LOO

LOO (formerly called LANTERLOO), a round game of cards. Loo may be played by any number of persons; from five to seven makes the best game. "Three-card loo" is the game usually played. A pack of fifty-two cards is required. The players being seated, the pack is shuffled and a card dealt face upwards to each. The player to whom a knave falls has the first deal, the player to his left deals next, and so on in rotation. Each player is entitled to a deal, *i.e.*, the game should not be abandoned till it returns to the original dealer; but, if there is a loo in the last deal of a round, the game continues till there is a hand without a loo. The pack is cut to the dealer, who deals three cards to each player and an extra hand called *miss*. The dealer turns up the top of the undealt cards for trumps. The dealer is sometimes permitted to deal the cards in any order he pleases; but the best rule is to require that the cards be dealt one at a time in rotation, as at whist. During the deal each player contributes to the *pool* a sum previously agreed upon, the dealer contributing double. The unit for a single stake should be divisible by three without a remainder, *e.g.*, three counters or three pence. The players are bound to put in the stake before the deal is completed; sometimes a penalty is enforced for neglect. The deal being completed and the pool formed, each player in rotation, beginning from the dealer's left, looks at his cards, and declares whether he will play, resign, or take miss. If the former, he says "I play." If he takes miss he places his cards face downwards in the middle of the table, and takes up the extra hand. If he resigns, he similarly places his cards face downwards in the middle of the table. If miss is taken, the subsequent players only have the option of playing or resigning. A player who takes miss must play. Those who have declared to play, and the one—if there is one—who has taken miss, then play one card each in rotation, beginning from the dealer's left, the cards thus played constituting a *trick*. The trick is won by the highest card of the suit led, or, if trumped, by the highest trump, the cards ranking as at whist. The winner of the trick leads to the next, and so on, until the hand is played out. The cards remain face upwards in front of the persons playing them.

Rules of Play.—If the leader holds ace of trumps he must lead it (or king, if ace is turned up). If the leader has two trumps he must lead one of them, and if one is ace (or king, ace being turned up) he must lead it. With this exception the leader is not bound to lead his highest trump if more than two declare to play; *but if there are only two declared players* the leader with more than one trump must lead the highest. Except with trumps as above stated he may lead any card he chooses. The subsequent players must head the trick if able, and must follow suit if able. Holding none of the suit led, they must head the trick with a trump, if able. Otherwise they may play any card they please. The winner of the first trick is subject to the rules already stated respecting the lead, and in addition he must lead a trump if able (called *trump after trick*).

When the hand has been played out, the winners of the tricks divide the pool, each receiving one-third of the amount for each trick. If only one declared to play, the dealer plays miss either for himself or for the pool. If he plays for the pool he must declare before seeing miss that he does not play for himself. Any tricks he may win, when playing for the pool, remain there as an addition to the next pool.

If each declared player wins at least one trick it is a *single*, *i.e.*, a fresh pool is made as already described; but if one of the declared players fails to make a trick he is *looed*. Then, only the player who is looed contributes to the next pool, together with the dealer, who puts in a single stake. If more than one player is looed, each has to contribute. At *unlimited loo* each player looed has to put in the amount there was in the pool. But it is generally agreed to *limit* the loo, so that it shall not exceed a certain fixed sum. Thus, at eighteen-penny loo, the loo is generally limited to half a guinea. If there is less than the limit in the pool the payment is regulated as before; but if there is more than the limit, the loo is the fixed sum agreed on.

The game is sometimes varied by *forces*, *i.e.*, by compelling every one to play, either whenever there is no loo the previous deal (*a single*), or whenever clubs are trumps (*club law*). When there is a force no miss is dealt. *Irish loo* is played by allowing declared players to exchange some or all of their cards for cards dealt from the top of the pack. There is no miss, and it is not compulsory to lead a trump with two trumps, unless there are only two declared players. At *five-card loo* each player has five cards instead of three, and a single stake should be divisible by five. *Pam* (knave of clubs) ranks as the highest trump, whatever suit is turned up. There is no miss, and cards may be exchanged as at Irish loo. If ace of trumps is led, the leader says "Pam be civil," when the holder of that card must pass the trick if he can do so without revoking. A flush (five cards of the same suit, or four with Pam) *loos the board*, *i.e.*, the holder receives the amount of a loo from every one, and the hand is not played. A trump flush takes precedence of flushes in other suits. If more than one flush is held, or if Pam is held, the holder is exempted from payment. As between two flushes which do not take precedence, the elder hand wins.

