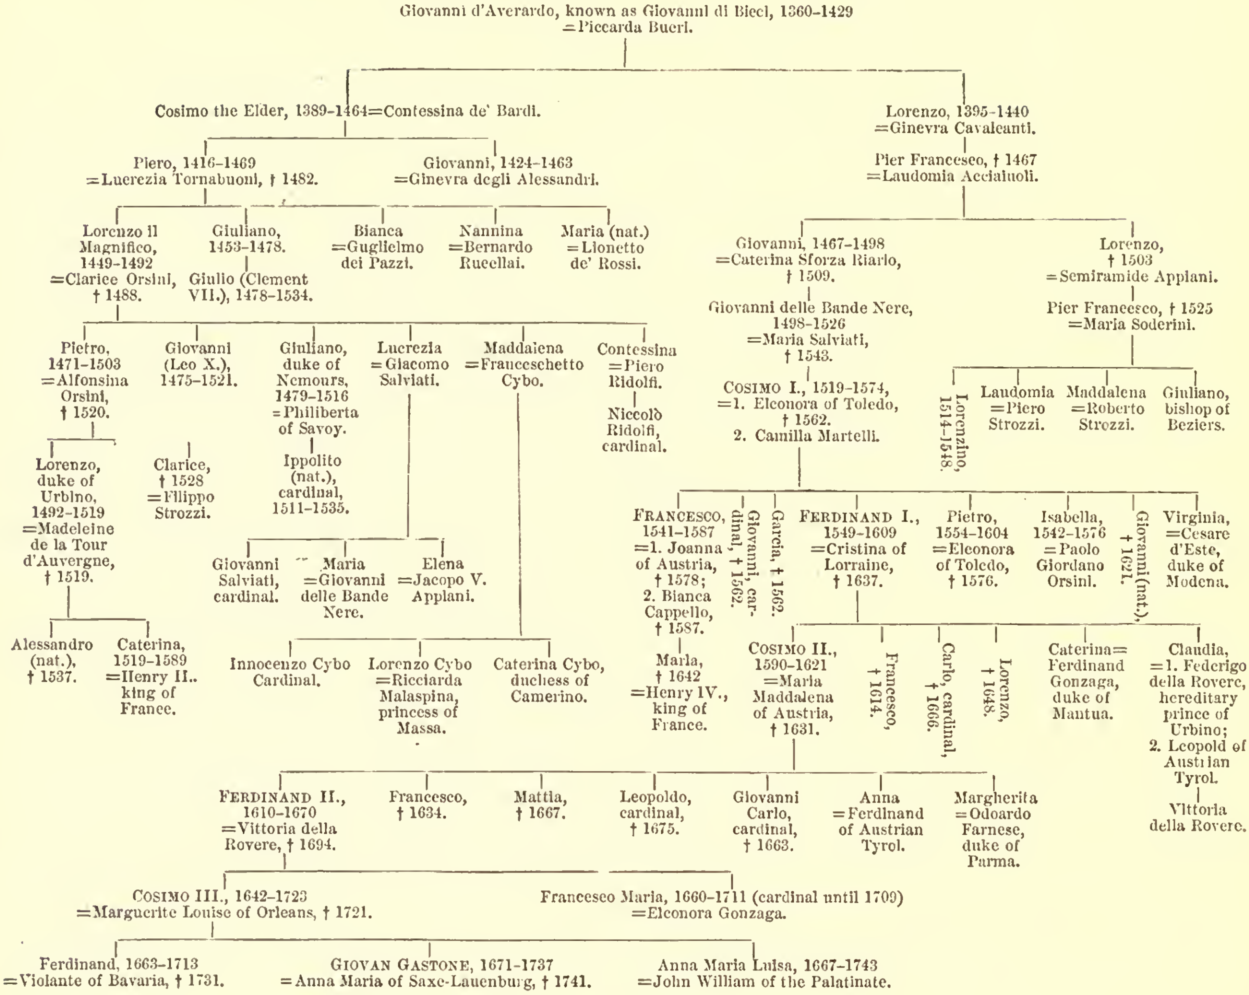
GENEALOGICAL TABLE OF THE MEDICI.



MEDICINE

PART I.—SYNOPTICAL VIEW OF MEDICINE.

MEDICINE, the subject-matter of one of the learned professions, includes, as it now stands, a wide range of scientific knowledge and practical skill. The history of its growth from small beginnings in Greece is traced in the second section of the present article; it remains here to give a synoptical view of medicine, including its scientific or philosophical position, its subdivisions or ramifications as an art and discipline, and its relations to the body politic.

Scientific Position of Medicine.—The science of medicine is the theory of diseases and of remedies. While the notion of disease is necessarily or inevitably correlated with the notion of health, there is no necessary and invariable relation, but, on the other hand, a merely conventional association, between a disease and a remedy. That part of the science of medicine which corresponds to the theory of remedies is not therefore in a position scientifically inferior to the theory of diseases; for each article of the materia medica—apart from a few inert substances—has a certain effect on the organism in health and in disease, which is ascertainable with scientific precision. Those properties and actions of drugs are the subject of pharmacology and toxicology; the circumstances under which the several articles of the materia medica become remedial are the subject of therapeutics, and therapeutics is dependent for its scientific position upon the completeness of the theory of diseases, or pathology.

Disease is the correlative of health, and the word is not capable of a more penetrating definition. From the time of Galen, however, it has been usual to speak of the life of the body either as proceeding in accordance with nature (κατὰ φύσιν, *secundum naturam*) or as overstepping the bounds of nature (παρὰ φύσιν, *præter naturam*). Taking disease to be a deflexion from the line of health, the first requisite of medicine is an extensive and intimate acquaintance with the norm of the body. The normal condition of the body is capable of being determined without ambiguity; it is the absence from its structures and functions of every disease hitherto known. The structure and functions of the body form the subject of anatomy and physiology.

Physiology is, strictly speaking, the science of that which is κατὰ φύσιν, or *secundum naturam*, and it is usual to say that the theory of diseases is based upon physiology. But, although all that was implied in the Hippocratic term φύσις (*natura*) may be claimed as the subject-matter of physiology, yet, in the ordinary connotation of the term, physiology divides the empire with anatomy. To physiology the functions of the body are usually assigned, and to anatomy its form and structure. But, as a matter of fact, the structures and functions of the organism are not separable; structure is correlated to function, whether active, dormant, or extinguished, and in like manner function is the twin notion of structure. In the ultimate analysis neither term means anything without the other, and both together mean life. It is owing mostly to its name that physiology is supposed to have a preponderant interest for the theory of disease; the word anatomy is not well adapted to carry its own half of the structure-and-function dualism. Both in the historical development and in the logical connotation, anatomy is as much associated with the living and moving body as physiology itself; but its etymology has always been against it, and it has become more and more difficult to retain for anatomy anything beyond the technicalities of the dissecting-room. The subject of general anatomy has for the most part disappeared from modern text-books, its place being taken by histology, which deals with the minute structure of the simple tissues, and, in a wider acceptation, with the finer anatomy of all the organs and parts of the body. Histology, like anatomy, has had a somewhat technical or descriptive rôle assigned to it; and it is now mainly under physiology that the processes, activities, or living mechanisms of the body fall to be considered. The development of the body as a whole, and of its several tissues and organs, forms the subject of embryology; many of the physiological types of diseased processes, especially the cellular, are discoverable in the embryological period. For the period of development, no arbitrary separation has been attempted hitherto between structure and function, and embryology is, in theory at least, as much physiological as anatomical. The development of function is a legitimate and even desirable subject of scientific study, and a more distinctive place is probably awaiting it in the future; but so indissoluble does the union of structure and function present itself in the period of genesis and growth that the function has hardly as yet come to be abstracted from the structure, or the structure from the function.

The theory of disease rests, therefore, upon physiology, with its more or less technical adjuncts. Pathology is all that physiology is, with the engrossing and difficult element of perturbation, deflexion, or shortcoming added. By virtue of this element of deviation from the line of health, pathology is a discipline apart, with an abundant literature of its own, and with separate academical institutes and chairs. But pathology is also a discipline apart by virtue of concepts proper to itself. A great part of the theory of disease deals with changes or defects of structure and perturbations or failings of function, which may be intricate or difficult to analyse, but are still well within sight of the line of health. Such are the common diseases of the organs and systems—the inflammations, catarrhs, degenerations, hypertrophies, and functional derangements without lesion of the respiratory, circulatory, nervous, genito-urinary, locomotor, and cutaneous systems. Constitutional or general diseases belong also to the province of perturbations from the physiological course,—such diseases as chlorosis, leukæmia, diabetes, gout, rheumatism, scurvy, rickets, Addison's disease, exophthalmic goitre, and the febrile state. Again, congenital deficiencies or malformations, non-cancerous tumours, and the repairing of injuries exemplify no other laws than those of development and growth.

But with those examples the catalogue of physiological diseases is exhausted. We are left with a vast residue of diseases, which have always bulked largely in the popular mind, and have carried the most terrible associations with them. Such are the pestilences or diseases of peoples:—the plague, sweating sickness, cholera, yellow fever, typhus fever, relapsing fever, typhoid fever, diphtheria, small-pox, measles, scarlet fever, influenza, dengue. Such also are the cancers, consumptions, leprosies, and other loathsome infections. This enormous residue is more than the half of disease, and the definition of disease or the scheme of pathology is brought to a test in finding room within its scientific categories for such maladies as those. The popular imagination in all countries has personified them; medicine in its metaphysical period has regarded them as entities or things in themselves; and it remains to be seen in what way or to what extent medicine in its scientific period will bring them within the category of perturbations of the physiological life.

In considering, for a moment, where to place cancer in the pathological scheme, we shall arrive at a point of view from which the relation of the acute and chronic infections (or contagions) to diseases of the physiological order may be contemplated at least provisionally. Taking cancers, in a generic sense, to mean tumours that have acquired or are possessed of malignancy, we find that such tumours have many points in common with simple tumours,—that they have grown out of the tissues of particular organs or parts under particular (functional) circumstances, and that they may, in general terms, be traced back to that point at which they left the line of health (see PATHOLOGY). The tracing back of tumours along the physiological track is often difficult and laborious; but there is no tumour of the body whose origins are not at length discoverable within the limits of physiological action. That which makes any tumour a cancer is something over and beyond; it is a remarkable acquired property of reproducing its structure in manifold copies, or of infecting the organism of which it is itself a part. The tumour thus becomes a semi-independent power within the body; it may be said, in a political figure, to have acquired *autonomy*, or to have become *imperium in imperio*. A due consideration of such a phenomenon as the infectiveness or cancerousness of some tumours will satisfy one that there are concepts in pathology which carry the investigator entirely beyond physiological bounds or out of sight of the line of health, which bring him face to face with the notion of a disease as a thing in itself, and which thus constitute a peculiar subject-matter. There is nothing that we know among biological phenomena altogether analogous to the semi-independence which an integral part of the body, or condition of the body, manifests towards the organism as a whole, and that, too, strictly in respect of its acquired devious or rebellious habit. The familiar definition of disease, *morbus est vita præter naturam*, which embodies the notion of divergence from the line of health, makes no provision for an acquired autonomy of a morbid state; and that definition has to be supplemented by another, which will recognize the possibility of a disease becoming a thing in itself. The old definition of Van Helmont, *morbus est ens reale subsistens in corpore*, appears to satisfy the requirement; but that definition, although it grew out of the phenomena of disease as observed in fevers, was made too general, and has now associations that are too exclusively ontological and metaphysical. The supplementary definition should be as far as possible in the terms of the principal definition; and we shall provide best in the pathological scheme for such a disease as cancer if, in addition to the formula *morbus est vita præter naturam*, we construct a secondary formula, *morbus est vivum in vivo*.

The notion of autonomy acquired by a morbid state implies, naturally, a pre-autonomous stage of the disease, which had been a mere perturbation of the norm of the body, capable of being measured by the physiological standard. The autonomous stage and the pre-autonomous stage, which may be demonstrated, in individual cases, for cancers, are a philosophical necessity for all other infective diseases that are marked by morphological features, or by structural characters rooted in and growing out of the proper textures of the body. Thus the peculiar skin eruption of small-pox, which is communicable from person to person, along with a distinctive course of fever, must have had pre-autonomous antecedents (not altogether historically vague) in certain casual conditions of the skin and associated constitutional disturbance, which had recurred and become inveterate, and had so attained to a degree of individuality or a point of autonomy at which they began to be propagated as an organic unit. Again, a second group of infections, exemplified by glanders, bovine tubercle, and syphilis, are rooted in deeper textural processes, which must have been at one time (and may still be) set up by the casual operation of ordinary causes, and at length became the occasion of infective mimicry. It is not so easy to picture (and it is not difficult, with a modern dominant school, to ignore) the casual morbid conditions or ordinary physiological perturbations out of which powerful infections like cholera, typhoid fever, or yellow fever may have arisen; but if the rise and consolidation of their autonomy be a subtle or even untraceable history, yet there are diseases, such as dysentery and erysipelas, which are apt to occur both as casual or spontaneous conditions and as specific infections side by side. Ophthalmia is an example of a purulent catarrh which is constantly arising *de novo* in Egypt from local causes in a non-infective manner, and yet has become, on at least one memorable occasion, a powerful and widespread infection for British troops returning from that country and for the home garrisons for many years subsequently. Infective pneumonia in cattle, and more rarely in man, is an analogous case. In such an episode we observe the actual rise of the disease-autonomy. Again, all the infective diseases have degrees of intensity, at one extreme of which there must occur the vanishing point of their infective property; and those gradations of infectiveness are nowhere more noticeable than in the relation of cholera to choleraic diarrhœa. Further, the remarkable group of climatic fevers are not communicable from person to person (see MALARIA); in that respect, and for the reason that the liability of the patient is anything but exhausted by one attack, they are examples of fevers without autonomy. There is not one of the infections that may not be profitably studied from the point of view of its autonomy, and of its more or less obscure pre-autonomous stage. That is a point of view from which even the pestilences and other specific diseases may be regarded as coming within the physiological categories. The large residue of diseases, which are more than perturbations of the physiological life, may still be joined by natural descent to the class of simple perturbations, if we can show for them how their autonomy was acquired, or what was their origin as disease-species.

There is an established place in the history of medicine, and there ought therefore to be room in the definition of disease, for epidemic outbreaks of purely psychical diseased states, such as the dancing madness (*Tanzwuth*), and the boys' crusades; the epidemic diffusion of such morbid states is best approached from the point of view of an acquired autonomy (fixed idea) and an infective mimicry.

The physiological definition of disease, *morbus est vita præter naturam*, affords no place for parasitic diseases. However, the supplementary formula that has been proposed to meet the case of diseases existing autonomously in the body, *morbus est vivum in vivo*, will meet the case of parasitic diseases also. According to many pathologists of the present generation, the whole class of pestilences, fevers, and specific infections generally are caused by certain species of minute parasites invading the body; according to one form of that hypothesis the distinctive characters or specific marks (morphological and other) of those diseases are neither more nor less than the appropriate effects wrought upon the textures and fluids of the body by the respective species of parasites. In this way the great group of infective diseases, which are apt to be the stumbling-block of a scientific definition and logical scheme of disease, are easily disposed of by placing them beside the otherwise insignificant group of parasitic diseases. Whether all or any of those diseases are due in a sense to the invasion of parasites, or wholly caused by parasites, are questions that naturally fall to be settled by a careful sifting of a mass of evidence which has already proved to be peculiarly rich in opportunities for mistake. It may be expected that the facts of infective parasitism and the facts of acquired disease-autonomy will in the end find their place in a common theory of specific diseases, which might be expressed in terms of the physiological formula *morbus est vita præter naturam* with the rider *morbus est vivum in vivo.*

The theory of remedies, which forms the second division of the science of medicine, is chiefly based upon pharmacology or toxicology. If pharmacology be considered as not co-extensive with toxicology, it will be taken to be in great part pharmacographia, or the systematic description of articles of the materia medica—their source, preparation, physical properties, and the like. Toxicology is in its general sense the investigation of the physiological action of drugs, a science which is largely dependent upon experiments on the lower animals; in a more technical sense toxicology relates to the effects of poisons and the art of detecting them (see POISONS). The physiological action of drugs is the key to their therapeutical action. Therapeutics has been defined as "the discovery of the means by which a system of forces competent to eliminate any given perturbation may be introduced into the economy." The adaptation of remedies to diseases is, however, greatly wanting in precision, and continues to be in large part empirical and traditional. It may be objected to the above definition that all diseases are not reducible to the category of "perturbations," and that there is a certain scientific justification for the doctrine of specifics. Besides the articles of the materia medica proper, agencies such as electricity, baths, sea-voyages, and changes of climate generally, enter into the consideration of therapeutics, and two of those form the subject of special departments, viz., electro-therapeutics and hydropathy. Regimen and diet are also important factors in the treatment of disease; according to a contention of Hippocrates, it was in the dietetic needs of mankind that the medical art had its origin.

Subdivisions of Medicine as an Art and Discipline.—The medical art (*ars medendi*) breaks away at once from the unity of the theory of disease. While there is but one body of pathological doctrine for either sex, for every period of life, and for every region and part of the organism, the practical art divides itself into departments and subdepartments. The most fundamental division is into internal and external medicine, or into medicine proper and surgery. The treatment of wounds, injuries, and deformities, with operative interference in general, is the special department of surgical practice (the corresponding parts of pathology, including inflammation, repair, and removable tumours, are sometimes grouped together as surgical pathology); and where the work of the profession is highly subdivided, surgery becomes the exclusive province of the surgeon, while internal medicine remains to the physician. A third great department of practice is formed by obstetric medicine or midwifery, and with obstetrics there is usually associated gynæcology, or the diseases peculiar to women. Diseases of children are the subject of a voluminous separate literature. Dermatology (diseases of the skin) is an important province of practice which, like the diseases of women and children, pertains as much to medicine as to surgery. The greatest of the so-called special departments of practice is ophthalmology (diseases and injuries of the eye). Laryngology is a department that owes its existence mainly to the invention of the laryngoscope, its special province being the treatment of the inflammations (ordinary and specific), tumours, and the like, to which the larynx is liable in common with other parts. Diseases of the ear (otology) form even a more restricted department of practice, owing to the comparative inaccessibility of the chief part of the organ of hearing. The congenital condition of deaf-mutism may or may not be taken as falling within the province of the last-mentioned subdivision. Dentistry or odontology is extremely limited in the range of its subject-matter; but it affords great opportunities for refinements of technical skill, and it is given up to a distinct branch of the profession.

The care of the weak-minded and the insane (psychological medicine) is an integral part of medical practice, inasmuch as it is concerned with diseases of the nervous system and with numerous correlated states of other organs; but it occupies a unique place by reason of the engrossing interest of the subjective phenomena. Habitual drunkenness is also a subject of special treatment.

A state of war, actual or contingent, gives occasion to special developments of medical and surgical practice (military hygiene and military surgery). Wounds caused by projectiles, sabres, &c., are the special subject of naval and military surgery; while under the head of military hygiene we may include the general subject of ambulances, the sanitary arrangements of camps, and the various forms of epidemic camp sickness.

The administration of the civil and criminal law involves frequent relations with medicine, and the professional subjects most likely to arise in that connexion, together with a summary of *causes célèbres*, are formed into the department of medical jurisprudence. It is the practice in Great Britain to call independent medical evidence on both sides of a cause, whether the proceedings be civil or criminal.

The system of life assurance is based upon the co-operation of the medical profession. Heredity, constitution, and diathesis are here the chief subjects of general consideration, while prognosis is the skilled faculty specially called into play.

Relations of Medicine to the Body Politic.—The statutes of the United Kingdom which have direct relation to medicine are (1) those relating to the public health; (2) those relating to lunacy (and habitual drunkenness); (3) those relating to the status of the medical profession, to dentists, and to pharmaceutical chemists; (4) those relating to restrictions on the "practice" of anatomy and physiology. There are, besides, several statutes in which medicine is concerned indirectly,—such as the Poor Laws, the Prisons Acts, the Shipping Acts, the Registration of Births and Deaths Act, the Sale of Food and Drugs Act, the Sale of Poisons Act, the Factory and Workshops Act, the Artisans' Dwellings (Metropolitan) Act, the Rivers Pollution Prevention Act, the Contagious Diseases (Animals) Act (1878), and the Public Health (Water) Act.

1. Most of the statutes relating to the public health in England and Wales were consolidated by an Act of 1875, the Acts relating to the metropolis being excepted; there are separate statutes of about the same period for Ireland and Scotland. The system of administration is by local sanitary authorities, in correspondence with the local government boards in London and Dublin and the board of supervision in Edinburgh. The board in London has a medical department, consisting of a chief medical officer, assistant medical officer, and inspectors, while the Dublin and Edinburgh boards are professionally advised on a somewhat different system. The sanitary authorities throughout the United Kingdom are divided into rural, urban, port, and metropolitan (sanitary and nuisance); they are formed out of pre-existing bodies, either the corporations of cities and towns, the improvement commissioners, or the local authorities. A medical officer of health is attached to most of the several sanitary authorities, or to the combined sanitary authorities of a large district; his duties include making reports on the death-rate and the causes of mortality, the denunciation of nuisances and unwholesome dwellings, workshops, &c., inquiries into the local causes or favouring circumstances of epidemic outbreaks of disease, measures to prevent the spread of contagion (by disinfection, isolation, and otherwise), and other more occasional duties arising under a variety of statutes. Each sanitary authority is required by law to appoint an inspector of nuisances, who practically carries out the instructions of the medical officer when there is one.

The Vaccination Acts (consolidated 1871) are an important part of the public health law of the kingdom; they are administered by the local government board, for the most part through the agency of the medical profession at large, but in some populous parishes also by means of public vaccination stations. Prosecutions under the Acts are instituted by the parochial authorities. The practice formerly (and not unsuccessfully) resorted to of inoculating with the small-pox has been made a criminal offence; but there is still much uncertainty as to the theory of vaccination, and, in particular, as to the relation of vaccinia to variola.

Other statutes which were not consolidated in the Public Health Act of 1875 are the Burials Act, the Contagious Diseases Act, and the Quarantine Act. The first of these is administered by a department of the home office, with a medical inspector. The second (1866 and 1869) relates, under a too general title, to the regulation of prostitution in certain garrison towns, the surgeons under the act being appointed by the board of admiralty or the secretary of state for war, and the administration otherwise carried out by the police.

The quarantine laws stand in the somewhat anomalous position of statutes which it is not thought desirable to repeal, while yet they are stripped bare of all their executive machinery. The Quarantine Act can be set in motion, as occasion arises, by an order of council; not only, however, is there no official medical advice at the disposal of the privy council, upon which action under the act might be taken, but there is not even the framework remaining (except the ghost of a quarantine station on the Motherbank between Portsmouth and the Isle of Wight) of the once considerable quarantine establishment, by which the provisions of the Act might be enforced. On the other hand, port sanitary authorities enjoy certain limited powers under the Public Health Acts of isolating vessels arriving with contagious sickness on board. A quarantine at British ports has not been put in force for many years, opinions being divided as to the abstract efficacy and suitableness of quarantine measures to prevent the importation and diffusion of plague, cholera, or yellow fever (see QUARANTINE).

Numerous instances having occurred of the extensive diffusion of scarlet fever, typhoid fever, and diphtheria by means of milk, the privy council has issued an order, under the Contagious Diseases (Animals) Act of 1878, called the Dairies, Milkshops, and Cowsheds Order, with the object of enforcing extreme cleanliness in the premises and appurtenances of the milk trade, and particularly of guarding against the well-known liability of milk to take up effluvia existing or arising near it. The order of council having remained inoperative, it is proposed to deal with the matter by a new Act of Parliament, to be administered by the local government board. While cows' milk has thus been recognized by the sanitary law as a carrier of certain of the human contagia, the milk of diseased cows, and more especially of tuberculous cows, continues to be sold with impunity, the alleged communication of tubercular disease from the cow to man being difficult to prove to the satisfaction of the legislature. The want of constant supervision of the slaughter-houses is thought by many to be a serious defect in the sanitary law of the country; and there is no doubt that much flesh of diseased animals (especially the tuberculous) is sold merely as inferior meat.

Public Health Law of the United States.—Questions of public health in the United States come under the common law and the statute law. In the larger part of the Union they are subject to the common law only; in a certain number of the States there is statute law; and there has been since 1879 a national board of health and a quarantine law established by Act of Congress. Generally speaking, the public health procedure of the United States suffers from the want of organization. Decisions at common law relate chiefly to nuisances, and to the recovery of damages for loss caused by the same. The first attempt at statute law was an Act of 1866 creating a metropolitan sanitary district and board of health for the city of New York; in 1869 a board of health was created by the State legislature for Massachusetts; the District of Columbia obtained its board of health in 1870; and other States have followed at intervals, so that there are now at least nineteen State boards of health, New York State and Pennsylvania having health boards only for their respective capitals and other individual towns. Besides the municipal boards in those States, there are very few others for towns in the Union, and still fewer for counties. The powers and activity of the boards of health are very various; the Massachusetts board has powers amounting to that of a court, while the function of several of the State boards is hardly more than advisory. The sanitary statutes made by the State legislatures are in some cases very numerous. Wherever questions of quarantine for yellow fever have arisen, as in Louisiana (New Orleans), Georgia, and Alabama, the State board of health has acquired vigour and has enlisted popular support, in the capitals at least; but in most of the States *laissez faire* is the ordinary feeling towards the board and its operations. The medical profession in each State is the most powerful force, and the State medical society is not unfrequently in a semi-official connexion with the sanitary board; on the other hand, it is alleged that the unfortunate sectarian differences in medicine (represented chiefly by homœopathy) have on several occasions prevented the formation of a State board of health, or have tended to paralyse the action of a board already existing. It is a charge also against boards of health, or at least against those in the great political centres, that their efficiency is apt to be impaired by the introduction of irrelevant political considerations in such matters as the making of appointments. The first step towards a national public health law was gained by the Act (approved 3d March 1879) "to prevent the introduction of infectious or contagious diseases into the United States, and to establish a national board of health." The board consists of seven members appointed by the president and of four officials detached from the public departments of State. Its duties are "to obtain information upon all matters affecting the public health, to advise the several departments of the government, the executives of the several States, and the commissioners of the District of Columbia, on all questions submitted to them, or whenever, in the opinion of the board, such advice may tend to the preservation and improvement of the public health." Quarantine was to be a special object of the board's attention, especially the establishment, if possible, of a federal quarantine system which would preserve the legitimate commercial interests of the several States and their seaports. A quarantine law passed in 1879 provides that all vessels coming from any foreign port where contagious or infectious diseases exist shall obtain a bill of health from the consular officer of the United States at the port of sailing. One of the principal functions of the national board of health hitherto has been to institute scientific inquiries into the nature and causation of diseases of national importance, such as malarial fever. Among the acknowledged desiderata in the national sanitary law of the United States are a uniform carrying out of the practice of vaccination—there is no vaccination law in certain States, and in others it is imperfectly applied—and a uniform system of registration of births and deaths. See Bowditch, *Public Hygiene in America, together with a Digest of American Sanitary Law* (by Pickering), Boston, 1877; Billings, Introduction to *Hygiene and Public Health*, edited by Buck (Eng. ed., London), and in the *Transactions of the Internat. Medical Congress*, London, 1880, vol. iv., sect. "Public Health."

Public Health Law of other Countries.—In France there is a council of health for each district, composed of medical practitioners, pharmacists, engineers, and other experts, its function being purely advisory with respect to nuisances, unwholesome dwellings, schools, food, drugs, epidemics, and the like. The executive power rests with the prefect (to be carried out by the police), and is often not put in motion even when advice is tendered. In Paris there are two heads of executive, the prefect of the Seine and the prefect of police. The minister of agriculture and commerce is responsible to the chambers. In Prussia there is a certain amount of bureaucratic care of the public health under the ministry for ecclesiastical, educational, and medical affairs. The minister is advised by a scientific commission (*Wissenschaftliche Deputation für das Medicinalwesen*); and there is a subordinate board for each province, and a medical officer for each district or town (*Kreisphysikus*, or *Stadtphysikus*). Numerous offences against the public health are defined in the code, and penalties fixed (see Eulenberg's work, taken from official sources, *Das Medicinalwesen in Preussen*, Berlin, 1874).

2. The lunacy laws have been fully treated of in a special section of the article INSANITY (*q.v.*). By an Act of 1879 habitual drunkards have been placed in a position somewhat analogous to that of lunatics, and there are now existing certain licensed asylums for their detention.

3. The Acts relating to the status of the medical profession are known as the Medical Acts. The principal measure, passed in 1858, created a body of twenty-four, called the general council of medical education and registration; by a subsequent Act the council received a charter of incorporation, so that it might draw up, and become the publisher and proprietor of, a list and description of officinal drugs, which should be called the British Pharmacopœia, and should supersede previous pharmacopœias. The principal duty of the medical council is to keep a register of qualified medical practitioners. The preamble of the Act by which the medical register was created asserts the desirability of those in want of medical aid being able to distinguish qualified from unqualified practitioners; and those whose names are on the register are alone presumably qualified. To be a registered medical practitioner confers a certain positive legal status (right to sue for fees, hold appointments, give certificates, &c.); but there is nothing in the English law to prevent any person whomsoever from practising medicine and taking fees, provided he does not assume misleading titles. Those who are entitled (on payment of five pounds) to have their names inserted in the medical register are graduates in medicine or surgery of the universities of the United Kingdom, licentiates, members, or fellows of the Royal Colleges of Physicians or Surgeons in London, Dublin, and Edinburgh, licentiates or fellows of the Faculty of Physicians and Surgeons of Glasgow, and licentiates of the Apothecaries' Halls of London and Dublin. The council consists of the representatives of those bodies, of six crown nominees, and the president. The medical council possesses certain judicial and executive powers over the names on its register; if, after due inquiry, a registered practitioner be judged by the medical council to have been guilty of infamous conduct in any professional respect, the medical council may, if they see fit, direct their registrar to erase the practitioner's name from the register. The medical council keeps also a register (unpublished) of medical students; whoever has passed a recognized examination in arts, and has forwarded a certificate signed by a teacher of medicine that he has *bona fide* begun the study of medicine, is entitled to have his name entered in the register of students of medicine, with the date of his commencement. The object of the students' register is merely to provide a common and convenient record of the date of commencement of medical study, and, by implication, of the fact that the examination in arts has been passed.

The medical council owes its title of a "council of education" to certain powers possessed by it of visiting the examinations of the universities and corporations, and certain ill-defined powers of visiting the medical schools. The council may, if they see fit, report to the privy council any deficiencies that they may have discovered in the teaching or examining, and the privy council may proceed to further steps. But, beyond publishing the reports of their visitations, the medical council do not appear to have had occasion to put the machinery in force. The state has not otherwise interfered to prescribe the subject-matter or the minimum standard of medical education, although there has been at least one unsuccessful attempt by the Government of the day to establish a uniform minimum. By an Act of 1876 parliament has interposed to affirm the principle that women are entitled to become registered practitioners of medicine.

Under the Dentists' Act of 1878 the profession of dentistry acquired a legal status corresponding to that of the medical profession, the general medical council having charge of its register also.

Pharmaceutical chemists are now licensed under an Act passed in 1876; since that date licences are granted only to those who pass either the minor or the major examination of the Pharmaceutical Society of Great Britain, a Pharmacy Act for Ireland (1876) having corresponding provisions.

The Medical Profession in other Countries.—In the United States there are usually no restrictions upon the practice of medicine, and in only a few of the States has the medical profession any legal standing. The ordinary medical title is that of doctor of medicine, and that degree is conferred by a large number of institutions after a curriculum of study that varies much in length, and after examinations that are equally various as tests of proficiency. In France the medical profession is divided into two grades: those in the higher grade are all doctors of medicine of the faculties of Paris, Lille, Nancy, Bordeaux, Lyons, or Montpellier; those in the lower grade are *officiers de santé*. In Germany the right to practise is conferred by a state licence granted on passing the *staats-examen*; the examination, which is almost entirely oral and practical, may be passed in stages at any one of the universities in the empire, the professors of anatomy, physiology, and pathological anatomy being practically *ex officio* examiners, while the other examiners are very frequently also professors in the medical faculty. The *staats-examen* is usually passed before the candidate seeks the degree of doctor of medicine; that degree is almost always taken by those who pass the examination for the state licence, and it is usually conferred after a more or less formal examination of the candidate before the medical faculty, and on the approval of his thesis. In Austria, the right to practise is carried by the degree of doctor of medicine; there is no separate state licence, and no examination except that of the medical faculty of the universities (see Billroth's *Lehren and Lernen der medicinischen Wissenschaften*, Berlin, 1876). In most Continental countries there are penalties directed in effect against practising medicine without the state licence, or the university degree equivalent thereto, and in France the law now extends to resident foreign practitioners who have qualified only in their own country. The regulations for the practice of pharmacy in Germany and other Continental countries have long been of a very stringent kind. The training and licensing of midwives is also under state control.

4. Lastly, the state has interposed to restrict the "practice" of anatomy and physiology. By the Anatomy Act of 1832 (amended in 1871) licences are required for schools of anatomy, as well as licences for teachers, "to practise anatomy." Licensed teachers of anatomy are empowered to receive subjects for dissection under certain conditions. The Act is administered by the home office, with a staff of four inspectors of anatomy, one for the metropolis, one for provincial medical schools in England, and one each for Ireland and Scotland. The Act restricting the practice of physiology is the Vivisection Act of 1876; it is intended for the protection of vertebrate animals liable to be employed alive in physiological experiments, and it resorts to a controlling machinery of licence and inspection similar to that of the Anatomy Act, and under the same Government department. (C. C.)

PART II.—HISTORY.

The history of medicine falls naturally under two heads, or might be conceivably written from two different points of view. It might be a history of the medical profession or a history of medical doctrine,—in other words, the history of medicine in its relation to society or in its relation to science. We shall here deal chiefly with the history of medical knowledge, remembering also that the histories of anatomy, of physiology, and of surgery are dealt with in the articles referring to those subjects. But a still more trenchant limitation is necessary to preserve the unity of the subject. Attention can be given to so much only of the history as is directly antecedent to and leads up to the medical science of modern Europe. For this purpose, the history of medicine must start with the earlier period of Greek civilization.

Medicine as Portrayed in the Homeric Poems.—In the state of society pictured by Homer it is clear that medicine has already had a history. We find a distinct and organized profession; we find a system of treatment, especially in regard to injuries, which it must have been the work of long experience to frame; we meet with a nomenclature of parts of the body substantially the same (according to Daremberg) as that employed long afterwards in the writings of Hippocrates; in short, we find a science and an organization which, however imperfect as compared with those of later times, are yet very far from being in their beginning. The Homeric heroes themselves are represented as having considerable skill in surgery, and as able to attend to ordinary wounds and injuries, but there is also a professional class, represented by Machaon and Podalirius, the two sons of Asclepius, who are treated with great respect. It would appear, too, from the *Æthiopis* of Archinus (quoted by Welcker and Haeser) that the duties of these two were not precisely the same. Machaon's task was more especially to heal injuries, while Podalirius had received from his father the gift of "recognizing what was not visible to the eye, and tending what could not be healed." In other words, a rough indication is seen of the separation of medicine and surgery. Asclepius appears in Homer as a Thessalian king, not as a god, though in later times divine honours were paid to him. There is no sign in the Homeric poems of the subordination of medicine to religion which is seen in ancient Egypt and India, nor are priests charged, as they were in those countries, with medical functions,—all circumstances which throw grave doubts on the commonly received opinion that medicine derived its origin in all countries from religious observances.

Although the actual organization of medicine among the Homeric Greeks was thus quite distinct from religion, the worship of Asclepius (or Æsculapius) as the god of healing demands some notice. This cult spread very widely among the Greeks; it had great civil importance, and lasted even into Christian times; but there is no reason to attribute to it any special connexion with the development of the science or profession of medicine. Sick persons repaired, or were conveyed, to the temples of Asclepius in order to be healed, just as in modern times relief is sought by a devotional pilgrimage or from the waters of some sacred spring, and then as now the healing influence was sometimes sought by deputy. The sick person, or his representative, after ablution, prayer, and sacrifice, was made to sleep on the hide of the sacrificed animal, or at the feet of the statue of the god, while sacred rites were performed. In his sleep (incubatio, ἐγκοίμησις) the appropriate remedy was indicated by a dream. Moral or dietetic remedies were more often prescribed than drugs. The record of the cure was inscribed on the columns or walls of the temple; and it has been thought that in this way was introduced the custom of "recording cases," and that the physicians of the Hippocratic school thus learnt to accumulate clinical experience. But the priests of Asclepius were not physicians. Although the latter were often called Asclepiads, this was in the first place to indicate their real or supposed descent from Asclepius, and in the second place as a complimentary title. No medical writing of antiquity speaks of the worship of Asclepius in such a way as to imply any connexion with the ordinary art of healing. The two systems appear to have existed side by side, but to have been distinct, and if they were ever united it must have been before the times of which we have any record. The theory of a development of Greek medicine from the rites of Asclepius, though defended by eminent names, must accordingly be rejected.

Development of Medicine in Greece.—It is only from non-medical writers that anything is known of the development of medicine in Greece before the age of Hippocrates. The elaborate collections made by Daremberg of medical notices in the poets and historians illustrate the relations of the profession to society, but do little to prepare us for the Hippocratic period. Nor is much importance to be attached to the influence of the philosophical sects on medicine except as regards the school of Pythagoras. That philosopher and several of his successors were physicians, but we do not know in what relation they stood to later medical schools. We must therefore hasten onward to the age of Pericles, in which Hippocrates, already called "the Great," was in medicine as complete a representative of the highest efforts of the Greek intellect as were his contemporaries the great philosophers, orators, and tragedians. The medical art as we now practise it, the character of the physician as we now understand it, both date for us from Hippocrates. The justification of this statement is found in the literary collection of writings known by his name. Of these certainly many are falsely ascribed to the historical Hippocrates of Cos; others are almost as certainly rightly so ascribed; others again are clearly works of his school, whether from his hand or not. But which are to be regarded as the "genuine works" is still uncertain, and authorities are conflicting. There are clearly two schools represented in the collection,—that of Cnidus in a small proportion, and that of Cos in far the larger number of the works. The latter was that to which Hippocrates belonged, and where he gave instruction; and accordingly it may be taken that works of this school, when not obviously of a different date, are Hippocratic in doctrine if not in actual authorship.

Hippocratic Medicine.—The first grand characteristic of Hippocratic medicine is the high conception of the duties and status of the physician, shown in the celebrated "Oath of Hippocrates" and elsewhere,—equally free from the mysticism of a priesthood and the vulgar pretensions of a mercenary craft. So matured a professional sentiment may perhaps have been more the growth of time and organization than the work of an individual genius, but certainly corresponds with the character universally attributed to Hippocrates himself. The second great quality is the singular artistic skill and balance with which the Hippocratic physician used such materials and tools as he possessed. Here we recognize the true Greek σωφροσύνη. But this artistic completeness was closely connected with the third cardinal virtue of Hippocratic medicine,—the clear recognition of disease as being equally with life a process governed by what we should now call natural laws, which could be known by observation, and which indicated the spontaneous and normal direction of recovery, by following which alone could the physician succeed. In the fourth place, these views of the "natural history of disease" (in modern language) led to habits of minute observation and accurate interpretation of symptoms, in which the Hippocratic school was unrivalled in antiquity, and has been the model for all succeeding ages, so that even in these days, with our enormous advances in knowledge, the true method of clinical medicine may be said to be the method of Hippocrates.

The actual science of the Hippocratic school was of course very limited. In anatomy and physiology little advance had been made, and so of pathology in the sense of an explanation of morbid processes or knowledge of diseased structures there could be very little. The most valuable intellectual possession was a large mass of recorded observations in individual cases and epidemics of disease. Whether these observations were systematic or individual, and how they were recorded, are points of which we are quite ignorant, as the theory that the votive tablets in the temples supplied such materials must be abandoned.

Though the Hippocratic medicine was so largely founded on observation, it would be an error to suppose that dogma or theory had no place. The dominating theory of disease was the *humoral*, which has never since ceased to influence medical thought and practice. According to this celebrated theory, the body contains four humours,—blood, phlegm, yellow bile, and black bile, a right proportion and mixture of which constitute health; improper proportions or irregular distribution, disease. It is doubtful whether the treatise in which this theory is fully expounded (περὶ φύσιος ἀνθρώπου) is as old as Hippocrates himself; but it was regarded as a Hippocratic doctrine, and, when taken up and expanded by Galen, its terms not only became the common property of the profession, but passed into general literature and common language. Another Hippocratic doctrine, the influence of which is not even yet exhausted, is that of the healing power of nature. Not that Hippocrates taught, as he was afterwards reproached with teaching, that nature is sufficient for the cure of diseases; for he held strongly the efficacy of art. But he recognized, at least in acute diseases, a natural process which the humours went through,—being first of all *crude*, then passing through *coction* or digestion, and finally being expelled by resolution or *crisis* through one of the natural channels of the body. The duty of the physician was to foresee these changes, "to assist or not to hinder them," so that "the sick man might conquer the disease with the help of the physician." The times at which crises were to be expected were naturally looked for with anxiety; and it was a cardinal point in the Hippocratic system to foretell them with precision. Hippocrates, influenced as is thought by the Pythagorean doctrines of number, taught that they were to be expected on days fixed by certain numerical rules, in some cases on odd, in others on even numbers,—the celebrated doctrine of "critical days." This false precision can have had no practical value, but may have enforced habits of minute observation. It follows from what has been said that *prognosis*, or the art of foretelling the course and event of the disease, was a strong point with the Hippocratic physicians. In this they have perhaps never been excelled. Diagnosis, or recognition of the disease, must have been necessarily imperfect, when no scientific nosology, or system of disease, existed, and the knowledge of anatomy was quite inadequate to allow of a precise determination of the seat of disease; but symptoms were no doubt observed and interpreted skilfully. The pulse is not spoken of in any of the works now attributed to Hippocrates himself, though it is mentioned in other works of the collection.

In the treatment of disease, the Hippocratic school attached great importance to diet, the variations necessary in different diseases being minutely defined. Medicines were regarded as of secondary importance, but not neglected, two hundred and sixty-five drugs being mentioned at different places in the Hippocratic works. Blood-letting was known, but not greatly practised. The highest importance was attached to applying all remedies at the right moment, and the general principle enforced of making all influences—internal and external—co-operate for the relief of the patient. The principles of treatment just mentioned apply more especially to the cure of acute diseases; but they are the most salient characteristics of the Hippocratic school. In chronic cases diet, exercise, and natural methods were chiefly relied upon.

The school of Cnidus, as distinguished from that of Cos, of which Hippocrates is the representative, appears to have differed in attaching more importance to the differences of special diseases, and to have made more use of drugs. A treatise on the diseases of women, contained in the Hippocratic collection, and of remarkable practical value, is attributed to this school.

The above sketch of Hippocratic medicine will make it less necessary to dwell upon the details relating to subsequent medical schools or sects in ancient times. The general conception of the physician's aim and task remained the same, though, as knowledge increased, there was much divergence both in theory and practice,—even opposing schools were found to be developing some part of the Hippocratic system. Direct opponents or repudiators of the authority of Hippocrates were rare, all generally appealing to his authority. But, insensibly, the least valuable part of the Hippocratic work, the theory, was made permanent; the most valuable, the practical, neglected.

Post-Hippocratic Medicine.—After Hippocrates the progress of medicine in Greece does not call for any special remark in such a sketch as this, but mention must be made of one great name. Though none of Aristotle's writings are strictly medical, he has by his researches in anatomy and physiology contributed greatly to the progress of medicine. It should also be remembered that he was of an Asclepiad family, and received that partly medical education which was traditional in such families, and also himself is said to have practised medicine as an amateur. Moreover, his works on natural history doubtless furthered the progress among the Greeks of sciences tributary to medicine, though the only specimens of such works which have come down to us from the Peripatetic school are those of Theophrastus, who may be considered the founder of the scientific study of botany. Among his encyclopædic writings were some on medical subjects, of which fragments only have been preserved. The Peripatetic school may have been more favourable to the development of medicine, as of other departments of natural knowledge, than any other; but there is no evidence that any of the philosophical schools had important influence on the progress of medicine. The fruit of Aristotle's teaching and example was seen later on in the schools of Alexandria.