Declaring to Play, and Playing (three-card loo).—Play on two trumps. The first to declare should play on an honour in trumps and an ace in plain suits. Play also on king of trumps; but some players throw up king of trumps single unless with it another king or a guarded queen is held. Also play on one trump with two other cards as high as queens; some players throw up this hand. Holding a trump and two aces, lead the trump if three others declare to play; but otherwise lead an ace. Do not play on a hand without a trump; except, play on any cards that give a reasonable chance of a trick, or take miss, if the amount in the pool is considerable, and the loo is limited. If the number of players is less than five, or if several throw up, weaker hands may be played; on the other side, if several have declared to play, only a very strong hand should be risked. If there are only three left in, all others having thrown up, miss should be taken, but not when there are more than two to follow the player whose turn it is to declare.

Laws of Loo.—These vary greatly, and should be agreed on before commencing to play. The ordinary rules, which loo the player for nearly every error, are very bad. The following are based on the laws of the late Blenheim Club. 1. First knave deals. 2. Each player has a right to shuffle. 3. The player to the dealer's right cuts the pack. 4. The dealer must deliver the cards, one by one, in rotation, as at whist, and must deal one card for miss at the end of each round; he must turn up the top card of the undealt cards for trumps. 5. If the dealer deals without having the pack cut, or shuffles after it is cut, or deals except as provided in law 4, or deals two cards together and then deals a third without rectifying the error, or exposes a card, or deals too many cards, he forfeits a single to the pool, and deals again.[1] 6. The player to the left of the dealer deals next. If a player deals out of turn, he may be stopped before the trump card is turned, otherwise the deal stands good, and the player to his left deals next. 7. Players must declare to play in rotation, beginning to the dealer's left. A player looking at his cards before his turn forfeits a single to the pool. 8. A player who declares before his turn, or who exposes a card, forfeits a single to the pool, and must throw up his hand.[2] 9. If a declared player exposes a card before his turn to play, or plays out of turn, or before all have declared, or detaches a card so that it can be named by any other declared player, or revokes, he must leave in the pool any tricks he may make, and forfeit four times the amount of a single. If he makes no trick he is looed, and there is no further penalty. 10. If the leader holds ace of trumps and does not lead it (or king, ace being turned up), or if he holds two trumps and does not lead one, or the highest of two or more trumps when there are only two declared players (unless his cards are sequence cards or cards of equal value), or if a player does not head the trick when able, or if he does not lead trump after trick (if he holds a trump), he is liable to the same penalty as in law 9.[3] 11. In case of revokes or errors in play the hand must be replayed if so desired by any one except the offender. 12. The place of an aftercomer is decided by dealing a card between every two of the players. The aftercomer sits where the first knave falls. (H. J.)

LOOCHOO. See Lew-chew Islands.

LOOM. See Weaving.

LOOM, or Loon (Icelandic, *Lómr*), a name applied to water-birds of three distinct Families, all remarkable for their clumsy gait on land.[4] The first of them is the *Colymbidæ*, to which the term Diver (*q.v.*) is nowadays usually restricted in books; the second the *Podicipedidæ*, or Grebes (see vol. xi. p. 30); and the third the *Alcidæ*. The form Loo*n* is most commonly used both in the British Islands and in North America for all the species of the genus *Colymbus*, or *Eudytes* according to some ornithologists, frequently with the prefix Sprat, indicating the kind of fish on which they are supposed to prey; though it is the local name of the Great Crested Grebe (*Podiceps cristatus*) wherever that bird is sufficiently well known to have one; and, as appears from Grew (*Mus. Reg. Soc.*, p. 69), it was formerly given to the Little Grebe or Dabchick (*P. fluviatilis* or *minor*) as well. The other form Loo*m* seems more confined in its application to the north, and is said by Mr T. Edmonston (*Etym. Gloss. Shetl. and Orkn Dialect*, p. 67) to be the proper name in Shetland of *Colymbus septentrionalis*[5]; but it has come into common use among Arctic seamen as the name of the species of Guillemot (*Alca arra* or *bruennichi*) which in thousands throngs the cliffs of far northern lands, from whose (hence called) "loomeries" they obtain a considerable stock of wholesome food, while the writer believes he has heard the word locally applied to the Razorbill (*q.v.*). (A. N.)