The century after the death of Hippocrates is a time almost blank in medical annals. It is probable that the science, like others, shared in the general intellectual decline of Greece after the Macedonian supremacy; but the works of physicians of the period are almost entirely lost, and were so even in the time of Galen. Galen classes them all as of the dogmatic school; but, whatever may have been their characteristics, they are of no importance in the history of the science.

Alexandrian School of Medicine.—The dispersion of Greek science and intellectual activity through the world by the conquests of Alexander and his successors led to the formation of more than one learned centre, in which medicine among other sciences was represented. Pergamum was early distinguished for its medical school; but in this as in other respects its reputation was ultimately effaced by the more brilliant fame of Alexandria. It is here that the real continuation and development of Hippocratic medicine can be traced.

In one department the Alexandrian school rapidly surpassed its Greek original, namely, in the study of anatomy The dissection of the human body, of which some doubtful traces or hints only are found in Greek times, was assiduously carried out, being favoured or even suggested perhaps by the Egyptian custom of disembowelling and embalming the bodies of the dead. There is no doubt that the organs were also examined by opening the bodies of living persons,—criminals condemned to death being given over to the anatomists for this purpose.

Two eminent names stand in the first rank as leaders of the two earliest schools of medicine which arose in Alexandria, Herophilus and Erasistratus.

Herophilus was a Greek of Chalcedon, a pupil of the schools both of Cos and of Cnidus. He was especially noted for his profound researches in anatomy (see vol. i. p. 802), and in the knowledge and practice of medicine he appears to have been equally renowned. He professed himself a close adherent of Hippocrates, and adopted his theory of the humours. He also made extensive use of drugs, and of bleeding. The reputation of Herophilus is attested by the fact that four considerable physicians wrote works about him and his writings, and he is further spoken of with the highest respect by Galen and Celsus. By the general voice of the medical world of antiquity he was placed only second to Hippocrates.

Erasistratus was the contemporary and rival of Herophilus. Little is known of his life, except that he spent some time at the court of Seleucus Nicator at Antioch before coming to Alexandria, and that he cultivated anatomy late in life, after he had taken up his abode in the latter city. His numerous works are also almost entirely lost, fragments only being preserved by Galen and others. Erasistratus, instead of following Hippocrates as Herophilus did, depreciated him, and seems to have been rather aggressive and independent in his views. He appears to have leaned to mechanical explanations of the symptoms of disease, as was especially the case with inflammation, of which he gave the first rational, though necessarily inadequate, theory.

The two schools composed of the followers of Herophilus and Erasistratus respectively long divided between them the medical world of Alexandria. The names of many prominent members of both sects have been preserved, but it would be useless to repeat them. The Herophilists still reverenced the memory of Hippocrates, and wrote numerous commentaries on his works. They produced many eminent anatomists, but in the end seem to have become lost in theoretical subtleties, and to have maintained too high a standard of literary cultivation. The school of Erasistratus was less distinguished in anatomy than that of Herophilus, but paid more attention to the special symptoms of diseases, and employed a great variety of drugs. It was longer-lived than that of Herophilus, for it still numbered many adherents in the 2d century after Christ, a century after the latter had become extinct.

The Erasistrateans paved the way for what was in some respects the most important school which Alexandria produced, that known as the empiric, which, though it recognized no master by name, may be considered to have been founded by Philinus of Cos (280 B.C.), a pupil of Herophilus; but Serapion, a great name in antiquity, and Glaucias of Tarentum, who traced the empirical doctrine back to the writings of Hippocrates, are also named among its founders. The most striking peculiarity of the empirics was that they rejected anatomy, regarding it as useless to inquire into the causes of things, and thus, as they contended, being the more minute in their observation of the actual phenomena of disease. They professed that their whole practice was based upon experience, to which word they gave a special meaning. Three sources, and three only, could experience draw from:—observation, history (*i.e.*, recorded observation), and judgment by analogy. These three bases of knowledge were known as the "tripod" of the empirics. It should not, however, be forgotten that the empirics read and industriously commented on the works of Hippocrates. They were extremely successful in practical matters, especially in surgery and in the use of drugs, and a large part of the routine knowledge of diseases and remedies which became traditional in the times of the Roman empire is believed to have been derived from them. In the 2d century the school became closely connected with the philosophical sect of the Sceptics, whose leader, Sextus, was an empirical physician. It lived and flourished far beyond this time, when transplanted to Rome, not less than in its native Alexandria, and appears to be recognizable even up to the beginning of the Middle Ages.

If we look at the work of the Alexandrian schools in medicine as a whole, we must admit that the progress made was great and permanent. The greatest service rendered to medicine was undoubtedly the systematic study of anatomy. It is clear that the knowledge of function (physiology) did not by any means keep pace with the knowledge of structure, and this was probably the reason why the important sect of the empirics were able entirely to dispense with anatomical knowledge. The doctrines of Hippocrates, though lightly thought of by the Erasistrateans, still were no doubt very widely accepted, but the practice of the Hippocratic school had been greatly improved in almost every department,—surgery and obstetrics being probably those in which the Alexandrian practitioners could compare most favourably with those of modern times. We have now to trace the fortunes of this body of medical doctrine and practice when transplanted to Rome, and ultimately to the whole Roman world.

Roman Medicine.—The Romans cannot be said to have at any time originated or possessed an independent school of medicine. They had from early times a very complicated system of superstitious medicine, or religion, related to disease and the cure of disease, borrowed, as is thought, from the Etruscans; and, though the saying of Pliny that the Roman people got on for six hundred years without doctors was doubtless an exaggeration, and not, literally speaking, exact, it must be accepted for the broad truth which it contains. When a medical profession appears, it is, so far as we are able to trace it, as an importation from Greece.

The first Greek physician whose name is preserved as having migrated to Rome was Archagathus, who came over from the Peloponnesus in 218 B.C.; but there were probably others before him. When Greece was made a Roman province, the number of such physicians who sought their fortunes in Rome must have been very large. The bitter words of M. Porcius Cato, who disliked them as he did other representatives of Greek culture, are evidence of this. The most eminent of these earlier Greek physicians at Rome was Asclepiades, the friend of Cicero (born 124 B.C. at Prusa in Bithynia). He came to Rome as a young man, and soon became distinguished both for his medical skill and his oratorical power. He introduced a system which, so far as we know, was his own, though founded upon the Epicurean philosophical creed; on the practical side it conformed pretty closely to the Stoic rule of life, thus adapting itself to the leanings of the better stamp of Romans in the later times of the republic. According to Asclepiades all diseases depended upon alterations in the size, number, arrangement, or movement of the "atoms," of which, according to the doctrine of Epicurus, the body consisted. These atoms were united into passages (πόροι) through which the juices of the body were conveyed. This doctrine, of which the developments need not further be followed, was important chiefly in so far that it was perfectly distinct from, and opposed to, the humoral pathology of Hippocrates. In the treatment of disease Asclepiades attached most importance to diet, exercise, passive movements or frictions, and the external use of cold water,—in short, to a modified athletic training. He rejected the *vis medicatrix naturæ*, pointing out that nature in many cases not only did not help but marred the cure. His knowledge of disease and surgical skill were, as appears from the accounts given by Celsus and Cœlius Aurelianus, very considerable. Asclepiades had many pupils, who adhered more or less closely to his doctrines, but it was especially one of them, Themison, who gave permanence to the teachings of his master by framing out of them, with some modifications, a new system of medical doctrine, and founding on this basis a school which lasted for some centuries in successful rivalry with the Hippocratic tradition, which, as we have seen, was up to that time the prevailing influence in medicine.

This system was known as methodism, its adherents as the methodici or methodists. Its main principles were that it was useless to consider the causes of a disease, or even the organ affected by the disease, and that it was sufficient to know what was common to all diseases, viz., their common qualities (communitates, κοινότητες). Of these there were three possible forms—(1) relaxation, (2) contraction of the minute passages or πόροι, and (3) a mixed state, partly lax, partly constricted. The signs of these morbid states were to be found in the general constitution of the body, especially in the excretions. Besides this it was important only to consider whether the disease was acute or chronic, whether it was increasing, declining, or stationary. Treatment of disease was directed not to any special organ, nor to producing the crises and critical discharges of the Hippocratic school, but to correcting the morbid common condition or "community," relaxing the body if it was constricted, causing contraction if it was too lax, and in the "mixed state" acting according to the predominant condition. This simple rule of treatment was the system or "method" from which the school took its name.

The methodists agreed with the empirics in one point, in their contempt for anatomy; but, strictly speaking, they were dogmatists, though with a dogma different from that of the Hippocratic school. Besides Themison, its systematic founder, the school boasted many physicians eminent in their day, among whom Thessalus of Tralles, a half-educated and boastful pretender, was one of the most popular. He reversed the Hippocratic maxim "art is long," promising his scholars to teach them the whole of medicine in six months, and had inscribed upon his tomb ἰατρονίκης, as being superior to all living and bygone physicians.

In the 2d century a much greater name appears among the methodists, that of Soranus of Ephesus, a physician mentioned with praise even by Tertullian and Augustine, who practised at Rome in the reigns of Trajan and Hadrian. Soranus is known by a work, still extant in the Greek original, on the diseases of women, and also by the Latin work of Cœlius Aurelianus, three centuries later, on acute and chronic diseases, which is based upon, if not, as some think, an actual translation of, the chief work of Soranus, and which is the principal source of our knowledge of the methodic school. The work on diseases of women is the only complete work on that subject which has come down to us from antiquity, and shows remarkable fulness of practical knowledge in relation to its subject. It is notable that an important instrument of research, the speculum, which has been reinvented in modern times, was used by Soranus; and specimens of still earlier date, showing great mechanical perfection, have been found among the ruins of Pompeii. The work on acute and chronic diseases is also full of practical knowledge, but penetrated with the theories of the methodists.

The methodic school lasted certainly for some centuries, and influenced the revival of medical science in the Middle Ages, though overshadowed by the greater reputation of Galen. It was the first definite product of Greek medicine on Roman soil, but was destined to be followed by others, which kept up a more or less successful rivalry with it, and with the Hippocratic tradition.

The so-called pneumatic school was founded by Athenæus, in the 1st century after Christ. According to its doctrines the normal as well as diseased actions of the body were to be referred to the operation of the pneuma or universal soul. This doctrine, crudely transferred from philosophical speculation, was intended to reconcile the humoral (or Hippocratic) and solidist (or methodic) schools; but the methodists seem to have claimed Athenæus as one of themselves.

The conflicts of the opposing schools, and the obvious deficiencies of each, led many physicians to try and combine the valuable parts of each system, and to call themselves eclectics. Among these were found many of the most eminent physicians of Græco-Roman times. It may be sufficient to name Rufus of Ephesus, and Archigenes, who is mentioned by Juvenal.

Although no system or important doctrine of medicine was originated by the Roman intellect, and though the practice of the profession was probably almost entirely in the hands of the Greeks, the most complete picture which we have of medical thought and activity in Roman times is due to a Latin pen, and to one who was, in all probability, not a physician. A. Cornelius Celsus, a Roman patrician, who lived probably in the first century, appears to have studied medicine as a branch of general knowledge. Whether he was a practising physician or not has been a matter of controversy. The conclusion supported by most evidence seems to be that he practised on his friends and dependants, but not as a remunerative profession. His well-known work, *De Medicina*, was one of a series of treatises intended to embrace all knowledge proper for a man of the world. It was not meant for the physicians, and was certainly little read by them, as Celsus is quoted by no medical writer, and when referred to by Pliny is spoken of as an author, not a physician. There is no doubt that his work is chiefly a compilation; and Daremberg, with other scholars, has traced a large number of passages of the Latin text to the Greek originals from which they were translated. In the description of surgical operations the vagueness of the language seems sometimes to show that the author had not performed such himself; but in other parts, and especially in his historical introduction, he speaks with more confidence; and everywhere he compares and criticizes with learning and judgment. The whole body of medical literature belonging to the Hippocratic and Alexandrian times is ably summarized, and a knowledge of the state of medical science up to and during the times of the author is thus conveyed to us which can be obtained from no other source. The work of Celsus is thus for us only second in importance to the Hippocratic writings and the works of Galen; but it is valuable rather as a part of the history of medicine than as the subject of that history. It forms no link in the general chain of medical tradition, for the simple reason that the influence of Celsus (putting aside a few scanty allusions in mediæval times) commenced in the 15th century, when his works were first discovered in manuscript or committed to the press. Since then, however, he has been almost up to our own times the most popular and widely-read of all medical classics, partly for the qualities already indicated, partly because he was one of the few of those classics accessible to readers of Latin, and partly also because of the purity and classical perfection of his language.

Of Pliny, another encyclopædic writer, a few words must be said, though he was not a physician. In his *Natural History* we find as complete a summary of the popular medicine of his time as Celsus gives of the scientific medicine. Pliny disliked doctors, and lost no opportunity of depreciating regular medicine; nevertheless he has left many quotations from, and many details about, medical authors which are of the highest value. He is useful to us for what he wrote about the history of medicine, not for what he contributed. Like Celsus, he had little influence on succeeding medical literature or practice.

We now come to the writer who, above all others, gathered up into himself the divergent and scattered threads of ancient medicine, and out of whom again the greater part of modern European medicine has flowed. Galen (see vol. i. 803 and x. 23) was a man furnished with all the anatomical, medical, and philosophical knowledge of his time; he had studied all kinds of natural curiosities, and had stood in near relation to important political events; he possessed enormous industry, great practical sagacity, and unbounded literary fluency. He had, in fact, every quality necessary for an encyclopædic writer, or even for a literary and professional autocrat. He found the medical profession of his time split up into a number of sects, medical science confounded under a multitude of dogmatic systems, the social status and moral integrity of physicians degraded. He appears to have made it his object to reform these evils, to reconcile scientific acquirements and practical skill, to bring back the unity of medicine as it had been understood by Hippocrates, and at the same time to raise the dignity of medical practitioners.

Galen was as devoted to anatomical and, so far as then understood, physiological research as to practical medicine. He worked enthusiastically at dissection, though, the liberty of the Alexandrian schools no longer existing, he could dissect only animals, not the human body. In his anatomical studies Galen had a twofold object,—a philosophical, to show the wisdom of the Creator in making everything fit to serve its purpose, and a practical, to aid the diagnosis, or recognition, of disease. The first led him into a teleological system so minute and overstrained as to defeat its own end; the second was successfully attained by giving greater precision and certainty to medical and surgical practice in difficult cases. His general physiology was essentially founded upon the Hippocratic theory of the four elements, with which he combined the notion of spirit (pneuma) penetrating all parts, and mingled with the humours in different proportions. It was on this field that he most vehemently attacked the prevailing atomistic and materialistic views of the methodic school, and his conception of the pneuma became in some respects half metaphysical. His own researches in special branches of physiology were important, but do not strictly belong to our present subject.

The application of physiology to the explanation of diseases, and thus to practice, was chiefly by the theory of the temperaments or mixtures which Galen founded upon the Hippocratic doctrine of humours, but developed with marvellous and fatal ingenuity. The normal condition or temperament of the body depended upon a proper mixture or proportion of the four elements—hot, cold, wet, and dry. From faulty proportions of the same arose the *intemperies* ("distempers"), which, though not diseases, were the occasions of disease. Equal importance attached to faulty mixtures or dyscrasiæ of the blood. By a combination of these morbid predispositions with the action of deleterious influences from without all diseases were produced. Galen showed extreme ingenuity in explaining all symptoms and all diseases on his system. No phenomenon was without a name, no problem without a solution. And, though it was precisely in his fine-spun subtlety that he departed farthest from scientific method and practical utility, it was this very quality which seems in the end to have secured his popularity and established his pre-eminence in the medical world.

Galen's use of drugs was influenced largely by the same theories. In drugs were to be recognized the same elementary qualities—hot, cold, moist, dry, &c.—as in the human body; and, on the principle of curing by contraries, the use of one or other was indicated. The writings of Galen contain less of simple objective observation than those of several other ancient physicians, all being swept into the current of dogmatic exposition. But there is enough to show the thoroughness and extent of his practical knowledge. Unfortunately it was neither this nor his zeal for research that chiefly won him followers, but the completeness of his theoretical explanations, which fell in with the mental habits of succeeding centuries, and were such as have flattered the intellectual indolence of all ages. But the reputation of Galen grew slowly; he does not appear to have enjoyed any pre-eminence over other physicians of his time, to most of whom he was strongly opposed in opinion. In the next generation he began to be esteemed only as a philosopher; gradually his system was implicitly accepted, and it enjoyed a great though not exclusive predominance till the fall of Roman civilization. When the Arabs possessed themselves of the scattered remains of Greek culture, the works of Galen were more highly esteemed than any others except those of Aristotle. Through the Arabs the Galenical system found its way back again to Western Europe. Even when Arabian medicine gave way before the direct teaching of the Greek authors rescued from neglect, the authority of Galen was increased instead of being diminished; and he assumed a position of autocracy in medical science which was only slowly undermined by the growth of modern science in the 17th and 18th centuries.

But the history of medicine in Roman times is by no means the same thing as the history of the fate of the works of Galen. For some centuries the methodic school was popular at Rome, and produced one physician, Cœlius Aurelianus, who must be pronounced, next to Celsus, the most considerable of the Latin medical writers. His date was in all probability the end of the 4th or beginning of the 5th century. The works bearing his name are, as has been said, entirely based upon the Greek of Soranus, but are important both because their Greek originals are lost, and because they are evidence of the state of medical practice in his own time. The popularity of Cœlius is evidenced by the fact that in the 6th century an abridgment of his larger work was recommended by Cassiodorus to the Benedictine monks for the study of medicine.

Before quitting this period the name of Aretæus of Cappadocia must be mentioned. So little is known about him that even his date cannot be fixed more closely than as being between the second half of the 1st century and the beginning of the 3d. His works have been much admired for the purity of the Greek style, and his accurate descriptions of disease; but, as he quotes no medical author, and is quoted by none before Alexander of Aphrodisias at the beginning of the 3d century, it is clear that he belonged to no school and founded none, and thus his position in the chain of medical tradition is quite uncertain. Alexander of Aphrodisias, who lived and wrote at Athens in the time of Septimius Severus, is best known by his commentaries on Aristotle, but also wrote a treatise on fevers, still extant.

Ancient Medicine after Galen.—The Byzantine school of medicine, which closely corresponds to the Byzantine literary and historical schools, followed closely in Galen's footsteps, and its writers were chiefly compilers and encyclopædists. The earliest is Oribasius (326–403), whose date and position are fixed by his being the friend and court physician of Julian the Apostate. He was a Greek of Pergamum, educated in Alexandria, and long resident in Byzantium. His great work Συναγωγαὶ ἰατρικαί, of which only about one-third has been preserved, was a medical encyclopædia founded on extracts from Hippocrates, Galen, Dioscorides, and certain Greek writers who are otherwise very imperfectly known. The work is thus one of great historical value but of no originality. The next name which requires to be mentioned is that of Aetius (550 A.D.), a compiler who closely followed Oribasius, but with inferior powers, and whose work also has an historical but no original value. A higher rank among medical writers is assigned to Alexander of Tralles (525–605), whose doctrine was that of an eclectic. His practical and therapeutical rules are evidently the fruit of his own experience, though it would be difficult to attribute to him any decided advance in medical knowledge. But the most prominent figure in Byzantine medicine is that of Paul of Ægina (Paulus Ægineta), who lived probably in the early part of the 7th century. His skill, especially in surgery, must have been considerable, and his Ἰατρικά gives a very complete picture of the achievements of the Greeks in this department. Another work, on obstetrics, now lost, was equally famous, and procured for him, among the Arabs, the name of "the Obstetrician." His reputation lasted through the Middle Ages, and was not less in the Arabian schools than in the West. In this respect Paulus is a most important influence in the development of medicine. His great work on surgery was early translated into Arabic, and became the foundation of the surgery of Abulcasis, which in turn (to anticipate) was one of the chief sources of surgical knowledge to Europe in the Middle Ages. The succeeding period of Byzantine history was so little favourable to science that no name worthy of note occurs again (though many medical works of this period are still extant) till the 13th century, when we meet with a group of writers;—Demetrius Pepagomenus, Nicolaus Myrepsus, and Johannes, called Actuarius, who flourished under the protection of the Palæologi. The work of the last has some independent merit; but all are interesting as showing a fusion of Greek and Arabian medicine, the latter having begun to exercise even in the 11th century a reflex influence on the schools of Byzantium. Something was borrowed even from the school of Salerno, and thus the close of Byzantine medicine is brought into connexion with the dawn of science in modern Europe.

In the West the period after Galen affords little evidence of anything but a gradual though unvarying decline in Roman medicine. Cœlius Aurelianus, already referred to as the follower of Soranus, must be mentioned as showing the persistence of the methodic school. An abridgment of one of his writings, with the title of *Aurelius*, became the most popular of all Latin medical works. As a writer he was worthy of a better period of medical literature. Little else was produced in these times but compilations, of the most meagre kind, chiefly of the nature of herbals, or domestic receipt-books; among the authors of which it may be sufficient to name Serenus Sammonicus (3d century), Gargilius Martialis (3d century), and Marcellus Empiricus (5th century). Certain compilations still extant bear the falsely-assumed names of eminent writers, such as Pliny and Hippocrates. A writer with the (perhaps assumed) name of Apuleius Platonicus produced a herbal which held its ground till the 15th century at least, and was in the 9th translated into Anglo-Saxon. These poor compilations, together with Latin translations of certain works of Galen and Hippocrates, formed a medical literature, meagre and unprogressive indeed, but of which a great part survived through the Middle Ages till the discovery of printing and revival of learning. It is important to remember that this obscure stream of tradition flowed on, only partially affected by the influx of Arabian, or even the early revival of purer classical learning.

Arabian Medicine.—The rise of the Mohammedan empire, which influenced Europe so deeply both politically and intellectually, made its mark also in the history of medicine. As in the parallel case of the Roman conquest of Greece, the superior culture of the conquered race asserted its supremacy over their Arab conquerors. After the Mohammedan conquests became consolidated, and learning began to flourish, schools of medicine, often connected with hospitals and schools of pharmacy, arose in all the chief seats of Moslem power. At Damascus Greek medicine was zealously cultivated with the aid of Jewish and Christian teachers. In Baghdad, under the rule of Hárún el Rashíd and his successors, a still more flourishing school arose, where numerous translations of Greek medical works were made. The names of Mesua, or Yahyá ibn Másawaih (*ob.* 243 A.H., 857–8 A.D.), celebrated for his knowledge of drugs, and Honein ibn Ishak el 'Ibádí (*ob.* 873) or Joannitius, the translator and commentator of Hippocrates and Galen, belong to this period. Certain writings of Joannitius, translated into Latin, were popular in the Middle Ages in Europe, and were printed in the 16th century. At the same time the Arabs became acquainted with Indian medicine, and Indian physicians lived at the court of Baghdad. The Islamite rulers in Spain were not long behind those of the East in encouraging learning and medical science, and developed culture to a still higher degree of perfection. In that country much was due to the Jews, who had already established schools in places which were afterwards the seats of Moslem dominion. From the 10th to the 13th century was the brilliant period of Arabian medicine in Spain.[1]

The classical period of Arabian medicine begins with Rhazes (Abú Bakr Mohammed ibn Zakaríyá el-Rází, 313 A.H., 925–26 A.D.), a native of Ray in the province of Dailam (Persia), who practised with distinction at Baghdad; he followed the doctrines of Galen, but learnt much from Hippocrates. He was the first of the Arabs to treat medicine in a comprehensive and encyclopædic manner, surpassing probably in voluminousness Galen himself, though but a small proportion of his works are extant. Rhazes is deservedly remembered as having first described small-pox and measles in an accurate manner. Haly, *i.e.*, 'Alí ibn el-'Abbás (*ob.* 994), a Persian, wrote a medical text-book, known as the "Royal Book," which was the standard authority among the Arabs up to the time of Avicenna, and was more than once translated into Latin and printed. Other writers of this century need not be mentioned here; but the next, the 11th century, is given as the probable though uncertain date of a writer who had a great influence on European medicine, Mesua the younger of Damascus, whose personality is obscure, and of whose very existence some historians have doubted, thinking that the name was assumed by some mediæval Latin writer. The work *De Simplicibus*, which bears his name, was for centuries a standard authority on what would now be called materia medica, was printed in twenty-six editions in the 15th century and later, and was used in the formation of the first London pharmacopœia, issued by the College of Physicians in the reign of James I. Either to the 10th or the 11th century must be referred the name of another Arabian physician who has also attained the position of a classic, Abu'l Kásim, or Abulcasis, of El-Zahra, near Cordova in Spain. His great work, *Altasríf*, a medical encyclopædia, is chiefly valued for its surgical portion (already mentioned), which was translated into Latin in the 12th century, and was for some centuries a standard if not the standard authority on surgery in Europe. Among his own countrymen the fame and position of Abulcasis were soon eclipsed by the greater name of Avicenna (Ibn Síná).

Avicenna (see vol. iii. p. 152 *sq.*) has always been regarded as the chief representative of Arabian medicine. He wrote on philosophy also, and in both subjects acquired the highest reputation through the whole of Eastern Islam. In Mohammedan Spain he was less regarded, but in Europe his works even eclipsed and superseded those of Hippocrates and Galen. His style and expository power are highly praised, but the subject-matter shows little originality. The work by which he is chiefly known, the celebrated "canon," is an encyclopædia of medical and surgical knowledge, founded upon Galen, Aristotle, the later Greek physicians, and the earlier Arabian writers, singularly complete and systematic, but is thought not to show the practical experience of its author. As in the case of Galen, the formal and encyclopædic character of Avicenna's works was the chief cause of his popularity and ascendency, though in modern times these very qualities in a scientific or medical writer would rather cause him to become more speedily antiquated.

In the long list of Arabian medical writers none can here be mentioned except the great names of the Hispano-Moorish school, a school both philosophically and medically antagonistic to that of Avicenna. Of these the earliest is Avenzoar, or Abumeron, that is, Abú Merwán 'Abd el-Malik Ibn Zohr (1113–62), a member of a family which gave several distinguished members to the medical profession. His chief work, *Al-Teysír* (facilitatio), is thought to show more practical experience than the writings of Avicenna, and to be less based upon dialectical subtleties. It was translated into Latin, and more than once printed, as were some of his lesser works, which thus formed a part of the contribution made by the Arabians to European medicine. His friend and pupil AVERROES of Cordova (*q.v.*), so well known for his philosophical writings, was also an author in medical subjects, and as such widely read in Latin. The famous Rabbi MAIMONIDES (*q.v.*) closes for us the roll of medical writers of the Arabian school. His works exist chiefly in the original Arabic or in Hebrew translations; only some smaller treatises have been translated into Latin, so that no definite opinion can be formed as to their medical value. But, so far as is known, the independent and rationalistic spirit which the two last-named writers showed in philosophy did not lead them to take any original point of view in medicine.

The works of the Arabian medical writers who have now been mentioned form a very small fraction of the existing literature. Three hundred medical writers in

[1] See Dozy, *Cat. Cod. Or. Lug. Bat.*, ii. 296.

Arabic are enumerated by Wüstenfeld, and other historians have enlarged the list (Haeser), but only three have been printed in the original; a certain number more are known through old Latin translations, and the great majority still exist in manuscript. It is thus evident that the circumstance of having been translated (which may have been in some cases almost an accident) is what has chiefly determined the influence of particular writers on Western medicine. But it is improbable that further research will alter the general estimate of the value of Arabian medicine. There can be no doubt that it was in the main Greek medicine, modified to suit other climates, habits, and national tastes, and with some important additions from Oriental sources. The greater part is taken from Hippocrates, Galen, Dioscorides, and later Greek writers. The Latin medical writers were necessarily unknown to the Arabs; and this was partly the cause that even in Europe Galenic medicine assumed such a preponderance, the methodic school and Celsus being forgotten or neglected. In anatomy and physiology the Arabians distinctly went back; in surgery they showed no advance upon the Greeks; in practical medicine nothing new can be traced, except the description of certain diseases (*e.g.*, small-pox and measles) unknown or imperfectly known to the Greeks; the only real advance was in pharmacy and the therapeutical use of drugs. By their relations with the further East, the Arabs became acquainted with valuable new remedies which have held their ground till modern times; and their skill in chemistry enabled them to prepare new chemical remedies, and form many combinations of those already in use. They produced the first pharmacopœia, and established the first apothecaries' shops. Many of the names and many forms of medicines now used, and in fact the general outline of modern pharmacy, except so far as modified by modern chemistry, started with the Arabs. Thus does Arabian medicine appear as judged from a modern standpoint; but to mediæval Europe, when little but a tradition remained of the great ancient schools, it was invested with a far higher degree of originality and importance.

It is now necessary to consider what was the state of medicine in Europe after the fall of the Western empire and before the influence of Arabian science and literature began to be felt. This we may call the pre-Arabian or Salernitan period.

Medicine in the Early Middle Ages: School of Salerno.—In medical as in civil history there is no real break. A continuous thread of learning and practice must have connected the last period of Roman medicine already mentioned with the dawn of science in the Middle Ages. But the intellectual thread is naturally traced with greater difficulty than that which is the theme of civil history; and in periods such as that from the 5th to the 10th century in Europe it is almost lost. The chief homes of medical as of other learning in these disturbed times were the monasteries. Though the science was certainly not advanced by their labours, it was saved from total oblivion, and many ancient medical works were preserved either in Latin or vernacular versions. The "Anglo-Saxon Leechdoms" of the 11th century, published in the Master of the Rolls series of mediæval chronicles and memorials, admirably illustrate the mixture of magic and superstition with the relics of ancient science which constituted monastic medicine. Similar works, in Latin or other languages, exist in manuscript in all the great European libraries. It was among the Benedictines that the monastic study of medicine first received a new direction, and aimed at a higher standard. The study of Hippocrates, Galen, and other classics was recommended by Cassiodorus (6th century), and in the original mother-abbey of Monte Cassino medicine was studied; but there was not there what could be called a medical school; nor had this foundation any connexion (as has been supposed) with the famous school of Salerno.

The origin of this, the most important source of medical knowledge in Europe in the early Middle Ages, is involved in obscurity. It is known that Salerno, a Roman colony, in a situation noted in ancient times for its salubrity, was in the 6th century at least the seat of a bishopric, and at the end of the 7th century of a Benedictine monastery, and that some of the prelates and higher clergy were distinguished for learning, and even for medical acquirements. But it has by recent researches been clearly established that the celebrated *Schola Salernitana* was a purely secular institution. All that can with certainty be said is that a school or collection of schools gradually grew up in which especially medicine, but also, in a subordinate degree, law and philosophy were taught. In the 9th century Salernitan physicians were already spoken of, and the city was known as *Civitas Hippocratica.* A little later we find great and royal personages resorting to Salerno for the restoration of their health, among whom was William of Normandy, afterwards the Conqueror. The number of students of medicine must at one time have been considerable, and in a corresponding degree the number of teachers. Among the latter many were married, and their wives and daughters appear also in the lists of professors. The most noted female professor was the celebrated Trotula in the 11th century. The Jewish element appears to have been important among the students, and possibly among the professors. The reputation of the school was great till the 12th or 13th century, when the introduction of the Arab medicine was gradually fatal to it. The foundation of the university of Naples, and the rise of Montpellier, also contributed to its decline.

The teachings of the Salernitan doctors are pretty well known through existing works, some of which have only recently been discovered and published. The best-known is the anonymous rhyming Latin poem on health, *Regimen Sanitatis Salerni*, professedly written for the use of the "king of England," supposed to mean Robert, son of William the Conqueror; it had an immense reputation in the Middle Ages, and was afterwards many times printed, and translated into most European languages. This was a popular work intended for the laity; but there are others strictly professional. Among the writers it may be sufficient to mention here Gariopontus; Copho, who wrote the *Anatome Porci*, a well-known mediæval book; Joannes Platearius, first of a family of physicians bearing the same name, whose *Practica*, or medical compendium, was afterwards several times printed; and Trotula, believed to be the wife of the last-named. All of these fall into the first period before the advent of Arabian medicine. In the transitional period, when the Arabian school began to influence European medicine, but before the Salernitans were superseded, comes Nicolaus Præpositus, who wrote the *Antidotarium*, a collection of formulæ for compound medicines, which became the standard work on the subject, and the foundation of many later compilations. An equally popular writer was Gilles de Corbeil (Ægidius Corboliensis), at one time a teacher at Salerno, afterwards court physician to Philip Augustus of France, who composed several poems in Latin hexameters on medical subjects. Two of them, on the urine and the pulse respectively, attained the position of medical classics.

None of these Salernitan works rise much above the rank of compilations, being founded on Hippocrates, Galen, and later Greek writers, with an unmistakable mixture of the doctrines of the methodists. But they often show much practical experience, and exhibit the naturalistic method of the Hippocratic school. The general plan of treatment is dietetic rather than pharmaceutical, though the art of preparing drugs had reached a high degree of complexity at Salerno. Anatomy was as little regarded as it was in the later ancient schools, the empiric and methodic, but demonstrations of the parts of the body were given on swine. Although it cannot be said that the science of medicine was advanced at Salerno, still its decline was arrested at a time when every other branch of learning was rapidly falling into decay; and there can be no doubt that the observation of patients in hospitals, and probably clinical instruction, were made use of in learning and teaching. The school of Salerno thus forms a bridge between the ancient and the modern medicine, more direct though less conspicuous than that circuitous route, through Byzantium, Baghdad, and Cordova, by which Hippocrates and Galen, in Arabian dress, again entered the European world. Though the glory of Salerno had departed, the school actually existed till it was finally dissolved by an edict of the emperor Napoleon I. in the year 1811.

Introduction of Arabian Medicine: The Scholastic Period.—About the middle of the 11th century the Arabian medical writers began to be known by Latin translations in the Western world. Constantinus Africanus, a monk, was the author of the earliest of such versions (1050 A.D.); his labours were directed chiefly to the less important and less bulky Arabian authors, of whom Haly was the most noted; the real classics were not introduced till later. For some time the Salernitan medicine held its ground, and it was not till the conquest of Toledo by Alphonso of Castile that any large number of Western scholars came in contact with the learning of the Spanish Moors, and systematic efforts were made to translate their philosophical and medical works. Jewish scholars, often under the patronage of Christian bishops, were especially active in the work. In Sicily also the Oriental tendencies of Frederick Barbarossa and Frederick II. worked in the same direction. Gerard of Cremona, a physician of Toledo (1114–87), made translations, it is said by command of Barbarossa, from Avicenna and others. It is needless to point out the influence of the crusades in making Eastern ideas known in the Western world. The influence of Arabian medicine soon began to be felt even in the Hippocratic city of Salerno, and in the 13th century is said to have held an even balance with the older medicine. After this time the foreign influence predominated; and by the time that the Aristotelian dialectic, in the introduction of which the Arabs had so large a share, prevailed in the schools of Europe, the Arabian version of Greek medicine reigned supreme in the medical world. That this movement coincided with the establishment of some of the older European universities is well known. The history of medicine in the period now opening is closely combined with the history of scholastic philosophy. Both were infected with the same dialectical subtlety, which was, from the nature of the subject, especially injurious to medicine.

At the same time, through the rise of the universities, medical learning was much more widely diffused, and the first definite forward movement was seen in the school of Montpellier, where a medical faculty existed early in the 12th century, afterwards united with faculties of law and philosophy. The medical school owed its foundation largely to Jewish teachers, themselves educated in the Moorish schools of Spain, and imbued with the intellectual independence of the Averroists. Its rising prosperity coincided with the decline of the school of Salerno. Montpellier became distinguished for the practical and empirical spirit of its medicine, as contrasted with the dogmatic and scholastic teaching of Paris and other universities. In Italy, Bologna and Padua were earliest distinguished for medical studies,—the former preserving more of the Galenical tradition, the latter being more progressive and Averroist. The northern universities contributed little,—the reputation even of Paris being of later growth.

The supremacy of Arabian medicine lasted till the revival of learning, when the study of the medical classics in their original language worked another revolution. The medical writers of this period, who chiefly drew from Arabian sources, have been called Arabists (though it is difficult to give any clear meaning to this term), and were afterwards known as the neoterics.

The medical literature of this period is extremely voluminous, but essentially second-hand, consisting mainly of commentaries on Hippocrates, Galen, Avicenna, and others, or of compilations and *compendia* still less original than commentaries. Among these may be mentioned the *Conciliator* of Peter of Abano (1250–1315), the *Aggregator* of Jacob de Dondi (1298–1359), both of the school of Padua, and the *Pandectæ Medicinæ* of the Salernitan Matthæus Sylvaticus (*ob.* 1342), a sort of medical glossary and dictionary. But for us the most interesting fact is the first appearance of Englishmen as authors of medical works having a European reputation, distinguished, according to the testimony of Haeser, by a practical tendency characteristic of the British race, and fostered in the school of Montpellier.

The first of these works is the *Compendium Medicinæ*, also called *Laurea* or *Rosa Anglicana*, of Gilbert (Gilbertus Anglicus, about 1290), said to contain good observations on leprosy. A more important work, the *Practica seu Lilium Medicinæ*, of Bernard Gordon, a Scottish professor at Montpellier (written in the year 1307), was more widely spread, being translated into French and Hebrew, and printed in several editions. Of these two physicians the first probably, the latter certainly, was educated and practised abroad, but John Gaddesden, the author of *Rosa Anglica seu Practica Medicinæ* (between 1305 and 1317), was a graduate in medicine of Merton College, Oxford, and court physician. His compendium is entirely wanting in originality, and perhaps unusually destitute of common sense, but it became so popular as to be reprinted up to the end of the 16th century. Works of this kind became still more abundant in the 14th and in the first half of the 15th century, till the wider distribution of the medical classics in the original put them out of fashion.

In surgery this period was far more productive than in medicine, especially in Italy and France, but the limits of our subject only permit us to mention Gulielmus de Saliceto of Piacenza (about 1275), Lanfranchi of Milan (died about 1306), the French surgeon, Guy de Chauliac (about 1350), and the Englishman, John Ardern (about 1350). In anatomy also the beginning of a new epoch was made by Mondino de Liucci, or Mundinus (1275–1326), and his followers. Some advance was made in chemistry by the celebrated Arnold de Villanova (1235–1312), whose medical writings (if the *Breviarium Practicæ* be rightly ascribed to him) rise above the rank of compilations. Finally, in the 13th and especially the 14th century, we find, under the name of *consilia*, the first mediæval reports of medical cases which are preserved in such a form as to be intelligible. Collections of *consilia* were published, among others, by Gentilis Fulgineus before 1348, by Bartolomeo Montagnana (died in 1470), and by Baverius de Baveriis of Imola (about 1450). The last-named, we can say from experience, contains much that is interesting and readable.

Period of the Revival of Learning.—The impulse which all departments of intellectual activity received from the revival of Greek literature in Europe was felt by medicine among the rest. Not that the spirit of the science, or of its corresponding practice, was at once changed. The basis of medicine through the Middle Ages had been literary and dogmatic, and it was literary and dogmatic still; but the medical literature now brought to light, including as it did the more important works of Hippocrates and Galen, many of them hitherto unknown, and in addition the forgotten element of Latin medicine, especially the work of Celsus, was in itself far superior to the second-hand compilations and incorrect versions which had formerly been accepted as standards. The classical works, though still regarded with unreasoning reverence, were found to have a germinative and vivifying power that carried the mind out of the region of dogma, and prepared the way for the scientific movement which has been growing in strength up to our own day.

Two of the most important results of the revival of learning were indeed such as are excluded from the scope of this brief sketch, namely, the reawakening of anatomy, which to a large extent grew out of the study of the works of Galen, and the investigation of medicinal plants, to which a fresh impulse was given by the revival of Dioscorides and other ancient naturalists. The former brought with it necessarily a more accurate conception of physiology, and thus led up to the great discovery of Harvey, which was the turning-point in modern medicine. The latter gave rise, on the one hand, to the modern science of botany, on the other to a more rational knowledge of drugs and their uses. At the same time, the discovery of America, and increased intercourse with the East, by introducing a variety of new plants, greatly accelerated the progress both of botany and pharmacology.

But it was not in these directions that improvement was first looked for. It was at first very naturally imagined that the simple revival of classical and especially of Greek literature would at once produce the same brilliant results in medicine as in literature and philosophy. The movement of reform started, of necessity, with scholars rather than practising physicians,—more precisely with a group of learned men, whom we may be permitted, for the sake of a name, to call the medical humanists, equally enthusiastic in the cause of letters and of medicine. From both fields they hoped to expel the evils which were summed up in the word barbarism. Nearly all mediæval medical literature was condemned under this name; and for it the humanists proposed to substitute the originals of Hippocrates and Galen, thus leading back medicine to its fountain-head. Since a knowledge of Greek was still confined to a small body of scholars, and a still smaller proportion of physicians, the first task was to translate the Greek classics into Latin. To this work several learned physicians, chiefly Italians, applied themselves with great ardour. Among the earliest were Nicolaus Leonicenus of Vicenza (1428–1524), Giovanni de Monte or Montanus (1498–1552), and many others in Italy. In northern Europe should be mentioned Gulielmus Copus (1471–1532) and Günther of Andernach (1487–1584) better known as Guinterius Andernacensis, both for a time professors at Paris; and, among the greatest, Thomas Linacre (about 1460–1524; see LINACRE). A little later Janus Cornarius or Hagenbut (1500–58) and Leonard Fuchs (1501–66) in Germany, and John Kaye or Caius (1510–72) in England, carried on the work. Symphorien Champier (Champerius or Campegius) of Lyons (1472–1539), a contemporary of Rabelais, and the patron of Servetus, wrote with fantastic enthusiasm on the superiority of the Greek to the Arabian physicians, and possibly did something to enlist in the same cause the two far greater men just mentioned. Rabelais not only lectured on Galen and Hippocrates, but edited some works of the latter; and Servetus, in a little tract *Syruporum universa ratio*, defended the practice of Galen as compared with that of the Arabians. The great Aldine press made an important contribution to the work, by *editiones principes* of Hippocrates and Galen in the original. Thus was the campaign opened against the mediæval and Arabian writers, till finally Greek medicine assumed a predominant position, and Galen took the place of Avicenna. The result was recorded in a formal manner by the Florentine Academy, sometime shortly before 1535: "quæ, excusso Arabicæ et barbaræ servitutis medicæ jugo, ex professo se Galenicam appellavit et profligato barbarorum exercitu unum totum et solum Galenum, ut optimum artis medicæ authorem, in omnibus se sequuturam pollicita est." Janus Cornarius, from whom this is quoted, laments, however, that the Arabians still reigned in most of the schools of medicine, and that the Italian and French authors of works called *Practica* were still in high repute. The triumph of Galenism was therefore not complete by the middle of the 16th century. It was probably most so, and earliest, in the schools of Italy and in those of England, where the London College of Physicians might be regarded as an offshoot of the Italian schools. Paris was the stronghold of conservatism, and Germany was stirred by the teachings of one who must be considered apart from all schools—Paracelsus. The nature of the struggle between the rival systems may be well illustrated by a formidable controversy about the rules for bleeding in acute diseases. This operation, according to the Arabian practice, was always performed on a vein at a distance from the organ affected. The Hippocratic and also Galenic rule, to let blood from, or near to, the diseased organ, was revived by Brissot (1470–1522), a professor in the university of Paris. His attempt at reform, which was taken to be, as in effect it was, a revolt against the authority of the Arabian masters, led to his expulsion from Paris, and the formal prohibition by the parliament of his method. Upon this apparently trifling question arose a controversy which lasted many years, occupied several universities, and led to the interposition of personages no less important than the pope and the emperor, but which is thought to have largely contributed to the final downfall of the Arabian medicine.

Paracelsus and Chemical Medicine.—Contemporary with the school of medical humanists, but little influenced by them, lived in Germany a man of strange genius, of whose character and importance the most opposite opinions have been expressed. The first noticeable quality in Paracelsus (*c.* 1490–1541) is his revolutionary independence of thought, which was supported by his immense personal arrogance. Himself well trained in the learning and medical science of the day, he despised and trampled upon all traditional and authoritative teachings. He began his lectures at Basel by burning the books of Avicenna and others; he afterwards boasted of having read no books for ten years; he protested that his shoe buckles were more learned than Galen and Avicenna. On the other hand, he spoke with respect of Hippocrates, and wrote a commentary on his *Aphorisms*. In this we see a spirit very different from the enthusiasm of the humanists for a purer and nobler philosophy than the scholastic and Arabian versions of Greek thought. There is no record of Paracelsus's knowledge of Greek, and as, at least in his student days, the most important works of Greek medicine were very imperfectly known, it is probable he had little first-hand acquaintance with Galen or Hippocrates, while his breach with the humanists is the more conspicuous from his lecturing and writing chiefly in his native German.