LOPE DE VEGA. See Vega Carpio.

LOPEZ, Carlos Antonio (1790–1862), a Paraguayan ruler of great ability, born at Asuncion, November 4, 1790, was educated in the ecclesiastical seminary of that city, and by his ability attracted the hostility of the dictator, Francia, in consequence of which he was forced to keep in hiding for several years. He acquired, however, by study, so unusual a knowledge of law and governmental affairs that, on Francia's death in 1840, he soon acquired an almost undisputed control of the Paraguayan state, which he maintained uninterruptedly until his own death in 1862. He was successively secretary of the ruling military *junta* (1840–41), one of the two consuls (1841–44), and president with dictatorial powers (1844–1862) by successive elections for ten and three years, and in 1857 again for ten years, with power to nominate his own successor. Though nominally a president acting under a republican constitution, he ruled despotically, the congress assembling only rarely and on his call, and then only to ratify his decrees. His government was in general directed with wise energy towards developing the material resources and strengthening the military power of the country. His jealousy of foreign approach several times involved him in diplomatic disputes with Brazil, England, and the United States, which nearly resulted in war, but each time he extricated himself by skilful evasions. Paraguay rapidly advanced under his firm and, on the whole, patriotic administration. He died September 10, 1862.

LOPEZ, Francisco Solano (1826–1870), eldest son of Carlos Antonio Lopez above noticed, was born near Asuncion, Paraguay, July 24, 1826. During his boyhood his father was in hiding, and in consequence his education was wholly neglected. Soon after his father's accession to the presidency, Francisco, then in his nineteenth year, was made commander-in-chief of the Paraguayan army, during the spasmodic hostilities then prevailing with the Argentine Republic. After receiving successively the highest offices of the state, he was sent in 1853 as minister to England, France, and Italy, to ratify formally treaties made with these powers the previous year. He spent a year and a half in Europe, and succeeded in purchasing large quantities of arms and military supplies, together with several steamers, and organized a project for building a railroad and establishing a French colony in Paraguay. He also formed the acquaintance of Madame Lynch, an Irish adventuress of many talents and popular qualities, who became his mistress, and strongly influenced his later ambitious schemes. Returning to Paraguay, he became in 1855 minister of war, and on his father's death in 1862 at once assumed the reins of government as vice-president, in accordance with a provision of his father's will, and called a congress by which he was chosen president for ten years. He had long cherished ambitious designs, and now set himself to enlarge the army, and purchase in Europe large quantities of military stores. In 1864 he began open aggression on Brazil by demanding, in his self-styled capacity of "protector of the equilibrium of the La Plata," that Brazil should abandon her armed interference in a

[1] The law which loos a player for misdealing is atrocious, and should always be opposed.

[2] Forfeits of a single go to increase the pool already formed, and see note to law 5.

[3] Tricks left in the pool and fines under laws 9 and 10 go to the next pool and not to the pool already formed. Many players inflict the penalty of a loo for the offences named in laws 9 and 10; but the rule above, as played at the Blenheim, is the best.

[4] The word also takes the form "Lumme" (*fide* Montagu), and, as Professor Skeat observes, is probably connected with *lame*. The signification of *loon*, a clumsy fellow, and metaphorically a simpleton, is obvious to any one who has seen the attempt of the birds to which the name is given to walk.

[5] Dunn and Saxby, however, agree in giving "Rain-Goose" as the name of this species in Shetland.

revolutionary struggle then in progress in Uruguay. No attention being paid to his demand, he treacherously seized a Brazilian merchant steamer in the harbour of Asuncion, and threw into prison the Brazilian governor of the province of Matto Grosso who was on board. In the following month (December 1864) he despatched a force to invade Matto Grosso, which seized and sacked its capital Cuyabá, and took possession of the province and its diamond mines. Lopez next sought to send an army to the relief of the Uruguayan president Aguirro against the revolutionary aspirant Flores, who was supported by Brazilian troops. The refusal of the Argentine president, Mitre, to allow this force to cross the intervening province of Corrientes, was seized upon by Lopez as an occasion for war with the Argentine Republic.