Having thus made a clean sweep of nearly the whole of the dogmatic medicine, what did Paracelsus put in its place? Certainly not pure empiricism, or habits of objective observation. He had a dogma of his own,—one founded, according to his German expositors, on the views of the

Neo-Platonists, of which a few disjointed specimens must here suffice. The human body was a "microcosm" which corresponded to the "macrocosm," and contained in itself all parts of visible nature,—sun, moon, stars, and the poles of heaven. To know the nature of man and how to deal with it, the physician should study, not anatomy, which Paracelsus utterly rejected, but all parts of external nature. Life was a perpetual germinative process controlled by the indwelling spirit or Archeus; and diseases, according to the mystical conception of Paracelsus, were not natural, but spiritual. Nature was sufficient for the cure of most diseases; art had only to interfere when the internal physician, the man himself, was tired or incapable. Then some remedy had to be introduced which should be antagonistic, not to the disease in a physical sense, but to the spiritual seed of the disease. These remedies were *arcana*,—a word corresponding partly to what we now call specific remedies, but implying a mysterious connexion between the remedy and the "essence" of the disease. Arcana were often shown to be such by their physical properties, not only by such as heat, cold, &c., but by fortuitous resemblances to certain parts of the body; thus arose the famous doctrine of "signatures," or signs indicating the virtues and uses of natural objects, which was afterwards developed into great complexity. Great importance was also attached to chemically prepared remedies as containing the essence or spiritual quality of the material from which they were derived. The actual therapeutical resources of Paracelsus included a large number of metallic preparations, in the introduction of some of which he did good service, and, among vegetable preparations, the tincture of opium, still known by the name he gave it, laudanum. In this doubtless he derived much advantage from his knowledge of chemistry, though the science was as yet not disentangled from the secret traditions of alchemy, and was often mixed up with imposture.

German historians of medicine attach great importance to the revolt of Paracelsus against the prevailing systems, and trace in his writings anticipations of many scientific truths of later times. That his personality was influential, and his intrepid originality of great value as an example in his own country, is undeniable. As a national reformer he has been not inaptly compared to Luther. But his importance in the universal history of medicine we cannot estimate so highly. The chief immediate result we can trace is the introduction of certain mineral remedies, especially antimony, the use of which became a kind of badge of the disciples of Paracelsus. The use of these remedies was not, however, necessarily connected with a belief in his system, which seems to have spread little beyond his own country. Of the followers of Paracelsus some became mere mystical quacks and impostors. Others, of more learning and better repute, were distinguished from the regular physicians chiefly by their use of chemical remedies. In France the introduction of antimony gave rise to a bitter controversy which lasted into the 17th century, and led to the expulsion of some men of mark from the Paris faculty. In England "chemical medicine" is first heard of in the reign of Elizabeth, and was in like manner contemned and assailed by the College of Physicians and the Society of Apothecaries. But it should be remembered that all the chemical physicians did not call Paracelsus master. The most notorious of that school in England, a certain Anthony, never quotes Paracelsus, but relies upon Arnold de Villanova and Raymund Lully. From this time, however, it is always possible to trace a school of chemical practitioners, who, though condemned by the orthodox Galenists, held their ground, till in the 17th century a successor of Paracelsus arose in the celebrated Van Helmont.

Consequences of the Revival of Ancient Medicine.—The revival of Galenic and Hippocratic medicine, though ultimately it conferred the greatest benefits on medical science, did not immediately produce any important or salutary reform in practical medicine. The standard of excellence in the ancient writers was indeed far above the level of the 16th century; but the fatal habit of taking at second hand what should have been acquired by direct observation retarded progress more than the possession of better models assisted it, so that the fundamental faults of mediæval science remained uncorrected.

Nevertheless some progress has to be recorded, even if not due directly to the study of ancient medicine. In the first place the 15th and 16th centuries were notable for the outbreak of certain epidemic diseases, which were unknown to the old physicians. Of these the chief was the "sweating sickness" or "English sweat," especially prevalent in, though not confined to, the country whence it is named. Among many descriptions of this disease, that by John Kaye or Caius, already referred to, was one of the best, and of great importance as showing that the works of Galen did not comprise all that could be known in medicine. The spread of syphilis, a disease equally unknown to the ancients, and the failure of Galen's remedies to cure it, had a similar effect.

In another direction the foundations of modern medicine were being laid during the 16th century, namely, by the introduction of clinical instruction in hospitals. In this Italy, and especially the renowned school of Padua, took the first step, where De Monte (Montanus), already mentioned as a humanist, gave clinical lectures on the patients in the hospital of St Francis, which may still be read with interest. Pupils flocked to him from all European countries; Germans are especially mentioned; a Polish student reported and published some of his lectures; and the Englishman Kaye was a zealous disciple, who does not, however, seem to have done anything towards transplanting this method of instruction to his own country. Inspections of the dead, to ascertain the nature of the disease, were made, though not without difficulty, and thus the modern period of the science of morbid anatomy was ushered in.

Medicine in the 17th century.—The medicine of the early part of the 17th presents no features to distinguish it from that of the preceding century. The practice and theory of medicine were mainly founded upon Hippocrates and Galen, with ever-increasing additions from the chemical school. But the development of mathematical and physical science soon introduced a fundamental change in the habits of thought with respect to medical doctrine.

These discoveries not only weakened or destroyed the respect for authority in matters of science, but brought about a marked tendency to mechanical explanations of life and disease. When Harvey by his discovery of the circulation furnished an explanation of many vital processes which was reconcileable with the ordinary laws of mechanics, the efforts of medical theorists were naturally directed to bringing all the departments of medicine under similar laws. It is often assumed that the writings and influence of Bacon did much towards introducing a more scientific method into medicine and physiology. But, without discussing the general philosophical position or historical importance of Bacon, it may safely be said that his direct influence can be little traced in medical writings of the first half of the 17th century. Harvey, as is well known, spoke slightingly of the great chancellor, and it is not till the rapid development of physical science in England and Holland in the latter part of the century, that we find Baconian principles explicitly recognized.

The dominant factors in the 17th century medicine were the discovery of the circulation by Harvey (published in 1628), the mechanical philosophy of Descartes and the contemporary progress of physics, the teaching of Van Helmont and the introduction of chemical explanations of morbid processes, and finally, combined of all these, and inspiring them, the rise of the spirit of inquiry and innovation, which may be called the scientific movement. Before speaking in detail of these, we may note that by other influences, quite independent of theories, important additions were made to practical medicine. The method of clinical instruction in hospitals, commenced by the Italians, was introduced into Holland, where it was greatly developed, especially at Leyden, in the hands of the celebrated Sylvius. It is noteworthy that concurrently with the rise of clinical study the works of Hippocrates were more and more valued, while Galen began to sink into the background.

At the same time the discovery of new diseases, unknown to the ancients, and the keener attention which the great epidemics of plague caused to be paid to those already known, led to more minute study of the natural history of disease. The most important disease hitherto undescribed was rickets, first made known by Arnold de Boot, a Frisian who practised in Ireland, in 1649, and afterwards more fully in the celebrated work of Glisson in 1651. The plague was carefully studied by Diemerbroek (*De Peste*, 1646) and others. Hodges, of London, in 1665 seems to have been the first who had the courage to make a post-mortem inspection of a plague patient. Bennet wrote an important work on consumption in 1654. During the same period many new remedies were introduced, the most important being cinchona bark, brought to Spain in the year 1640. The progress of pharmacy was shown by the publication of *Dispensatories* or *Pharmacopœiæ*, such as that of the Royal College of Physicians of London in 1618. This, like the earlier German works of the same kind (on which it was partly founded), contains both the traditional (Galenical) and the modern or chemical remedies.

Van Helmont.—The medicine of the 17th century was especially distinguished by the rise of systems; and we must first speak of an eccentric genius who endeavoured to construct a system for himself, as original and opposed to tradition as that of Paracelsus. Van Helmont (1578–1644) was a man of noble family in Brussels, who, after mastering all other branches of learning as then understood, devoted himself with enthusiasm to medicine and chemistry. By education and position a little out of the regular lines of the profession, he took up in medicine an independent attitude. Well acquainted with the doctrines of Galen, he rejected them as thoroughly as Paracelsus did, and borrowed from the latter some definite ideas as well as his revolutionary spirit. The archeus of Paracelsus appears again, but with still further complications,—the whole body being controlled by the *archeus influus*, and the organ of the soul and its various parts by the *archei insiti*, which are subject to the central archeus. Many of the symptoms of diseases were caused by the passions and perturbations of the archeus, and medicines acted by modifying the *ideas* of the same archeus. These and other notions cannot be here stated at sufficient length to be intelligible. It is enough to say that on this fantastic basis Helmont constructed a medical system which had some practical merits, that his therapeutical methods were mild and in many respects happy, and that he did service by applying newer chemical methods to the preparation of drugs. He thus had some share, though a share not generally recognized, in the foundation of the iatro-chemical school, now to be spoken of. But his avowed followers formed a small and discredited sect, which, in England at least, can be clearly traced in the latter part of the century.

Discovery of the Circulation of the Blood.—The influence of Harvey's discovery began to be felt before the middle of the century. Its merits were recognized by Descartes, among the first, nine years after its publication. For the history of the discovery, and its consequences in anatomy and physiology, we must refer to the article HARVEY. In respect of practical medicine, much less effect was at first noticeable. But this example, combined with the Cartesian principles, set many active and ingenious spirits to work to reconstruct the whole of medicine on a physiological or even a mechanical basis,—to endeavour to form what we should now call physiological or scientific medicine. The result of this was not to eliminate dogma from medicine, though it weakened the authority of the old dogma. The movement led rather to the formation of schools or systems of thought, which under various names lasted on into the 18th century, while the belief in the utility or necessity of schools and systems lasted much longer. The most important of these were the so-called iatro-physical or mechanical and the iatro-chemical schools.

Iatro-Physical School.—The iatro-physical school of medicine grew out of physiological theories. Its founder is held to have been Borelli of Naples (1608–79), whose treatise *De motu animalium*, published in 1680, is regarded as marking an epoch in physiology. The tendency of the school was to explain the actions and functions of the body on physical and especially on mechanical principles. The movements of bones and muscles were referred to the theory of levers; the process of digestion was regarded as essentially a process of trituration; nutrition and secretion were shown to be dependent upon the tension of the vessels, and so forth. The developments of this school belong rather to the history of physiology, where they appear, seen in the light of modern science, as excellent though premature endeavours in a scientific direction. But the influence of these theories on practical medicine was not great. The more judicious of the mechanical or physical school refrained, as a judicious modern physiologist does, from too immediate an application of their principles to daily practice. Mechanical theories were introduced into pathology, in explanation of the processes of fever and the like, but had little or no influence on therapeutics. The most important men in this school after Borelli were Steno (1638–86), Baglivi (1673–1707), and Bellini (1643–1704). An English physician, Cole (1660–1700), is also usually ranked with them. One of the most elaborate developments of the system was that of Pitcairn, a Scottish physician who became professor at Leyden (1652–1713), to be spoken of hereafter.

Iatro-Chemical School. — The so-called iatro-chemical school stood in a much closer relation to practical medicine than the iatro-physical. The principle which mainly distinguished it was not merely the use of chemical medicines in addition to the traditional, or, as they were called in distinction, "Galenical" remedies, but a theory of pathology or causation of disease entirely different from the prevailing "humoral" pathology. Its chief aim was to reconcile the new views in physiology and chemistry with practical medicine. In some theoretical views, and in the use of certain remedies, the school owed something to Van Helmont and Paracelsus, but took in the main an independent position. The founder of the iatro-chemical school was Francis de le Boë, called Sylvius (1614–72), belonging to a French family settled in Holland. Sylvius was for fourteen years professor of medicine at Leyden, where he attracted students from all quarters of Europe. He made a resolute attempt to reconstruct medicine on the two bases of the doctrine of the circulation of the blood and the new views of chemistry. Fermentation, which was supposed to take place in the stomach, played an important part in the vital processes. Chemical disturbances of these processes, called *acridities*, &c., were the cause of fevers and other diseases. Sometimes acid sometimes alkaline properties predominated in the juices and secretions of the body, and produced corresponding disturbances. In nervous diseases disturbances of the vital "spirits" were most important. Still in some parts of his system Sylvius shows an anxiety to base his pathology on anatomical changes. The remedies he employed were partly Galenical, partly chemical. He was very moderate in the use of bleeding.

The doctrines of Sylvius became widely spread in Holland and Germany; less so in France and Italy. In England they were not generally accepted till adopted with some modifications by Thomas Willis the great anatomist (1622–75), who is the chief English representative of the chemical school. Willis was as thorough-going a chemist as Sylvius. He regarded all bodies, organic and inorganic, as composed of the three elements—spirit, sulphur, and salt, the first being only found abundantly in animal bodies. The "intestine movement of particles" in every body, or fermentation, was the explanation of many of the processes of life and disease. The sensible properties and physical alterations of animal fluids and solids depended upon different proportions, movements, and combinations of these particles. The elaborate work *Pharmaceutice Rationalis*, based on these materials, had much influence in its time, though it was soon forgotten. But some parts of Willis's works, such as his descriptions of nervous diseases, and his account (the earliest) of diabetes, are classical contributions to scientific medicine. In the application of chemistry to the examination of secretions Willis made some important steps. The chemical school met with violent opposition, partly from the adherents of the ancient medicine, partly from the iatro-mechanical school. Towards the end of the 17th century appeared an English medical reformer who sided with none of these schools, but may be said in some respects to have surpassed and dispensed with them.

Sydenham and Locke.—Thomas Sydenham (1624–89) was educated at Oxford and at Montpellier. He was well acquainted with the works of the ancient physicians, and probably fairly so with chemistry. Of his knowledge of anatomy nothing definite can be said, as he seldom refers to it. His main avowed principle was to do without hypothesis, and study the actual diseases in an unbiassed manner. As his model in medical methods, Sydenham repeatedly and pointedly refers to Hippocrates, and he has not unfairly been called the English Hippocrates. He resembled his Greek master in the high value he set on the study of the "natural history of disease"; in the importance he attached to "epidemic constitution," that is, to the influence of weather and other natural causes in modifying disease; and further in his conception of the healing power of nature in disease, a doctrine which he even expanded beyond the teaching of Hippocrates. According to Sydenham, a disease is nothing more than an effort of nature to restore the health of the patient by the elimination of the morbific matter. The extent to which his practice was influenced by this and other *a priori* conceptions prevents us from classing Sydenham as a pure empiric, but he had the rare merit of never permitting himself to be enslaved even by his own theories. Still less was his mind warped by either of the two great systems, the classical and the chemical, which then divided the medical world. Sydenham's influence on European medicine was very great. His principles were welcomed as a return to nature by those who were weary of theoretical disputes. He introduced a milder and better way of treating fevers, especially small-pox, and gave strong support to the use of specific medicines, especially Peruvian bark. He was an advocate of bleeding, and often carried it to excess. Another important point in Sydenham's doctrine is his clear recognition of many diseases as being what would be now called *specific*, and not due merely to an alteration in the primary qualities or humours of the older schools. From this springs his high appreciation of specific medicines.

One name should always be mentioned along with Sydenham—that of his friend John Locke. The great sensational philosopher was a thoroughly trained physician, and practised privately. He shared and defended many of Sydenham's principles, and in the few medical observations he has left shows himself to be even more thorough-going than the "English Hippocrates." It is deeply to be regretted in the interests of medicine that he did not write more. It is, however, reasonable to suppose that his commanding intellect often makes itself felt in the words of Sydenham. One sentence of Locke's in a letter to W. Molyneux sums up the practical side of Sydenham's teaching.

> "You cannot imagine how far a little observation carefully made by a man not tied up to the four humours [Galen], or sal, sulphur, and mercury [Paracelsus], or to acid and alcali [Sylvius and Willis] which has of late prevailed, will carry a man in the curing of diseases though very stubborn and dangerous; and that with very little and common things, and almost no medicine at all."

We thus see that, while the great anatomists, physicists, and chemists, men of the type of Willis, Borelli, and Boyle, were laying foundations which were later on built up into the fabric of scientific medicine, little good was done by the premature application of their half-understood principles to practice. The reform of practical medicine was effected by men who aimed at, and partly succeeded in, rejecting all hypothesis and returning to the unbiassed study of natural processes, as shown in health and disease.

Sydenham showed that these processes might be profitably studied and dealt with without explaining them; and, by turning men's minds away from explanations and fixing them on facts, he enriched medicine with a *method* more fruitful than any discoveries in detail. From this time forth the reign of canonical authority in medicine was at an end, though the dogmatic spirit long survived.

The 18th century.—The medicine of the 18th century is notable, like that of the latter part of the 17th, for the striving after complete theoretical systems. The influence of the iatro-physical school was by no means exhausted; and in England, especially through the indirect influence of Newton's great astronomical generalizations, it took on a mathematical aspect, and is sometimes known as iatro-mathematical. This phase is most clearly developed in Pitcairn (1652–1713), who, though a determined opponent of metaphysical explanations, and of the chemical doctrines, gave to his own rude mechanical explanations of life and disease almost the dogmatic completeness of a theological system. His countryman and pupil, George Cheyne, who lived some years at Bath, published a new theory of fevers on the mechanical system, which had a great reputation. Their English contemporaries and successors, Freind, Cole, and Mead, leaned also to mechanical explanations, but with a distrust of systematic theoretical completeness, which was perhaps partly a national characteristic, partly the result of the teaching of Sydenham and Locke. Freind (1675–1728) in his *Emmenologia* gave a mechanical explanation of the phenomena of menstruation. He is also one of the most distinguished writers on the history of medicine. Cole (see above) published mechanical hypotheses concerning the causation of fevers which closely agree with those of the Italian iatro-mechanical school. More distinguished in his own day than any of these was Richard Mead (1673–1754), one of the most accomplished and socially successful physicians of modern times. Mead was the pupil of the equally popular and successful John Radcliffe

(1650–1714), who had acquired from Sydenham a contempt for book learning, and belonged to no school in medicine but the school of common sense. Radcliffe left, however, no work requiring mention in a history of medicine. Mead, a man of great learning and intellectual activity, was an ardent advocate of the mathematical doctrines. "It is very evident," he says, "that all other means of improving medicine have been found ineffectual, by the stand it was at for two thousand years, and that, since mathematicians have set themselves to the study of it, men already begin to talk so intelligibly and comprehensibly, even about abstruse matters, that it is to be hoped that mathematical learning will be the distinguishing mark of a physician and a quack." His *Mechanical Account of Poisons*, in the first edition (1702), gave an explanation of the effects of poisons, as acting only on the blood. Afterwards he modified his hypothesis, and referred the disturbances produced to the "nervous liquor," which he supposed to be a quantity of the "universal elastic matter" diffused through the universe, by which Newton explained the phenomena of light, *i.e.*, what was afterwards called the luminiferous ether. Mead's treatise on *The Power of the Sun and Moon over Human Bodies* (1704), equally inspired by Newton's discoveries, was a premature attempt to assign the influence of atmospheric pressure and other cosmical causes in producing disease. His works contain, however, many original experiments, and excellent practical observations. James Keill (1673–1719) applied Newtonian and mechanical principles to the explanation of bodily functions with still greater accuracy and completeness; but his researches have more importance for physiology than for practical medicine.

Boerhaave.—None of these men founded a school,—a result due in part to their intellectual character, in part to the absence in England of medical schools equivalent in position and importance to the universities of the Continent. An important academical position was, on the other hand, one of the reasons why a physician not very different in his way of thinking from the English physicians of the age of Queen Anne was able to take a far more predominant position in the medical world. Hermann Boerhaave (1668–1738) was emphatically a great teacher. He was for many years professor of medicine at Leyden, where he lectured five hours a day, and excelled in influence and reputation, not only his greatest forerunners, Montanus of Padua and Sylvius of Leyden, but probably every subsequent teacher. The hospital of Leyden, though with only twelve beds available for teaching, became the centre of medical influence in Europe. Many of the leading English physicians of the 18th century studied there; Van Swieten, a pupil of Boerhaave, transplanted the latter's method of teaching to Vienna, and founded the noted Vienna school of medicine. As the organizer, and almost the constructor, of the modern method of clinical instruction, the services of Boerhaave to the progress of medicine were immense, and can hardly be overrated. In his teaching, as in his practice, he avowedly followed the method of Hippocrates and Sydenham, both of whom he enthusiastically admired. In his medical doctrines he must be pronounced an eclectic, though taking his stand mainly on the iatro-mechanical school. The best known parts of Boerhaave's system are his doctrines of inflammation, obstruction, and "plethora." By the last-named especially he was long remembered. His object was to make all the anatomical and physiological acquisitions of his age, even microscopical anatomy, which he diligently studied, available for use in the practice of medicine. He thus differed from Sydenham, who took almost as little account of modern science as of ancient dogma. Boerhaave may be in some respects compared to Galen, but again differed from him in that he always abstained from attempting to reduce his knowledge to a uniform and coherent system. Boerhaave attached great importance to the study of the medical classics, but rather treated them historically than quoted them as canonical authorities. It almost follows from the nature of the case that the great task of Boerhaave's life, a synthesis of ancient and modern medicine, and the work in which this is chiefly contained, his celebrated *Institutions*, could not have any great permanent value. Nearly the same thing is true even of the *Aphorisms*, in which, following the example of Hippocrates, he endeavoured to sum up the results of his long experience.

Hoffmann and Stahl.—We have now to speak of two writers in whom the systematic tendency of the 18th century showed itself most completely.

Friedrich Hoffmann (1660–1742), like Boerhaave, owed his influence, and perhaps partly his intellectual characteristics, to his academical position. He was in 1693 appointed the first professor of medicine in the university of Halle, then just founded by the elector Frederick III. Here he became, as did his contemporary and rival Stahl, a popular and influential teacher, though their university had not the European importance of Leyden. Hoffmann's "system" was apparently intended to reconcile the opposing "spiritual" and "materialistic" views of nature, and is thought to have been much influenced by the philosophy of Leibnitz. His medical theories rest upon a complete theory of the universe. Life depended upon a universally diffused ether, which animals breathe in from the atmosphere, and which is contained in all parts of the body. It accumulates in the brain, and there generates the "nervous fluid" or *pneuma*,—a theory closely resembling that of Mead on the "nervous liquor," unless indeed Mead borrowed it from Hoffmann. On this system are explained all the phenomena of life and disease. Health depends on the maintenance of a proper "tone" in the body,—some diseases being produced by excess of tone, or "spasm"; others by "atony," or want of tone. But it is impossible here to follow its further developments. Independently of his system, which has long ceased to exert any influence, Hoffmann made some contributions to practical medicine; and his great knowledge of chemistry enabled him to investigate the subject of mineral waters. He was equally skilful in pharmacy, but lowered his position by the practice, which would be unpardonable in a modern physician, of trafficking in secret remedies. Some of these are even to this day sold for the benefit of the orphanage at Halle.

George Ernest Stahl (1660–1734) was for more than twenty years professor of medicine at Halle, and thus a colleague of Hoffmann, whom he resembled in constructing a complete theoretical system, though their systems had little or nothing in common. Stahl's chief aim was to oppose materialism. For mechanical conceptions he substituted the theory of "animism,"—attributing to the soul the functions of ordinary animal life in man, while the life of other creatures was left to mechanical laws. The symptoms of disease were explained as efforts of the soul to rid itself from morbid influences, the soul acting reasonably with respect to the end of self-preservation. The anima thus corresponds partly to the "nature" of Sydenham, while in other respects it resembles the archeus of Van Helmont. Animism in its completeness met with little acceptance during the lifetime of its author, but influenced some of the iatro-physical school. Stahl was the author of the theory of "phlogiston" in chemistry, which in its day had great importance.

Haller and Morgagni.—From the subtleties of rival systems it is a satisfaction to turn to two movements in the medicine of the 18th century which, though they did not extinguish the spirit of system-making, opened up paths of investigation by which the systems were ultimately superseded. These are physiology in the modern sense, as dating from Haller, and pathological anatomy, as dating from Morgagni.

Albrecht von Haller (1708–77) was a man of even more encyclopædic attainments than Boerhaave. He advanced chemistry, botany, anatomy, as well as physiology, and was incessantly occupied in endeavouring to apply his scientific studies to practical medicine, thus continuing the work of his great teacher Boerhaave. Besides all this he was probably more profoundly acquainted with the literature and bibliography of medicine than any one before or since. Haller occupied in the new university of Göttingen (founded 1737) a position corresponding to that of Boerhaave at Leyden, and in like manner influenced a very large circle of pupils. The appreciation of his work in physiology belongs to the history of that science; we are only concerned here with its influence on medicine. Haller's definition of irritability as a property of muscular tissue, and its distinction from sensibility as a property of nerves, struck at the root of the prevailing hypothesis respecting animal activity. It was no longer necessary to suppose that a half conscious "anima" was directing every movement. Moreover, Haller's views did not rest on *a priori* speculation, but on numerous experiments. He was among the first to investigate the action of medicines on healthy persons. Unfortunately the lesson which his contemporaries learnt was not the importance of experiment, but only the need of contriving other "systems" less open to objection; and thus the influence of Haller led directly to the theoretical subtleties of Cullen and John Brown, and only indirectly and later on to the general anatomy of Bichat. The great name of Haller does not therefore occupy a very prominent place in the history of practical medicine.

The work of Giovanni Battista Morgagni (1682–1771) had and still preserves a permanent importance beyond that of all the contemporary theorists. In a series of letters *De sedibus et causis morborum per anatomen indagatis*, published when he was in his eightieth year, he describes the appearances met with at the post-mortem examination as well as the symptoms during life in a number of cases of various diseases. It was not the first work of the kind. Bonet had published his *Sepulcretum* in 1679; and observations of post-mortem appearances had been made by Montanus, Tulp, Vieussens, Valsalva, Lancisi, Haller, and others. But never before was so large a collection of cases brought together, described with such accuracy, or illustrated with equal anatomical and medical knowledge. Morgagni's work at once made an epoch in the science. Morbid anatomy now became a recognized branch of medical research, and the movement was started which has lasted till our own day.

The contribution of Morgagni to medical science must be regarded as in some respects the counterpart of Sydenham's. The latter had, in neglecting anatomy, neglected the most solid basis for studying the natural history of disease; though perhaps it was less from choice than because his practice, as he was not attached to a hospital, gave him no opportunities. But it is on the combination of the two methods, that of Sydenham and of Morgagni, that modern medicine rests; and it is through these that it has been able to make steady progress in its own field, independently of the advance of physiology or other sciences.

The method of Morgagni found many imitators, both in his own country and in others. In England the first important name in this field is at the same time that of the first writer of a systematic work in any language on morbid anatomy, Matthew Baillie (1761–1823), who published his treatise in 1793.

Cullen and Brown.—It remains to speak of two systematic writers on medicine in the 18th century, whose great reputation prevents them from being passed over, though their real contribution to the progress of medicine was not great—Cullen and Brown.

William Cullen (1712–90) was a most eminent and popular professor of medicine at Edinburgh. The same academical influences as surrounded the Dutch and German founders of systems were doubtless partly concerned in leading him to form the plan of a comprehensive system of medicine. Cullen's system was largely based on the new physiological doctrine of irritability, but is especially noticeable for the importance attached to nervous action. Thus even gout was regarded as a "neurosis." These pathological principles of Cullen are contained in his *First Lines of the Practice of Physic*, an extremely popular book, often reprinted and translated. More importance is to be attached to his *Nosology or Classification of Diseases*. The attempt to classify diseases on a natural-history plan was not new, having been commenced by Sauvages and others, and is perhaps not a task of the highest importance. Cullen drew out a classification of great and needless complexity, the chief part of which is now forgotten, but several of his main divisions are still preserved.

It is difficult to form a clear estimate of the importance of the last systematizer of medicine, John Brown (1735–88), for, though in England he has been but little regarded, the wide though short-lived popularity of his system on the Continent shows that it must have contained some elements of brilliancy, if not originality. His theory of medicine professed to explain the processes of life and disease, and the methods of cure, upon one simple principle,—that of the property of "excitability," in virtue of which the "exciting powers," defined as being (1) external forces and (2) the functions of the system itself, call forth the vital phenomena "sense, motion, mental function, and passion." All exciting powers are stimulant, the apparent debilitating or sedative effect of some being due to a deficiency in the degree of stimulus; so that the final conclusion is that "the whole phenomena of life, health as well as disease, consist in stimulus and nothing else." Brown recognized some diseases as *sthenic*, others as *asthenic*, the latter requiring stimulating treatment, the former the reverse; but his practical conclusion was that 97 per cent. of all diseases required a "stimulating" treatment. In this he claimed to have made the most salutary reform because all physicians from Hippocrates had treated diseases by depletion and debilitating measures with the object of curing by elimination. It would be unprofitable to attempt a complete analysis of the Brunonian system; and it is difficult now to understand why it attracted so much attention in its day. To us at the present time it seems merely a dialectical construction, having its beginning and end in definitions, the words power, stimulus, &c., being used in such a way as not to correspond to any precise physical conceptions, still less to definite material objects or forces. One recommendation of the system was that it favoured a milder system of treatment than was at that time in vogue; Brown may be said to have been the first advocate of the modern stimulant or feeding treatment of fevers. He advocated the use of "animal soups" or beef tea. Further he had the discernment to see that certain symptoms, such as convulsions and delirium, which were then commonly held always to indicate inflammation, were often really signs of weakness.

The fortunes of Brown's system (called, from having been originally written in Latin, the Brunonian) form one of the strangest chapters in the history of medicine. In Scotland, Brown so far won the sympathy of the students that riotous conflicts took place between his partisans and opponents. In England his system took little root. In Italy, on the other hand, it received enthusiastic support, and, naturally, a corresponding degree of opposition. The most important adherent to Brown's system was Rasori (1763-1837), who taught it as professor at Pavia, but afterwards substituted his own system of contra-stimulus. The theoretical differences between this and the "stimulus" theory need not be expounded. The practical difference in the corresponding treatment was very great, as Rasori advocated a copious use of bleeding and of depressing remedies, such as antimony. Joseph Frank, a German, professor at Pavia, afterwards of Vienna, the author of an encyclopædic work on medicine now forgotten, embraced the Brunonian system, though he afterwards introduced some modifications, and transplanted it to Vienna. Many names are quoted as partisans or opponents of the Brunonian system in Italy, but scarcely one of them has any other claim to be remembered. In Germany the new system called forth, a little later, no less enthusiasm and controversial heat. Girtanner first began to spread the new ideas (though giving them out as his own), but Weikard was the first avowed advocate of the system. Röschlaub (1768-1835) modified Brown's system into the theory of excitement (*Erregungstheorie*), which for a time was extremely popular in Germany. The enthusiasm of the younger Brunonians in Germany was as great as in Edinburgh or in Italy, and led to serious riots in the university of Göttingen. In America the system was enthusiastically adopted by a noted physician, Benjamin Rush, of Philadelphia, who was followed by a considerable school. France was not more influenced by the new school than England. In both countries the tendency towards positive science and progress by objective investigation was too marked for any theoretical system to have more than a passing influence. In France, however, the influence of Brown's theories is very clearly seen in the writings of Broussais, who, though not rightly classed with the system-makers, since his conclusions were partly based upon anatomical investigation, resembled them in his attempt to unite theory and practice in one comprehensive synthesis. The explanation of the meteoric splendour of the Brunonian system in other countries seems to be as follows. In Italy the period of intellectual decadence had set in, and no serious scientific ardour remained to withstand the novelties of abstract theory. In Germany the case was somewhat different. Intellectual activity was not wanting, but the great achievements of the 18th century in philosophy and the moral sciences had fostered a love of abstract speculation; and some sort of cosmical or general system was thought indispensable in every department of special science. Hence another generation had to pass away before Germany found herself on the level, in scientific investigation, of France and England.

Before the theoretic tendency of the 18th century was quite exhausted, it displayed itself in a system which, though in some respects isolated in the history of medicine, stands nearest to that of Brown,—that, namely, of Hahnemann (see HOMŒOPATHY). Hahnemann (1753-1844) was in conception as revolutionary a reformer of medicine as Paracelsus. He professed to base medicine entirely on a knowledge of symptoms, regarding all investigation of the causes of symptoms as useless. While thus rejecting all the lessons of morbid anatomy and pathology, he put forward views respecting the causes of disease which hardly bear to be seriously stated. All chronic maladies result either from three diseases—psora (the itch), syphilis, or sycosis (a skin disease), or else are maladies produced by medicines. Seven-eighths of all chronic diseases are produced by itch driven inwards.[1] (It is fair to say that these views were published in one of his later works.) In treatment of disease Hahnemann rejected entirely the notion of a *vis medicatrix naturæ*, and was guided by his well-known principle "similia similibus curantur," which he explained as depending on the law that in order to get rid of a disease some remedy must be given which should substitute for the disease an action dynamically similar, but weaker. The original malady being thus got rid of, the vital force would easily be able to cope with and extinguish the slighter disturbance caused by the remedy. Something very similar was held by Brown, who taught that "indirect debility" was to be cured by a lesser degree of the same stimulus as had caused the original disturbance. Generally, however, Hahnemann's views contradict those of Brown, though moving somewhat in the same plane. In order to select remedies which should fulfil the indication of producing symptoms like those of the disease, Hahnemann made many observations of the action of drugs on healthy persons. He did not originate this line of research, for it had been pursued if not originated by Haller, and cultivated systematically by Tommasini, an Italian "contra-stimulist;" but he carried it out with much elaboration. His results, nevertheless, were vitiated by being obtained in the interest of a theory, and by singular want of discrimination. Hahnemann's doctrines met with much opposition on the part of the medical profession, and he was hence led to state his case to the "lay" public as a sort of court of appeal; and thus matters of science were made the theme of much popular controversy. This expedient, in which Hahnemann had been in a small degree anticipated by Brown, contributed largely to the success of his system. The appeal flattered a prevalent belief in the right of private judgement, even in technical and learned subjects. Hahnemann was thus able to take up the position (and not without justification) of a victim of professional prejudice. The anomalous position into which professional scorn and extra-professional popularity brought him produced a distinct deterioration in the character of his work. In his second period he developed the extraordinary theory of "potentiality" or dynamization,—namely, that medicines gained in strength by being diluted, if the dilution was accompanied by shaking or pounding, which was supposed to "potentialize" or increase the potency of the medicine. On this extraordinary principle Hahnemann ordered his original tinctures to be reduced in strength to one-fiftieth; these first dilutions again to one-fiftieth; and so on, even till the thirtieth dilution, which he himself used by preference, and to which he ascribed the highest "potentiality." It is hardly necessary to point out that even the lower dilutions involve quantities which no analysis can weigh, measure, or even recognize. The still greater eccentricities of Hahnemann's later works need not be recounted. From a theoretical point of view Hahnemann's is one of the abstract systems, pretending to universality, which modern medicine neither accepts nor finds it worth while to controvert. In the treatment of disease his practical innovations came at a fortunate time, when the excesses of the depletory system had only partially been superseded by the equally injurious opposite extreme of Brown's stimulant treatment. Hahnemann's use of mild and often quite inert remedies contrasted favourably with both of these. Further he did good by insisting upon simplicity in prescribing, when it was the custom to give a number of drugs, often heterogeneous and inconsistent, in the same prescription. But these indirect benefits were quite independent of the truth or falsity of his theoretical system.

Positive Progress in the 18th Century.—In looking back on the repeated attempts in the 18th century to construct a universal system of medicine, it is impossible not to

[1] The itch is really an affection produced by the presence in the skin of a species of mite (*Acarus scabiei*), and when this is destroyed or removed the disease is at an end.

regret the waste of brilliant gifts and profound acquirements which they involved. It was fortunate, however, that the accumulation of positive knowledge in medicine did not cease. While Germany and Scotland, as the chief homes of abstract speculation, gave birth to most of the theories, progress in objective science was most marked in other countries,—in Italy first, and afterwards in England and France. We must retrace our steps a little to enumerate several distinguished names which, from the nature of the case, hardly admit of classification.

In Italy the tradition of the great anatomists and physiologists of the 17th century produced a series of accurate observers and practitioners. Among the first of these were Antonio Maria Valsalva (1666–1723), still better known as an anatomist; Giovanni Maria Lancisi (1654–1720), also an anatomist, the author of a classical work on the diseases of the heart and aneurisms; and Ippolito Francisco Albertini (1662–1738), whose researches on the same class of diseases were no less important.

In France Jean Baptiste Sénac (1693-1770) wrote also an important work on the affections of the heart. Sauvages, otherwise F. B. de Lacroix (1706–67), gave under the title *Nosologia Methodica* a natural-history classification of diseases; Jean Astruc (1684–1766) contributed to the knowledge of general diseases. But the state of medicine in that country till the end of the 18th century was unsatisfactory as compared with some other parts of Europe.

In England the brilliancy of the early part of the century in practical medicine was hardly maintained to the end, and presented indeed a certain contrast with the remarkable and unflagging progress of surgery in the same period. The roll of the College of Physicians does not furnish many distinguished names. Among these should be mentioned John Fothergill (1712–80), who investigated the "putrid sore throat" now called diphtheria, and the form of neuralgia popularly known as tic douloureux. A physician of Plymouth, John Huxham (1694-1768), made researches on epidemic fevers, in the spirit of Sydenham and Hippocrates, which are of the highest importance. William Heberden (1710-1801), a London physician, called by Samuel Johnson *ultimus Romanorum*, "the last of our learned physicians," left a rich legacy of practical observations in the *Commentaries* published after his death. More important in their results than any of these works were the discoveries of EDWARD JENNER (*q.v.*), respecting the prevention of small-pox by vaccination, in which he superseded the partially useful but dangerous practice of inoculation, which had been introduced into England in 1721. The history of this discovery need not be told here, but it may be pointed out that, apart from its practical importance, it has had great influence on the scientific study of infectious diseases. The name of John Pringle (1707–82) should also be mentioned as one of the first to study epidemics of fevers occurring in prisons and camps. His work entitled *Observations on the Diseases of an Army* was translated into many European languages, and became the standard authority on the subject.

In Germany the only important school of practical medicine was that of Vienna, as revived by Van Swieten (1700–72), a pupil of Boerhaave, under the patronage of Maria Theresa. Van Swieten's commentaries on the aphorisms of Boerhaave are thought more valuable than the original text. Other eminent names of the same school are Anton de Haen (1704–76), Anton Störck (1731-1803), Maximilian Stoll (1742-88), and John Peter Frank (1745–1821), father of Joseph Frank beforementioned as an adherent of the Brownian system, and like his son carried away for a time by the new doctrines. This, the old "Vienna School," was not distinguished for any notable discoveries, but for success in clinical teaching, and for its sound method of studying the actual facts of disease during life and after death, which largely contributed to the establishment of the "positive medicine" of the 19th century.

One novelty, however, of the first importance is due to a Vienna physician of the period, Leopold Avenbrugger (1722–1809), the inventor of the method of recognizing diseases of the chest by percussion. Avenbrugger's method was that of *direct* percussion with the tips of the fingers, not that which is now used, of *mediate* percussion with the intervention of a finger or plessimeter; but the results of his method were the same, and its value nearly as great. Avenbrugger's great work, the *Inventum Novum*, was published in 1761. The new practice was received at first with contempt and even ridicule, and afterwards by Stoll and Peter Frank with only grudging approval. It did not receive due recognition till 1808, when Corvisart translated the *Inventum Novum* into French, and Avenbrugger's method rapidly attained a European reputation. Surpassed, but not eclipsed, by the still more important art of auscultation introduced by Laennec, it is hardly too much to say that this simple and purely mechanical invention has had more influence on the development of modern medicine than all the "systems" evolved by the most brilliant intellects of the 18th century.

Early Part of the 19th Century.—It is not possible to carry the history of medicine, in a sketch such as this, beyond the early years of the 19th century, both because the mass of details becomes so large as to require more minute treatment, and because it is difficult as we approach our own times to preserve the necessary historical perspective. It was, however, in this period that what we regard as the modern school of medicine was formed, and took the shape which it has preserved to our own days. The characteristic of the modern school is the adoption in medicine of the methods of research of physical science, and the gradually declining importance attached to theory and abstract reasoning,—hypotheses, though not neglected, being used as means of research rather than as ultimate conclusions. Its method may therefore be called the positive method, or that of rational empiricism. The growth of the new school was first seen in two European countries, in France and England, and must be separately followed in the two. Germany entered the field later.

Rise of the Positive School in France.—The reform of medicine in France must be dated from the great intellectual awakening caused by the Revolution, but more definitely starts with the researches in anatomy and physiology of Marie François Xavier Bichat (1771–1802). The importance in science of Bichat's classical works, especially of the *Anatomie générale*, cannot be estimated here; we can only point out their value as supplying a new basis for pathology or the science of disease. Among the most ardent of his followers was François Joseph Victor Broussais (1772–1838), whose theoretical views, partly founded on those of Brown and partly on the so-called vitalist school of Bordeu and Barthez, differed from these essentially in being avowedly based on anatomical observations. Broussais's chief aim was to find an anatomical basis for all diseases, but he is especially known for his attempt to explain all fevers as a consequence of irritation or inflammation of the intestinal canal (gastro entérite). A number of other maladies, especially general diseases and those commonly regarded as nervous, were attributed to the same cause. It would be impossible now to trace the steps which led to this wild and long since exploded theory. It led, among other consequences, to an enormous misuse of bleeding. Leeches were his favourite instruments, and so much so that he is said to have used 100,000 in his own hospital wards during one year. He was equalled if not surpassed in this excess by his follower Bouillaud, known for his important work on heart diseases. Broussais's system, to which he gave the name of "Médecine Physiologique" did much indirect good, in fixing attention upon morbid changes in the organs, and thus led to the rise of the strongly opposed anatomical and pathological school of Corvisart, Laennec, and Bayle.

Jean Nicolas Corvisart (1755–1821) has already been mentioned as the translator and introducer into France of Avenbrugger's work on percussion. He introduced some improvements in the method, but the only real advance was the introduction of mediate percussion by Piorry in 1828. The discovery had, however, yet to be completed by that of auscultation, or listening to sounds produced in the chest by breathing, the movements of the heart, &c. The combination of these methods constitutes what is now known as *physical diagnosis*. René Théophile Hyacinthe Laennec (1781–1826) was the inventor of this most important perhaps of all methods of medical research. Except for some trifling notices of sounds heard in certain diseases, this method was entirely new. It was definitely expounded in an almost complete form in his work *De l'auscultation médiate*, published in 1819. Laennec attached undue importance to the use of the stethoscope, and laid too much weight on specific signs of specific diseases; otherwise his method in its main features has remained unchanged. The result of his discovery was an entire revolution in the knowledge of diseases of the chest; but it would be a mistake to forget that an essential factor in this revolution was the simultaneous study of the condition of the diseased organs as seen after death. Without the latter, it is difficult to see how the information conveyed by sounds could ever have been verified. This increase of knowledge is therefore due, not to auscultation alone, but to auscultation combined with morbid anatomy. In the case of Laennec himself this qualification takes nothing from his fame, for he studied so minutely the relations of post-mortem appearances to symptoms during life that, had he not discovered auscultation, his researches in morbid anatomy would have made him famous. The pathologico-anatomical method was also followed with great zeal and success by Gaspard Laurent Bayle (1774–1816), whose researches on tubercle, and the changes of the lungs and other organs in consumption, are the foundation of most that has been done since his time. It was of course antecedent to the discovery of auscultation. Starting from these men arose a school of physicians who endeavoured to give to the study of symptoms the same precision as belonged to anatomical observations, and by the combination of both methods made a new era in clinical medicine. Among these were Chomel (1788–1858), Louis (1787–1872), Cruveilhier (1791–1874), and Andral (1797–1876). Louis, by his researches on pulmonary consumption and typhoid fever, had the chief merit of refuting the doctrines of Broussais. In another respect also he aided in establishing an exact science of medicine by the introduction of the numerical or statistical method. By this method only can the fallacies which are attendant on drawing conclusions from isolated cases be avoided; and thus the chief objection which has been made to regarding medicine as an inductive science has been removed. Louis's method was improved and systematized by Gavarret; and its utility is now universally recognized. Space does not permit us to trace further the history of this brilliant period of French medicine, during which the superiority of the school of Paris could hardly be contested. We can only mention the names of Bretonneau (1771–1862), Rostan (1790–1866), D'Alibert (1766–1837), Rayer (1793–1867), and Trousseau (1801–1866), the eloquent and popular teacher.

English Medicine from 1800 *to* 1840.—The progress of medicine in England during this period displays the same characteristics as at other times, viz., a gradual and uninterrupted development, without startling changes such as are caused by the sudden rise or fall of a new school. Hardly any theoretical system is of English birth; Erasmus Darwin (1731–1802), the grandfather of the great Charles Darwin, alone makes an exception. In his *Zoonomia* (1794) he expounded a theory of life and disease which had some resemblance to that of Brown, though arrived at (he says) by a different chain of reasoning.

Darwin's work shows, however, the tendency to connect medicine with physical science, which was an immediate consequence of the scientific discoveries of the end of the 18th century, when Priestley and Cavendish in England exercised the same influence as Lavoisier in France. The English school of medicine was also profoundly stirred by the teachings of the two brothers William and John Hunter, especially the latter,—who must therefore be briefly mentioned, though their own researches were chiefly concerned with subjects lying a little outside the limits of this sketch. William Hunter (1718–1783) was known in London as a brilliant teacher of anatomy and successful obstetric physician; his younger brother and pupil, John Hunter (1728–1793), was also a teacher of anatomy, and practised as a surgeon. His immense contributions to anatomy and pathology cannot be estimated here, but his services in stimulating research and training investigators belong to the history of general medicine. They are sufficiently evidenced by the fact that Jenner and Baillie were his pupils.

The same scientific bent is seen in the greater attention paid to morbid anatomy (which dates from Baillie), and the more scientific method of studying diseases. An instance of the latter is the work of Robert Willan (1757–1812) on diseases of the skin,—a department of medicine in which abstract and hypothetical views had been especially injurious. Willan, by following the natural-history method of Sydenham, at once put the study on a sound basis; and his work has been the starting point of the most important modern researches. About the same time William Charles Wells (1757–1817), a scientific investigator of remarkable power, and the author of a celebrated essay on dew, published observations on alterations in the urine, which, though little noticed at the time, were of great value as assisting in the important discovery made some years afterwards by Bright.

These observers, and others who cannot be mentioned here, belong to the period when English medicine was still little influenced by the French school. Shortly after 1815, however, when the Continent was again open to English travellers, many English doctors studied in Paris, and the discoveries of their great French contemporaries began to be known. The method of auscultation was soon introduced into this country by pupils of Laennec. John Forbes in 1824, and William Stokes of Dublin in 1825, published treatises on the use of the stethoscope. Forbes also translated the works of Laennec and Avenbrugger, and an entire revolution was soon effected in the knowledge of diseases of the chest. James Hope and Peter Mere Latham further developed this subject, and the former was also known for his researches in morbid anatomy. The combination of clinical and anatomical research led, as in the hands of the great French physicians, to important discoveries by English investigators. The discovery by Richard Bright (1789–1858) of the disease of the kidneys known by his name, has proved to be one of the most momentous of this century. It was published in *Reports of*

Medical Cases, 1827–31. Thomas Addison takes, somewhat later, a scarcely inferior place. The remarkable physiological discoveries of Bell and Marshall Hall for the first time rendered possible the discrimination of diseases of the spinal cord. Several of these physicians were also eminent for their clinical teaching,—an art in which Englishmen had up till then been greatly deficient.

Although many names of scarcely less note might be mentioned among the London physicians of the early part of the century, we must pass them over to consider the progress of medicine in Scotland and Ireland. In Edinburgh the admirable teaching of Cullen had raised the medical faculty to a height of prosperity of which his successor, James Gregory (1758–1821), was not unworthy. His nephew, William Pulteney Alison (1790–1859), was even more widely known. These great teachers maintained in the northern university a continuous tradition of successful teaching, which the difference in academical and other circumstances rendered hardly possible in London. Nor was the northern school wanting in special investigators, such as John Abercrombie, known for his work on diseases of the brain and spinal cord published in 1828, and many others. Turning to Ireland, it should be said that the Dublin school in this period produced two physicians of the highest distinction. Robert James Graves (*c.* 1800–1853) was a most eminent clinical teacher and observer, whose lectures are regarded as the model of clinical teaching, and indeed served as such to the most popular teacher of the Paris school in the middle of this century, Trousseau. William Stokes (1804–1878) was especially known for his works on diseases of the chest and of the heart, and for his clinical teaching.

German Medicine from 1800 *to* 1840.—Of the other countries of Europe, it is now only necessary to mention Germany. Here the chief home of positive medicine was still for a long time Vienna, where the "new Vienna school" continued and surpassed the glory of the old. Joseph Skoda (born 1805) extended, and in some respects corrected, the art of auscultation as left by Laennec. Karl Rokitansky (1804–1878), by his colossal labours, placed the science of morbid anatomy on a permanent basis, and enriched it by numerous discoveries of detail. Most of the ardent cultivators of this science in Germany in the next generation were his pupils. In the other German schools, though some great names might be found, as Romberg (1795–1873), the founder of the modern era in the study of nervous diseases, the general spirit was scholastic and the result barren, till the teaching of one man, whom the modern German physicians generally regard as the regenerator of scientific medicine in their country, made itself felt. Johann Lucas Schönlein (1793–1864) was first professor at Würzburg, afterwards at Zurich, and for twenty years at Berlin (from 1839–1859). Schönlein's positive contributions to medical science were not large; but he made in 1839 one discovery, apparently small, but in reality most suggestive, namely, that the contagious disease of the head called favus is produced by the growth in the hair of a parasitic fungus. In this may be found the germ of the startling modern discoveries in parasitic diseases. His systematic doctrines founded the so-called "natural history school;" but his real merit was that of the founder or introducer of a method. In the words of Haeser, "Schönlein has the incontestable merit of having been the first to establish in Germany the exact method of the French and the English, and to impregnate this method with the vivifying spirit of German research." The name of Schönlein thus brings us to the threshold of the modern German school of medicine,—the most scientific and exact in Europe, and in its spirit strikingly in contrast with the theoretical subtlety of German systematists in the last century.

Literature.—The earliest work of authority on the history of medicine is that of Daniel le Clerc (*Histoire de la Médecine*, Geneva, 1696; Amsterdam, 1704, 1723, &c.), which ends with Galen. Freind's *History of Physick* (London, 1725–26, 2 vols.) carries on the subject from Galen to the beginning of the 16th century. The first complete history is that of Kurt Sprengel (*Versuch einer pragmatischen Geschichte der Arzneikunde*, Halle, 1792; 3d edition, Halle, 1821–28, 5 vols.; also in French, Paris, 1815). Beside these may be mentioned Hecker, *Geschichte der Heilkunde*, Berlin, 1822, and *Gesch. der neueren Heilkunde*, Berlin, 1839; Ch. Daremberg, *Histoire des sciences médicales*, Paris, 1870, 2 vols.; Edward Meryon, *History of Medicine*, London, 1861 (left unfinished, vol. i. only having appeared). The most recent and complete text-book is Haeser's *Lehrbuch der Geschichte der Medicin und der Epidemischen Krankheiten* (3d edition, Jena, 1875–79, 3 vols., in course of completion), to which the preceding sketch is very largely indebted.

In special departments of the subject the authorities are the following:—For classical medicine: Celsus, *De Medicina*; Littré, *Œuvres d'Hippocrate*, Paris, 1839–61, 10 vols. (especially vol. i.); Francis Adams, *Genuine Works of Hippocrates translated, with a Preliminary Discourse*, London (Syd. Soc.), 1849, and *Paulus Ægineta, translated, with a Commentary*, London (Syd. Soc.), 1844; Daremberg, *La Médecine dans Homère*, Paris, 1865, and *La Médecine entre Homère et Hippocrate*, Paris, 1869; and W. A. Greenhill's articles "Galen," "Hippocrates," &c., in Smith's *Classical Dictionary*, 1844. For Arabian medicine: Wüstenfeld, *Geschichte der Arabischen Aerzte und Naturforscher*, Göttingen, 1840; and Lucien Leclerc, *Histoire de la Médecine Arabe*, Paris, 1876, 2 vols. For Salernitan medicine: *Collectio Salernitana*, edited by De Renzi, Daremberg, &c., Naples, 1852, 5 vols.; *Regimen Sanitatis*, with introduction by Sir A. Croke, Oxford, 1830; and Daremberg, *L'École de Salerne*, Paris, 1861. For medicine in England: John Aikin, *Biographical Memoirs of Medicine in Great Britain, to the time of Harvey*, London, 1780; *Lives of British Physicians*, London, 1830 (chiefly by Dr Macmichael, partly by Dr Bisset Hawkins and Dr H. H. Southey); and Munk, *Roll of the Royal College of Physicians of London*, 2d ed., 1878, 3 vols. For the modern schools: Hirschel, *Geschichte des Brown'schen Systems und der Erregungs Theorie*, Leipsic, 1846; Bouchut, *Histoire de la Médecine et des Doctrines Médicales*, 2 vols., Paris, 1873 (comparison of ancient and modern schools); Buckle, *History of Civilization in England*, 1858–61. (J. F. P.)

MEDINA, or rather EL-MEDÍNA (the city), or MEDÍNAT RASÚL ALLÁH (the city of the apostle of God), a town of the Hijáz in Arabia, in 25° N. lat., 40 E. long.,[1] the refuge of Mohammed on his flight from Mecca, and a renowned place of Moslem pilgrimage, consecrated by the possession of his tomb. The name El-Medína goes back to the Koran (*sur.* xxxiii. 60); the old name was Yathrib, the Lathrippa of Ptolemy and Iathrippa of Stephanus Byzantius.

Medina stands in a sort of basin at the northern extremity of an elevated plain, on the western skirt of the mountain range which divides the Red Sea coast-lands from the central plateau of Arabia. At an hour's distance to the north it is dominated by Mount Ohod, an outlying spur of the great mountains, which is now visited by the pious as the scene of the well-known battle (see MOHAMMED), and the site of the tomb and mosque of the Prophet's uncle Hamza. To the east the plain is bounded by a long line of hills eight or ten hours distant, over which the Nejd road runs. A number of torrent courses (of which W. Kanát to the north, at the foot of Mount Ohod, and W. 'Akík, some miles to the south, are the most important) descend from the mountains, forming considerable streams and pools after rain, and converge in the

[1] This can only be viewed as a very rough estimate. The road from Yanbu' on the Red Sea, which runs somewhat north of east, is by Burton's estimate 132 miles. From Medina to Mecca by the inland or high road he makes 248 miles. The usual road near the coast by Rábigh and Kholeys and thence to W. Fátima cannot be very different in length. Caravans traverse it in about ten or eleven days.

neighbourhood of the town to unite farther west at a place called Zaghába, whence they descend to the sea through the "mountains of the Tiháma"—the rough country between Medina and its port of Yanbuʿ—under the name of W. Idam. Southwards from Medina the plain extends unbroken, but with a slight rise, as far as the eye can reach. The convergence of torrent courses in the neighbourhood of Medina makes this one of the best-watered spots in northern Arabia. The city lies close to one of the great volcanic centres of the peninsula, which was in violent eruption as late as 1266 A.D., when the lava stream approached within an hour's distance of the walls, and dammed up W. Ḳanát. The result of this and older prehistoric eruptions has been to confine the underground water, so important in Arabian tillage, which can be reached at any point of the oasis by sinking deep wells. Many of the wells are brackish, and the natural fertility of the volcanic soil is in many places impaired by the salt with which it is impregnated; but the date palm grows well everywhere, and the groves, interspersed with gardens and corn-fields, which surround the city on all sides except the west, have been famous from the time of the Prophet. Thus situated, Medina was originally a city of agriculturists, not like Mecca a city of merchants; nor, apart from the indispensable trade in provisions, has it ever acquired commercial importance like that which Mecca owes to the pilgrimage.[1] Landowners and cultivators are still a chief element in the population of the city and suburbs. The latter, who are called Nawákhila, and more or less openly profess the Shíʿa opinions, form a sort of separate caste, marrying only among themselves. The townsmen proper, on the other hand, are a very motley race.[2] The mechanical arts, which the true Arab despises, are chiefly practised by foreigners. New settlers remain behind with each pilgrimage; and the many offices of profit connected with the mosque, the stipends paid by the sultan to every inhabitant, and the gains to be derived by pilgrim-cicerones (Muzawwirs) or by those who make it a business to say prayers at the Prophet's mosque for persons who send a fee from a distance, as well as the alms which the citizens are accustomed to collect when they go abroad, especially in Turkey, keep up an idle population greatly in excess of that which the district would naturally support in the present defective state of agriculture. The population of the city and suburbs may be from 16,000 to 20,000 souls.

The city proper is surrounded by a solid stone wall,[3] with towers and four massive gateways of good architecture, forming an irregular oval running to a kind of angle at the north-west, where stands the castle, held by a Turkish garrison. The houses are good stone buildings similar in style to those of Mecca; the streets are narrow but clean, and in part paved.[4] There is a copious supply of water conducted from a tepid source at the village of Ḳubá, 2 miles south, and distributed in underground cisterns in each quarter.[5] The glory of Medina, and the only important building, is the mosque of the Prophet, in the eastern part of the city, a spacious enclosed court between 400 and 500 feet in length from north to south, and two-thirds as much in breadth. The minarets and the lofty dome above the sacred graves are imposing features, but the circuit is hemmed in by houses or narrow lanes, and is not remarkable except for the principal gate (Báb el-Salám) at the southern end of the west front, facing the sacred graves, which is richly inlaid with marbles and fine tiles, and adorned with golden inscriptions. This gate leads into a deep portico, with ten rows of pillars, running along the southern wall. Near the further end of the portico, but not adjoining the walls, is a sort of doorless house or chamber hung with rich curtains, which is supposed to contain the graves of Mohammed, Abubekr, and ʿOmar. To the north of this is a smaller chamber of the same kind, draped in black, which is said to represent the house or tomb of Fátima. Both are enclosed within an iron railing, so closely interwoven with brass wire-work that a glimpse of the so-called tombs can only be got through certain apertures where intercessory prayer is addressed to the prophet, and pious salutations are paid to the other saints.[6] The portico in front of the railing is not ineffective, at least by night light. It is paved with marble, and in the eastern part with mosaic, laid with rich carpets; the southern wall is clothed with marble pierced with windows of good stained glass, and the great railing has a striking aspect; but an air of tawdriness is imparted by the vulgar painting of the columns, especially in the space between the tomb and the pulpit, which has received, in accordance with a tradition of the Prophet, the name of the Garden (rauḍa), and is decorated with barbaric attempts to carry out this idea in colour.[7] The throng of visitors passing along the south wall from the Báb el-Salám to salute the tombs is separated from the Garden by a wooden partition about 8 feet high, painted in arabesques. The other three sides of the interior court have porticos of less depth and mean aspect, with three or four rows of pillars. Within the court are the well of the Prophet and some palm trees said to have been planted by Fátima.

The original mosque was a low building of brick roofed with palm branches, and much smaller than the present structure. The wooden pulpit from which Mohammed preached appears to have stood on the same place with the present pulpit in the middle of the south portico. The dwelling of the Prophet and the huts of his women adjoined the mosque. Mohammed died in the hut of ʿÁisha, and was buried where he died; Abubekr and ʿOmar were afterwards buried beside him. Now in 711 A.D. the mosque, which had previously been enlarged by ʿOmar and ʿOthmán, was entirely reconstructed on a grander scale and in Byzantine style by Greek and Coptic artificers at the command of the caliph Walíd and under the direction of ʿOmar ibn ʿAbd elʿAzíz. The enlarged plan included the huts above named, which were pulled down. Thus the place of the Prophet's burial was brought within the mosque; but the recorded discontent of the city at this step shows that the feeling which regards the tomb as the great glory of the mosque, and the pilgrimage to it as the most meritorious that can be undertaken except that to Mecca, was still quite unknown. It is not even certain

[1] The pilgrimage to Medina, though highly meritorious, is not obligatory, and it is not tied to a single season, so that there is no great concourse at one time, and no fair like that of Mecca.

[2] A small number of families in Mecca still claim to represent the ancient Anṣár, the "defenders" of Mohammed. But in fact the old population emigrated *en masse* after the sack of Medina by Muslim in 683, and passed into Spain in the armies of Músá. In the 13th century one old man of the Khazraj and one old woman of the Aus tribe were all that remained of the old stock in Medina (Makkarí, i. 187; Dozy, *Mus. d'Espagne*, i. 111). The aristocratic family of the Beni Ḥoseyn, who claim descent from the martyr of Kerbela, and so from the Prophet, have apparently a better established pedigree.

[3] According to Ibn Khallikán (Slane's transl., iii. 927) the walls are of the 12th century, the work of Jamál el-Dín el-Ispaháni.

[4] The Baláṭ or great paved street of Medina, a very unusual feature in an Eastern town, dates from the 1st century of Islám. See Wüstenfeld's abstract of Samhúdí, p. 115.

[5] Ḳubá is famous as the place where the prophet lived before he entered Medina, and the site of the first mosque in which he prayed. It lies amidst orchards in the richest part of the oasis

[6] The space between the railing and the tomb is seldom entered except by the servants of the mosque. It contains the treasures of the mosque in jewels and plate, which were once very considerable but have been repeatedly plundered, last of all by the Wahhábís in the beginning of the present century.

[7] The word *rauḍa* also means a mausoleum, and is applied by Ibn Jubair to the tomb itself. Thus the tradition that the space between the pulpit and tomb was called by the Prophet one of the gardens of Paradise probably arose from a mistake.

what was done at this time to mark off the graves. Ibn 'Abd Rabbih, in the beginning of the 10th century (*'Ikd*, Cairo ed., iii. 366), describes the enclosure as a hexagonal wall, rising within three cubits of the ceiling of the portico, clothed in marble for more than a man's height, and above that height daubed with the unguent called khalúk. This may be supplemented from Iṣṭakhrí, who calls it a lofty house without a door. That there are no gravestones or visible tombs within is certain from what is recorded of occasions when the place was opened up for repairs. Ibn Jubair (p. 193 *sq.*) and Samhúdí speak of a small casket adorned with silver, fixed in the eastern wall, which was supposed to be opposite the head of the Prophet, while a silver nail in the south wall indicated the point to which the corpse faced, and from which the salutation of worshippers was to be addressed (Burton misquotes). The European fable of the coffin suspended by magnets is totally unknown to Moslem tradition. The smaller chamber of Fáṭima is pretty modern. In the time of Ibn Jubair and of Ibn Baṭúṭa (unless the latter, as is so often the case, is merely copying his predecessor) there was only a small marble trough north of the rauḍa (or grave) which "is said to be the house of Fáṭima or her grave, but God only knows." It is more probable that Fáṭima was buried in the Baḳí, where her tomb was also shown in the 12th century (Ibn Jubair, p. 198 *sq.*).

The mosque was again extended by El-Mahdí (781 A.D.), and was burned down in 1256. Of its appearance before the fire we have two authentic accounts by Ibn 'Abd Rabbih early in the 10th century, and by Ibn Jubair, who visited it in 1184. The old mosque had a much finer and more regular appearance than the present one; the interior walls were richly adorned with marble and mosaic arabesques of trees and the like, and the outer walls with stone marquetry; the pillars of the south portico (seventeen in each row) were in white plaster with gilt capitals, the other pillars were of marble. Ibn 'Abd Rabbih speaks of eighteen gates, of which in Ibn Jubair's time, as at present, all but four were walled up. There were then three minarets. After the fire which took place just at the time of the fall of the caliphate, the mosque long lay in a miserable condition. Its repair was chiefly due to the Egyptian sultans, especially to Ḳáit Bey, whose restoration after a second fire in 1481 amounted almost to a complete reconstruction. Of the old building nothing seems to have remained but some of the columns and part of the walls; and, as the minarets have also been rebuilt and two new ones added, the architectural character is now essentially Egyptian. The great dome above the tomb, the railing round it, and the pulpit, all date from Ḳáit Bey's restoration.

The suburbs, which occupy as much space as the city proper, and are partly walled in, lie south-west of the town, from which they are separated by an open space, the halting-place of caravans. Through the suburbs runs the watercourse called W. Buṭḥán, a tributary of W. Ḳanát, which the Yanbu' road crosses by a stone bridge. The suburbs are the quarter of the peasants. Thirty or forty families with their cattle occupy a single courtyard (ḥósh), and form a kind of community often at feud with its neighbours. The several clans of Medina must have lived in much the same way at the time of the Prophet. The famous cemetery called Baḳí' el-Gharḳad, the resting-place of a multitude of the "companions" of the Prophet, lies immediately to the west of the city. It once contained many monuments, the chief of which are described by Ibn Jubair. Burckhardt in 1815 found it a mere waste, but some of the mosques have since been rebuilt.

History.—The story of the Amalekites in Yathrib and of their conquest by the Hebrews in the time of Moses is purely fabulous, see Nöldeke, *Ueber die Amalekiter*, 1864, p. 36. The oasis, when it first comes into the light of history, was held by Jews, among whom emigrants from Yemen afterwards settled. From the time of the flight of Mohammed (622 A.D.) till the Omayyads removed the seat of empire from Medina to Damascus, the town springs into historic prominence as the capital of the new power that so rapidly changed the fate of the East. Its fall was not less rapid and complete, and since the battle of Ḥarra and the sack of the city in 683 it has never regained political importance. The history of Medina in this period will be told in the articles MOHAMMED and MOHAMMEDAN EMPIRE. Mohammed invested the country round Medina with an inviolable character like that of the Ḥaram round Mecca; but this provision has never been observed with strictness. After the fall of the caliphs, who maintained a governor in Medina, the native emírs enjoyed a fluctuating measure of independence, interrupted by the aggressions of the sherifs of Mecca, or controlled by an intermittent Egyptian protectorate. The Turks after the conquest of Egypt held Medina for a time with a firmer hand; but their rule grew weak, and was almost nominal long before the Wahhábís took the city in 1804. A Turko-Egyptian force retook it in 1812, and the Turks still maintain a pasha with a military establishment, while the cadi and chief agha of the mosque (a eunuch) are sent from Constantinople. But the internal government is largely in Arab hands, and is said to be much better than that of Mecca.

Sources.—Medina has been described from personal observation by Burckhardt, who visited it in 1815, and Burton, who made the pilgrimage in 1853. Sadlier on his journey from Ḳaṭíf to Yanbu' (1819) was not allowed to enter the holy city. Burckhardt was prevented by ill health from examining the city and country with his usual thoroughness. Little is added to our information by the report of 'Abd el-Razzáḳ, who performed the pilgrimage in 1878, on a medical commission from the English Government. The chief Arabic authority besides Ibn 'Abd Rabbih and Ibn Jubair is Samhúdí, of whose history Wüstenfeld published an abstract in the Göttingen *Abhandlungen*, vol. ix., 1861. It goes down to the end of the 15th century. The topography of the country about Medina is interesting both historically and geographically; Bekrí, Yáḳút, and other Arabic geographers supply much material on this topic, but completer European accounts are wanting to permit of its full utilization. Medina now offers a more promising, but also a more perilous, field for an explorer than Mecca. (W. P. S.)

MEDINA SIDONIA, a town of Spain, in the province of Cadiz, and about 21 miles by road westward from that city, stands at a height of 600 feet above the sea-level, on an isolated hill surrounded by a cultivated plain. Apart from its picturesque airy situation it has nothing to interest the traveller; the streets are narrow, steep, and dirty, and its buildings and ruins are unimportant. The occupations of the inhabitants are connected chiefly with the agriculture and cattle-breeding carried on in the surrounding district; bricks and pottery are also made to some extent. The population in 1877 was 12,234.

Medina Sidonia has been identified by some with the *Asiao* of Pliny, but it is uncertain whether Jerez is not more probably the locality referred to by that name. Under the Visigoths the place was erected into a bishopric (Assidonia), and attained some importance; in the beginning of the 8th century it was taken by Tarik. In the time of Edrisi the province of Shadúna or Shidona included, among other towns, Seville and Carmona; later Arab geographers place Shadúna in the province of Seville. The town gives its title to the ducal house of Guzman el Bueno, the hero of Tarifa (1292).

MEDITERRANEAN SEA. The southern shores of Europe are separated from the northern shores of Africa by the Mediterranean Sea. It extends in a generally east and west direction from longitude 5° 21′ W. to 36° 10′ E. Its length from Gibraltar to its eastern extremity in Syria is about 2100 miles. Its breadth is very various, being 400 miles from the mouth of the Rhone to the Algerian coast, 500 miles from the Gulf of Sidra to the entrance to the Adriatic, and 250 miles from the mouth of the Nile to the south coast of Asia Minor. From the very indented nature of its coasts, the general mass of the water is much cut up into separate seas, which have long borne distinctive names, as the Adriatic, the Ægean, the Sea of Marmora, the Black Sea, &c. The area of the whole system, including the Sea of Azoff, is given by Admiral Smythe as 1,149,287 square miles. If we deduct that of the Black Sea and Sea of Azoff, 172,506 square miles, we have for the area of the Mediterranean proper 976,781, or, roughly speaking, a million of square miles.

The Mediterranean is sharply divided into two great principal basins, the western and the eastern or Levant basin. The western possesses a comparatively smooth and unindented coast-line. It is bounded on the south by the coast of Africa and the north coast of Sicily, and it is further enclosed by the coasts of Spain, France, and Italy, which form a roughly arc-shaped coast-line. There are comparatively few small islands in this basin, though some of the more important large ones occur in it. The eastern basin is by far the larger of the two, and extends from Cape Bon to the Syrian coast, including as important branches the Adriatic and the Ægean. The latter is connected directly, through the Hellespont, the Sea of Marmora, and the Bosphorus, with the Black Sea. The entrance to the western basin and to the sea generally from the ocean is through the Straits of Gibraltar in 36° N. lat. If this parallel be drawn out through the sea it will be found that the western basin lies almost wholly to the northward, and the main body of the eastern one to the southward of it, the mean latitude of the western basin being about 39° 30′, and that of the eastern basin 35°. They communicate with each other by the channels separating Sicily from Italy and from Africa. The former is known as the Strait of Messina, and is of insignificant size, the latter is a wide channel apparently without any distinctive name, and generally shallow. The greatest depth on the shallowest ridge reaching from the African to the Sicilian coast is under 200 fathoms, and agrees very closely with the corresponding depth at the entrance to the Straits of Gibraltar.

Depth.—So far as is at present known, the maximum depth is pretty nearly alike in the two basins, being 2040 fathoms in the western and 2150 fathoms in the eastern. Many lines of soundings have been run in the Mediterranean for telegraph purposes, and they afford a very good idea of the general configuration of the bottom. Between Marseilles and Algiers the depth ranges generally from 1200 to 1600 fathoms; between Naples and Sardinia from 1500 to 2000; between Alexandria and Rhodes from 1200 to 1600; and between Alexandria and Cyprus from 900 to 1100. The basin of the Mediterranean really begins about 50 miles to the westward of Gibraltar. It is here that the shallowest ridge stretches across from Africa to Spain; the maximum depth on it is probably not more than 180, and certainly less than 200 fathoms. From this ridge the bottom slopes quickly westward into the depths of the Atlantic, and gently eastward into the Mediterranean. The depth nowhere reaches 1000 fathoms until beyond Alboran Island, 120 miles east of Gibraltar. This is a small low island separated from the mainland on all sides by water of more than 400 fathoms; it must therefore be considered an oceanic as distinguished from a continental island.[1] Further to the north, and off the coast of Valencia, we have the Balearic Islands,—namely, Majorca, Minorca, Iviza, and Formentera. These also must be considered oceanic islands, and indeed two groups of oceanic islands. Iviza and Formentera are isolated both from the Spanish coast and from the other two islands by water of over 300 fathoms depth; Majorca and Minorca are connected by a bank with no more than 50 fathoms of water on it. Thirty miles east of Minorca there are more than 1400 fathoms; beyond that there are no soundings between the Baleares and the large and important group of Corsica and Sardinia. These islands are continental, being connected with the Italian mainland by the bank on which Elba occurs, and which is covered by little over 50 fathoms of water. The Straits of Bonifacio, which separate Corsica from Sardinia, are also quite shallow, so that Corsica and Sardinia may be looked on as a secondary peninsula attached to the Tuscan shore of Italy by a shallow bank not more than 15 or 20 miles broad, the deep water coming close up all round it. Almost the same may be said of Sicily, including the Malta group, but excluding the Lipari group, which is purely volcanic. From Cape Passaro, in the south-east end of Sicily, a line can be drawn connecting it with the town of Tripoli, and without passing over water of more than 300 fathoms. As has already been said, the west end of Sicily is connected with the coast of Tunis by a ridge in no part covered by more than 200 fathoms of water. Between these two ridges lies a small but comparatively deep basin of 600 to 700 fathoms. At the western extremity of it lies the mountainous island of Pantellaria. The bank on which Malta is situated stretches for nearly 100 miles in a southerly direction from Cape Passaro in Sicily. Opposite, on the African shore, is a similar bank of much larger dimensions, on which are the small islands Lampion and Lampedusa belonging to Italy. In the deep channel between them and Malta is the small but lofty island Limosa. It is entirely volcanic, with an extinct crater on its north-eastern side, and three smaller ones to the southward. It resembles the Lipari group off the north coast of Sicily, which rise abruptly out of deep water, being connected by no bank either with the African or the Sicilian coasts. Some of the Lipari group are still active, Stromboli and Vulcano being of the number. Off the south coast of Sicily, and between it and the island of Pantellaria, occurs the famous Graham's shoal, the remains of what was for a few weeks an island.[2]

The deepest water of the Mediterranean is found in its widest part between Malta and Crete, and the deep water comes close up to the Italian and Greek coasts, while on the African shore the water shoals more gradually. In the Strait of Messina, close to Reggio, there are depths of over 500 fathoms, and similar depths are found inside gulfs such as those of Taranto (nearly 1000 fathoms), of Corinth, Kalamata, and others. Also all through the Ægean in its many bights and channels very deep water is met with; in the Sea of Marmora we have 500 fathoms, and in the Black Sea over 1000 fathoms. All along the south coast of Asia Minor the water is very deep, and the large islands of Cyprus and Crete are both separated by very deep water from the mainland. If we take the eastern basin, and run along its western and southern coasts from the mouth of the Po along the shore of Italy, Sicily, and Africa to the mouth of the Nile, and even further along the Syrian shore, we do not find a single off-lying island of any importance except the Malta group, while all along the eastern and northern coasts from Trieste to Asia Minor the coast is deeply indented, and the water broken up by many large and important islands. These islands are grouped along the west coast of Turkey and Greece, and irregularly throughout the Ægean. The east coast of the Adriatic is studded with islands and inlets, and resembles in this respect the Ægean; the west coast, on the other hand, is low, and the water off it shallow, and there are few harbours. The Adriatic stretches in a north-westerly direction for about 460 miles from its entrance between

[1] Continental islands are those separated from the mainland by comparatively shallow seas, generally under 100 fathoms.

[2] With regard to its appearance and disappearance Admiral Smythe (*Mediterranean*, p. 111) says:—"It seems that, as early as the 28th of June 1831, Captain Swinburne, in passing nearly over the spot, felt several shocks of a sea-quake, proving that the cause was then in operation; but on the 19th of the following July the crater had accumulated to a few feet above the level of the sea, and was in great activity, emitting vast volumes of steam, ashes, and scoriæ. From that time it gradually increased in all its dimensions till towards the end of August its circumference was about 3240 feet and its height 107; then from October various changes took place, and it entirely disappeared in December." Since that time it has changed considerably. In 1863 the least water on it was 15 feet. It has two heads close together, and at the distance of about 20 yards all round there are from 7 to 9 fathoms of water.

Cape Sta Maria di Leuca and the island of Corfu to the Venetian shore in the Gulf of Trieste. Its average width is about 100 miles. A ridge with little over 400 fathoms appears to run across its entrance. Inside this the water reaches a depth of 765 fathoms, but shoals again rapidly towards Pelagosa Island, from which to the northward, including quite two-thirds of the sea, the depth is under 100 fathoms; indeed no part of the sea within 150 miles of its northern extremity is over 50 fathoms deep. There is authentic historical evidence of the encroachment of the Italian shores on the Adriatic, causing thereby a diminution of its area. As a consequence many towns which were once thriving seaports are now many miles inland; thus Adria, which was a station of the Roman fleet, is now 15 miles inland, and there are many similar examples. The large rivers Po and Adige, which bring the drainage of the southern slopes of the Alps to the sea, deliver large quantities of sediment in the course of the year. The distribution of this mud is affected, not only by its own weight tending to make it sink to the bottom, but also by the set of the currents, which, running up the eastern coast, turn to the westward and southward at the upper end of the sea, and so tend to distribute the river mud along the bottom in the neighbourhood of the Italian coasts. The fact that towns which were formerly seaports are now inland does not therefore necessitate the assumption of a general rise of the land, it is merely a reclamation by natural agencies of land from the sea at the expense of the inland mountainous country. Precisely similar phenomena are observed in the neighbourhood of the mouths of the Rhone and of the Nile.

Specific Gravity, Currents, &c.—On the specific gravity Dr Carpenter reports many and interesting observations. In round numbers, that of the surface-water of the Atlantic off the Straits of Gibraltar is 1·0260 to 1·0270, that of the western basin of the Mediterranean 1·0280 to 1·0290, and that of the eastern basin 1·0290 to 1·0300, while that of the Black Sea is 1·0120 to 1·0140. It will thus be seen that the water of the Mediterranean proper is very much salter than either the Atlantic on the west or the Black Sea on the east, and this great density of the water affords a useful means of recognizing it when investigating the interchange of waters which takes place at the two extremities of the sea. Both the temperature and the specific gravity of the water are evidences of the local climate. The great concentration of the water shows how dry the atmosphere at the surface must be, and how insignificant the contributions of fresh water. With regard to the balance existing between the two factors, evaporation and precipitation, it would be impossible to give figures with any claim to accuracy, but a rough estimate may be formed by taking such data as Fischer has given. He puts the rainfall over the whole Mediterranean drainage area at 759·4 millimetres, or almost exactly 30 inches. If we remember that the average rainfall of the eastern slopes of Great Britain is less than 30 inches, and that therefore this may be taken as the maximum yearly supply to the North Sea, we may be sure that the Mediterranean does not receive more than 30 inches of fresh water in the year. With regard to the rate of evaporation over the area of the Mediterranean there is but very meagre information, but wherever it has been observed it has been found to exceed the rainfall, even as much as three times. Thus at Madrid it is 65 inches, or more than four times the rainfall, at Rome 105 inches, and at Cairo 92 inches. It may therefore without exaggeration be assumed that the evaporation is at least twice as great as the precipitation. Putting the latter at 30 inches, we should have 60 inches for the yearly evaporation, and a balance of 30 inches evaporation over precipitation. Were there no provision for making good this deficiency, the level of the Mediterranean would sink until its surface was so far contracted as to lose no more by evaporation than would be supplied by rain. This condition would probably not be fulfilled before all the Ægean and Adriatic and the whole of the western basin west of the island of Sardinia were laid dry, and what is now the Mediterranean would be reduced to two "Dead Seas," one between Sardinia and Naples and the other between Africa and the mouth of the Adriatic. That the level and the salinity of the Mediterranean remain constant is due to the supply of water which enters at the Straits of Gibraltar. The currents in this passage have frequently engaged attention both from their scientific and their nautical interest. The most detailed investigation was that carried out by Captain Nares and Dr Carpenter in H.M.S. "Shearwater" in the year 1871.[1] From these investigations it appears that there are usually two currents in the Straits at the same time, one superposed on the other. Both are affected by tidal influence, but, after allowing for it, there is still a balance of inflow in the upper and of outflow in the under current. The waters of the two currents are sharply distinguished from each other by their salinity. Further, the upper current appears to affect by preference the middle of the channel and the African coast, while the under current appears to crop out at the surface on the Spanish coast. This distribution, however, is much modified by the state of the tide, and it must be remembered that in such places the surface separating the upper and under currents is rarely, if ever, a horizontal plane. That there is a balance of outflow over inflow at the bottom was well shown by the result of soundings as much as 200 miles north-west of the entrance of the Straits, where, in a depth of 1560 fathoms, water of decided Mediterranean origin was got from the bottom. There can be no doubt that this outflow of warm and dense Mediterranean water is largely instrumental in causing the comparatively very high bottom temperature in the eastern basin of the North Atlantic.

We have assumed that the balance of water removed by evaporation is 30 inches, or 2·5 feet. If we take the area of the Mediterranean to be 1,000,000 square miles, we have the volume of water removed—

$$v = 2{\cdot}5 \times 36 \times 10^{12} = 90 \times 10^{12} \text{ cubic feet.}$$

This quantity of water has to be supplied from the Atlantic without raising the total quantity of salt in the sea. We have seen that the only provision for the removal of the surplus salt is the outward under current in the Straits. Hence the inward upper current must be sufficient to replace the water lost both by evaporation and by the outflow of the under current. We may take the Atlantic water to contain 3·6 per cent. and the Mediterranean to contain 3·9 per cent. of salt. In order that the under current may remove exactly as much salt as is brought in by the upper one, their volumes must be in the inverse ratio of their saline contents, or the volume of the upper current must be to that of the under one in the ratio 39 : 36 or 1000 : 923; so that only 7·7 per cent. of the inflow goes to replace the water removed by evaporation, while the remaining 92·3 per cent. replaces the water of the under current. We have then for the total volume of the inward current per annum

$$V = \frac{100}{7{\cdot}7} v = 1170 \times 10^{12} \text{ cubic feet.}$$

The width of the Straits from Tarifa to Point Cires is 8 miles, or 48,000 feet, and the average depth of the stream may fairly be taken as 100 fathoms; hence the sectional area is in round numbers 29,000,000 square feet.

[1] *Proc. Roy. Soc.* (1872), xx. 97, 414.

Dividing the volume by the area we have for the mean annual flow

$$R = \frac{1170 \times 10^{12}}{29 \times 10^6} = 40 \times 10^6 \text{ feet.}$$

Reducing this to miles per day, we find that if the above data are correct the inflowing current at the Straits of Gibraltar ought to be equivalent to a current 8 miles wide, 100 fathoms deep, and running with the uniform velocity of 18·3 miles in twenty-four hours. As the currents are reversed with the tides this is the balance of inflow over outflow in the upper current. It is worthy of remark that the flood tide runs to the westward at the surface and the ebb to the eastward. The following table of tides at places inside and outside the Straits will show that the mere differences of level due to the different tidal ranges at adjacent localities are sufficient to cause strong local currents.

Places.	High Water. Full and Change.	Springs Rise.	Neaps Rise.	Neaps Range.
	H. M.	Ft. in.	Ft. in.	Ft. in.
Chipiona	1 30	12 5	8 0	3 6
Rota	1 24	12 6	8 0	3 6
Cadiz	1 23	12 9	8 2	...
Conil	1 18	12 0	7 5	3 3
Cape Plata	1 45	8 0	5 3	2 6
Tarifa	1 46	6 0	3 6	1 3
Algesiras	1 49	3 9	2 6	1 3
Gibraltar	1 47	4 1	2 7	1 3
Ceuta	2 6	3 7	2 5	1 3
Tetuan	2 23	2 6	1 6	0 6
Tangier	1 42	8 3	5 1	2 0
Rabat	1 46	11 0	7 1	3 3
Mogador	1 18	12 4	8 0	3 6

A similar phenomenon is witnessed at the other end of the sea. Here the fresher waters of the Black Sea rush in through the narrow channel of the Dardanelles, causing a surface inflow of comparatively fresh water, while there is an outflow below of denser Mediterranean water. The dimensions of the Straits are too small to make the phenomenon of any importance for the supply of the Mediterranean. The conditions both in the Dardanelles and in the Bosphorus were examined very carefully in the year 1872 by Captain Wharton, R.N., of H.M.S. "Shearwater," and his results are published in an interesting report to the admiralty, of that date. It is remarkable that the comparatively fresh water of the Black Sea persists without sensible mixture through the Sea of Marmora and into the Dardanelles, while there is constantly a current of Mediterranean water running underneath, and the depth in the two channels is only from 30 to 50 fathoms. There can be little doubt that the saltness of the Black Sea is due wholly to the return current of Mediterranean water entering through the Bosphorus. Were the exit of the Black Sea a channel with sufficient fall to bring the surface of the Sea of Marmora below the level of the highest part of its bottom, so that no return current could take place, the waters of the Black Sea would be fresh.

In the body of the sea the rise and fall are much less than at any of the places in the above table. At Algiers a self-recording tide gauge was set up by Aimé, and from its records he deduced a rise and fall of 88 millim. (say $3\frac{1}{2}$ in.) at springs and half that amount at neaps, a fluctuation which would escape ordinary observation, as it would be masked by the effects of atmospheric disturbances. At Venice and in the upper reaches of the Adriatic, the true lunisolar tide seems to be more accentuated than in other parts; but here also its effects are subordinate to those of the wind. In summer the Mediterranean is within the northern limit of the north-east trade wind; consequently, throughout a great part of the year, the winds are tolerably constant in direction; and, blowing as they do over large areas of water, they are instrumental in moving large masses of it from one point to another, and so producing streams and currents.

The effect of wind on a surface of water is twofold: it produces the rhythmic motion of waves and the motion of translation of currents. Besides the motion produced by the direct action of the wind on the surface-water, there are currents due in the first instance to the accumulation of water produced by a wind which has been blowing constantly in one direction. The phenomenon of an abnormally high tidal rise with a gale of wind blowing on shore is one with which inhabitants of the British Islands are familiar. It is also a matter of frequent observation that, for instance, a south-west gale which exaggerates the height of high water on the western coasts of Britain reduces it on the east coasts. It blows the water on the west coast and off the east coast, so that the difference in the high-water levels on the two coasts is very pronounced. Supposing free communication were quickly made between the two coasts, a current would be the result, and its violence would be much greater than would be due to the local action of the wind on its surface. In the Mediterranean the winds blow during a great portion of the year very constantly from one direction or another, and generally from north and east. The extent of the sea is so great that the slope produced by the transference of the surface water constantly in one direction might have a sine or arc capable of being measured in feet and inches when the radius is as much as 200 miles long. Thus at Port Mahon, in the island of Minorca, according to the *Admiralty Sailing Directions*, the water rises and falls according to the direction of the wind. With wind from south-east or south-west the water rises, but from north-west or north-east it falls. When northerly or north-westerly winds prevail, and this is the case for two-thirds of the year, a strong current sets to the south-west off Ayre Island, which is reversed in seasons when south-westerly winds prevail. This current is due to the water escaping round the end of Minorca having been driven southward so as to raise a head on the north coasts of the island. Similarly in the Faro or Strait of Messina the currents, of which the famous Scylla and Charybdis are swirls or eddies, are the evidence of a tendency towards equalizing the levels of the eastern extremity of the western basin and of the western extremity of the eastern basin. In addition to this peculiarity of position with reference to the two basins, it has been found that there is a very strong purely tidal influence at work which alone produces an alteration in the direction of the currents, and thus adds to the confusion of the waters. At Capo di Faro the rise is scarcely perceptible, at Messina it may attain a maximum of 10 to 13 inches. In the Straits of Bonifacio, between Corsica and Sardinia, the currents follow entirely the direction of the prevailing winds, and are at times very rapid. In the channel between Sicily and the African coast the currents also follow the winds. In long periods of calm weather a steady easterly set is observed, no doubt a prolongation or reproduction of the Gibraltar current.

Temperature.—Nothing whatever was known of the temperature of the deep water of the Mediterranean until Saussure extended to it his classical investigation into that of the Swiss lakes. In October 1780 he sank his thermometer to a depth of 160 fathoms off Genoa and of 320 fathoms off Nice, and at both depths he found the temperature of the water to be 55°·8 F. These observations have a special value, for, owing to Saussure's method of experimenting, his results were not affected by the pressure obtaining at great depths in the sea. Fifty years elapsed before any similar experiments were made, when D'Urville, in the "Astrolabe," made a few observations at the beginning and the end of his famous expedition. There is some uncertainty about his observations in 1826 and 1829, and also about the later ones of Bérard in 1831, as we are not informed whether the self-registering instruments used were protected from pressure or not. Mr Prestwich,[1] however, who has collected and critically discussed all the older deep-sea temperature observations, concludes, from a comparison of their results with those obtained by Aimé with protected instruments, that they were so protected, and admits their results into his tables without correction. In the deep water to the northward of the Balearic Islands D'Urville found in April 1826 54°·5 F. in 270 fathoms, and in March 1829 54°·7 at the same depth, and the same temperature (54°·7) in 530 fathoms. Bérard, experimenting in the sea between the Balearic Islands and Algeria, found the temperature of the deep water nearly a degree higher, namely 55°·4 F., in depths of 500 to 1000 fathoms. Aimé[2] relates his own careful experiments on the temperature of both surface and deeper water in the neighbourhood of Algiers, and discusses them in connexion with those of other observers with very great ability. He concludes from his own observations and those of Bérard that the uniform temperature at great depths is 54°·86 F. From a consideration of the general climate of the Mediterranean, he comes to the conclusion that the temperature in the deeper layers of the sea ought to be lower than the annual mean of the surface, and that it ought to be not very different from the mean surface temperature in the winter months. From observations at Toulon and Algiers, he finds that at neither place does the surface temperature fall below 50° F., and that the mean surface temperatures in the months December, January, February, March, and April is at Toulon 53°·06 F. and at Algiers 56°·84 F. The mean of these two temperatures is 54°·9 F., which is almost exactly what he finds to be the mean annual temperature of the deepest water of the western basin. During the forty years which have elapsed since Aimé made his experiments and speculations, further observations have only tended to confirm his theory. It is true that the temperatures observed in the many soundings which have been made of late years have not shown absolute identity of temperature, and it is probable that the greater the refinement in the instruments used the more decided will the local differences appear. Especially it will be apparent that the bottom temperature varies with the climate of the preceding winter, and the distribution of temperature varies much with the prevalence of the winds. At the few stations where the temperature of the sea-water and that of the air are regularly examined, it appears that the water is generally for the greater part of the year warmer than the air, and in winter considerably so. The existing observations, however, are too few to justify any very definite statement on the subject. At Palermo the sea is warmer than the air throughout the whole year with the exception of the months May and June. In Algiers Aimé found but little difference; in autumn and winter the water was slightly warmer, in spring and summer slightly colder, than the air. In the eastern basin we have first Admiral Spratt's observations in July 1845 in Ægina Gulf. In all his experiments made previous to the year 1860 he determined the temperature of the bottom water by taking that of the mud brought up in the dredge. This is a very excellent method; in fact it is probably the best of all methods if a sufficient quantity of mud be obtained. From 1860 he used self-registering unprotected thermometers, which gave results necessarily too high, and it is impossible to apply any reliable correction to them without experimentally determining it on each thermometer which was used. By the first method Admiral Spratt found 55°·5 F. at depths between 100 and 200 fathoms.

From these observations it seemed reasonable to conclude, as Aimé had done, that all over the Mediterranean a practically uniform temperature is found at all depths greater than 100 or 200 fathoms, and that this temperature is 54° to 56° F. In order thoroughly to investigate this matter, as well as the biological conditions of the deep water of the Mediterranean, H.M.S. "Porcupine," Captain Calver, with Messrs Carpenter and Gwyn Jeffreys, visited the western basin of the Mediterranean in the autumn of 1870. A large number of temperature observations were made in the western basin near its southern coasts, and one sounding with temperature observation in the eastern basin a short distance from the Sicilian coast, the result of which was to confirm the conclusion arrived at from earlier observations, that, however high the temperature of the surface may be (and it may reach 90° F.), the water becomes rapidly cooler as we go below the surface until we reach a depth of about 100 fathoms, where a temperature of 54° to 56° F. is found, and persists without sensible variation to the greatest depths. The average of all the bottom temperatures in the western basin was 54°·88 F. Three soundings were made in the intermediate basin to the eastward of Pantellaria in depths of 266, 390, and 445 fathoms, and in each case the bottom temperature was found to be 56°·5 F., or about a degree and a half warmer than in the deeper western basin. This is precisely what might have been expected from what we know of inland seas divided into several basins. In summer the shallower basin has usually a higher temperature at the bottom than is found at the same depth in the deeper one. Only one observation was made in the eastern basin, namely off Cape Passaro, in 1743 fathoms, with a bottom temperature of 56°·0 F. That the temperature in this basin should be lower than in the Pantellaria basin is due to its greater depth, and that it should be higher than is found in the western basin is due to its lower latitude. These researches were further prosecuted in the autumn of 1871 in the "Shearwater," Captain Nares, accompanied by Dr Carpenter. At two stations in the eastern basin "serial temperatures" were taken. At the first, 35° 54′ N. lat., 16° 23′ E. long., depth 1650 fathoms, the bottom temperature was 56°, or the same as had been observed the year before in 1743 fathoms; at the second, 32° 17½′ N. lat., 26° 44′ E. long., depth 1970 fathoms, the bottom temperature was 56°·7, and the temperature at all intermediate depths was much higher than at the first station. The mean temperature of the water from the surface to a depth of 200 fathoms was, at the first station, 63°·75 F., and at the second 66°·78 F., or three degrees higher. At the first station all the temperatures down to 100 fathoms are higher than were observed in 1870 in the western basin, but it must be remembered that temperature observations made in different years cannot with justice be closely compared, as the climates of the two years are sure to differ considerably, and in the present case the difference in climate between the summers of 1870 and 1871 appears to have been very considerable.

In the autumn of 1881 a very interesting series of observations were made by Captain Magnaghi, hydrographer of the Italian navy, and Professor Giglioli, on board the Italian surveying ship "Washington," in that part of the western basin which is enclosed between the islands Corsica and Sardinia on the one side and the Italian coasts on the other. It is here that the deepest water of the western basin was found; and, apart from the great interest attaching to the physical results obtained, the collections made with the dredge in the comparatively lifeless waters were of the very highest importance, showing, as they did, a practical identity in the abyssal fauna with that of the open ocean. This is the more remarkable as we have hitherto been accustomed to consider the similarity in the fauna of portions of the ocean remotely distant from each other as being due to the likeness of their temperatures. In the Mediterranean, however, the bottom temperature is quite 20° F. higher than is found in great depths anywhere in the open ocean.

For determining the temperature of the deep water Captain Magnaghi used the half-turn reversing thermometer of Negretti and Zambra, which in itself is a very beautiful instrument. The mechanical arrangement, however, for reversing, even as improved by Magnaghi, was not so satisfactory, and from certain irregularities in the temperature observations reported the writer is inclined to think that some of the remarkable results obtained, for instance on the 11th August, are due to this instrumental imperfection. On that day the water at 70 metres was found to have a temperature of 25°·1 C., while that at 50 metres was 20°·1 C., and that at 90 metres was 16°·7 C. The results obtained in the deep water are no doubt quite reliable, for the temperature is so uniform that a few fathoms more or less in the depth at which it turned would make no difference in the temperature registered. In the more northern parts of this portion of the western basin, off the coast of Corsica, we find a practically uniform temperature from 250 metres down to the bottom in 2800 metres, the mean bottom temperature being 55°·96 F. Further to the south the temperature of the abyssal water appears to be distinctly higher. Thus between the south end of Sardinia and the Bay of Naples, in the deepest water, the practical uniformity of temperature is not reached until a depth of 1000 metres has been passed, and it is there 56°·7 F. It is unfortunate that we do not know what the bottom temperature in other parts of the Mediterranean was. In this summer of 1881 it was quite one degree higher than that observed by Dr Carpenter in 1870.

The great value of such a volume of water as an equalizer of temperature on its shores must be apparent, though in this respect it is inferior to the Atlantic Ocean in its immediate neighbourhood. Places on the west coast of Spain and Portugal have a much higher winter temperature and lower summer temperature than places in the same latitude in Italy. The reason of this is simple: on the Atlantic coast the principal winds in winter are from the south-west, and have a warming effect, while in summer the source of the north-east trade wind is pushed back into the Bay of Biscay, causing in this season constant northerly winds along the coast of Portugal. The winds of the Mediterranean have no seas of remote latitudes to draw on either for heating or cooling purposes, though the sandy deserts of Africa which bound its southern coasts have at certain seasons a very decided influence on the climate. The tempering action of the sea does not extend very far inland, as is evident from the climate of inland towns in Italy. As the Mediterranean shores have so much importance as health-resorts, the data presented in the following table are of interest. They are taken chiefly from Theobald Fischer's *Studien über das Klima der Mittelmeerländer*.

Nature of the Bottom.—In the western basin the bottom consists chiefly of clay of a grey to brownish colour. Without doubt, when freshly collected, the surface layer is reddish-brown and the lower ones dark grey. There is always some carbonate of lime, chiefly due to *Foraminifera*. The mud very much resembles that obtained from similar depths in those parts of the open ocean whose bottom waters are shut off from free communication by ridges which may not approach within 2000 or 1500 fathoms of the surface, and with the exception of the *Foraminifera* it much resembles the mud from enclosed and comparatively shallow basins off the west coast of Scotland. In the following table the analyses are given of a few samples on the line of the submarine cable connecting Marseilles with Algiers.

To the student of the physical conditions of the sea the Mediterranean possesses a very high interest; its size is such as to entitle it to rank among oceans, while it is so completely cut off from the remaining world of water that it presents us with a type which is purely local, and one might almost say provincial. (J. Y. B.)

MEDLAR, *Mespilus Germanica*, L., of the tribe *Pomeæ* of the order *Rosaceæ*, regarded by Bentham and Hooker as a subgenus of *Pyrus* (*Gen. Pl.*, i. 626; see also DC., *Prod*, ii. 633; *Trans. Lin. Soc.*, xiii. 99), is a native of European woods, &c., from Holland southwards, and of western Asia (London, *Arb.*, ii. 877). It occurs in hedges, &c., in middle and south England, as a small much-branched spinous tree, but is not indigenous to Great Britain (Hooker's *Stud. Fl. of Br. Isles*, 132; Baxter's *Brit. Gen. of Pl.*, 493, and *Mag. Nat. Hist.*, vol. ix. 86). The medlar was well known to the ancients. Pickering (*Chron. Hist. of Pl.*, 201) identifies it with a tree mentioned in a Siao-ya ode (*She-King*, ii. 1, 2), 827 B.C. It is the *μεσπίλη* of Theophrastus and *Mespilus* of Pliny. Loudon (*l.c.*) gives three varieties, *diffusa*, *stricta*, and *sylvestris*,—the last being spiny, but losing its spines under cultivation,—as well as four varieties of fruit. He also mentions several instances of large specimens throughout England. The well-known fruit is globular, but depressed above, with leafy persistent sepals, and contains stones of a hemispherical shape. It is not fit to eat until it begins to decay. (For culture of the medlar see HORTICULTURE.) The Japanese medlar is *Eriobotrya japonica*, L, a genus of the same tribe of *Rosaceæ*.

MÉDOC is the name given to the district in France adjoining the left bank of the Gironde from Ambès, the point where the Garonne and Dordogne unite, to Lesparre, where the marshes and polders which border on the mouth of the river begin; its length varies from 35 to 40 miles, its breadth from 12 to 5, and the area is about 386 square miles. It is formed by a number of low hills, which separate the Landes from the Gironde, and is traversed only by small streams; the Gironde itself is muddy, and often enveloped in fog, and the region as a whole is very far from being picturesque; but a fifth part of its soil is occupied by vineyards, the products of which form the finest growths of Bordeaux. Of these the most esteemed are Château-Margaux, Château-Laffitte, and Château-Latour. Prior to the ravages of the *Phylloxera*, the annual product of the Médoc district was 40,000 tuns, of which 9000 were of fine quality.

MEDUSA. See GORGON, vol. x. p. 785. See also HYDROZOA, vol. xii. p. 547 *sq.*

MEDYN, a district town of Russia, situated in the government of Kaluga, 39 miles north-west of the capital of the province, on the highway from Moscow to Warsaw. It was formerly known under the name of Mezetsk, and in the 14th century formed part of the Smolensk principality. The soil of the surrounding country being rather infertile, the population is engaged to some extent in manufactures of linen, cotton, and paper, and the merchants of Medyn carry on a brisk trade in this produce, as well as in rye, oats, and hemp seed. The population is 8000.

MEER, JAN VAN DER (1632–1675), of Delft,—not to be confounded with the elder or younger Van der Meer of Haarlem or with Van der Meer of Utrecht,—is one of the excellent painters of Holland about whom the Dutch biographers give us little information.[1] Van der Meer, or Vermeer, by which name he is also known, was born in Delft in 1632. There is a tradition, handed down by the Dutch writers, that he was a pupil of Carel Fabritius, but, in the strict sense of the word, this is almost impossible, for Fabritius was but eight years older than Van der Meer, and entered the guild of St Luke only one year before our painter. From his early death the works by Fabritius are few, but his contemporaries speak of him as a man of remarkable power, and the paintings now ascertained to be from his hand, and till recently ascribed to Rembrandt, prove him to have been deeply imbued with the spirit and manner of that master. Whether Van der Meer had ever any closer relation to Rembrandt than through companionship with Fabritius remains as yet uncertain. In 1653 he married Catherine Bolenes, and in the same year he entered the guild of St Luke of Delft, becoming one of the heads of the guild in 1662, and again in 1670. He died at Delft in 1675, leaving a widow and eight children. His circumstances cannot have been flourishing, for at his death he left twenty-six pictures undisposed of, and his widow had to apply to the court of insolvency to be placed under a curator, who, it is interesting to know, was Leeuwenhoek, the naturalist.

It is his works, however, that claim our attention. For more than two centuries he has been almost completely forgotten, and his pictures have been sold under the names

[1] This undeserved neglect seems to have fallen on him at an early period, for Houbraken (*Groote Schouburgh*, 1718), writing little more than forty years after his death, does not even mention him. The only definite information we have from a contemporary is given by Bleyswijck (*Beschrijving der Stad Delft*. 1687), who tells us that he was born in 1632, and that he worked along with Carl Fabritius, an able disciple of Rembrandt, who lost his life by an explosion of a powder magazine in Delft in 1654. It is to the patient researches of W. Bürger (Th. Thoré), Havard, Obreen, Soutendam, and others that we owe our knowledge of the main facts of his life, discovered in the archives of his native town.

and forged signatures of the more popular De Hooch, Metzu, Terborch, and even of Rembrandt. The honour of first recalling the attention of the art-world to this most original painter belongs undoubtedly to Thoré, an exiled Frenchman, who described his then known works in his *Musées de la Hollande* (1858-60), published under the assumed name of W. Bürger. The result of his researches, continued in his *Galerie Suermondt* and *Galerie d'Arenberg*, was afterwards given by him in a charming, though incomplete, monograph (*Gazette des Beaux-Arts*, 1866, pp. 297, 458, 542). The task has since been prosecuted with success by Havard (*Les Artistes Hollandais*), and by Obreen (*Nederlandsche Kunstgeschiedenis*, Dl. iv.), and we are now in a position to refer to Van der Meer's works. His pictures are rarely dated, but, luckily for us, one of the most important bears the date 1656, and thus gives us a key to his styles. The picture referred to is the only one that has figures of life size. It is the Woman and Soldier, with other two figures, of the Dresden gallery, and is painted with remarkable power and boldness, great command over the resources of colour, and with wonderful expression of life. For strength and colour it more than holds its own beside the neighbouring Rembrandts. To this early period of his career belong, from internal evidence, the Reading Girl of the same gallery, the luminous and masterly view of Delft in the museum of the Hague, La Laitière and the small street view, both in the collection of M. Six van Hillegom at Amsterdam, Le Soldat et la Fillette qui Rit of M. Double, the Country House in the gallery at Berlin, and others. In all these we find the same brilliant style and vigorous work, a solid impasto and a crisp sparkling touch. His first manner seems to have been influenced by the pleiad of painters circling round Rembrandt, a school which we know lost favour in Holland in the last quarter of the century. During the last ten or twelve years of his life Van der Meer adopted a second manner. We now find his painting smooth and thin, and his colours paler and softer. Instead of masculine vigour we have refined delicacy and subtlety, but in both styles beauty of tone and perfect harmony are conspicuous. Through all his work may be traced his love of lemon-yellow and of blue of all shades. Of his second style typical examples are to be seen in La Coquette of the Brunswick gallery, in the Woman Reading in the Van der Hoop collection at the Hague, in the Lady at a Casement belonging to Lord Powerscourt (exhibited at Burlington House, 1878), and in the Music Master and Pupil belonging to the Queen (exhibited at Burlington House, 1876).

Van der Meer's works are extremely rare. There is but one in the Louvre, the Lace Maker; Dresden has the two above-mentioned, while Berlin has three, all acquired in the Suermondt collection, and the Czernin gallery of Vienna is fortunate in possessing a fine picture, believed to represent the artist in his studio. In the Arenberg gallery at Brussels there is a remarkable head of a girl, half the size of life, which seems to be intermediate between his two styles. Several of his paintings are to be found in private foreign collections. In all his work there is a singular completeness and charm. In rendering momentary expression he is a master, and his pictures attract by the perfect delineation of character as well as by the technical skill of the painter. His tone is usually silvery with pearly shadows, and the lighting of his interiors is equal and natural. In all cases his figures seem to move in light and air, and in this respect he resembles greatly his fellow-worker De Hooch, who entered the guild of St Luke only two years later than Van der Meer. It is curious to read that, at one of the auctions in Amsterdam about the middle of last century, a De Hooch is praised as being "nearly equal to the famous Van der Meer of Delft." So nearly are they allied that the best judges are divided in opinion whether the Dutch Family ("La Promenade") of the academy of Vienna should be attributed to our painter or to De Hooch. Doubtless many of Van der Meer's works have yet to be restored to their proper author; but, as he is now in vogue, much care will have to be used in judging. This is specially true in regard to the landscapes and "still life" subjects which are attributed to him. The task is made more difficult by the diversity of style of this "Protean painter," as he is called by Dr Waagen, or, as Bürger names him, "the Sphinx of Delft." (J. F. W.)

MEERANE, a rapidly increasing industrial town in south-eastern Saxony, lies in the district of Zwickau, about 37 miles to the south of Leipsic. It contains an old church, a "Realschule," and a technical school for weavers. The leading industry is the weaving of woollen and half-woollen cloth, employing 3000 power-looms and 15,000 hand-looms, and producing goods of the annual value of upwards of £200,000. A large proportion of the cloth is exported to America and Japan. Meerane also possesses several important dye-works, besides smaller industrial establishments of various kinds. The population in 1880 was 22,293.

MEERSCHAUM. This German name is applied to a certain mineral, in consequence of its lightness, softness, and white colour, which suggest a resemblance to "sea foam." In like manner it is called in French *écume de mer*. By the German mineralogist Glocker it was termed *sepiolite*, in allusion to its resemblance to the so-called bone of the sepia or cuttle-fish. Possibly the fact that pieces of meerschaum, washed out of their matrix, are occasionally found floating on the Black Sea, may have led to the association of the mineral with marine products. Meerschaum is an opaque earthy mineral, of white, greyish, or yellowish colour, compact in texture, and breaking with a conchoidal or fine earthy fracture; it adheres to the tongue, and is so soft as to be scratched by the nail, its degree of hardness being about 2 or 2·5. Its specific gravity varies from 0·988 to 1·279; hence it floats in sea-water until saturated. Meerschaum is a hydrated silicate of magnesium, represented by the formula $Mg_2Si_3O_8 + nH_2O$. The value of n, according to some analyses, is 2. Most of our meerschaum comes from Asia Minor, especially from the plains of Eski-shehr, where it occurs in nodular masses, of variable size and irregular shape, distributed through the alluvial deposits of the plain, which are systematically worked for its extraction by means of pits and galleries. The mineral is associated with magnesite, or carbonate of magnesium, and has probably been derived from the neighbouring mountains, where a similar carbonate is found in connexion with serpentine. Meerschaum is found also, though less abundantly, in Greece and in some of the Grecian islands; at Hrubschitz in Moravia, where it occurs in a serpentinous matrix; and in Morocco, where it is used, when soft and fresh, as a substitute for soap; while a coarse variety is found at Vallecas near Madrid, and is employed as a building stone. Meerschaum also occurs in South Carolina.

By far the greatest quantity of meerschaum is used in the manufacture of tobacco-pipes, a purpose for which it is well fitted by its porosity. The nodular masses are first roughly scraped in order to remove the red earthy matrix; they are then dried, scraped again, and finally polished with wax. In this state the rudely-shaped nodular pieces are sent from the East principally to Vienna and to various parts of Germany. The pipe-bowls, after having been turned and carved, are rubbed with glass-paper and Dutch rushes; they are next boiled in wax, spermaceti, or stearine, and afterwards subjected to careful polishing with bone-ash, chalk, &c.

An imitation of meerschaum for common pipes is made of hardened plaster of Paris, treated with paraffin, and coloured by gamboge and dragon's blood. A peculiar preparation, into which potato largely enters, is said to have been successfully employed in France as a substitute for meerschaum.

MEERUT, or MÍRATH, a district in the division[1] of

[1] The division lies between 27° 38′ and 30° 57′ N. lat., and between 77° 7′ and 78° 42′ E. long., and comprises the six districts of Dehra Dun, Sahâranpur, Muzaffarnagar, Meerut, Bulandshahr, and Alígarh. The area in 1878 was 11,138 square miles, and the population in 1872 4,977,173.

Meerut and the lieutenant-governorship of the North-Western Provinces, India, lying between 28° 28′ and 29° 18′ N. lat., and 77° 10′ and 78° 14′ E. long., is bounded on the N. by Muzaffarnagar district, on the E. by the Ganges, on the S. by Bulandshahr district, and on the W. by the Jumna. The area in 1881 was given as 2361 square miles. Meerut forms a portion of the long and narrow plain lying between the Ganges and the Jumna, with a very gentle slope from north to south. Though well wooded in places and abundantly supplied with mango groves, it has but few patches of jungle or waste land to break the general expanse of cultivated soil. Sandy ridges run along the low watersheds which separate the minor channels, but with this exception the whole district is one continuous expanse of careful and prosperous tillage. Its fertility is largely due to the system of irrigation canals, which intersect it in every direction. The eastern Jumna canal runs through the whole length of the district, and supplies the rich tract between the Jumna and the Hindan with a network of distributary streams. The main branch of the Ganges canal passes across the centre of the plateau in a sweeping curve, and waters the midland tract. The Anúpshahr branch supplies irrigation to the Ganges slope. Besides these natural and artificial channels, the country is everywhere cut up by small water-courses. The Burh Gangá, or ancient bed of the Ganges, lies at some distance from the modern stream; and on its bank stood the abandoned city of Hastinapur, the legendary capital of the Pandavas at the period of the *Mahâbhârata*, said to have been deserted many centuries before the Christian era, owing to the encroachments of the river.

The census of 1872 returned the population of the district at 1,276,104, the Hindus numbering 991,226. Among the higher castes Bráhmans muster strong (109,804). The Rájputs (both Hindus and Mohammedans) number 55,083, and enjoy great social distinction as landholders; the Baniás, or traders (66,942), also now hold considerable landed property. The great cultivating castes are the Chamárs (197,273) and Játs (145,514). The Gujars (60,350) are a pastoral tribe, with an ancient character for plunder and cattle-lifting, which is now passing away. The Mohammedans (281,857) are for the most part the descendants of converted Hindus. The Christian population consists of 2149 Europeans, 142 Eurasians, and 730 natives. Fifteen towns in the district contain a population exceeding 5000; namely, Meerut, 81,386; Hápur, 14,544; Sardhána, 12,466; Garhmukhtesar, 7962; Bágpat, 7367; Ghaziábád, 7365; Shahdara, 7257; Baro, 7056; Mawána, 6864; Pilkhuá, 6239; Khekara, 6045; Tikri, 5698; Kirthal, 5651; Dasna, 5605; Chaprauli, 5594.

Meerut is one of the most flourishing and best tilled districts of the Doáb. Out of a total area of 1,505,824 acres, as many as 1,048,221 were under cultivation in 1881, 281,095 acres being irrigated by Government works, and 303,526 by private individuals. The grazing lands comprehended 242,091 acres, and the waste 185,400. The condition both of agricultural labourers and of artisans and workmen in the towns has considerably improved of late years. About one-half the soil is cultivated by the proprietors themselves, the remainder being about equally divided between tenants with occupancy rights and tenants-at-will. Rents are paid in money, and range from 18s. 10d. per acre for the best canal-watered lands down to 2s. 5¼d. per acre for "dry" unirrigated soils. The chief exports of the district are grain, cotton, and indigo; and the principal imports are Manchester goods, English hardware, tobacco, drugs, and spices. The chief commercial centres are Meerut, Ghaziábád, and Bágpat. Besides the great waterways of the Jumna and Ganges, and the navigable canals, communication is afforded by the East Indian and the Punjab and Delhi Railways; also by 1505 miles of made roads. In 1876 the district was in the administrative charge of four covenanted civilians, and contained seventeen magisterial and fifteen civil courts. The gross revenue in 1881 was £248,754, of which £203,977 was derived from the land-tax; the cost of officials and police was £27,520. In 1881 there were 214 schools, attended by 6677 pupils. The comparatively high latitude and elevated position of Meerut make it one of the healthiest districts in the plains of India. The average temperature varies from 57° Fahr. in January to 87° in June. The rainfall is small, less than 30 inches annually. The only endemic disease in the district is malarial fever; but small-pox and cholera occasionally visit it as epidemics.

The authentic history of the district commences with the Moslem invasions. Until the 11th century it is probable that Meerut was mainly in the hands of predatory native tribes, such as the Játs and Dors. The first undoubted Mohammedan invasion was that of Kutab-ud-dín in 1191, when Meerut town was taken, and all the Hindu temples turned into mosques. In 1398 Timúr swooped down upon the district, captured the fort of Loni after a desperate resistance, and put all his Hindu prisoners to death. He then proceeded to Delhi, and after his memorable sack of that city, returned to Meerut, captured the town, razed all the fortifications and houses of the Hindus, and put the male inhabitants to the sword. The firm establishment of the great Mughal dynasty in the 16th century, under Bábar and his successors, gave Meerut a period of internal tranquillity and royal favour. After the death of Aurangzeb, however, it was exposed to alternate Síkh and Mahrattá invasions. From 1707 till 1775 the country was the scene of one perpetual strife, and was only rescued from anarchy by the exertions of the military adventurer Walter Reinhardt, afterwards the husband of the celebrated Begám Samru, who established himself at Sardhána in the north, and ruled a large estate. The southern tract, however, remained in its anarchic condition under Mahrattá exactions until the fall of Delhi in 1803, when the whole of the country between the Jumna and the Ganges was ceded by Sindhia to the British. It was formed into a separate district in 1818. In the British period it has become memorable as being the place where the first outbreak of the great mutiny of 1857 took place.

MEERUT, a city and cantonment in the above district, is situated about half way between the Ganges and the Jumna, in 29° 0′ 41″ N. lat. and 77° 45′ 3″ E. long. The city proper lies south of the cantonments, and although a very ancient town, dating as far back as the days of the Buddhist emperor Asoka (*circ.* 250 B.C.), Meerut owes its modern importance to its selection by the British Government as the site of a great military station. In 1805 it is mentioned as "a ruined depopulated town." The cantonment was established in 1806, and the population rose rapidly to 29,014 in 1847, and 82,035 in 1853. In 1872 the census returned the population (exclusive of the military) at 81,386, viz., Hindus, 47,606; Mohammedans, 33,532; Christians, 248. The slight decline of population between 1853 and 1872 may probably be attributed to the mutiny of 1857. Most of the streets have a poor appearance, owing to the hasty manner in which they were erected. The cantonment, a little to the north of the city, forms the headquarters of a military division. The principal building is the Meerut church with its handsome tall spire. There are also a Roman Catholic church, mission chapel, asylum for the relief of Europeans and Christians, and a club. The Mall is one of the finest drives in India.

MEGALOPOLIS, a city of southern Arcadia, situated in a plain about 20 miles south-west of Tegea, on both banks of the Helisson, about 2½ miles above its junction with the Alpheus. Like Messene, it owed its origin to Epaminondas, and was founded in 370 B.C., the year after the battle of Leuctra, as a bulwark for the southern Arcadians against Sparta, and as the seat of the Arcadian federal diet, which consisted of ten thousand men. The builders of the city were protected by a Theban force, and directed by ten native œcists, who likewise attended to the peopling of the new city, which apparently drew inhabitants from all parts of Arcadia, but more especially from the neighbouring districts of Mænalia and Parrhasia. Forty townships are mentioned by Pausanias (viii. 27, 3–5) as having been incorporated in it. It was fifty stadia in circumference, and was surrounded with strong walls. Its territory was the largest in Arcadia, extending northward 24 miles. The city was built on a magnificent scale, and adorned with many handsome buildings, both public and private. Its temples contained many ancient statues brought from the towns incorporated in it. On the north side of the Helisson, which divided it into two nearly equal parts, was the agora with four porticos, the gymnasium, a sacred grove, temples to the Lycæan Zeus, Pan Oinoeis, Rhea, Tyche, the great goddesses (Demeter and Core), Zeus Philios (with a statue by Polycletus), Aphrodite, Core, Athena Polias, and Hera Teleia. Among the numerous statues which stood in the open air the finest was that of Apollo Epicurius, 12 feet high, brought from the beautiful temple of Bassæ, which was built by Ictinus, and is still in great part standing. On the south side of the river were the theatre, the largest in Greece, the Thersilion or hall for the assembly of the Arcadian diet, a house built for Alexander the Great, with a statue of Zeus Ammon, the stadium, temples to the Muses, Apollo, and Hermes, to Aphrodite, to Ares, to Dionysus, to Hercules and Hermes, to Artemis Agrotera, to Asclepius and Hygiea, to the son of Asclepius, and to Apollo. Of all these buildings, with the exception of the theatre, hardly a trace remains above ground. The ruins of Megalopolis are near Sinanou.

The foundations of Megalopolis were hardly laid when Agesilaus undertook an expedition in the hope of breaking up the union of which it was the visible sign and capital. He accomplished nothing, and had hardly reached home when the Thebans and their allies under Epaminondas and Pelopidas entered the Peloponnesus and marched through Laconia almost unopposed. After the departure of Epaminondas, Lycomedes of Mantinea succeeded in drawing the Arcadian federation away from its alliance with Thebes, in consequence of which it had to make common cause with Athens. An attempt on the part of the federation to use the treasures of the temple of Zeus at Olympia led to internal dissensions, so that in the battle of Mantinea (362) one half of the Arcadians fought on the side of the Spartans, the other on that of the Thebans. After this battle many of the inhabitants of Megalopolis sought to return to their former homes, and it was only by the assistance of three thousand Thebans under Pammenes that the authorities were able to prevent them from doing so. In the year 352, when Thebes had her hands full with the so-called Sacred War, the Spartans made an attempt to reduce Megalopolis; but the Thebans promptly sent assistance, and the city was rescued. Not sure of this assistance, the Megalopolitans had appealed to Athens, an appeal which gave occasion to Demosthenes's oration Περὶ Μεγαλοπολιτῶν. The Spartans were now obliged to conclude peace with Megalopolis and acknowledge her autonomy. Nevertheless their feeling of hostility did not cease, and Megalopolis consequently entered into friendly relations with Philip of Macedon. Twenty years later, when the Spartans and their allies rebelled against the power of Macedon, Megalopolis remained firm in its allegiance, and was subjected to a siege of considerable duration. After the death of Alexander, Megalopolis was governed by native tyrants. In the war between Cassander and Polysperchon it took part with the former, and was, in consequence, besieged by the latter. On this occasion it was able to send into the field an army of fifteen thousand. In 234 B.C. Lydiades, the last tyrant of Megalopolis, voluntarily resigned his power, and the city joined the Achæan league. In consequence of this it was once more exposed to the bitter hatred of Sparta. In 222 Cleomenes took and plundered it, and killed or dispersed its inhabitants, but in the year following it was restored and its inhabitants reinstated by Philopœmen, a native of the city. At this time the circuit of its walls always too great, seems to have been contracted. At all events it never again attained political importance, and gradually sank into insignificance. The only great men whom it produced were Philopœmen and Polybius the historian. Lycortas, the father of the latter, may be accounted a third. In the time of Pausanias the city was mostly in ruins.

MEGALOSAURUS. See REPTILES.

MEGAPODE, the name given generally to a small but remarkable Family of birds, highly characteristic of some parts of the Australian Region, to which it is almost peculiar. The *Megapodiidæ* with the *Cracidæ* form that division of the Order *Gallinæ* named by Professor Huxley *Peristeropodes* (*Proc. Zool. Society*, 1868, p. 296), and morphologically seem to be the lowest of the Order, with which apparent fact may perhaps be correlated their singular habit of leaving their eggs to be hatched without incubation, burying them in the ground (as many Reptiles do) or heaping over them a mound of earth, leaves, and rotten wood. This habit attracted attention more than three hundred years ago,[1] but the accounts given of it by various travellers were generally discredited by naturalists,[2] and as examples of the birds, probably from their unattractive plumage, appear not to have been brought to Europe, no one of them was seen by any ornithologist or scientifically described until near the end of the first quarter of the present century. The first member of the Family to receive authoritative recognition was one of the largest, inhabiting the continent of Australia, where it is known as the Brush-Turkey, and was originally described by Latham in 1821 under the name of the New-Holland Vulture, a misleading designation which he subsequently tried to correct on perceiving its Galline character. It is the *Talegallus lathami* of modern ornithologists, and is nearly the size of a hen Turkey. Six smaller species of the same genus have since been described, all from New Guinea or the neighbouring islands, but two of them, *T. pyrrhopygius* and *T. bruyni*, have been separated to form a group *Æpypodius*. The Australian bird is of a sooty-brown colour, relieved beneath by the lighter edging of some of the feathers, but the head and neck are nearly bare, beset with fine bristles, the skin being of a deep pinkish-red, passing above the breast into a large wattle of bright yellow. The tail is commonly carried upright and partly folded, something like that of a domestic Fowl.

The next form of which we may speak is another inhabitant of Australia, commonly known in England as the Mallee-bird, but to the colonists as the "Native Pheasant"—the *Lipoa ocellata*, described by Gould in the zoological *Proceedings* for 1840 (p. 126), which has much shorter tarsi and toes, the head entirely clothed, and the tail expanded. Its plumage presents a pleasing combination of greys and browns of various tints, interspersed with black, white, and buff, the wing-coverts and feathers

[1] Antonio Pigafetta, one of the survivors of Magellan's glorious but disastrous voyage, records in his journal, under date of April 1521, among the peculiarities of the Philippine Islands, then first discovered by Europeans, the existence of a bird there, about the size of a Fowl, which laid its eggs, as big as a Duck's, in the sand, and left them to be hatched by the heat of the sun (*Premier Voyage autour du Monde*, ed. Amoretti, Paris, A.R. ix. p. 88). More than a hundred years later the Jesuit Nieremberg, in his *Historia Naturæ*, published at Antwerp in 1635, described (p. 207) a bird called "Daie," and by the natives named "Tapun," not larger than a Dove, which, with its tail (!) and feet, excavated a nest in sandy places and laid therein eggs bigger than those of a Goose. The publication at Rome in 1651 of Hernandez's *Hist. Avium Novæ Hispaniæ* shews that his papers must have been accessible to Nieremberg, who took from them the passage just mentioned, but, as not unusual with him, misprinted the names which stand in Hernandez's work (p. 56, cap. 220) "Daic" and "Tapum" respectively, and omitted his predecessor's important addition "Viuit in Philippicis." Not long after, the Dominican Navarrete, a missionary to China, made a considerable stay in the Philippines, and returning to Europe in 1673 wrote an account of the Chinese empire, of which Churchill (*Collection of Voyages and Travels*, vol. i.) gave an English translation in 1704. It is therein stated (p. 45) that in many of the islands of the Malay Archipelago "there is a very singular bird call'd *Tabon*," and that "What I and many more admire is, that it being no bigger in Body than an ordinary Chicken, tho' long legg'd, yet it lays an Egg larger than a Gooses, so that the Egg is bigger than the bird itself. . . . In order to lay its Eggs, it digs in the Sand above a yard in depth; after laying, it fills up the hole and makes it even with the rest; there the Eggs hatch with the heat of the Sun and Sand." He adds further information which need not be quoted here. Gemelli Careri, who travelled from 1663 to 1699, and in the latter year published an account of his voyage round the world, gives similar evidence respecting this remarkable bird, which he calls "Tavon," in the Philippine Islands (*Voy. du tour du Monde*, ed. Paris, 1727, v. pp. 157, 158). The Megapode of Luzon is fairly described by Camel or Camelli in his observations on the Birds of the Philippines communicated by Petiver to the Royal Society in 1703 (*Phil. Trans.*, xxiii. p. 1398). In 1726 Valentyn published his elaborate work on the East Indies, wherein (deel iii. bk. v. p. 320) he very correctly describes the Megapode of Amboina under the name of "Malleloe," and also a larger kind found in Celebes, so as to shew he had in the course of his long residence in the Dutch settlements become personally acquainted with both.

[2] Thus Willughby (*Ornithologia*, p. 297), or Ray for him, who had, however, only Nieremberg's evidence to cite, and they can scarcely be blamed for their hesitation, considering the number of other marvels narrated by the same worthy father. Buffon also (*Oiseaux*, ix. p. 436) was just as sceptical in regard to the relation of Careri.

of the back bearing each near the tip an oval or subcircular patch, whence the trivial scientific name of the bird is given, while a stripe of black feathers with a median line of white extends down the front of the throat, from the chin to the breast. There is but one species of this genus known, as is also the case with the next to be mentioned, which is a singular bird long known to inhabit Celebes, but not fully described until 1846,[1] when it received from Salomon Müller (*Arch. f. Naturgeschichte*, xii. pt. 1, p. 116) the name of *Macrocephalon maleo*, but, being shortly afterwards figured by Gray and Mitchell (*Gen. Birds*, iii. pl. 123) under the generic term of *Megacephalon*, has since commonly borne the latter appellation. This is a very remarkable form, bearing a helmet-like protuberance on the back of its head, all of which as well as the neck is bare and of a bright red colour; the plumage of the body is glossy black above, and beneath roseate-white.

Of the Megapodes proper, constituting the genus *Megapodius*, many species have been described, but authorities are greatly at variance as to the validity of several, and here it would be impossible to name all that have been supposed to exist. Some are only known from very young examples—mere chickens; and some have even been described from their eggs alone. In 1870 Mr G. R. Gray enumerated twenty species, of which sixteen were represented in the British Museum, and several have been described since; but ten years later Professor Schlegel recognized only seventeen species, of which examples of twelve were contained in the Leyden Museum (*Mus. des Pays-Bas*, viii., Monogr. 41, pp. 56–86), while M. Oustalet, in his elaborate monograph of the Family (*Ann. Sc. Nat., Zoologie*, ser. 6, vols. x. and xi.), admits nineteen species. The birds of this genus range from the Samoa Islands in the east, through the Tonga group, to the New Hebrides, the northern part of Australia, New Guinea and its neighbouring islands, Celebes, the Pelew Islands, and the Ladrones, and have also outliers in detached portions of the Indian Region, as the Philippines (where indeed they were first discovered by Europeans), Labuan, and even the Nicobars—though none are known from the intervening islands of Borneo, Java, or Sumatra. Within what may be deemed their proper area they are found, says Mr Wallace (*Geogr. Distr. Animals*, ii. p. 341) "on the smallest islands and sand-banks, and can evidently pass over a few miles of sea with ease." Indeed proof of their roaming disposition is afforded by the fact that the bird described by Lesson (*Voy. Coquille: Zoologie*, p. 703) as *Alecthelia urvillii*, but now considered to be the young of *Megapodius freycineti*, flew on board his ship when more than 2 miles from the nearest land (Guebé), in an exhausted state, it is true, but that may be attributed to its extreme youth. The species of *Megapodius* are about the size of small Fowls, the head generally crested, the tail very short, the feet enormously large, and, with the exception of *M. wallacii* (*Proc. Zool. Society*, 1860, *Aves*, pl. 171), from the Moluccas, all have a sombre plumage.

The extraordinary habit possessed by the Megapodes generally of relieving themselves of the duty of incubation, as before mentioned,—a habit which originally attracted the attention of travellers, whose stories were on that very account discredited,—as well as the highly developed condition of the young at birth, has been so fully described by Gould (*Handb. B. Australia*, ii. pp. 152–175), G. R. Gray (*Proc. Zool. Society*, 1861, pp. 292–296), and Mr Wallace (*Malay Archipelago*, i. pp. 415–419; ii. pp. 147–149), and so often repeated by other writers, as to be very commonly known, and here there seems no necessity to enter into further details concerning it. (A. N.)

[1] As we have seen, it was mentioned in 1726 by Valentyn, and a young example was in 1830 described and figured by Quoy and Gaimard (*Voy. de l'Astrolabe: Oiseaux*, p. 239, pl. 25) as the *Megapodius rubripes* of Temminck, a wholly different bird.

MEGARA was the name of two Greek towns, one in Sicily, which has been already described under HYBLA, the other on the road from Attica to Corinth. The country which belonged to the city was called Μεγαρίς or ἡ Μεγαρική; it occupied the broader part of the isthmus between Attica, Bœotia, Corinth, and the two gulfs, and its whole area is estimated by Clinton at 143 square miles. The range of Mount Geraneia extends across the country from east to west, forming a barrier between continental Greece and the Peloponnesus. The shortest road across this range passes along the eastern side of the mountains, and the most difficult part is the celebrated Scironian rocks, the mythic home of the robber Sciron. The only plain in the rugged little country was the White Plain, in which was situated the only important town, Megara. The town was one of the most important commercial and colonizing centres of Greece in early times, and there is no doubt that its trade, like that of Corinth, owed its origin to the Phœnicians, who found its situation on the isthmus convenient. It became a Dorian city when that tribe conquered the Peloponnesus. Like many other cities of Greece, Megara was formed out of five villages, which were united on one political foundation; and this event must have taken place not later than the middle of the 8th century. From this time for two centuries Megara was among the most powerful cities of Greece. Though it had a harbour called Pegæ on the Corinthian Gulf, and founded a Sicilian colony, Megara Hyblæa, in 728 B.C., yet it did not long compete with Corinth and Corcyra for the western trade. Nisæa on the Saronic Gulf was a better harbour, and gave the Megarians a stronger footing on the eastern seas. In order to keep their hold on the Black Sea traffic, they founded numerous trading stations alongside of their chief rivals, the people of Miletus: Chalcedon and Byzantium on the Bosphorus, and Astacus and Heraclea in Bithynia were colonies of Megara. Wealth and culture increased in the city; the country festivals were celebrated in a more elaborate and orderly manner, and Susarion of Tripodiscus first gave literary form to Grecian comedy, which was soon transferred to Attica.

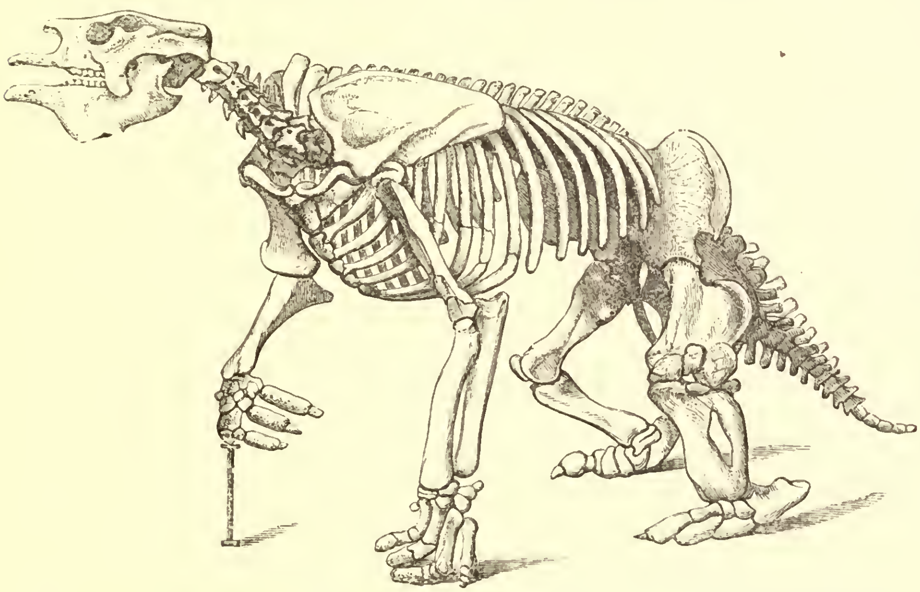
The situation of Megaris on the isthmus gave it great political power, inasmuch as it commanded all the roads from the Peloponnesus into continental Greece; and so long as the people continued united under an orderly government they maintained their high position. But the development of education prompted the lower classes to demand from the nobles an equal share in the government, and Megara did not, like Athens and Sparta, produce a constitution which could reconcile the contending parties. A tyrant Theagenes raised himself to supreme power as the leader of the popular party; he made an aqueduct for the city, and appears to have maintained its power and splendour. But he was expelled by the nobles about 600 B.C., and for many years Megara was the scene of continual struggles. The poor, who were indebted to the rich, refused to pay what they counted exorbitant interest, and plundered the houses of the nobles. A vivid picture of the state of the city in the 6th century B.C. is preserved in the writings of the poet Theognis, who belonged to the aristocratic party. Meanwhile Athens was rising to power, and maintained a long war with Megara for the island of Salamis. The Megarians gradually lost strength, and finally Solon wrested the island from them for ever. They sent three thousand troops to fight at Platæa. In the wars between Athens and Sparta they were impelled by jealousy of their neighbours of Corinth to join the Athenian alliance, 455–45; but they soon found that they were only the subjects of Athens, and finally enrolled themselves among the allies of Sparta. They suffered terribly during the Peloponnesian War: Athenian ships blockaded their harbours and Athenian armies ravaged their land once or twice every year. The long famine in the city is referred to by Aristophanes in the *Acharnians*. The city maintained a flourishing existence throughout the Greek and Roman periods, but played a very subordinate part in history. In the unsettled time when the Roman empire had decayed, it was often plundered by pirates.

As regards literature, Megara's chief distinction, besides the poems of Theognis and the comedy of Susarion, was the school of philosophy founded there by Euclid, a disciple of Socrates. The coinage of the city is a very confused and difficult subject; no very early coins can be with certainty attributed to it. The usual types are Apolline. The topography is described by Pausanias, bk. i. Megara is about four hours' carriage-drive from Athens.

MEGATHERIUM is the name given by Cuvier to a large extinct animal belonging to the order *Edentata* (see MAMMALIA, p. 384). A nearly complete skeleton, found on the banks of the river Luxan, near Buenos Ayres, and sent in 1789 to the Royal Museum at Madrid, long remained the principal if not the only source of information with regard to the species to which it belonged, and furnished the materials for many descriptions, notably that of Cuvier, who determined its affinities with the Sloths.[1] In 1832 an important collection of bones of the Megatherium were discovered near the Rio Salado, and were secured for the museum of the College of Surgeons of England, and these, with another collection found at Luxan in 1837, and now in the British Museum, supplied the materials for the complete description of the skeleton published by Professor Owen in 1861. Other skeletons have subsequently been received by several of the Continental museums, as Milan and Paris, and, consequently, our knowledge of the organization of the Megatherium, so far as it can be deduced from the bones and teeth, is as complete as that of any other animal, recent or extinct.

The remains hitherto spoken of are all referred to one species, *Megatherium americanum* of Blumenbach, *M. cuvieri* of Desmarest, and are all from the newest or post-Tertiary geological formations of the Argentine Republic and Paraguay, or the lands forming the basin of the Rio de la Plata. Dr Leidy has described, from similar formations in Georgia and South Carolina, bones of a closely allied species, about one-fourth smaller, which he has named *M. mirabile*. A third species, *M. laurillardi* of Lund, is founded upon remains found in Brazil.

The following description will apply especially to the best-known South American form, *Megatherium americanum*. In size it exceeded any existing land animal except the elephant, to which it was inferior only in consequence of the comparative shortness of its limbs, for in length and bulk of body it was its equal, if not superior. The full length of a mounted skeleton from the fore part of the head to the end of the tail is 18 feet, of which the tail occupies 5 feet. The head, which is small for the size of the animal, presents a general resemblance to that of the Sloth; the anterior part of the mouth is, however, more elongated, and the malar bone, though branched posteriorly in the same way as that of the Sloth, meets the zygomatic process of the squamosal, completing the arch. The lower jaw has the middle part of its horizontal ramus curiously deepened, so as to admit of implantation of the very long-rooted teeth. In number the teeth exactly resemble those of the Sloths, being five above and four below on each side, and they are limited to the lateral parts of the mouth, front teeth being entirely wanting. They resemble those of the Sloths also in their persistent growth, and in their composition of three tissues — vaso-dentine, true dentine, and cement; but they are of prismatic or quadrate form, and the constituent materials of different densities are so arranged that, as they wear, two transverse ridges of hard dentine remain at a greater elevation than the rest of the tooth, producing a very efficient triturating apparatus (see figs. 35 and 36, article MAMMALIA, p. 385). The vertebral column consists of seven cervical, sixteen dorsal, three lumbar, five sacral, and eighteen caudal vertebræ. The spinous processes are much better developed than in the Sloths, and are all directed backwards, there being no reversing of the inclination near the posterior end of the dorsal series, as in most active-bodied mammals. In the lumbar region, the accessory zygapophyses, rudimentary in Sloths, are fully developed, as in the Anteaters.



Skeleton of the Megatherium, from the specimen in the Museum of the Royal College of Surgeons of England. × $\frac{1}{25}$.

The tail is large, and its basal vertebræ have strong lateral and spinous processes and chevron bones, indicating great muscular development. The scapula resembles that of the Sloths in the union of the acromion with the coracoid, and in the bridging over of the supra-scapular notch. The clavicle is complete and very large much resembling that of man on a large scale. The fore limbs are longer than the hind limbs. The radius and ulna are both well-developed, and have a considerable amount of freedom of movement. The hand is singularly modified. The first digit is represented only by a rudimentary metacarpal, but the next three are large, and terminate in phalanges

[1] An excellent figure of this skeleton, which unfortunately was incorrectly articulated, and wanted the greater part of the tail, was published by Pander and D'Alton in 1821, and has been frequently reproduced in subsequent works.

adapted for the support of immense claws, the middle one being especially large. The outer or fifth digit has no claw, and it may be considered as certain that the weight of the foot was, in standing and walking, chiefly thrown upon this, and that it was protected by a callous pad below as in the existing great Anteater, while the other toes were curved inwards towards the palm, only coming in contact with the ground by their outer surfaces. The mechanical arrangements by which the weight of the body was thrown entirely upon the outer side of the foot are very curious, and are fully described in Professor Owen's memoir. The pelvis is remarkably wide, even more so than that of the Elephant, but it is formed on the same principle as in the Sloths. The femur is extremely broad and flattened; the tibia and fibula are short and strong, and united together at each end. The hind foot, contrary to the usual rule in the *Edentata*, is even more singularly modified than the hand. The ankle-joint is formed upon a peculiar plan, quite unlike that of the Sloths, or of any other mammal, except the Megatherium's nearest allies. The calcaneum projects nearly as far backwards as the fore part of the foot does forwards. There is no trace of great toe or hallux, or of its corresponding cuneiform bone. The second toe is rudimentary. The third has an enormous ungual phalanx, which, like those of the hand, is remarkable for the immense development of the bony sheath which is reflected from its proximal end around the base of the claw. The two outer toes have large and very peculiarly-shaped metatarsals, but only small phalanges, and no claws. The creature probably walked upon the outer edge of the sole, so that the great falcate claw of the third toe did not come into contact with the ground, and so was kept in a state of sharpness ready for use. The foot was therefore formed upon quite a different principle from that of the Anteaters or Sloths, though somewhat like the latter in having two of the toes aborted.

Taking all the various points of its structure together, they clearly indicate affinities both with the existing Sloths and with the Anteaters, the skull and teeth more resembling those of the former, and the vertebral column and limbs the latter It is also not difficult to infer the food and habits of this enormous creature. That it was a leaf-eater there can be little doubt, but the greater size and more complex structure of its teeth might have enabled it to crush the smaller branches as well as the leaves and succulent shoots which form the food of the existing Sloths. It is, however, very improbable that it climbed into the branches of the trees like its diminutive congeners, but it is far more likely that it obtained its subsistence by tearing them down with the great hook-like claws of its powerful prehensile fore limbs, being easily enabled to reach them by raising itself up upon the massive tripod formed by the two hind feet, firmly fixed to the ground by the one huge falcate claw, and the stout, muscular tail. The whole conformation of the hinder part of the animal is strongly suggestive of such an action. There can also be little doubt but that all its movements were as slow and deliberate as those of its modern representatives.

An idea at one time prevailed that the Megatherium was covered externally with a coat of bony armour like that of the Armadillos, but this originated in dermal plates belonging to the Glyptodon, a totally distinct animal, having been accidentally associated with bones of the Megatherium. Similar plates, on a smaller scale, have indeed been found in connexion with the skeleton of both Mylodon and Scelidotherium, animals of the same family, but never yet with the Megatherium, which we may therefore imagine with a covering of coarse hair like that of its nearest living allies, the Sloths and Anteaters.

MEGHNÁ, a river of India, forming, in the lower part of its course, the great estuary of the Bengal delta, which conveys to the sea the main body of the waters of the Ganges and the Brahmaputra, which unite at Goalánda in Farídpur district. The united waters thence roll south—a mighty river of great depth and turbidness, sometimes split up into half a dozen channels by sand-banks of its own formation, sometimes spreading out into a widespread sheet of water which the eye cannot see across. The river enters the sea by four principal mouths, enclosing the three large islands of Dakshin Sháhbazpur, Hatia, and Sandwíp. It is navigable by native boats of the largest burden, and also by river steamers, all the year through; but the navigation is difficult, and sometimes dangerous, on account of shifting sand-banks and "snags," and boisterous weather when the monsoon is blowing. The most favourable season for navigation is between November and February. Alluvion and diluvion are constantly taking place, especially along the seaboard, and in Noákhálí district the land is said to have advanced seawards 4 miles in twenty-three years; while the islands fringing the mouth are annually being cut away and redeposited in fresh shapes.

The tidal phenomena of the Meghná surpass those of any other Indian river. The regular rise of the tide is from 10 to 18 feet, and at springs the sea rushes up in a single wave, known as the "bore,"—on the Meghná a justly dreaded danger to boatmen. It is greatest at the time of the biennial equinoxes, when navigation is sometimes impeded for days together. The tidal wave is suddenly beheld advancing like a wall topped with foam of the height of nearly 20 feet, and at the rate of 15 miles an hour; in a few minutes all is over, and the river has changed from ebb to flood tide. A still greater danger is the "storm wave," which occasionally sweeps up the Meghná in the shape of cyclones. The latest and most destructive of these disasters were those of May 1867 and October 1876, when the whole islands and sea-face of the mainland were entirely submerged. In the latter calamity it has been officially estimated that about 19 per cent. of the population in the mainland portion of Noákhálí, and in the islands of Sandwíp and Hatia, were drowned, and that a like proportion subsequently died of cholera and other diseases caused by the results of the storm.

MEHÁDIA, a market-town in the county of Szörény, Hungary, is situated on the Bella-Reka, or Bereka, 13½ miles north of Orsova, in 44° 55′ N. lat., 22° 22′ E. long. The town is small but thriving, and contains Greek Orthodox and Roman Catholic churches, the ruins of a castle, and some interesting Roman antiquities. Mehádia is, however, chiefly of importance as the station for the Hercules Baths, distant about 3 miles east from the town, and situated in a narrow pass in the romantic valley of the Cserna. Of the twenty-two hot springs of Mehádia, nine are now in use, the most powerful one being the Hercules, which yields about 5000 cubic feet of water per hour. The springs are all strongly impregnated with salts of sulphur, iodine, bromine, and chlorine, and their average temperature is 70° to 145° Fahr. They are much used for chronic rheumatism, gout, and cutaneous eruptions, and, during the season, which usually lasts from the middle of

May to the end of September, are resorted to by over a thousand visitors. The town of Mehádia has about 2200 inhabitants, principally Roumanians and Germans.

Already in the times of the Romans famous for their healing efficacy, the *Thermæ Herculis* (*Fontes Herculis, Aquæ Herculis*) were the resort of emperors, generals, and senators, whose sojourn there is attested by various inscriptions and relics. The town is the site of the ancient Roman colony of *Ad Mediam*, near which the Roman road from the Danube to Dacia passed in its course through the valley of the Cserna. Subsequent to the destruction of the Roman empire the baths fell into disuse until 1735; great improvements have been effected in them during the present century, and recently a spacious kursaal has been built at the expense of the Hungarian Government. The fortress of Mehádia was often stormed during the wars with the Turks, and notably in 1716, 1738, and 1789.

MEHEMET ALI, or MOHAMMED 'ALÍ. See EGYPT, vol. vii. p. 760 *sq.*

MÉHUL, ÉTIENNE HENRI (1763–1817), one of the most remarkable composers of France, was born at Givet, in Ardennes, on the 24th of June 1763. His father being too poor to give him a regular musical education, his first ideas of art were derived from a poor blind organist of Givet; yet such was his aptitude that, when ten years old, he was appointed organist of the convent of the Récollets. In 1775 an able German musician and organist, Wilhelm Hauser, was engaged for the monastery of Lavaldieu, a few miles from Givet, and Méhul became his occasional pupil. In his sixteenth year he was taken to Paris by a military officer, and placed himself under Edelmann, a good musician and harpsichord player. His first attempts at instrumental composition in 1781 did not succeed, and he therefore turned his attention to sacred and dramatic music. The great composer Gluck received him kindly, and gave him advice in his studies. After various delays and disappointments during his efforts for six years to obtain, at the Grand Opera, a representation of his *Cora et Alonzo*, he offered to the Opéra Comique his *Euphrosine et Coradin*, which, being accepted and performed in 1790, at once fixed his reputation. The critics acknowledged in it great energy of dramatic expression, and much brilliant instrumentation, but objected to a general want of graceful melody,—a strange complaint, since his style is far more refined than that of either Hérold or Auber. His opera of *Stratonice* had great success. After several other operas which did not succeed, his *Adrien* appeared, and added much to his fame, which was still further increased by his three best works, *Le jeune Henri*, *Uthal*, and *Joseph*, the finest of the series. He had been appointed one of the four inspectors of the Paris Conservatory, but that office made him feel continually the insufficiency of his early studies, a want which he endeavoured to remedy by incessant application. *Timoléon*, *Ariodant*, and *Bion* followed *Stratonice*, with various success. *Uthal* can scarcely be expected to live, since, by desire of Napoleon Bonaparte, it was written for an orchestra without violins. *Épicure* was composed by Méhul and Cherubini jointly; but the superiority of the latter was evident. Méhul's next opera, *L'Irato*, failed. After writing forty-two operas, besides a number of songs for the festivals of the republic, cantatas, and orchestral pieces of various kinds, his health gave way, from an affection of the chest, which terminated his life on the 18th of October 1817.

MEIBOM, HEINRICH (1555–1625), was born at Lemgo on December 4, 1555, and died on September 20, 1625, at Helmstädt, where he had held the chair of history and poetry from 1583. He was a writer of Latin verses (*Parodiarum Horatianarum Libri III. et Sylvarum Libri II.*, 1588), and his talents in this direction were recognized by the emperor Rudolph II., who ennobled him and made him poet laureate in 1590, but his claim to be remembered rests entirely on his services in elucidating the mediæval history of Germany. His *Opuscula Historica ad res Germanicas spectantia* were edited and published in 1660 by his grandson, Heinrich Meibom (1638–1700), who also was professor of history and poetry at Helmstädt, and incorporated the grandfather's work with his own *Rerum Germanicarum Scriptores* (1688).

MEININGEN, the capital of the little duchy of Saxe-Meiningen, in central Germany, and the seat of the provincial courts for Saxe-Meiningen, Saxe-Coburg, and the Prussian districts of Schmalkalden and Schleusingen, is situated on the right bank of the Werra, about 40 miles to the south of Eisenach. It consists of an old town and several handsome suburbs, but much of the former has been rebuilt in a modern style since a destructive fire in 1874. The chief buildings are the Elisabethenburg, or old ducal palace, dating chiefly from 1682, and containing several collections; the new palace; the new town-house; the post-office; the barracks; and the old town church, with its two towers, erected in 1003. The theatre has lately attained a European reputation for its admirably drilled actors and unexcelled scenic effects. The English Garden, a beautiful public park, contains the ducal mortuary chapel and several monuments. The industries, consisting of brewing and the weaving of woollen and cotton cloth, are insignificant. The population in 1880 was 11,227.

Meiningen, which was subject to the bishops of Würzburg for upwards of 500 years (1000–1542), came into the possession of the dukes of Saxony in 1583. At the partition of 1660 it fell to the share of Saxe-Altenburg, and in 1680 it became the capital of Saxe-Meiningen.

MEISSEN, an ancient and important industrial town of Saxony is situated on the left bank of the Elbe, between the streams Meisse and Triebisch, in the district and about 9 miles to the north-west of the town of Dresden. Its irregular hilly site and numerous fine old buildings give it a quaint and picturesque appearance, and most of the streets are narrow and uneven. The cathedral, one of the finest Early Gothic edifices in Germany, is conspicuously situated on the Schlossberg, 160 feet above the town. It is said to have been originally founded by the emperor Otho I., but the present building was begun in the 13th century, and completed soon after 1400. The lofty tower dates from the 15th century. Within the cathedral are the tombs of several Saxon princes of the 15th and 16th centuries, including those of Albert and Ernest, the founders of the present reigning lines. Adjoining the cathedral stands the castle, dating originally from 1473–81, but restored and named Albrechtsburg in 1676. Another thorough restoration was undertaken in 1863, when a series of historical frescos by celebrated modern artists was begun upon its walls. An old stone bridge of the 13th century connects the Schlossberg with the Afraberg, which owes its name to the old convent of St Afra. The convent was suppressed by Duke Maurice in 1543, and converted into the "Fürstenschule," one of the most renowned schools in Germany, counting Lessing and Gellert among its former pupils. The other chief buildings are the town-house, built in 1479, and restored in 1875; the fine old town church, also called the Frauenkirche or Marienkirche; and the churches of St Francis, St Nicholas (coeval with the town), and St Afra. Since 1710, immediately after Böttcher's great discovery, Meissen has been the seat of the manufacture of the so-called Dresden china. Till 1863 the porcelain factory was in the Albrechtsburg, but in that year it was transferred to a large new building in the Triebischthal, close to the town, where about six hundred and seventy hands are now employed. Meissen also contains iron foundries, manufactories of earthenware stoves and pottery, a jute-mill, sugar refineries, breweries, tanneries, &c. A considerable trade is carried on in the wine produced in the surrounding vineyards. The population in 1880 was 14,166.

Meissen, one of the oldest and most interesting towns in Saxony, was founded by the emperor Henry I. in 928 as an outpost against the Wends, and became the capital of a margraviate, which was afterwards merged in the duchy of Saxony. Its margraves were among the most powerful mediæval princes in Germany, and were the direct ancestors of the present royal house of Saxony. From 965 till 1581 Meissen was also the seat of an important line of bishops, who ranked as princes of the empire. The town suffered greatly from the Hussites in the 15th century, and it was captured by the imperial troops in the war of the Smalkaldian League, and again in the Thirty Years' War. In 1637 it was severely handled by the Swedes, and in 1745 it fell into the hands of the Prussians.

See *Die Stadt Meissen und ihre Umgegend*, 1855; and H. Herbst's *Praktischer Wegweiser durch die Stadt Meissen*, 1878.

MEKONG, Mekhong, or Makong, less frequently Nam-Kong, the Da-Kio of the Tibetans, the Lantsang-Kiang or Lankiang of the Chinese, and the Son-Kong of the Anamese, sometimes also called the Cambodia or Camboja, is one of the largest and most remarkable rivers of southern Asia. As it rises in Tibet, probably about 34° N. lat. and 94° E. long., and reaches the China Sea about 10° N. lat., after a somewhat devious course through Yunnan, Burmah, Siam, Cambodia, and Cochin-China, its total course may be safely stated at 2000 miles. In spite, however, of this great length, the Mekong must be regarded as little more than a mountain torrent on an unusually large scale. It certainly forms a very extensive delta (see Cochin-China, vol. vi. pp. 93, 94), and is navigable for steamboats as far up as Cratieh (about 280 miles from the river mouth), but navigation soon becomes difficult, not through want of water, but from the great irregularity of the bed. At Stung-Streng the river measures about 2 leagues from bank to bank, and its current is strong even to violence; it "twists into the sharpest eddies, and drives against the banks with fury." A little higher up are the great cataracts of Kong. Beyond these the channel again becomes navigable as far as Bassac, when it is still about 6500 feet in width; but before long the banks close in and the river, narrowed to about 900 feet, pours along a current of extraordinary depth. Above Khemarat the rapids again begin. At Paklay, Mouhot describes the Mekong as larger than the Menam at Bangkok, forcing its way between the lofty mountains with a noise like the roaring of the sea. About 130 miles farther up, at Luang-Prabang, it has again an unobstructed channel about 3000 feet wide; above Sien-kong the river winds through a magnificent plain; but soon afterwards, in spite of its volume of water, it becomes less navigable than before. The great French expedition of 1866–67 touched its course only at one place higher up, Sien-hong; but other travellers have crossed it at various points in Yunnan. Mr Grosvenor found it, near Yung-feng-chang, at a height of 4700 feet above the sea, a stream of from 60 to 80 yards wide, flowing smoothly and steadily in the floor of a deep gorge (see Coleborne Baker, "Trav. and Res. in Western China," *Roy. Geog. Soc. Suppl. Papers*, 1882). It is there crossed by an iron suspension bridge, of Chinese workmanship, consisting of twelve chains with links about 1 foot long (see Gill, *River of Golden Sand*, vol. ii. p. 330). Higher up, near Tse-ku mission-station, lies the terrific defile to which Cooper (*Trav. of a Pioneer of Commerce*, 1871) gave the name of Hogg's Gorge. The head waters of the Mekong have never been traced to their source; but Huc and Gabet saw the confluence of the two main branches at Tsiamdo (32° N. lat.), and the abbé Desgodins has followed the stream from that point down to Ye-tche in 27° 20′ N. lat. (see *La Mission du Thibet*, Paris, 1872, and the abbé's papers in *Bull. Soc. Géog.*, 1871, 1875, 1876, and 1877). At Yerkalo he observed a curious phenomenon: a number of wells from 12 to 24 feet deep were sunk down among the granite pebbles which form the bed of the river, just above mean-water mark; and they all yielded water with a greater or less degree of saltness and warmth. They are covered when the river is in full flood. The river basin in all the upper section is extremely narrow, being separated by long lines of high mountains from the valley of the Salwin on the west and from that of the Chin-sha-kiang or River of Golden Sands on the east. Not till the comparatively low country of Siam is reached are there any affluents of considerable size. The most important are the Se-mún and the Udong on the right, and the Attopeu or Se-Kong on the left. The Se-mún or Ubon river was explored as far as Korat by the Lagrée expedition, and its tributary the Se-dóm has been followed by Dr Harmand (*Bull. Soc. Géog.*, 1877). Both streams have a rapid and interrupted course. Like the Nile, the Mekong is subject to a great annual inundation, described as early as the 16th century by Camoens, who calls the river Mecom. At some places the difference between flood-mark and ordinary level is from 35 to 40 feet (see Cochin-China). The first Europeans to make true acquaintance with the river course were the Dutchman Wusthoff and his fellow ambassadors, who in 1641 ascended as far as Winkyan, *i.e.*, Vienchang; their narrative is given by Valentijn, and might have been enough to suggest that the Mekong could not form a trade route to the interior. For the French exploration which finally settled the question, see Garnier's *Expédition*, &c., 1873, and the notice of Garnier in vol. x. p. 82.

MELA, Pomponius, a Roman writer on geography. His little work, though a mere compendium, is the only systematic treatise on the subject preserved to us in the Latin language, with the exception of that which forms part of the encyclopædic work of the elder Pliny, and from this circumstance it derives a value to which it would be little entitled from its intrinsic merits. Nothing is known of the author except his name, and that he was born, as he himself informs us, at a small town called Tingentera in the south of Spain. But the date of his work may be fixed with little doubt from an allusion in the preface to a proposed expedition of the reigning emperor to Britain, which can hardly be referred to any other event than the visit to that island of the emperor Claudius in 43 A.D. This conclusion is accepted by all the recent editors; the view of some earlier scholars, who understood this passage as referring to the expedition of Julius Cæsar, is clearly disproved by the mention of several facts which were not anterior to the reign of Augustus. The little treatise is not only a mere abridgment, occupying less than one hundred pages of ordinary print, but is so deficient in method and systematic character that we should have supposed it to be little more than a mere schoolbook, were it not that we find the name of the author figuring in a prominent manner among the authorities cited by Pliny for the geographical books of his vast compilation.

His general views of the geography of the earth do not differ materially from those which were current among Greek writers from the time of Eratosthenes to that of Strabo, and are well known to us from the great work of the latter author, which was, however, in all probability unknown to Mela, as it certainly was to Pliny. But in one of his views he stands alone among ancient writers on geography, that after describing the division of the earth into five zones, of which two only were inhabitable, he states as an undoubted fact the existence of *antichthones*, who inhabited the southern temperate zone, but were inaccessible and consequently unknown to the inhabitants of the corresponding zone in the north, on account of the excessive heat of the intervening torrid zone. His views of the division and boundaries of the three continents of Europe, Asia, and Africa coincide with those of Eratosthenes; and, in common with all ancient geographers from the time of Alexander to that of Ptolemy, he regarded the Caspian Sea as an inlet from the Northern Ocean, corresponding to the Persian Gulf on the south. His ideas concerning India are extremely confused and imperfect,—altogether inferior to those possessed by Greek writers long before; he follows Eratosthenes in supposing that country to occupy the south-eastern angle of Asia, whence the coast trended northwards to Scythia, and then swept round to the westward to the opening of the Caspian Sea. As usual he places the Rhipæan Mountains and the Hyperboreans near the Scythian Ocean, which he of course connects with that supposed to exist to the north of Europe.

With regard to the west of Europe, on the other hand, his knowledge was somewhat in advance of the Greek geographers, as might be expected from the extension of the Roman dominion and civilization in that quarter, and from a writer who was himself a native of Spain. Accordingly we find him possessing a more accurate idea than either Eratosthenes or Strabo of the western coast-line of Spain and Gaul, and its deep indentation by a gulf (the Bay of Biscay) between the projecting headlands of the two countries. Of Britain, on the contrary, he has little to tell us, beyond what we find in Cæsar or Strabo, though he appears to have had a clearer idea of the position of the British Islands than the Greek geographer. He is also the first ancient writer who mentions the name of the Orcades or Orkneys, which he correctly describes as a large group of islands to the north of Britain. Of the north of Europe his knowledge was still utterly imperfect; but he had a vague notion of the existence to the north of Germany of a large bay, which he calls Codanus Sinus, containing many islands, large and small, among which was one much larger than the rest, which he calls Codanovia,—evidently the same name that reappears in Pliny under the form Scandinavia, which has been attached by modern writers to the great northern peninsula of Europe.

The method followed by Mela in describing the three continents is peculiar and inconvenient. Instead of treating each continent separately, and describing the countries included in it, he begins at the Strait of the Columns (the Straits of Gibraltar), which was close to his own birthplace, and describes the countries adjoining the south coast of the Mediterranean from Mauretania to Egypt, and afterwards those around the east coast of the same sea with its tributary the Euxine, and then back along the north of the Mediterranean from Scythia to Gaul and Spain. He then begins again with the countries bordering the western and northern ocean from Spain and Gaul round to India, and from thence by Persia and Arabia to the Ethiopians, and thence again round Africa to the straits from which he began. In common with most ancient geographers, he considered Africa as surrounded by the sea, but had a very inadequate idea of its extent towards the south.

The first edition of Pomponius Mela was published in 1471, and it was very often reprinted in the 15th and 16th centuries. The edition of Voss in 1658, with a valuable commentary, became the foundation of all the subsequent editions, of which those by Gronovius (in 1685 and 1742) are among the best-known and most useful. The edition by Tzschucke, in 6 vols. 8vo (1806), contains an overwhelming mass of notes and commentaries, but by far the best text is that of the recent edition by G. Parthey (Berlin, 1867), who has in many instances restored the original readings, which had been displaced by the conjectures of Voss and others. (E. H. B.)

MELANCHTHON, PHILIP (1497–1560), was born at Bretten, a town of the lower Palatinate, on February 16, 1497. His father, George Schwartzerd, was a kinsman of the famous Reuchlin, and by profession an armourer or commissary of artillery under the Palatinate princes. His mother, Barbara Reuter, was a thrifty housewife and affectionate parent, whose pious character is evidenced by a well-known German rhyme, of which she is the reputed author, beginning *Almosen geben armet nicht*. His mother's father, John Reuter, who was for many years mayor of Bretten, charged himself with the education of Philip. Taught first by John Hungarus, then by George Simler at the academy of Pfortzheim, where he lived in the house of Reuchlin's sister, young Schwartzerd exhibited remarkable precocity, and speedily won the regard of Reuchlin, who dubbed him Melanchthon (the Greek form of Schwartzerd), according to the fashion of that age. He lived two years at Heidelberg, and the next three at Reuchlin's university of Tübingen, where he studied law, medicine, and theology, taking his doctor's degree in 1514. He began soon after to give public lectures on rhetoric, and to comment on Virgil and Terence, and ere long it became known among European scholars that a new brilliant star of learning had risen on the horizon, Erasmus prophesying that he would himself be speedily eclipsed. In 1518, on Reuchlin's recommendation, Melanchthon was appointed by the elector of Saxony professor of Greek in the university of Wittenberg. This appointment marked an epoch in German university education; Wittenberg became the school of the nation; the scholastic methods of instruction were summarily set aside, and in a *Discourse on Reforming the Studies of Youth* Melanchthon gave proof, not only that he had thoroughly caught the Renaissance spirit, but that he was fitted to become one of its foremost leaders. He began to lecture on Homer and the Epistle to Titus, and in connexion with the former he announced that, like Solomon, he sought Tyrian brass and gems for the adornment of God's temple. Luther himself received a fresh impulse towards the study of Greek, and his translation of the Scriptures, begun as early as 1517, now made rapid progress, Melanchthon helping to collate the Greek versions and revising Luther's translation. Melanchthon on his part felt the spell of Luther's large personality and spiritual depth, and he seems to have been prepared on his first arrival at Wittenberg to accept the new theology, which indeed as yet existed mainly in subjective form, and as a living spiritual force, in the person of Luther. To reduce it to an objective system, to exhibit it dialectically, the calmer mind of Melanchthon, with its architectural faculty and delicate moral tact, was requisite. Theologically it is impossible to separate Melanchthon from Luther; "the miner's son drew forth the metal, the armourer's son fashioned it." Luther, in whom courage and energy were too much akin to violence and zealous decision to narrow intolerance, and Melanchthon, whose calm deliberation was apt to degenerate into vacillation and whose conciliatory temperament was too much allied to timidity, were each the fit complement of the other.

Melanchthon was first drawn into the arena of the Reformation controversy through the Leipsic discussion, of which he was an eager spectator. He had been sharply reproved by Dr Eck for giving aid to Carlstadt ("Tace tu, Philippe, ac tua studia cura nec me perturba"), and he was shortly afterwards himself attacked by the blustering Ingolstadt doctor. Melanchthon replied in a brief treatise—a model of Christian moderation—setting forth Luther's first principle of the supreme authority of Scripture in opposition to the patristic writings on which Eck so boastfully relied. His marriage in 1520 to Catherine Krapp of Wittenberg increased his own happiness, and gave a domestic centre to the Reformation. In 1521, during Luther's confinement in the Wartburg, Melanchthon occupied the important position of leader of the Reformation cause at the university. He defended the action of the Augustinian monks when they substituted for the celebration of the mass the sacrament of the supper partaken of by the people under both kinds; but, on the advent of the Anabaptist enthusiasts of Zwickau, he had a still more difficult part to play. Melanchthon was irresolute. In their attacks upon infant baptism they seemed to him to have hit upon a "weak point"; and in regard to their claim to personal inspiration his position was summed up in his own words, "Luther alone can decide; on the one hand let us beware of quenching the Spirit of God, and on the other of being led astray by the spirit of Satan." In the same year he published his *Loci Communes Rerum Theologicarum.*

After the first diet of Spires (1526), where a precarious peace was patched up for the Reformed faith, Melanchthon was deputed as one of twenty-eight commissioners to visit the Reformed states and regulate the constitution of churches, he having just published a famous treatise called the *Libellus Visitatorius*, a directory for the use of the commissioners. At the Marburg conference (1529) between the German and Swiss Reformers, Luther was pitted against Œcolampadius and Melanchthon against Zwingli in the discussion regarding the real presence in the sacrament. How far the candid conciliatory spirit of Melanchthon was biassed by Luther's intolerance is evident from the exaggerated and inaccurate accounts of the conference written by the former to the elector of Saxony. At the diet of Augsburg (1530) Melanchthon was the leading representative of the Reformation. With anxiety and tears he drew up for that diet the seventeen articles of the evangelical faith, which are known as the "Augsburg Confession." He held conferences with Romish divines appointed to adjust differences, and afterwards wrote an *Apology for the Augsburg Confession.* After the Augsburg conference further attempts were made to settle the Reformation controversy by a compromise, and Melanchthon, from his conciliatory spirit and facility of access, appeared to the Romanists the fittest of the Reformers to deal with. His historical instinct led him ever to revert to the original unity of the church, and to regard subsequent Romish errors as excrescences rather than proofs of an essentially anti-Christian system. He was weary of the *rabies theologorum*, and fondly dreamed that the evangelical leaven, if simply tolerated, would at length purify the church's life and doctrine. In 1537, when the Protestant divines signed the Lutheran Articles of Smalkald, Melanchthon appended to his signature the reservation that he would admit of a pope provided he allowed the gospel and did not claim to rule by divine right.

The year after Luther's death, when the battle of Mühlberg (1547) had given a seemingly crushing blow to the Protestant cause, an attempt was made to weld together the iron and clay of the evangelical and the papal doctrines, which resulted in the compilation by Pflug, Sidonius, and Agricola of the Augsburg "Interim." This was proposed to the two parties in Germany as a provisional ground of agreement till the decision of the council of Trent. Melanchthon, on being referred to, declared equivocally that, though the Interim was inadmissible, yet so far as matters of indifference (*adiaphora*) were concerned it might be received. Hence arose that "adiaphoristic" controversy in connexion with which he has been misrepresented as holding among matters of indifference such cardinal doctrines as justification by faith, the number of the sacraments, as well as the dominion of the pope, feast-days, and so on. The fact is that, in these tentative negotiations, Melanchthon sought, not really to minimize differences, but to veil them under an intentional obscurity of expression. Thus he allowed the necessity of good works to salvation, but not in the Romish sense, proposed to allow the seven sacraments, but only as rites which had no inherent efficacy to salvation, and so on. He afterwards retracted his compliance with the adiaphora, and never really swerved from the views set forth in the *Loci Communes*; but he regarded the surrender of more perfect for less perfect forms of truth or of expression as a painful sacrifice rendered to the weakness of erring brethren. Luther, though he had uttered certain expressions of dissatisfaction with Melanchthon, and had more keenly defended in his last years what was distinctively his own, yet maintained hearty and unbroken friendship with him; but after Luther's death certain smaller men arose in name of Luther who formed a party emphasizing the extremest points of the doctrine of the latter. Hence the later years of Melanchthon were much occupied with acrid controversies within the evangelical church; an account of these, however, would be out of place here. His last years were spent in fruitless conferences with his Romanist adversaries, and amid various controversies among the Reformed, but the flame of his piety burnt brightly till the close. He died in his sixty-third year, on the 19th April 1560, and his body was laid beside that of Martin Luther.

Melanchthon's ever ready pen, clear thought, and elegant style made him the scribe of the Reformation, most public documents on that side being drawn up by him. He never attained entire independence of Luther, though he gradually modified some of his positions from those of the pure Lutherism with which he set out. His development is chiefly noteworthy in regard to these two leading points—the relation of the *evangelium* or doctrine of free grace (1) to free will and moral ability, and (2) to the law and *pœnitentia* or the good works connected with repentance. At first Luther's cardinal doctrine of grace appeared to Melanchthon inconsistent with any view of free will; and, following Luther, he renounced Aristotle and philosophy in general, since "philosophers attribute everything to human power, while the sacred writings represent all moral power as lost by the fall." In the first edition of the *Loci* (1521) he held, to the length of fatalism, the Augustinian doctrine of irresistible grace, working according to God's immutable decrees, and denied freedom of will in matters civil and religious alike. In the Augsburg Confession (1530), which was largely due to him, freedom is claimed for the will in non-religious matters, and in the *Loci* of 1533 he calls the denial of freedom Stoicism, and holds that in justification there is a certain causality, though not worthiness, in the recipient subordinate to the Divine causality. In 1535, combating Laurentius Valla, he did not deny the spiritual incapacity of the will *per se*, but held that this is strengthened by the word of God, to which it can cleave. The will co-operates with the word and the Holy Spirit. Finally, in 1543, he says that the cause of the difference of final destiny among men lies in the different method of treating grace which is possible to believers as to others. Man may pray for help and reject grace. This he calls free will, as the power of laying hold of grace. Melanchthon's doctrine of the three concurrent causes in conversion, viz., the Holy Spirit, the word, and the human will, suggested the semi-Pelagian position called Synergism, which was held by some of his immediate followers.

In regard to the relation of grace to repentance and good works, Luther was disposed to make faith itself the principle of sanctification. Melanchthon, however, for whom ethics possessed a special interest, laid more stress on the law. He began to do this in 1527 in the *Libellus Visitatorius*, which urged pastors to instruct their people in the necessity of repentance, and to bring the threatenings of the law to bear upon men in order to faith. This brought down upon him the opposition of the Antinomian John Agricola. In the *Loci* of 1535 Melanchthon sought to put the fact of the co-existence of justification and good works in the believer on a secure basis by declaring the latter necessary to eternal life, though the believer's destiny thereto is already fully guaranteed in his justification. In the *Loci* of 1543 he did not retain the doctrine of the necessity of good works in order to salvation, and to this he added, in the Leipsic Interim, "that this in no way countenances the error that eternal life is merited by the worthiness of our own works." Melanchthon was led gradually to lay more and more stress upon the law and moral ideas; but the basis of the relation of faith and good works was never clearly brought out by him, and he at length fell back on his original position that we have justification and inheritance of bliss in and by Christ alone, and that good works are necessary by reason of immutable Divine command.

Melanchthon's life has been written by Camerarius. See also Matthes, *Ph. Melanchthon, sein Leben und Wirken*, 1841; Galle, *Charakteristik Melanchthons als Theologen*, Halle, 1845; Rothe's *Gedächtnissrede auf Melanchthon*, 1860; Nitzsch, *Melanchthon*, 1860; Schmidt, *Melanchthons Leben*, 1864. There is a biography in English by F. A. Cox, 2d ed., London, 1817. The works of Melanchthon, including his correspondence, are contained in the voluminous *Corpus Reformatorum*, edited by Bretschneider and Bindseil. (J. Wl.)

MELANESIA. This term comprises that long belt of island groups which, beginning in the Indian archipelago at the east limits of the region there occupied by the Malay race, and, as it were, a prolongation of that great island region, runs south-east for a distance of some 3500 English miles, *i.e.*, from New Guinea at the equator, in 130° E. long., to New Caledonia just within the Tropic, 167° E. long., and eastwards to Fiji, in 180°. This chain of groups has a certain geographical as well as ethnical unity. Its curve follows roughly the outline of the Australian coast, and large islands occur, with a number of small ones, along the whole length, with mountains of considerable height, coinciding pretty closely with a line of volcanic action. Melanesia is usually held to begin with New Guinea, this great island being then viewed as the headquarters of that dark Papuan race which, widely and variously modified in all the other groups, occupies the whole region, as the name Melanesia implies; but the race really extends farther west, for the large islands Flores and Timor, with several smaller ones, are also essentially Papuan.

New Guinea, 1490 miles long, and containing about 303,000 square miles, the largest island in the world after Australia, is clothed with almost impenetrable forests, through which mountain ranges rise to a height of 13,000 feet. Parallel to its longer axis, 150 miles to the north, are the Admiralty Islands, all small, with one exception, in which the hills rise to 1600 feet, and which is probably of volcanic origin, as the natives use spearheads and implements of obsidian. A Polynesian element seems to be present, and customs peculiar to both races have been observed. Mr H. N. Moseley, of the "Challenger," found them shrewd but honest traders, with much artistic skill in their carvings and designs. They have numerals up to 10, with an idiom for 8 and 9, viz., 10–2 and 10–1, which is found also at Yap in the Carolines, and in the Marshall Islands.

Next follow, east, the two large islands of New Britain, about 340 by 23 English miles, with active volcanoes up to 4000 feet, and New Ireland, about 240 by 22 miles. Next comes the Solomon group, 600 English miles in length, with seven large islands from 135 to 90 miles long, all running north-west and south-east, with volcanic peaks up to 8000 feet. The forms more characteristic of the New Guinea fauna do not extend beyond this group. Its forest vegetation is especially luxuriant. Then comes Santa Cruz, a small group partly volcanic, but with numerous coral reef islands. Then the Banks and New Hebrides group, over 500 English miles in length, all volcanic except the Torres reef islands in the north. Several spots in this group are occupied by people of purely Polynesian race, immigrants apparently from the eastward. Two hundred miles south-west from the New Hebrides lies the island of New Caledonia, about 240 by 25 English miles. It is in parts very mountainous, rising to 5380 feet, the rocks being sedimentary and plutonic, but there are no volcanoes. It lies half way between Australia and Fiji, 700 miles from each. Being outside the equatorial belt, it is much drier and more barren than the other groups, and its fauna and flora have many Australian and Polynesian affinities. The small Loyalty chain lies 70 miles east of New Caledonia, and parallel to it. Fiji is detached from the other Melanesian groups, and differs from them in various particulars. It consists of two large and about 300 small islands, the total area being about 7400 square miles.

Of the two great Pacific races—the brown Polynesian, and the dark Melanesian—the former, considering the vast region it occupies, is singularly homogeneous both in appearance and language, whereas in Melanesia even neighbouring tribes differ widely from each other in both respects. Still, all the Melanesians have certain common characteristics which distinguish them sharply from the other race. They stand at a lower level of civilization, as is well seen at certain spots in Melanesia where isolated Polynesian settlements exist, due probably to involuntary migration, and where the two races, though they have some peculiar customs in common, live in bitter mutual hostility. The Melanesians are mostly "negroid" in appearance, nearly black, with crisp curly hair elaborately dressed; the women hold a much lower position than among the Polynesians; their institutions, social, political, and religious, are simpler, their manners ruder and often indecent; they have few or no traditions; cannibalism, in different degrees, is almost universal; but their artistic skill and taste, as with some of the lower African negroes, are remarkable, and they are amenable to discipline and fair treatment. Their languages, amid considerable differences, which, as between the Melanesian proper and the Papuan, are very wide, have features which mark them off clearly from the Polynesian, notwithstanding certain fundamental relations with the latter.

The various Melanesian groups will be found described in detail under separate headings.

MELBOURNE, the capital of the colony of Victoria, and the most populous city in Australia, is situated at the head of the large bay of Port Phillip, on its northern bend known as Hobson's Bay, about 500 miles S.W. of Sydney by land and 770 by sea, the position of the observatory being 37° 49′ 53″ S. lat. and 144° 58′ 42″ E. long. Along the shores of the bay the suburbs

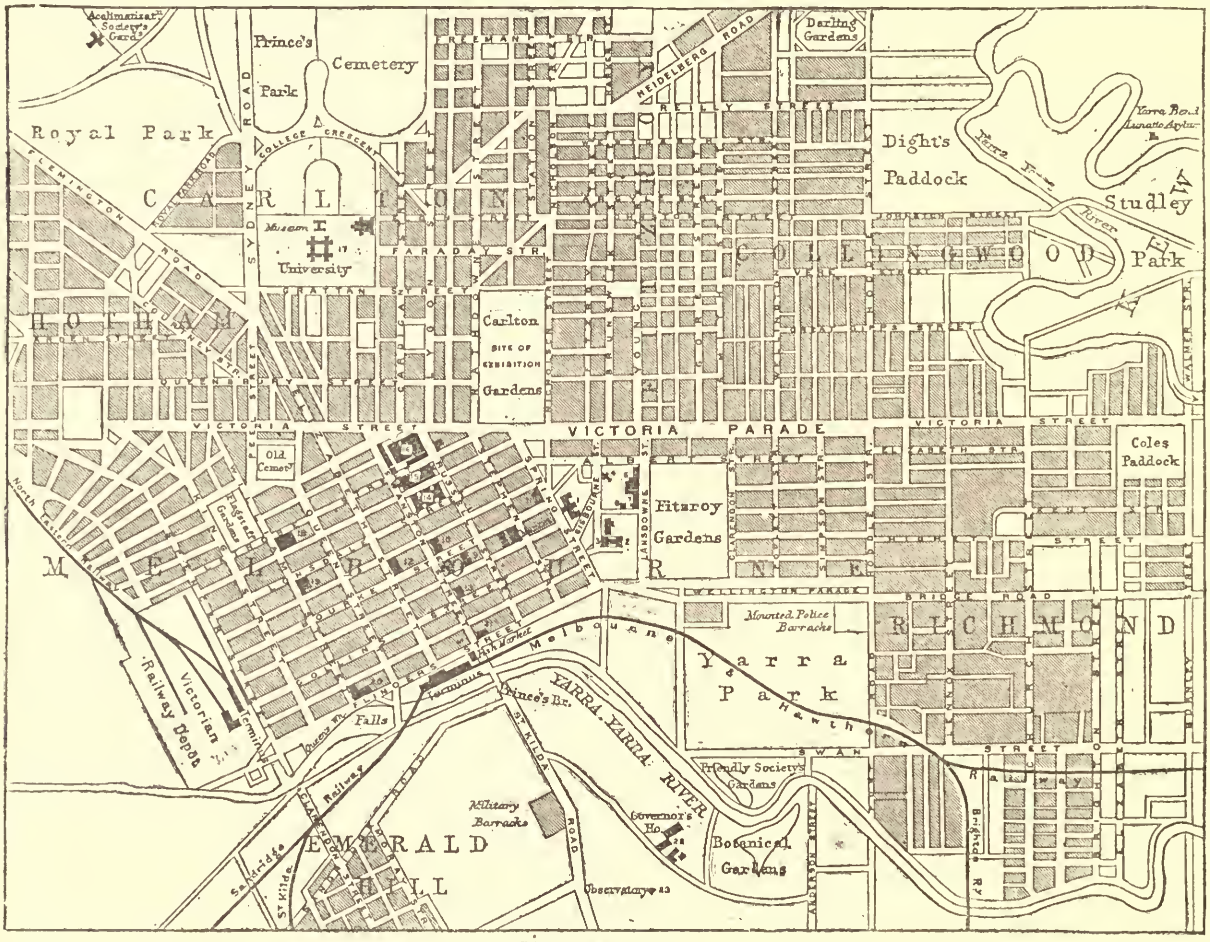
Port Phillip and Environs of Melbourne.

extend for a distance of over 10 miles, but the part distinctively known as the "city" occupies a site about 3 miles inland on the north bank of the Yarra river.

The appearance of Melbourne from the sea is by no means picturesque. The shipping suburbs of Sandridge and Williamstown occupy the alluvial land at the mouth of the Yarra, and, as the district is low and flat, and covered with factories, the prospect is not inviting. But the city itself has a very different aspect: its situation is relieved by numerous gentle hills, which show off to great advantage its fine public buildings; its streets are wide and well kept; and the universal appearance of prosperity, activity, and comfort under its usually clear blue sky impresses the visitor favourably.

That part specially known as the "city" had a population in 1881 of 65,800. It occupies the two hills of East Melbourne and West Melbourne; the valley that separates them, once occupied by a densely wooded little stream, is now partly filled in, and forms the busy thoroughfare of Elizabeth Street; parallel to this runs Swanston Street, and at right angles to these, and parallel to the river, are Bourke Street, Collins Street, and Flinders Street,—the first being the busiest in Melbourne, the second containing the most fashionable shops, and the third, which faces the river, being given over to maritime pursuits. These streets are the eighth of a mile apart; between them are narrower streets occupied by warehouses and business premises.

Round the "city" lies a circle of populous suburbs. North-east is Fitzroy with 23,000 inhabitants; farther east, Collingwood, 24,000; east of Melbourne, Richmond, 23,400; south-east, Prahran, 21,000; south, Emerald Hill, 25,300; south-west, Sandridge, 8700; north-west, Hotham, 17,800. These all lie within three miles of the general



Plan of Melbourne.

1. Houses of Parliament.
2. Treasury.
3. Government Offices.
4. St Patrick's Cathedral.
5. St Patrick's College.
6. Scotch Church.

20. Custom House.
21. Anglican Cathedral.
22. Governor's House.
23. Observatory.

post-office in Elizabeth Street; but outside of them, and within a radius of 5 miles, there is a circle of less populous suburbs: to the north, Brunswick, 6200; east, Kew, 4200, and Hawthorn, 6000; south-east, St Kilda, 11,600, and Brighton, 4700; south-west, Williamstown, 9000, and Footscray, 6000; north-west, Essenden and Flemington, 5000. Numerous smaller suburbs fill up the spaces between these,—the principal being Northcote, Preston, Camberwell, Toorak, Caulfield, Elsternwick, and Coburg, with a united population of 19,000.

Fifteen of these suburbs rank as independent municipalities, and many of them have streets which for importance rival the main streets of the city.

The following table shows the growth of the population since 1851:—

	1881.			Total.		
	Male.	Female.	Total.	1871.	1861.	1851.
Melbourne	34,526	31,333	65,859	54,993		
Suburbs	113,785	103,263	217,048	151,787		
Total	148,311	134,596	282,907	206,780	191,254	25,000

The land on which the city now stands was sold in allotments of half an acre, the prices realized being in June 1837 about £34 each, in November 1837 about £42, and in September 1838 about £120 each. These allotments are now (1882) sold at prices ranging from £20,000 to £40,000. But, though land has thus increased in value, Melbourne is by no means a crowded city; the streets are all 99 feet wide, and the parks, squares, and gardens are so numerous that with only one-thirteenth of the population of London it occupies very nearly half as great an area.

The public buildings are generally situated on positions from which they are seen to advantage. The Parliament Houses form a great pile of brickwork with four fronts in freestone, of which the main front is not yet completed; the interior decorations are highly elaborate. The Treasury is a well-proportioned building in freestone; behind it stands a vast building known as the Government offices. On the hill of West Melbourne there is a large structure, newly erected, for the law courts; it has four very handsome fronts, each about 300 feet in length, and the whole is surmounted by a lofty cupola, in the manner of the Capitol at Washington. The public library in Swanston Street forms one of four fronts of a building which was projected on a grand scale, but has never been completed. Much of the interior has been erected, but of the fronts only the main one is yet in existence, its cost having been £111,000. The lower story is devoted to sculpture; on one side there are casts of all the most famous statues; on the other there is a small collection of original works by modern sculptors, together with a gallery containing 8000 engravings and photographs; to the rear is the picture gallery, a very handsome hall, with oil paintings, chosen from the works of living artists. Another of the interior portions of the building is occupied by the technological museum, in which are arranged about 30,000 specimens illustrative of the industrial arts. The upper story of the front is devoted to the library, which occupies a chamber 240 feet long; 22 recesses contain each its own special branch of literature, the total number of volumes being 112,000. The book shelves rise to a height of 20 feet, but they are divided by a narrow gallery which runs all round the room, and gives access to the upper tiers. The library is open to the public; and every visitor ranges at will, being bound by the two conditions only that he is to replace each book where he found it, and that he is to preserve strict silence. During 1881 there were 261,886 visits made to the room.

The Melbourne University is a picturesque, but by no means imposing mass of buildings, buried among the trees of extensive and well-kept grounds about a mile from the heart of the city. In front of it stands the "Wilson Hall," erected at a cost of £40,000. Behind is the National Museum, containing collections of specimens of natural history. The museum, like all public places in Melbourne, is freely open to the people. About 98,000 visitors entered it in 1881. The university has a staff of 10 professors and 12 lecturers, with about 400 students. There are four courses open to students: arts, law, medicine, and civil engineering. Affiliated to the Melbourne University are the two denominational colleges, Trinity and Ormond, in which about 80 students reside, and where provision is made for instruction in theology.

The Exhibition building consists of a nave 500 feet long and 160 feet broad, surmounted by a dome, with two annexes each 460 feet long. These are built in brick with cement facings. The mint is a very handsome quadrangle, erected in 1872. In the year 1881 there were three millions of sovereigns coined in it, making a total of sixteen millions since its erection. The governor's residence is a large building on a hill overlooking the Yarra. The general post-office forms only half of a magnificent pile of buildings which will, when completed, include the central telegraph office.

The town-hall, at the corner of Swanston Street and Collins Street, contains, besides the usual apartments for municipal offices, a hall seated for nearly 3000 persons, and fitted with a colossal organ, on which the city organist performs two afternoons a week, the public being admitted at a nominal charge. Hotham, Richmond, Emerald Hill, Prahran, and Fitzroy have their own town-halls, all costly and somewhat pretentious buildings.

The markets, erected at a cost of £80,000, stand in Bourke Street. They are handsome in external appearance, and ingeniously contrived for convenience within. The observatory is a humble-looking building on the St Kilda Road; it contains an equatorial telescope, which had for some years the distinction of being the largest in the world.

There are two railway stations, one being the terminus of all the country lines, and the other devoted to suburban traffic. The suburbs of Williamstown, Sandridge, Footscray, St Kilda, Emerald Hill, Brighton, Elsternwick, Hawthorn, Richmond, and Essendon are connected by rail with the city.

The Melbourne Hospital is in the form of an extensive series of brick buildings, situated close to the public library. There are beds for about 300 patients. The Alfred Hospital, on the St Kilda Road, was built in commemoration of the visit of Prince Alfred; it has beds for nearly 100 patients. The lying-in hospital can accommodate 62 persons. The blind asylum has over 100 inmates; and there are a deaf and dumb asylum, an immigrants' home, and other charitable institutions.

Melbourne contains many churches, but few of them will compare with the public buildings in appearance. The Roman Catholic cathedral of St Patrick, when completed, will, however, be a conspicuous ornament to the city. The Anglican cathedral, now (1882) in the course of erection, is to cost about £100,000. The most striking ecclesiastical building is the Scotch church in Collins Street, which divides with Ormond College and the Wilson Hall the honour of being the finest specimen of architecture in the city.

There are in Melbourne, among its numerous state schools, about thirty whose size and proportions entitle them to rank with the architectural ornaments of the city. They have each accommodation for from 600 to 2000 scholars. Abundant provision has been made for secondary instruction by the denominations and by private enterprise. The Scotch College and the Presbyterian Ladies' College, the Wesley College and the Wesleyan Ladies' College, the Church of England Grammar School, St Patrick's College and St Francis Xavier's College, are all connected with the churches; and there are besides between twenty and thirty good private grammar schools.

Melbourne contains the offices of numerous banks, savings banks, and building societies.

The parks and public gardens of Melbourne are extensive and handsome. Within the city proper there are four gardens, which have been decorated with a lavish expenditure. The Fitzroy Gardens are one dense network of avenues of oak, elm, and plane, with a "fern-tree gully" in the middle. Casts of famous statues abound; and ponds, fountains, rustic houses, and small buildings after the design of Greek temples give a variety to the scene. The Treasury, Flagstaff, and Carlton Gardens are of the same class, but less costly in their decorations. Around the central city there lie five great parks. The Royal Park, of about 600 acres, is lightly timbered with the original gum trees; some portions of open land are used for recreation. About 30 acres in the centre are beautifully laid out to accommodate a very superior zoological collection. The Yarra Park, of about 300 acres, contains the leading cricket grounds; of these the "Melbourne" is the chief, distinguished by its very large stand and the excellence of its pitch. The Botanic Gardens occupy about 200 acres of land, sloping down to the banks of the river, and laid out with great taste and skill. Albert Park, about 500 acres in extent, is not so elaborately laid out, but contains a small lake, which is much used for boating purposes, as the bay is stormy and exposed. Studley Park, a favourite place for picnics, is a romantic corner on a bend of the upper Yarra, of about 200 acres extent, left entirely in a state of nature.

Besides these parks each suburb has its own "gardens" of moderate extent. At Flemington a large reserve is devoted to racing purposes, where in November the race for the Melbourne Cup is held, the great racing carnival of Australia, attended by about 100,000 persons.

The shipping of Melbourne is very considerable. In 1880 about 1500 vessels entered and cleared again, their tonnage being 960,000. Nearly all the intercolonial and a small proportion of the foreign vessels ascend the Yarra and unload in the heart of the city. The river was originally navigable for vessels of only 9 feet draught; but of late years the channel has been deepened so much that vessels drawing 16 feet can ascend with safety. Great works are now in operation by which the course is to be straightened and further deepened; and the quays which line the river banks will be made accessible to the large vessels which now have to lie in the bay off the Sandridge and Williamstown piers.

Shipbuilding is a comparatively unimportant industry, but a great deal of repairing is done; the graving dock at Williamstown is able to hold the largest vessels which enter the port.

The total values of the imports of Melbourne for 1879 and 1880 were respectively £15,035,000 and £14,557,000, and of the exports £12,454,000 and £15,954,000.

In 1881 Melbourne contained 2469 factories, employing 38,141 hands, and converting £8,012,745 worth of raw material into £13,384,836 worth of finished articles. The leading products are leather, flour, clothing, furniture, boots, carriages, preserved meats, ales, soap, candles, cigars, ironwork, jewellery, jams, confectionery, biscuits, and woollens.

The city is abundantly supplied with newspapers, including three morning and three evening dailies. Two reviews are published.

The climate of Melbourne is exceptionally fine, the only drawback being the occasional hot winds which blow from the north for two or three days at a time, and raise the temperature to an uncomfortable extent. But the proportion of days when the sky is clear and the air dry and mild is large. The mean annual temperature is 57°, which would make the climate of Melbourne analogous to that of Madrid, Marseilles, or Verona, but without the extremes experienced in those places. Snow falls every year in Italy, while it is unknown in Melbourne; and the highest temperature reached there in summer is below that of the cities mentioned.

As a field for emigration from European countries, Melbourne offers many advantages to the industrious mechanic or labourer.

The cost of living is about the same as in London. Rents are higher, and furniture and utensils dearer; but butcher meat, bread, and clothes are cheaper.

There is no city where more has been done for the working-classes or where they have made so good a use of their advantages. Many of their efforts at government (for they have all the power in their hands) have been ill-advised, but individually they have exhibited a prudence of which the community reaps the fruits. It is one of the peculiar features of Melbourne that about three out of every four mechanics who have reached middle life own the neat cottages they occupy.

History.—The city of Melbourne is without exception the most striking instance of the aptitude of the Anglo-Saxon race for colonization. It was not till the opening years of the present century that the first European sailed through the narrow entrance to Port Phillip, and it was only in 1835 that the white man made his habitation there. In that year John Fawkner sailed up the Yarra in his little vessel the "Enterprise," laden with materials for a settlement; he was stopped by a slight waterfall in a valley where dense groves of wattle trees all in bloom loaded the air with perfume, and where flocks of white cockatoos whirled aloft when the first stroke of the axe resounded in the forest. This spot is now the centre of a great city 10 miles in length, 6 in breadth, covering an area of 45,000 acres, and peopled by 283,000 persons. So rapid and solid a growth, at a distance from the mother country of the whole extent of the earth, is an example of colonizing enterprise altogether without parallel.

The settlement was at first called by the native name "Dootigala," but a desire for distinguished patronage caused the portion on the sea-shore, which was then esteemed the more important, to be called "Williamstown," after King William IV., while the little collection of huts some 3 or 4 miles inland was named "Melbourne," in honour of the prime minister Lord Melbourne.

For two years a constant stream of squatters with their sheep flowed in from Tasmania; then numerous "overlanders" drove their flocks from the Sydney side across the Murray and settled near Port Phillip. Captain Lonsdale was sent by the Sydney Government to act as police magistrate, but in 1838 Mr Latrobe was placed in charge with the title of superintendent. As the squatters prospered Melbourne increased in size, so that in 1841 it contained 11,000 inhabitants. A period of depression occurred in 1843, followed by several years of the greatest prosperity, till, in 1851, gold was discovered in New South Wales. The district of Port Phillip became infected by the excitement; many parties scoured that part of the country in search of the precious metal, and six weeks after the first discovery of it there the great riches of Ballarat were made known. Within a year from that time a hundred thousand men had landed in the colony in order to proceed to the diggings; for several years after the same number landed every twelve months; and Melbourne increased in population from 30,000 to 100,000 in the course of two or three years.

During the year of the gold discoveries, the Port Phillip district was separated from New South Wales, and formed into a separate colony with the name Victoria. In 1855 the British Government granted to it a complete autonomy; Melbourne became the capital of the new colony. (A. SU.)

MELBOURNE, William Lamb, second Viscount (1779–1848), second son of the first Viscount Melbourne, was born 15th March 1779. After completing his course at Trinity College, Cambridge, he studied law at the university of Glasgow, entered Lincoln's Inn in 1797, and was called to the bar in 1804. In 1805 he married Lady Caroline Ponsonby, daughter of the earl of Bessborough, who after her separation from him acquired some fame as a novelist, and was also a friend of Lord Byron. On entering parliament the same year Lamb joined the opposition under Fox, of whom he was an ardent admirer; but his Liberal tendencies were never of a very decided character, and he not unfrequently gave his support to Lord Liverpool during that statesman's long tenure of office. During the short ministry of Canning in 1827 he was chief secretary for Ireland, but he afterwards for a time adhered to the small remnant of the party who supported the duke of Wellington. The influence of Melbourne as a politician dates from his elevation to the peerage in 1828. Disagreeing with the duke of Wellington on the question of parliamentary reform, he in 1830 entered the ministry of Grey as home secretary. For the discharge of the difficult and multifarious duties of this office at such a critical time he was decidedly deficient both in insight and in energy, but his political success was totally independent of his official capacity; and, when the ministry of Grey was wrecked on the Irish question, Melbourne was chosen to succeed him. Almost immediately he had to give place to a Conservative ministry under Peel, but, the verdict of the country being in his favour, he resumed office in 1835. The period of his ministry was wholly uneventful, and for a considerable time before he resigned in 1841 he had lost the confidence of the country. From the time of his retirement from office he took little interest in politics. He died at Melbourne House, Derbyshire, 24th November 1848.

Lord Melbourne was without even the elementary qualification of diligent attention to details, which in the absence of higher endowments sometimes confers on a statesman the greater part of his success. Nor can it be said that in public he ever displayed any of those specious and brilliant talents which are often found an acceptable substitute for more solid acquirements. Though he possessed a fine and flexible voice, his manner as a speaker was ineffective, and his speeches were generally ill-arranged and destitute of oratorical point, notwithstanding his occasional indulgence in inelegant flights of rhetoric. Indeed his political advancement was wholly due to his personal popularity. He had a thorough knowledge of the private and indirect motives which influence politicians, and his genial attractive manner, easy temper, and vivacious, if occasionally coarse, wit helped to confer on him a social distinction which for a time led many to take for granted his eminence as a statesman. The most notable and estimable feature of his political conduct is his relation to Queen Victoria, whom he initiated into the duties of sovereign with the most delicate tact and the most friendly and conscientious care.

MELCHIADES, or MILTIADES (other forms of the name being Meltiades, Melciades, Milciades, and Miltides), was pope from July 2, 310, to January 10 or 11, 314. He appears to have been an African by birth, but of his personal history nothing is known. The toleration edicts of Galerius and of Constantine and Licinius were published during his pontificate, which was also marked by the holding of the Lateran synod in Rome (313), at which Cæcilianus was acquitted of the charges brought against him, and Donatus condemned. Melchiades was preceded and followed by Eusebius and Sylvester I. respectively.

MELCHITES. The name of Melchites (Syriac, *Malkâyê*; Arabic, *Malakîya*, or in the vulgar pronunciation *Milkîya*) means etymologically the royal party, and so is currently applied in the East to Syrian and Egyptian Christians of the Orthodox Greek Church, adherents of the creed supported by the authority of the king, that is, of the Byzantine emperor. The Melchites therefore are those who accept the decrees of Ephesus and Chalcedon as distinguished from the Nestorians and Jacobites, and the name reflects in an interesting manner the way in which the doctrinal controversies that agitated the Eastern empire associated themselves with national feelings of antagonism to the imperial rule.

MELCHIZEDEK (מַלְכִּי־צֶדֶק, "king of righteousness"), king of Salem and priest of "supreme El" (*El 'elyôn*), brought forth bread and wine to Abram, on his return from the expedition against Chedorlaomer, and blessed him in the name of the supreme God, possessor (or maker) of heaven and earth. And Abram gave him tithes of all his booty (Gen. xiv. 18–20). The Bible history tells us nothing more about Melchizedek (comp. Hebrews vii. 3); but the majestic figure of the king-priest, prior to the priesthood of the law, to whom even the father of all Israel paid tithes, suggested a figurative or typical application, first in Psalm cx. to the vicegerent of Jehovah, seated on the throne of Zion, the king of Israel who is also priest after the order of Melchizedek, and then, after the gospel had confirmed the Messianic interpretation of the Psalm (Matt. xxii. 42 *sq.*), to the kingly priesthood of Jesus, as that idea is worked out at length in the Epistle to the Hebrews.

The theological interest which attaches to the idea of the pre-Aaronic king-priest in these typical applications is practically independent of the historical questions suggested by the narrative of Gen. xiv. It is generally recognized that this chapter holds quite an isolated place in the Pentateuchal history; it is the only passage which presents Abraham in the character of a warrior, and connects him with historical names and political movements, and there are no clear marks by which it can be assigned to any one of the documents of which Genesis is made up. Thus, while one school of interpreters finds in the chapter the earliest fragment of the political history of western Asia, some even holding with Ewald that the narrative is probably based on old Canaanite records, other critics, as Nöldeke, regard the whole as unhistorical and comparatively late in origin. On the latter view, which finds its main support in the intrinsic difficulties of the narrative, it is scarcely possible to avoid the conclusion that the chapter is one of the latest additions to the Pentateuch (Wellhausen). The historical arguments *pro* and *con* may be seen at length in recent commentaries, but especially in Tuch's essay (*Z. D. M. G.*, i. 161 *sq.*, reprinted in the second edition of his *Genesis*), which was long viewed as decisive in favour of the narrative, and in Nöldeke's *Untersuchungen*, 1869, p. 156 *sq.*, with which compare Wellhausen in *Jahrb. f. D. Th.*, 1876, p. 414 *sq* The Assyrian monuments offer no decisive evidence, but are held to confirm the historical possibility of the proper names (Schrader, *KI. und AT.*, p. 46 *sq.*; Delitzsch, *Paradies*, p. 224). Here we can only speak of the episode of Melchizedek, which, though connected with the main narrative by the epithets given to Jehovah in verse 22, seems to break the natural connexion of verses 17 and 21, and may perhaps have come originally from a separate source. As the narrative now stands Salem must be sought in the vicinity of "the king's dale," which from 1 Sam. xviii. 18 probably but not necessarily lay near Jerusalem. That Salem is Jerusalem, as in Psalm lxxvi. 2, is the ancient and common view, and is necessarily followed by those who view Melchizedek as a late creation. Those who hold the opposite view now lean to the identification with the Σαλείμ of John iii. 23, 8 miles south of Bethshean, which Jerome (*Ep.* lxxiii. *ad Evangelium*) confirms by a worthless tradition. In a genuine record of extreme antiquity the union of king and priest in one person, the worship of El as the supreme deity by a Canaanite,[1] and the widespread practice of the consecration of a tithe of booty can present no difficulty; but, if the historical character of the narrative is denied, the origin of the conception must be placed as late as the rise of the temporal authority of the high priests after the exile. An ancient legend identifies Melchizedek with Shem (Palestinian Targum, Jerome on Isa. xli., Ephraem Syrus *in loco*).

MELCOMBE REGIS. See WEYMOUTH.

MELENDEZ VALDES, JUAN (1754–1817), minor poet of Spain, was born at Ribera del Fresno, Badajoz, on March 11, 1754. He was destined by his parents, who were in good circumstances, for an official career; and accordingly, after having completed his preliminary education at Madrid and Segovia, he went to Salamanca, and duly graduated in laws. At an early age he had begun to write verses in imitation of the then much admired though now justly forgotten Eugenio Lobo; but at Salamanca he came under the influence of the purer literary taste of the elder Moratin, while to the friendship of the cultivated and well-read Cadahalso he owed his introduction to the writings of recent English poets. At the age of twenty-six Melendez obtained the prize of the Spanish Academy for the best eclogue, one of the unsuccessful competitors being the well-known Iriarte; the poem (*Batilo: egloga en alabanza de la vida del campo*, 1780) continues to be highly spoken of by native critics, who echo in various forms the remark of one of the adjudicators, that it was "redolent of the wild thyme." In 1781 Melendez went to Madrid, where Jovellanos became his friend, and obtained for him in 1783 the appointment of professor of the humanities at Salamanca. In 1784, in competition for a prize offered by the city of Madrid, he produced his longest poem, a "dramatic eclogue" entitled *Las Bodas de Camacho* ("Camacho's Wedding"), which secured the vote of the judges, but did not add to his reputation, and soon fell into neglect. His genius does not seem to have been at all dramatic; at any rate he was unfortunate in his choice of a subject so little capable of dramatic treatment as the well-known episode in *Don Quixote*. In the following year, at the age of thirty-one, he published a little volume of lyrics and pastorals which gave him the first place he still holds among Spanish poets of the 18th century. Several editions were exhausted in a single year. With poetical fame came professional advancement, and in 1789 the "Restorer of Parnassus" (Restaurador del Parnaso), as Melendez is sometimes pedantically called by his countrymen, received a judicial appointment at Saragossa, which in 1791 he exchanged for a chancery

[1] On the other hand it is not correct to appeal to the *Pœnulus* of Plautus for the epithet 'elyôn.

auditorship at Valladolid. In 1797 the publication of a new and greatly enlarged edition of his works, dedicated to the prince of the peace, was followed by his removal to Madrid to a high post in connexion with the treasury. The new poems included somewhat heavy philosophical epistles written after the manner of Young, and an unmistakably dull epic canto entitled *Caida de Luzbel* ("The Fall of Lucifer"), suggested by Milton, as well as an *Ode to Winter*, which showed how well the author had made himself acquainted with Thomson. On the fall of his friend Jovellanos in 1798 Melendez was ordered away from Madrid, first to Medina del Campo and afterwards to Zamora, and it was not till 1802 that he was permitted to settle in Salamanca. For the next six years his literary activity was but slight, being limited to the production of a short poem on "Creation" and the preparation of an unfinished translation of the *Æneid*. After the revolution of Aranjuez (1808) Melendez accepted from King Joseph the post of councillor of state and afterwards that of minister of public instruction, a failure of patriotism which involved him in many indignities and even dangers; in 1813 he was of course compelled to quit his country, and, after sojourning successively at Alais, Nîmes, and Toulouse, he died in considerable poverty and neglect at Montpellier, on May 24, 1817. During his exile he employed himself in the preparation of a complete edition of his works, with numerous additions and corrections; this was afterwards published, along with a life of the author by Quintana, at the expense of the Government (4 vols. 8vo, Madrid, 1820; reprinted at Paris, 1832, and at Barcelona, 1838).

MELFI, a city of Italy, in the province of Potenza, 30 miles N. of Potenza, on the road and railway between that city and Foggia, is built on a small hill on the lower slopes of Monte Volture. The castle was originally erected by Robert Guiscard, but as it now stands it is mainly the work of the Doria family, who have possessed it since the time of Charles V.; and the noble cathedral which was founded in 1155 by Robert's son and successor, Roger, has had to be subjected to a modern restoration in consequence of the earthquake of 1851. In 1871 the city had 10,945 inhabitants; the commune had 9863 in 1861 and 12,657 in 1881.

Melfi is of doubtful origin, but appears to have existed at least as early as the 4th century. By the Normans it was made the capital of Apulia in 1041, and provided with fortifications. The council held by Nicholas I. in 1059, that of Urban II. in 1090, the rebellion against Roger in 1133 and the subsequent punishment, the plunder of the town by Barbarossa in 1167, the attack by Richard, count of Acerra in 1190, and the parliament of 1223, in which Frederick II. established the constitution of the kingdom of Naples, form the principal points of interest in the annals of Melfi during the more eventful period of its history. In 1348 Joanna I. of Naples bestowed the city on Niccolo Acciajuoli; but it was shortly afterwards captured, after a six months' siege, by the king of Hungary, who transferred it to Conrad the Wolf. In 1392 Goffredo Marzano was made count of Melfi; but Joanna II. granted the lordship to the Caracciolo family, and they retained it for one hundred and seven years till the time of Charles V. An obstinate resistance was offered by the city to Lautrec de Foix in 1528; and his entrance within its walls was followed by the massacre, it is said, of 18,000 of its citizens. As a bishopric Melfi is directly dependent on the Holy See.

MELITA (Μελίτη), the classical name for MALTA (*q.v.*), was also the name borne by the modern *Meleda*, one of the Dalmatian islands, situated immediately to the south of Sabbioncello and to the north of Ragusa. It is about 24 miles in length, averaging about $1\frac{1}{2}$ in breadth, and has a good harbour. At one time it was supposed by some authors to have been the scene of the shipwreck of St Paul, but this point has now for some time been conclusively settled in favour of Malta. See Smith, *Voyage and Shipwreck of St Paul*, 1848.

MELITO, bishop of Sardes, a Christian writer of the 2d century, is mentioned by Eusebius (*H. E.*, iv. 21) along with Hegesippus, Dionysius of Corinth, Apollinaris of Hierapolis, Irenæus, and others, his contemporaries, as a champion of orthodoxy and upholder of apostolic tradition. Of his personal history nothing is known, and of his numerous works (which are enumerated by Eusebius) only a few fragments are now extant. They included an *Apologia* addressed to Aurelius some time between 169 and 180 A.D., two books relating to the paschal controversy, and a work entitled Ἐκλογαί (selections from the Old Testament), which contained the well-known catalogue of "the books of the Old Covenant." The fragments have been edited with valuable notes by Routh (*Reliquiæ Sacræ*, vol. i., 1814). It seems more than doubtful whether the *Apologia* of Melito "the Philosopher," discovered in a Syriac translation by Tattam, and subsequently edited by Cureton and Renan, ought to be attributed to this writer and not rather to another of the same name.

MELLONI, MACEDONIO (1798–1854), a distinguished physicist, was born at Parma on April 11, 1798. From 1824 to 1831 he was professor at Parma, but in the latter year he was compelled to escape to France, having taken part in the revolution. In 1839 he went to Naples as director of the conservatory of arts and handicrafts. He was likewise director of the Vesuvius observatory, a post which he held until 1848. Melloni received the Rumford medal of the Royal Society in 1834. In 1835 he was elected correspondent of the Paris Academy, and in 1839 a foreign member of the Royal Society. He died from an attack of cholera on August 11, 1854.

From the Royal Society catalogue of papers we find that Melloni produced eighty-six memoirs by himself, as well as three in connexion with other physicists. These embrace a wide range of subjects, but the reputation of Melloni as a physicist rests more especially upon his discoveries in radiant heat. Men of science were, in the early part of this century, very much in the dark with regard to the nature of the invisible heat rays. Leslie and others had indeed advanced the subject by means of the differential thermometer, but such an instrument was at the best a very poor substitute for the human eye. It was necessary to invent an instrument more nearly capable of doing for the dark rays what the eye does for those of light before any great increase in our knowledge of this subject could be expected to take place. This step was taken (shortly after Seebeck's discovery of thermo-electricity) in the construction of the thermo-multiplier or combination of thermopile and galvanometer which formed the subject of a joint memoir by Nobili and Melloni in 1831. In this memoir, after describing their instrument, these physicists confirmed the experiments of Leslie and others. They tried screens of glass, sulphate of lime, mica, and ice, also of water, oil, alcohol, and nitric acid enclosed in glass, and found an instantaneous effect produced in the index of their instrument except for ice and water, the source of heat being an iron ball below redness. After finding that most substances when used as screens stopped a much larger proportion of dark heat than they did of light, Melloni set himself to discover some body that might be transparent for dark heat. In this search he was rewarded with complete success. Rock-salt was found to possess this property; and he immediately proceeded to construct prisms and lenses of rock-salt with which he proved the refraction of dark heat, that is to say, of the heat proceeding from bodies below incandescence.

Melloni was likewise very successful in studying the action upon dark heat of screens of various substances. His experiments in this and other directions are described by Baden Powell in his report to the British Association on *Radiant Heat* (1840). The rays of the lamp were thrown upon screens of various materials in such a manner that the effect transmitted from all the screens was of a certain uniform amount. This constant radiation was then intercepted by a plate of alum, and it was found that very different quantities of heat were transmitted through the alum in the different cases. Melloni concludes that the calorific rays issuing from the various diaphanous screens are, therefore, of different qualities, and possess what may be termed the diathermancy peculiar to each of the substances through which they have passed. One of his screens was made of green glass, and he found that a piece of alum transmitted only 1 per cent. of the heat which had passed through this screen. Green glass and alum form, therefore, an antagonistic combination.

These experiments suggest naturally a new analogy between dark heat and light which could not fail to strike Melloni, and accordingly we soon find him describing an experiment with the solar rays transmitted through green glass and then intercepted by other media. They pass copiously through rock-salt, he tells us, but feebly through alum, and hence Melloni concludes that there are amongst the solar rays some which resemble those of terrestrial heat, and in general that the differences observed between solar and terrestrial heat in the transmission of rays are to be attributed merely to the mixture in different proportions of these several species of rays. An instrument like the thermo-multiplier could not of course remain a monopoly, and shortly after its completion we find Professor James Forbes making use of it to prove the polarization of heat as well as to extend our knowledge of refraction. The brilliant researches of this experimentalist were, like those of Melloni, crowned with the Rumford medal of the Royal Society. On September 2, 1839, Arago communicated to the academy of sciences a letter by Melloni, who had found that rock-salt acquires by being smoked the power of transmitting most easily heat of low temperature, or dark heat. Forbes had discovered a similar property in mica split by heat, and he now showed that rock-salt roughened and mica scratched possess similar properties to blackened rock-salt. Melloni on his part took up the subject of polarization, and decided in favour of the equal polarizability of heat from different sources, a conclusion that did not then appear to Forbes to be in conformity with his experiments. It is very instructive to notice the loyalty which held both these experimentalists to the results of their observations. While Melloni differs from Forbes with regard to polarization, he will not allow the truth of a generalization proposed by Ampère, who had endeavoured to explain on the theory of undulations the identity of light and heat,—the difference of effect being dependent solely on the different wave-lengths, those producing heat being larger than those giving rise to light. Melloni admits that many phenomena may be explained by this hypothesis, but he mentions some experiments in which he thinks that this theory will not hold. The brilliant generalizer from without has of course a different point of view from the laborious experimentalist within. They are all worthy of scientific honour—for it is by the seeming conflict, but in reality the united efforts of workers such as these that the essential element of stability in the structure of scientific knowledge is finally secured.

MELON (*Cucumis Melo*, L.), a most polymorphic species of the order *Cucurbitaceæ*, the varieties of which are grouped by Naudin under ten tribes, while several other plants of less known characters probably belong to it.[1] The melon is an annual herb with palmately-lobed leaves, and bears tendrils. It is monœcious, having male and female flowers on the same plant. The flowers have deeply five-lobed campanulate corollas and three stamens. Naudin observed that in some varieties (*e.g.*, of Cantaloups) fertile stamens sometimes occur in the female flowers. It is a native of south Asia "from the foot of the Himalayas to Cape Comorin,"[2] where it grows spontaneously, but is cultivated in the temperate and warm regions of the whole world. It is excessively variable both in diversity of foliage and habit, but much more so in the fruit, which in some varieties is no larger than an olive, while in others it rivals the ponderous fruits of the gourd (*Cucurbita maxima*, L.). The fruit may be globular, ovoid, spindle-shaped, or serpent-like, netted or smooth-skinned, ribbed or furrowed, variously coloured externally, with white, green, or orange flesh when ripe, scented or scentless, sweet or insipid, bitter or even nauseous, &c. Like the gourd, the melon undergoes strange metamorphoses by crossing its varieties, though the latter preserve their characters when alone. The offspring, however, of all crossings are fertile. As remarkable cases of sudden changes produced by artificially crossing races, M. Naudin records that in 1859 the offspring of the wild melons m. sauvage de l'Inde (*C. melo agrestis*) and m. s. d'Afrique, le petit m. de Figari (*C. maculatus?*) bore quite different fruits from their parents, the former being ten to twelve times their size, ovoid, white-skinned, more or less scented, and with reddish flesh; though another individual bore fruits no larger than a nut. The offspring of m. de Figari after being crossed bore fruits of the serpent-melon. On the other hand, the serpent-melon was made to bear ovoid and reticulated fruit.[3]

With reference to the early cultivation of the melon, Naudin thinks it is probable that the culture in Asia is as ancient as that of all other alimentary vegetables. The Egyptians grew it, or at least inferior races of melon, which were either indigenous or introduced from Asia. The Romans and doubtless the Greeks were familiar with it, though some forms may have been described as cucumbers. Columella seems to refer to the serpent-melon in the phrase *ut coluber . . . ventre cubat flexo.* Pliny describes them as *pepones* (xix. 23 to xx. 6) and Columella as *melones* (xi. 2. 53); see Pickering, *Chron. Hist., of Pl.*, 229. The melon began to be extensively cultivated in France in 1629, according to Olivier de Serres. Gerard (*Herball*, 771) figured and described in 1597 several kinds of melons or pompions, but he has apparently included gourds under the same name. Pickering observes that the melon was carried by Columbus to America, and by the Portuguese to the Malayan Archipelago.

The origin of some of the chief modern races, such as "Cantaloups," "Dudaim," and probably the netted sorts, is due to Persia and the neighbouring Caucasian regions. The first of these was brought to Rome from Armenia in the 16th century, and supplies the chief sorts grown for the French markets; but many others are doubtless artificial productions of West Europe.

For cultivation of the melon, see art. HORTICULTURE, and also *Gard. Chron.*, May 6, 1882, p. 596; and for references to French literature on the same see Naudin, *ut supra*, p. 82.

MELOS (Att. Gr., Μῆλος), the modern Milo, one of the Sporades of the Ægean Sea, situated at the south-west corner of the archipelago, in 36° 45′ N. lat. and 24° 26′ E. long., 75 miles due east from the coast of Laconia. From east to west it measures about 14 miles, from north to south 8 miles, and its area is estimated at 52 square miles. The greater portion is rugged and hilly, and the culminating point, Mount Elias in the west, reaches a height of 2538 feet. Like the rest of the cluster to which it belongs, the island as a whole is of volcanic origin, with tuff, trachyte, and obsidian among its ordinary rocks. The great natural harbour, which, with a depth diminishing from 70 to 30 fathoms, strikes in from the north-west so as to cut the island into two fairly equal portions, with an isthmus not more than 1¼ miles broad, is evidently the hollow of the principal crater. In one of the caves on the south coast the heat is still so great that one cannot remain within more than a few minutes, and on the eastern shore of the harbour there is a remarkable cluster of hot sulphurous springs. Sulphur is found in abundance on the top of Mount Kalamo and elsewhere. In ancient times the alum of Milo was reckoned next to that of Egypt (Pliny, xxxv. 15 [52]), and millstones, salt (from a marsh at the east end of the harbour), and gypsum are still exported. The Melian earth (γῆ Μηλιάς), employed as a pigment by ancient artists, was probably native white-lead. Orange, olive, cypress, and arbutus trees grow throughout the island, which, however, is too dry to have any profusion of vegetation. The vine, the cotton plant, and barley are the main objects of cultivation. Including the neighbouring islands of Antimilos (4 square miles), Cimolos (16 square miles), and Polinos (5½ square miles), the total population of Melos was only 5538 in 1879.

Antimilo, 5½ miles north-west of Milo, is a mere uninhabited mass of trachyte, and is often called Eriomilo or Desert Melos. *Cimolos*, or *Argentiera*, less than 1 mile to the north-east, was famous in antiquity for its

[1] For generic characters see Benth. et Hook., *Gen. Pl.*, i. 826; and for a full account of the species of *Cucumis* and of the tribes of melon, by M. Naudin, see *Ann. des Sci. Nat.*, 4 sér., tom. xi. p. 34.

[3] See also Naudin, in *Nouv. rech. sur l. hyb. dans les veg.*, p. 118, 1861.

figs and fuller's earth (Κιμωλία γῆ), and contained a considerable city, the remains of which still cover the cliff of St Andrews. *Polinos*, *Polybos* or *Polivo*, and *Kaimeni*, or "Burned Island," the *Île Brulée* or *Isola Bruciata* of the French and Italians, lies rather more than a mile south-east of Cimolos. It was in antiquity the subject of dispute between the Melians and Cimolians. It has long been almost uninhabited.

In ancient times the city of Melos, built terrace-fashion round a hill in the north-east of the main island, was a place of considerable size; "the western wall, of Cyclopean masonry, is traceable all the way down from the summit to the sea," and among the ruins are a temple in the Corinthian style and a beautiful little theatre cleared in 1836 by order of the king of Bavaria. Painted vases (the ancient Melians were great makers of this kind of ware), bronzes, gold ornaments, and similar specimens of art workmanship have been recovered from the debris; and in 1820 the "Venus of Milo," now in the Louvre, the noblest extant representation of Aphrodite, was found in the neighbourhood of the theatre. The top of the hill is now occupied by Castro, the principal village in the island. At some distance to the south-east, at the place called Tripiti (*i.e.*, τρυπητή, "the perforated"), lies a remarkable cluster of catacombs containing frescos, &c., of evidently Christian origin. Palæa Chora, about 5 miles farther south-east, is now an almost deserted village, but down to the beginning of the last century it had about 5000 inhabitants, and it continued for a time to be considered the capital of the island.

The first occupants of Melos were probably Phœnicians, but the island was Hellenized at an early date by Minyans and Dorians from Laconia. Though its inhabitants sent a contingent to the Greek fleet at Salamis, they held aloof from the Attic league, and sought to remain neutral during the Peloponnesian War. But in 416 B.C. the Athenians, having attacked the island and compelled the Melians to surrender at discretion, slew all the men capable of bearing arms, made slaves of the women and children, and introduced a body of five hundred Athenian colonists. Lysander restored the island to its old Dorian possessors, but it never recovered its former prosperity. There were many Jewish settlers in Melos in the beginning of the Christian era, and Christianity was early introduced. During the "Frankish" period the island formed part of the duchy of Naxos, except for the few years (1341–83) when it was a separate lordship under Marco Sanudo and his daughter.

See Leycester, "The Volcanic Group of Milo, Anti-Milo, &c.," in *Jour. Roy. Geog. Soc.*, 1852; Tournefort, *Voyage*; Leake, *Northern Greece*, vol. iii.; Prokesch von Osten, *Denkwürdigkeiten, &c.*; and Burslan, *Geog. von Griechenland*, vol. ii.

MELROSE, a village of Roxburghshire, Scotland, on the south bank of the Tweed, 37 miles by rail south-south-east of Edinburgh. Its population has steadily advanced from 966 in 1851 to 1550 in 1881. Though a burgh of barony since 1609, it is a purely agricultural village, and would be of little interest but for the ruins of its abbey, now the property of the duke of Buccleuch. It was formerly called Little Fordell, and its present name even dates from the foundation of the monastery by David II. in 1136.

There had been a Columbite monastery of Melrose at the place now known as Old Melrose, about a mile and a half to the east of the village, but this establishment, probably never of much architectural magnificence, had, according to the *Chronicle of the Picts and Scots*, been destroyed by Kenneth M'Alpin in 839, and may never have recovered from the disaster. King David's abbey, which he entrusted to a body of Cistercian monks from Rievaulx (Riuall) in Yorkshire, was dedicated on Sunday 28th July 1146; it was laid in ruins by Edward II. of England in 1322; Bruce caused the work of restoration to be vigorously prosecuted, but the edifice was again burned by Richard II. in 1385. The abbey church as it now stands consequently belongs in the main to the latter half of the 14th century and the first half of the 15th, with a good many portions of a considerably later date.

Architecturally the abbey may be described as a splendid example of the Middle Pointed style, strongly affected on the one hand by Flamboyant and Perpendicular tendencies, and on the other by the individuality of some of the builders. Cruciform in plan, it measured 214½ feet from east to west, the width of the nave being 69 feet, and across the transepts 115¼. The noble edifice was damaged by the English in 1545; and since the Reformation it has been altered to suit the necessities of Presbyterian worship (1618–1810), and plundered by builders to supply ornaments for houses. The whole building is now in ruins. The west end and a good part of the north side have disappeared; but the elevation of the south side is nearly entire, both the transepts and the east end are externally in very fair preservation, part of the central tower is standing, and the sculptured roof still covers the east end of the chancel. Of the individual features of the building, the great eastern window has been generally most admired since Sir Walter Scott celebrated the moonlit aspect of its "slender shafts of shapely stone." It has five lights; the height is 37 feet and the width 16; and the upper portion is filled in with delicate tracery of a geometrical design. Very beautiful too is the whole gable of the south transept. In the interior, on the north side of the nave, there still stand four of the original square piers, and one of them shows a Norman "cap." The choir, the west end of which is shut off by a massive rood-screen, has been largely "spoiled by rough 17th century work"; but enough remains of the decorative detail to provoke the admiration and despair of the modern artist in stone. The facile and at the same time elaborate rendering of vegetable forms, such as the Scotch "kail," is particularly striking. It was in the abbey-church of Melrose, where Alexander II. had long before been buried near the high altar, that the heart of Bruce found its final resting-place; and among the many tombs which afterwards gathered under the same roof were those of his faithful knight James Lord Douglas, Sir William the dark knight of Liddesdale, and the hero of Chevy Chase.

The ancient muniments of the abbacy have been preserved in the archives of the earl of Morton; they were published by the Bannatyne Club (2 vols., 1837, *Liber Sancte Marie de Melros*), under the editorship of Cosmo Innes. Among the many interesting documents is one of the very earliest specimens of the Scotch tongue. The *Chronica de Mailros*, preserved among the Cotton MSS., has been twice printed,—at Oxford (1684) by Fulman, and by the Bannatyne Club (1835), edited by John Stevenson. From about 1140 till its close in 1265 the chronicle may be considered original; it was put largely under contribution by later compilers.

Bower, *Description of the Abbeys of Melrose and Old Melrose*, Kelso, 1813; J. A. Wade, *History of St Mary's Abbey, Melrose*, Edinburgh, 1861; Fred. Pinches, *The Abbey Church of Melrose* (a series of architectural drawings), London, 1879.

MELTON MOWBRAY, a market-town of England, county of Leicester, is pleasantly situated in a fertile vale, at the confluence of the Wreake and Eye, 15 miles north-east of Leicester and 104 north of London by rail. The Eye is spanned by a bridge of four arches. The town consists principally of two main streets, and is substantially built of brick. The church of St Mary, a handsome cruciform structure partly in the Early English style, and adorned by a lofty and richly ornamented tower, was heightened and otherwise enlarged in the reign of Elizabeth, and has also undergone modern improvements. There are largely endowed almshouses and several other charities. Melton is the seat of a celebrated hunting district, in connexion with which there are stables in the town capable of accommodating about eight hundred horses. It is also well known for its pork pies, and has a very large trade in Stilton cheese. There are breweries and tanneries, as well as an important cattle market. Ironworks have lately been erected. The town possesses great railway facilities. The population of the urban sanitary district in 1871 was 5033, and in 1881 it was 5766.

The old name of Melton was Medeltone, and the place is of considerable antiquity. During the Civil War it was in February 1644 the scene of the defeat, with great slaughter, of the parliamentary forces by the royalists. It is the birthplace of John Henley the orator.

MELUN, capital of the department of Seine-et-Marne, France, 28 miles south-east of Paris by railway, occupies a hill on the right bank of the Seine and the level ground at its foot. It owes its rank as "chef-lieu" to its central position merely; for there are two other towns in the department, Meaux and Fontainebleau, which have a larger population. Melun is near one of the most beautiful parts of the forest of Fontainebleau. Among the rich estates in its neighbourhood the most remarkable is the magnificent chateau of Vaux-Praslin, which belonged to Fouquet, superintendant of finances under Louis XIV. The church of Notre Dame formerly belonged to a nunnery, now occupied by a central house of detention for twelve hundred prisoners. On the apse of the church of St Aspais may be seen a modern medallion in bronze, the work of the sculptor Chapu, representing Joan of Arc as the liberator of Melun. The population in 1881 was 12,145.

Melun is a very ancient town, and has played an important part in history. As early as the time of Cæsar's Gallic wars it was taken possession of by his lieutenant Labienus, in order to attack Lutetia with greater ease by the right bank of the Seine. It was pillaged by the Normans, and afterwards became the favourite residence of the first kings of the race of Capet; Robert and Philip I. both died there. During the Hundred Years' War Melun was given up by Jeanne of Navarre to her brother, Charles the Bad, but was retaken by the dauphin Charles and Duguesclin. In 1420 it made an heroic defence against Henry V. of England and his ally the duke of Burgundy. Ten years later the people of Melun, with the help of Joan of Arc, drove out the English. It was occupied by the League in 1589, and retaken by Henry IV. in the following year. Jacques Amyot was born there in 1504.

MELVILLE, Henry Dundas, Viscount (1741–1811), younger son of the Right Honourable Robert Dundas, lord president of the Scottish court of session, was born at Edinburgh in 1741, and was educated at the high school and university there. Becoming member of the faculty of advocates in 1763, he soon acquired a leading position at the bar. After his appointment as lord advocate in 1775, he gradually relinquished his legal practice to devote his attention more exclusively to public business. On entering parliament in 1774, he had joined the party of Lord North, and, notwithstanding his provincial dialect and ungraceful manner, he soon distinguished himself in the debates by his clear and argumentative speeches. After holding subordinate offices under the marquis of Lansdowne and Pitt, he in 1791 entered the cabinet as home secretary. From 1794 to 1801 he was secretary at war under Pitt, who conceived for him a special friendship. In 1802 he was elevated to the peerage as Viscount Melville and Baron Dunira. Under Pitt in 1804 he again entered office as first lord of the admiralty, when he introduced numerous improvements in the details of the department. His impeachment in 1806, for the appropriation of balances of public money remaining in his hands, resulted in his acquittal, but he never again held office. He died May 27, 1811.

MELVILLE, Andrew (1545–1622), a distinguished Scottish scholar, theologian, and religious reformer, was the youngest son of Richard Melville, proprietor of Baldovy, near Montrose, at which place Andrew was born in 1545. His father fell at the battle of Pinkie, fighting in the van of the Scottish army, two years after the birth of his son; and, his wife having soon after followed him to the grave, the young orphan, then a gentle and delicate child, was tenderly cared for by his eldest brother Richard and his amiable and pious wife, whose memory the great scholar ever afterwards cherished with the warmest gratitude and affection. At a very early age Melville began to show a strong taste for learning, and his brother did every thing in his power to give him the best education the country could then afford. The rudiments of Latin he obtained at the grammar school of Montrose, after leaving which he prosecuted the study of Greek for two years under Pierre de Marsilliers, a Frenchman whom John Erskine of Dun had induced to settle at Montrose; and such was the proficiency Melville made that on going to the university of St Andrews he excited the astonishment of both students and professors by using the Greek text of Aristotle, which no one else there understood, the Latin translation being that which was alone employed in the teaching of logic. On completing his course of study, Melville left St Andrews with the character of "the best poet, philosopher, and Grecian of any young master in the land." He then, in 1564, being nineteen years of age, set out for France to perfect his education at the university of Paris. He there applied himself especially to the study of the Oriental languages, but he had also the advantage of attending the last course of lectures delivered by Turnebus in the Greek chair, as well as those of the celebrated Ramus, whose mode of philosophizing and plan of teaching he afterwards introduced into the universities of Scotland. From Paris he proceeded to Poitiers for the purpose of studying civil law, and though only twenty-one years of age he was apparently at once made a regent in the college of St Marceon. After a residence of three years, however, the political troubles of the country compelled him to leave France, and he then went on to Geneva, where he was warmly welcomed by Theodore Beza, at whose instigation he was appointed to fill the chair of humanity in the academy of Geneva, which then happened to be vacant. In addition to his teaching, however, he also applied himself to the further prosecution of his studies in Oriental literature, and in particular acquired from Cornelius Bertram, one of his brother professors, a knowledge of Syriac. While he resided at Geneva the massacre of St Bartholomew in 1572 drove an immense number of Protestant refugees to that city, including several of the most distinguished French men of letters of the time, with whom Melville had now the opportunity of intimate intercourse. Among these were several men deeply learned in civil law and political science, and their society no doubt tended greatly both to increase Melville's knowledge of the world and to enlarge his ideas of civil and ecclesiastical liberty—acquisitions which he must have found of essential service when at a later period as a leader of the General Assembly he had to struggle against the attempts of James VI. to crush the liberties of the church of the Scottish Reformation. In 1574 Melville returned to Scotland, and almost immediately afterwards received the appointment of principal of Glasgow University, which at the time had fallen into an almost ruinous state, the college having in fact been shut up and the students dispersed. Melville, however, with the knowledge of academic methods of training which he had obtained abroad, immediately set himself with immense energy to establish a good educational system, and in a short time his fame spread through the kingdom, and students flocked in from all quarters, till the class-rooms lately empty could not contain those who came for admission. After labouring for six years in Glasgow, and having brought the seminary into a state of the most thorough efficiency, it was thought desirable that he should undertake the same duties at St Andrews. He accordingly proceeded there in 1580, and was installed as principal of the new theological college. His duties there comprehended the teaching, not only of theology, but of the Hebrew, Chaldee, Syriac, and Rabbinical languages, and the great ability of his lectures was universally acknowledged, and excited quite a new interest in the university. The sweeping reforms, however, which his new modes of teaching necessarily involved, and even some of the new doctrines which he began to introduce, such as the non-infallibility of Aristotle, soon brought him into collision with some of the other teachers in the university; and this, along with the troubles which arose from the attempts of the court to force a bastard system of Episcopacy upon the Church of Scotland, forced him to flee into England in order to escape the consequences of an absurd charge of treason which was made against him, and which seemed to threaten a prolonged imprisonment and not improbably even his life. After an absence of twenty months he returned to Scotland in November 1585, and in March 1586 resumed his lectures in St Andrews, where he continued to fulfil the duties of his office for twenty more years. During the whole of that time, however, his more prominent work was that of contending with unwearied energy and indomitable courage against the encroachments of an unscrupulous and tyrannical Government upon the liberties of the Scottish Church. Into the details of these it is of course impossible to enter here. But that in the main he and his coadjutors were fighting for the constitutionally guaranteed rights of the church is now admitted by all candid inquirers. (See in particular *The History of England from* 1603 *to* 1616, by Samuel Rawson Gardiner, vol. i. chap. ix.). The chief charge against Melville is that his fervour often led him to forget the reverence due to an "anointed monarch." Of this, however, it is not very easy now to judge. Manners at that time were rougher than at present. Any thing more rude, insolent, and brutal than James's own occasional explosions it would be difficult to match, and a king so undignified could scarcely expect to be treated with dignity. Besides, what title had one who was acting in a purely arbitrary and illegal manner to receive other than the plainest dealing,—such as being reminded that though he was king over men he was only "God's silly vassal?" Melville's rudeness (if it is to be called so) was simply the outburst of just indignation from a brave, true, and upright man, zealous only for the purity of religion and regardless of consequences to himself, and it contrasts nobly with the grovelling sycophancy of most of the English bishops towards James. The close of Melville's career in Scotland was at length brought about by James in characteristic fashion. In 1606 he and seven other clergymen of the Church of Scotland were summoned to London in order "that his majesty might treat with them of such things as would tend to settle the peace of the church." The contention of the whole of these faithful men was that the only way to accomplish that purpose was a free Assembly. Melville delivered his opinion to that effect with his accustomed freedom and boldness, and, having shortly afterwards written a sarcastic Latin epigram on some of the superstitious practices he had observed in the chapel of Hampton Court, and some eavesdropper having conveyed the lines to the king, he was committed to the Tower, and detained there for the space of four years. On regaining his liberty, and being refused permission to return to his own country, he was invited to fill a professor's chair in the university of Sedan, and there he spent the last eleven years of his brave, active, noble, and useful life. He died at Sedan in 1622, at the age of seventy-seven.

MELVILLE, George John Whyte (1821–1878), has a right to be regarded as the founder of a school of fashionable novels,—the fashionable sporting novel. He was lamented on his death as the Tyrtæus of the hunting field, the laureate of fox-hunting; all his most popular and distinctive heroes and heroines, Digby Grand, Tilbury Nogo, the Honourable Crasher, Mr Sawyer, Kate Coventry, Mrs Lascelles, are or would be mighty hunters. The eldest son of Major Whyte Melville, of Mount Melville, Fifeshire, he received his school education, like so many of his heroes, at Eton, entered the army in 1839, became captain in the Coldstream Guards in 1846, and retired in 1849. His first appearance in literature was made soon after, with a translation of Horace into fluent and graceful verse, published in 1850. His first novel was *Digby Grand*, published in 1853. Although this first effort has a good deal more in it of Lytton's early high-flying style than Whyte Melville's later works, the unflagging verve and intimate knowledge with which he described sporting scenes and sporting characters at once drew attention to him as a novelist with a new vein. His power of sustaining interest in hunting and the things connected with hunting appeared more markedly in his next novel, *Tilbury Nogo*, contributed to the *Sporting Magazine* in 1853. He showed in the adventures of Mr Nogo, what became more apparent in his later works, that he had a surer hand in humorous narrative than in pathetic description; there are many pathetic scenes in his novels, but the pathos is sometimes rather forced, intended to point a moral—rather the pathos of the preacher than the poet. The hero of *General Bounce*, his next novel in order of publication (*Fraser's Magazine*, 1854), little as one would expect it from the title, ends in a painful manner, somewhat out of keeping with the lively middle and beginning. When the Crimean War broke out, Whyte Melville took part in it as a volunteer in the Turkish contingent; but this was the only break in his literary career from the time that he began to write novels till his death in 1878. By a strange accident, he lost his life in the hunting-field, the hero of many a stiff ride meeting his fate in galloping quietly over an ordinary ploughed field.

Twenty-one novels appeared from his pen after his return from the Crimea:—*Kate Coventry*, 1856; *The Interpreter*, 1858; *Holmby House*, 1860; *Good for Nothing*, 1861; *Market Harborough*, 1861; *The Gladiators*, 1863; *Brookes of Bridlemere*, 1864; *The Queen's Maries*, 1864; *Cerise*, 1865; *Bones and I*, 1868; *The White Rose*, 1868; *M or N*, 1869; *Contraband*, 1870; *Sarchedon*, 1871; *Satanella*, 1872; *Uncle John*, 1874; *Sister Louise*, 1875; *Katerfelto*, 1875; *Rosine*, 1876; *Roy's Wife*, 1878; *Black but Comely*, 1878. Several of these novels are historical, the *Gladiators* being perhaps the most famous of them. As an historical novelist Whyte Melville cannot be put on a level with Harrison Ainsworth for painstaking accuracy and minuteness of detail; he makes his characters live and move with great vividness, but he obviously did not know at first hand the history of the periods chosen by him. It is on his portraiture of contemporary sporting society that his reputation as a novelist must rest; and, though now and then a character reappears, such as the supercilious stud-groom, the dark and wary steeple-chaser, or the fascinating sporting widow, his variety in the invention of incidents is amazing. Whyte Melville was not merely the annalist of sporting society for his generation, but may also be fairly described as the principal moralist of that society; he exerted a considerable and a wholesome influence on the manners and morals of the gilded youth of his time. His *Songs and Verses* and his metrical *Legend of the True Cross*, though respectable in point of versification, are hardly worth mentioning on their own merits.

MELVILL VAN CARNBEE, Pieter, Baron, an eminent Dutch geographer, was born at the Hague 20th May 1816, and died October 24, 1856. He traced his descent from an old Scotch family, originally it is said of Hungarian extraction. Destined for the navy, in which his grandfather had won distinction, Melvill imbibed a taste for hydrography and cartography as a student under Pilaar in the college of Medemblik, and he showed his capacity as a surveyor on his very first voyage to the Dutch Indies (1835). In 1839 he was again in the East, and was now attached to the hydrographical bureau at Batavia. With the assistance of the long-neglected documents collected by the old company, he completed in wonderfully short time his first great hydrographical work—a map of Java in five sheets, accompanied by sailing directions (Amsterdam, 1842; 2d revised edition, 1849),—which was received with great applause. Melvill remained in India till 1845 collecting materials for his second great hydrographical work, the chart of the waters between Sumatra and Borneo (two sheets, 1845 and 1846, revised edition of first sheet 1847; compare the descriptive memoir in Tindal and

Swart's *Journal*, 1846). On his return to Holland Melvill was attached to the naval department with the special charge of studying the history of the hydrography of the Dutch Indies. He also undertook, in connexion with Von Siebold, the publication of the *Moniteur des Indes*, a valuable series of scientific papers, mainly from his own pen, on the foreign possessions of Holland, which was continued for three years. In 1850 Melvill returned to India as lieutenant of the first class and adjutant to Vice-Admiral Van den Bosch; and after the premature death of this commander he was again appointed keeper of the charts at Batavia. He was one of the founders and for a time the president of the new society for natural science (1850). In 1853 he obtained exemption from active naval service that he might devote himself to a general atlas of the Dutch Indies; and under the most unfavourable circumstances he prosecuted the task with incredible energy. But he was not to see its completion. Just after he had lost his young wife and new-born son he was called in 1856 to be director of the marine establishment of Onrust; and there he soon fell a victim to climate, dying after much suffering in the hospital of Weltevreden, only forty years of age. In spite of delays caused by the engraving of the maps in Holland, no fewer than twenty-five sheets were already finished, but it was not till 1862 that the whole plan, embracing sixty sheets, was ably brought to a close by Lieutenant-Colonel W. F. Versteeg. The premature loss of Melvill was severely felt not only in Holland but in foreign countries, where, as shown by his connexion with the geographical societies of Paris, London, Berlin, and Bergen, his labours were highly esteemed. His industry and energy were equalled only by the benevolence and warmth of his heart. In 1843 he received the decoration of the Netherlands Lion, in 1849 that of the Legion of Honour.

MEMEL, the most northerly town in Germany, and the principal seat of the Baltic timber trade, is situated in the district of Königsberg, Prussia, at the mouth of the Dange, and on the bank of a sound connecting the Kurische Haff with the Baltic Sea. On the side next the sea the town is defended by a citadel and other fortifications, and the entrance to the large and fine harbour is protected by a lighthouse. Largely rebuilt since a destructive fire in 1854, Memel contains several churches, a gymnasium, a school of navigation, an exchange, and various judicial and official establishments. It also possesses large iron-foundries, shipbuilding yards, breweries, distilleries, and manufactories of chemicals, soap, and amber wares. By far the most important interest of the town, however, is its trade, the chief items in which are timber and the grain and other agricultural products of Lithuania. The timber is brought by river from the forests of Russia, and is prepared for exportation by about thirty saw-mills. The annual value of timber exported is about £600,000. In 1880 the port of Memel was entered by 898 ships with an aggregate burden of 164,374 tons, and cleared by 932 vessels with a burden of 164,441 tons. The population of Memel in 1880 was 19,660.

Memel was founded in 1252 by Poppo von Osterna, grand master of the Teutonic order, and was at first called New Dortmund and afterwards Memmelburg. It soon acquired a considerable trade, and joined the Hanseatic League. During the 13th, 14th, and 15th centuries it was repeatedly burned down by its hostile neighbours, the Lithuanians and Poles, and in the 17th century it remained for some time in the possession of Sweden. In 1757, and again in 1813, it was occupied by Russian troops. After the battle of Jena, King Frederick William III. retired to Memel; and there, in 1807, a treaty was concluded between England and Prussia. The poet Simon Dach and the astronomer Argelander were natives of Memel.

MEMLING, Hans, a painter of the 15th century, whose art gave a passing lustre to Bruges in the period of its political and commercial decline. Though much has been written respecting the rise and fall of the school which made this city famous, it still remains a moot question whether that school ever truly existed. Like Rome or Naples, Bruges absorbed the talents which were formed and developed in humbler centres. John Van Eyck first gained repute at Ghent and the Hague before he acquired a domicile elsewhere, and Memling, we have reason to think, was a skilled artist before he settled at Bruges. Yet if the question should be asked where the manner of Memling was shaped, and where he acquired the skill which he displayed at Bruges, we shall be greatly at a loss to reply. The annals of the city are silent as to the birth and education of a painter whose name was inaccurately spelt by different authors, and whose identity was lost under the various appellations of Hans and Hausse, or Hemling and Memling. But no other city of the Netherlands has vindicated the right which Bruges had no means of proving. Travellers who came to Bruges were only told that Memling's masterpieces were preserved in the hospital of St John. In one of these pictures it was said a portrait of the artist might be discovered; on the sculptured ornaments of a porch enframing one of its subjects an incident of the master's life might be traced,—his danger as he lay senseless in the street, his rescue as charitable people carried his body to the hospital. The legend grew too. It came to be told how the great artist began life as a soldier who went to the wars under Charles the Bold, and came back riddled with wounds from the field of Nancy. Wandering homeward in a disabled state in 1477, he fainted in the streets of Bruges, and was cured by the Hospitallers. Unknown to them, and a stranger to Bruges, he gave tangible proofs of his skill to the brethren of St John, and showed his gratitude by refusing payment for a picture he had painted. Unhappily the legend refutes itself. The portrait of Memling is a myth; the carvings of the capitals of the porch represent the ordinary incidents attending the reception of patients at an hospital. Memling did indeed paint for the Hospitallers, but he painted not one but many pictures, and he did so in 1479 and 1480, being probably known to his patrons of St John by many masterpieces even before the battle of Nancy.

Memling is only connected with military operations in a mediate and distant sense. His name appears on a list of subscribers to the loan which was raised by Maximilian of Austria to push hostilities against France in the year 1480. When he signed this list his position was that of a resident at Bruges who had probably lived there long enough to acquire a large practice and its advantages in the form of lands and tenements. In 1477, when he is said to have fallen, and when Charles the Bold was killed, he was under contract to furnish an altarpiece for the guild chapel of the booksellers of Bruges; and this altarpiece, now preserved, under the name of the Seven Griefs of Mary, in the gallery of Turin, is one of the fine creations of his riper age, and not inferior in any way to those of 1479 in the hospital of St John, which for their part are hardly less interesting as illustrative of the master's power than the Last Judgment in the cathedral of Dantzic. Critical opinion has been unanimous in assigning the altarpiece of Dantzic to Memling, and by this it affirms that Memling was a resident and a skilled artist at Bruges in 1473; for there is no doubt that the Last Judgment was painted and sold to a merchant at Bruges, who shipped it there on board of a vessel bound to the Mediterranean, which was captured by a Dantzic privateer in that very year. But, in order that Memling's repute should be so fair as to make his pictures purchasable, as this had been, by an agent of the Medici at Bruges, it is incumbent on us to acknowledge that he had furnished sufficient proofs before that time of the skill which excited the wonder of such highly cultivated patrons; and thus we come to admit without much difficulty the possible truth of a report made by a chronicler of the 16th century that Memling had sittings from Isabella, consort of Philip the Good of Burgundy, in the year 1450.

It is characteristic that the very oldest allusions to pictures connected with Memling's name are those which point to relations with the Burgundian court. The inventories of Margaret of Austria, drawn up in 1524, allude to a triptych of the God of Pity by Roger van der Weyden, of which the wings containing angels were by "Master Hans." But this entry is less important as affording testimony in favour of the preservation of Memling's work than as showing his connexion with an older Flemish craftsman. For ages Roger van der Weyden was acknowledged as an artist of the school of Bruges, until records of undisputed authenticity demonstrated that he was bred at Tournai and settled at Brussels. Nothing seems more natural than the conjunction of his name with that of Memling as the author of an altarpiece, since, though Memling's youth remains obscure, it is clear from the style of his manhood that he was taught in the painting-room of Van der Weyden. Nor is it beyond the limits of probability that it was Van der Weyden who received commissions at a distance from Brussels, and first took his pupil to Bruges, where he afterwards dwelt. The clearest evidence of the connexion of the two masters is that afforded by pictures, and particularly an altarpiece, which has alternately been assigned to each of them, and which may possibly be due to the joint labours of both. In this altarpiece, which is a triptych ordered for a patron of the house of Sforza, we find the style of Van der Weyden in the central panel of the Crucifixion, and that of Memling in the episodes on the wings. Yet the whole piece was assigned to the former in the Zambeccari collection at Bologna, whilst it was attributed to the latter at the Middleton sale in London in 1872. At first, we may think, a closer resemblance might be traced between the two artists than that disclosed in later works of Memling, but the delicate organization of the younger painter, perhaps also a milder appreciation of the duties of a Christian artist, may have led Memling to realize a sweet and perfect ideal, without losing, on that account, the feeling of his master. He certainly exchanged the asceticism of Van der Weyden for a sentiment of less energetic concentration. He softened his teacher's asperities and bitter hardness of expression.

In the very oldest form in which Memling's style is displayed, or rather in that example which represents the Baptist in the gallery of Munich, we are supposed to contemplate an effort of the year 1470. The finish of this piece is scarcely surpassed, though the subject is more important, by that of the Last Judgment of Dantzic. But the latter is more interesting than the former because it tells how Memling, long after Roger's death and his own settlement at Bruges, preserved the traditions of sacred art which had been applied in the first part of the century by Roger van der Weyden to the Last Judgment of Beaune. All that Memling did was to purge his master's manner of excessive stringency, and add to his other qualities a velvet softness of pigment, a delicate transparence of colours and yielding grace of slender forms. That such a beautiful work as the Last Judgment of Dantzic should have been bought for the Italian market is not surprising when we recollect that picture-fanciers in that country were familiar with the beauties of Memling's compositions as shown in the preference given to them by such purchasers as Cardinal Grimari and Cardinal Bembo at Venice, and the heads of the house of Medici at Florence. But Memling's reputation was not confined to Italy or Flanders. The Madonna and Saints which so lately passed out of the Duchatel collection into the gallery of the Louvre, the Virgin and Child of Sir John Donne at Chiswick, and other noble specimens in English and Continental private houses show that his work was as widely known and appreciated as it could be in the state of civilization of the 16th century. It was perhaps not their sole attraction that they gave the most tender and delicate possible impersonations of the "Mother of Christ" that could suit the taste of that age in any European country. But the portraits of the donors with which they were mostly combined were more characteristic, and probably more remarkable as likenesses than any that Memling's contemporaries could produce. Nor is it unreasonable to think that his success as a portrait painter, which is manifested in isolated busts as well as in altarpieces, was of a kind to react with effect on the Venetian school, which undoubtedly was affected by the partiality of Antonello da Messina for trans-Alpine types studied in Flanders in Memling's time. The portraits of Sir John Donne and his wife and children in the Chiswick altarpiece are not less remarkable as models of drawing and finish than as refined presentations of persons of distinction; nor is any difference in this respect to be found in the splendid groups of father, mother, and children which fill the noble altarpiece of the Louvre. As single portraits, the busts of Burgomaster Morcel and his wife in the museum of Brussels, and their daughter the Sibyl Zambetha in the hospital of Bruges, are the finest and most interesting of specimens. The Seven Griefs of Mary in the gallery of Turin, to which we may add the Seven Joys of Mary in the Pinakothek of Munich, are illustrations of the habit which clung to the art of Flanders, of representing a cycle of subjects on the different planes of a single picture, where a wide expanse of ground is covered with incidents from the Passion in the form common to the action of sacred plays. The time came, no doubt, when the players took their cue from the painters, as in the Ghent procession, which was formed on the model of Van Eyck's Adoration of the Lamb. But in Memling's days there were still some original "players," and the public was not averse to seeing illustrations of their work. In the first period of the development of Belgian art too, when the Flemings assigned more importance to carved work than to painting, and yet refused to accept sculpture without colour, it was natural that the sculptor should multiply incidents on bas-reliefs which were coated with tinting in the semblance of nature. Memling's pictures imitate reliefs so far as they abound in variety of episodes, and are marked by absence of contrast in light and shade or want of toning by gradations of atmosphere. Yet with all these peculiarities his works are very pleasant to the eye, because they are always graceful and quiet.

The masterpiece of Memling's later years, a shrine containing relics of St Ursula in the hospital of Bruges, is fairly supposed to have been ordered and finished in 1480 after the painter had become acquainted with the scenery of the Rhine. This shrine is one of the most interesting monuments of mediæval art in Flanders, not only because it is beautifully executed, but because it reveals some part of the life of the painter who produced it, and illustrates the picturesque legend of Ursula and her comrades. The delicacy of finish in its miniature figures, the variety of its landscapes and costume, the marvellous patience with which its details are given, are all matters of enjoyment to the spectator. There is later work of the master in the St Christopher and Saints of 1484 in the academy, or the Newenhoven Madonna in the hospital of Bruges, or a large Crucifixion with scenes from the Passion, of 1491, in the cathedral of Lübeck. But as we near the close of Memling's career we observe that his practice has become larger than he can compass alone; and, as usual in such cases, the labour of disciples is substituted for his own. The registers of the painters' corporation at Bruges give the names of two apprentices who served their time with Memling and paid dues on admission to the guild in 1480 and 1486. These subordinates remained obscure.

It would be easy to form a long list of pictures by Memling in the galleries of Berlin, Florence, London, Madrid, Paris, Rome, and Vienna, and pieces equally remarkable in many private collections of England and the Continent. These have all been described, and are widely known. The present notice must be closed with the admission that pictures tell more of Memling's life than records. The date of the master's death is not better certified than that of his birth. This much, however, is certain. The trustees of Memling's will appeared before the court of wards at Bruges on the 10th of December 1495, and we gather from records of that date and place that Memling died a short time before, leaving behind several children and a considerable property. (J. A. C.)

MEMMI. See MARTINI, SIMONE.

MEMMINGEN, a town of Bavaria, in the district of Schwaben and Neuburg, is situated about 35 miles to the south-west of Augsburg, near the river Iller. It is a well-built town, still partly surrounded with walls, and contains a Roman Catholic and three Protestant churches, a town-house of 1580, and several schools and charitable institutions. Its industrial products are yarn, calico, woollen goods, and thread. A considerable trade is carried on in hops, which are extensively cultivated in the neighbourhood, and in wool, leather, and grain. The population in 1880 was 8050.

Memmingen, first mentioned in a document of 1010, belonged originally to the Guelph family. In 1286 it became a free city of the empire, a position which it maintained down to 1802, when it was allotted to Bavaria. In 1529 Memmingen was one of the "protesting" towns represented at the diet of Spires. During the Thirty Years' War it was alternately occupied by Swedes and Imperialists. In 1800 the French under Moreau gained a victory over the Austrians near Memmingen. Compare Dobel, *Memmingen im Reformationszeitalter*, 1877–78.

MEMNON. In the Homeric mythology (or rather the mythology of the *Troica* in the much fuller form in which it existed in the times of Pindar and the tragic poets) this hero was called the son of Tithonus (the half-brother of Priam) and Eos (Aurora). Tradition represented him as an Ethiopian prince who came to assist the Trojans against the Greeks, and performed prodigies of valour, but was at length killed by Achilles, after having himself slain Antilochus, the son of Nestor, an event alluded to in Pindar, *Pyth.*, vi. 32–39. His story must have been very famous, for more than one Greek play was composed bearing the title.

The chief source from which our knowledge about Memnon as a chief is derived is the second book of the *Post-Homerica*, by Quintus Smyrnæus, where his exploits and death are described at length. That Memnon was slain by Achilles is more than once affirmed by Pindar (*Nem.*, vi. 52; *Isthm.*, iv. 41, vii. 54). He is mentioned also in the *Odyssey* (xi. 522), with especial praise for personal beauty; but the allusion to him is quite casual, and is one of many proofs that the compilation of that and the sister epic presupposes in the reader or hearer a full knowledge of the whole tale of Troy. Modern philology associates Memnon—like Achilles, whom he so closely resembles in many particulars, and like Sarpedon, who seems the representative of Memnon in the Iliad—with solar phenomena. He was the son of the dawn, and, though he might vanish from sight for a time, he could not be destroyed, and therefore it was said that Zeus, moved by the tears of his mother, granted him immortality. In this respect, as also in wearing bright armour made by Hephæstus, he is the counterpart of Achilles, who symbolizes the mid-day sun in his glory; and that Memnon is said to have come from the far east, *i.e.*, from the region of sunrise, is in itself significant. Ovid, in a beautiful elegy on the death of Tibullus, *Amor.*, lib. iii. 9, 3, thus associates the fates of Memnon and Achilles:—

Memnona si mater, mater ploravit Achillem,
Et tangunt magnas tristia fata deas,
Flebilis indignos, Elegeia, solve capillos;
Ah nimis ex vero nunc tibi nomen erit.

Like the body of the dead hero Sarpedon (*Il.*, xvi. 681), so that of Memnon was borne through the air, a legend represented on Greek vases of a rather early date. This appears to mean that the sun, the offspring of the dawn, careers through the sky to the place of his departure in the west. Another account represents Zeus as having sent forth birds from the funeral-pile of Memnon, which straightway fought with each other, and many fell back as victims to the soul of the hero.

The mere fact that a *Memnonium*, or temple in honour of the hero, was erected both at Susa and at Egyptian Thebes, both of which places were centres of sun-worship, is a strong confirmation of the probability, derived from his mythical pedigree, that he was really a sun-god. Sir G. W. Cox remarks,[1] "of Memnon's head the story was told that it retained the prophetic power of the living Helios or of Surya. The story is found in the myth of the Teutonic Wismir, and it might have been related of Kephalos, the head of the sun;" and again (p. 267), "Eos, the mother of Memnon, is so transparently the morning that her child must rise again as surely as the sun reappears to run his daily course across the heaven."

With respect to the meaning of the name, it may possibly be the same as Agamemnon, which has a prefix meaning *brave*.[2] It has been thought that Μέμνων and μνήμων, "mindful," are but forms of the same word, and that the prophetic power attributed to the head of the Egyptian Memnon, which was said to utter sounds at sunrise, is connected with this idea. It was said that the sound resembled the moaning noise or the sharp twang of a harp-string, and it may even be surmised that the syllables *mem-non* imitated the resonance. The Egyptian head is said to be a bust of King Amenophis;[3] but if the Greeks fancied it uttered the word *memnon*, they would have called it by that name. The tendency, however, to give a Greek shape and inflexion to words which sounded barbarous will sufficiently account for the misnaming of the statue.

Strabo, lib. xvii. p. 816, declares that he himself heard it in company with Ælius Gallus and several of his friends, and Pausanias (i. 42, 2) says "one would compare the sound most nearly to the broken chord of a harp or a lute." See also Juv., *Sat.*, xv. 5; Tac., *Ann.*, ii. 61.

Memnon, as an Ethiopian, was of course represented as a black; hence Virgil (*Æn.*, i. 493) speaks of "nigri Memnonis arma." The figure itself was cut out of black basalt, but that is a material not uncommon in Egypt. Speaking quite generally, it seems reasonable to conclude that the Memnon from Ethiopia (which the early Greeks placed in the far east rather than in the south) typifies the eastern sun summoned to oppose the enemies of darkness from the west.

MEMPHIS, the capital of the old Egyptian empire, founded by Menes, the first historical king; see vol. vii. pp. 731, 770. In the time of Strabo (xvii. p. 807) it was the second city of Egypt, inferior only to Alexandria, and with a mixed population like the latter. Memphis was still an important though declining place at the time of the Moslem conquest. Its final fall was due to the rise of the Arabic city of Fosṭáṭ on the right bank of the Nile almost opposite the northern end of the old capital; and its ruins, so far as they still lay above ground, gradually disappeared, being used as a quarry for the new city. The remains of "Menf" were still imposing late in the 12th century, when they were described by ʿAbd el-Laṭíf. In the Old Testament Memphis is mentioned under the names of Moph (Hos. ix. 6) and Noph (Isa. xix. 13; Jer. ii. 16; Ezek. xxx. 13, 16).

MEMPHIS, a city of the United States, and port of entry, capital of Shelby county, Tennessee, is situated on the east bank of the Mississippi river just below the mouth of Wolf river, in about 35° 8′ N. lat. and 90° 5′ W. long., 450 miles below St Louis and 826 miles above New Orleans. The bluff on which the city stands has an average elevation of 47½ feet above high-water mark, with a further fall of 36 feet to extreme low water. Memphis is methodically and tastefully planned, and is adorned with many elegant private residences and public buildings, conspicuous among the latter being the United States custom house, located upon the esplanade between Front Street and the river, and built of the best quality of marble, the product of Tennessee quarries. A small park in the centre of the city contains a bust of Andrew Jackson. The streets are mostly well-paved, and are supplied with water from the Wolf river by the Holly system. The bayou Gayoso, with several branches, intersects the city, and prior to 1880 received most of its drainage. Since that date over 40 miles of sewers and more than that length of subsoil drain-tiles have been constructed on the Waring system, providing the city with a superior system of drainage.

[3] Φαμένωφ, as the Thebans themselves said, according to Pausanias, cited below.

Memphis is the largest city of the State, and the most important commercial city on the Mississippi between St Louis and New Orleans. The largest sea-going vessels ascend the river to this point, and navigation is open at all seasons of the year. The city also possesses abundant facilities for transportation by railway in every direction. Memphis ranks as the largest interior cotton-market in the United States. The receipts for the season ending September 1, 1881, were 470,267 bales, with a value of $23,090,109. The aggregate receipts from the mercantile and manufacturing interests for the year ending September 1, 1882, amounted to about $60,000,000, of which the trade in groceries and western products contributed nearly $40,000,000; dry goods, clothing, boots and shoes, and general merchandise $15,000,000; and various home manufactures about $5,000,000. There are oil-mills and refineries, whose annual product of about 30,000 barrels of cotton-seed oil, together with oil-cake and re-ginned cotton, amounts to over $1,000,000. There are also numerous foundries, machine shops, flouring-mills, and manufactories of carriages, furniture, and tobacco.

The city contains, besides the usual religious, educational and commercial institutions, a public library of 9000 volumes, three daily and ten weekly newspapers, a chamber of commerce, and a cotton exchange.

Memphis was laid out as a village in 1820, and incorporated as a city in 1831. Its population at each census since has been as follows:—3360 in 1840, 8841 in 1850, 22,623 in 1860, 40,226 in 1870, and 33,592 in 1880. According to a census taken on October 1, 1882, the population within the city limits was 47,976 (29,130 white and 18,846 coloured).

During the civil war Memphis was early occupied by the Union forces (June 6, 1862) after a naval engagement in which Commodore Davis with a fleet of nine gunboats and rams defeated a similar Confederate fleet of eight vessels, and captured or destroyed all of them but one. The city was held by Federal troops to the close of the war, with the exception of a brief occupation, in August 1864, by General Forrest, who captured several hundred prisoners, but immediately withdrew. The decrease of population between 1870 and 1880 was due to the ravages of yellow fever in 1873, 1878, and 1879. The epidemic of 1873 resulted in over two thousand deaths. In 1878, according to the report of the Howard Relief Association, the number of those attacked with the fever was 15,000, and the number of deaths reached the total of 5150, of whom 4250 were whites and 900 coloured. At the return of the fever in 1879 better care and strict quarantine arrangements prevailed, but there were 1595 cases, with 497 deaths. During the epidemics of 1878 and 1879 fully two-thirds of the population fled from the city, many of whom died of the fever at other places, and a still larger number did not return. For three months during each year business was wholly suspended, and all ingress or egress except for the most necessary purposes was forbidden. The prostration of the business of the place left the city almost hopelessly bankrupt, and as a means of relief the legislature of the State in January 1879 repealed the city's charter, and, assuming exclusive control of its taxation and finances, constituted it simply a "taxing district," placing its government in the hands of a "legislative council." This anomalous proceeding has been declared constitutional by the supreme court of Tennessee. Under it Memphis is at least regaining its prosperity, and by thoroughly cleansing, repaving, and sewering its streets, and supervising the construction of buildings, is likely to become one of the healthiest cities on the Mississippi river.

Vol. XV.—(LOO–MEM).

PRINCIPAL CONTENTS.

MALDIVE ISLANDS. Col. Henry Yule, C.B.
MALTA. Miss L. Toulmin Smith.
MALTHUS. Thomas Kirkup, M.A.
MAMMALIA. W. H. Flower, LL.D., F.R.S., Professor of Comparative Anatomy, Royal College of Surgeons, London, and G. E. Dobson, M.A., M.B., Royal Victoria Hospital, Netley.
MAMMOTH CAVE. Rev. H. C. Hovey.
MANATEE. Prof. Flower.
MANCHESTER. W. E. A. Axon.
MANCHURIA. R. K. Douglas, Professor of Chinese, King's College, London.
MANDÆANS. Prof. K. Kessler, University of Marburg.
MANDEVILLE, BERNARD DE. Prof. Minto.
MANDEVILLE, JEHAN DE. E. B. Nicholson, M.A., Librarian, Bodleian Library, Oxford, and Col. Yule.
MANGANESE. Prof. Dittmar.
MANICHÆISM. Adolf Harnack, Professor of Church History, University of Giessen.
MANITOBA. Prof. George Bryce, Winnipeg.
MANOMETER. Prof. James Blyth.
MANSFIELD. Alexander Gibson, M.A., Advocate.
MANTEGNA. W. M. Rossetti, author of "Fine Art, chiefly Contemporary."
MANURE. A. Voelcker, F.R.S., Professor of Chemistry to the Royal Agricultural Society of England.
MANUTIUS. J. A. Symonds.
MAP. Sophus Ruge, Ph.D., author of "Geschichte des Zeitalters der Entdeckungen."
MARAT. H. Morse Stephens, Balliol College, Oxford.
MARBLE. F. W. Rudler, Curator of Museum of Practical Geology, London.
MARCANTONIO. Sidney Colvin, M.A., Slade Professor of Fine Art, University of Cambridge.
MARCION. Prof. Harnack.
MARINES. Captain C. C. King, Professor of Tactics, &c., Royal Military College, Sandhurst.
MARITIME PROVINCE. P. A. Kropotkine.
MARK. Rev. E. Hatch.
MARLBOROUGH. W. P. Courtney.
MARLOWE. Algernon C. Swinburne.
MARMOT. Oldfield Thomas, British Museum.
MAROT. George Saintsbury, M.A.
MARRIAGE. Edmund Robertson, M.A., Professor of Roman Law, University College, London.
MARSEILLES. Gaston Meissas.
MARTEN. Prof. Flower.
MARTIAL. Prof. Sellar.
MARTINEAU. Miss Clementina Black, author of "Orlando."
MARVELL. Osmund Airy, M.A.
MARY (the Virgin). Rev. J. Sutherland Black, M.A.
MARY (of England). James Gairdner, Public Record Office, London.
MARY (of Scotland). A. C. Swinburne.
MARYLAND. W. T. Brantly, Baltimore.
MASANIELLO. G. H. Bianchi, M.A., St Peter's College, Cambridge.
MASSACHUSETTS. Justin Winsor, Librarian, Harvard University, Cambridge, Mass.
MASSINGER. Prof. Minto.
MATCHES. James Paton, Curator of Corporation Galleries of Art, Glasgow.
MATHEMATICS. Prof. Chrystal.
MATTHEW OF PARIS. J. Bass Mullinger, M.A., author of "History of the University of Cambridge."
MAURITIUS. Rev. J. Sibree, Jun.
MAZARIN. H. Morse Stephens.
MAZZINI. Rev. J. S. Black.
MEASLES. J. O. Affleck, M.D.
MEASUREMENT. R. S. Ball, LL.D., F.R.S., Royal Astronomer for Ireland.
MECCA. Prof. W. Robertson Smith.
MECHANICS. P. G. Tait, M.A., Professor of Natural Philosophy, University of Edinburgh.
MECHANICS, APPLIED. W. J. Macquorn Rankine, LL.D., F.R.S., late Professor of Civil Engineering, University of Glasgow.
MECKLENBURG. J. F. Muirhead, Leipsic.
MEDICAL JURISPRUDENCE. Thomas Stevenson, M.D., Lecturer on Chemistry, &c., Guy's Hospital, London.
MEDICI. Prof. P. Villari, Royal Institute, Florence, author of "Savonarola" and "Machiavelli."
MEDICINE—
Synoptical View. C. Creighton, M.D.
History. J. F. Payne, M.D., Lecturer on Pathology, St Thomas's Hospital, London.
MEDINA. Prof. W. Robertson Smith.
MEDITERRANEAN. J. Y. Buchanan, late of the "Challenger" Expedition.
MELANCHTHON. Rev. John Wilson, M.A.
MELBOURNE. A. Sutherland, M.A., Carlton College, Melbourne.
MEMLING. J. A. Crowe, author of "Painting in Italy."