A congress, hastily summoned and composed of his own nominees, bestowed upon Lopez the title of marshal, with extraordinary war powers, and on April 13, 1865, he declared war, at the same time seizing two Argentine war-vessels in the bay of Corrientes, and on the next day occupied the town of Corrientes, instituted a provisional government of his Argentine partisans, and summarily announced the annexation to Paraguay of the provinces of Corrientes and Entre Rios. Meantime the party of Flores had been successful in Uruguay, and that state on April 18 united with the Argentine Republic in a declaration of war on Paraguay, the news of the treacherous proceedings of Lopez having then but just reached Buenos Ayres. On May 1st Brazil joined these two states in a secret alliance, which stipulated that they should unitedly prosecute the war "until the existing government of Paraguay should be overthrown," and "until no arms or elements of war should be left to it." This agreement was literally carried out.

The war which ensued, lasting until April 1, 1870, was on the largest scale of any that South America had experienced, and was carried on with great stubbornness and with alternating fortunes, though with a steadily increasing tide of disasters to Lopez (see PARAGUAY). In 1868, when the allies were pressing him hard before the various strongholds still remaining to him in Paraguay, his mind, naturally suspicious and revengeful, led him to conceive that a conspiracy had been formed against his life in his own capital and by his chief adherents. His bloodthirsty rage knew no bounds. In a short time several hundred of the chief Paraguayan citizens were seized and executed by his order, including his brothers and brothers-in-law, cabinet ministers, judges, prefects, military officers of the highest grade, the bishops and priests, and nine-tenths of the civil officers, together with more than two hundred foreigners, among them several members of the different diplomatic legations.

Lopez was at last driven with a mere handful of troops to the northern frontier of Paraguay, where on April 1, 1870, he was surprised by a Brazilian force and killed as he was endeavouring to escape by swimming the river Aquidaban. His ill-starred ambition had in a few years reduced Paraguay from the prosperity which it had enjoyed under his father to a condition of hopeless weakness, and it has since remained a virtual dependency of Brazil.

LORCA, a town of Spain, in the province of Murcia, on the right side of the Sangonera (here called the Guadalentin), by which it is separated from the suburb or quarter of San Cristobal. It is situated about 38 miles west from Cartagena, and 37 south-west from Murcia, at the foot of the Sierra del Caño. The principal buildings are the collegiate church of San Patricio, with a Corinthian façade, and the parish church of Santa Maria, in the Gothic style. The principal manufactures are soda, saltpetre, gunpowder, and cloth; the trade, apart from that which these articles involve, is insignificant. The population of the municipality was 52,934 in 1877.

Lorca (Arab. *Lurka*) is the *Eliocroca* of the *Itin. Ant.*, and probably also the *Ilorci* of Pliny (iii. 3). It was the key of Murcia during the Moorish wars, and was frequently taken and retaken. On April 30, 1802, it suffered severely by the bursting of the reservoir known as the Pantano de Puentes, in which the waters of the Guadalentin were stored for purposes of irrigation; the Barrio de San Cristobal was completely ruined, and more than six hundred persons perished in the disaster. In 1810 it suffered greatly from the French.

LORENZO MARQUES, or LOURENÇO MARQUES, the chief place, and indeed the only European settlement, in the district of its own name in the Portuguese province of Mozambique in south-eastern Africa, is situated on Delagoa Bay, at the mouth of the Lorenzo Marques or English River, in 25° 58′ S. lat. and 32° 30′ E. long. At the time of Mr Erskine's visit in 1871 it was a poor place, with narrow streets, fairly good flat-roofed houses, grass huts, decayed forts, and rusty cannon, enclosed by a wall 6 feet high recently erected and protected by bastions at intervals. In 1878 Governor Castelho returned the white population of all the district (whose area is estimated at 210,000 square miles) as 458, and the natives as from 50,000 to 80,000. A commission sent by the Government in 1876 to drain the marshy land near the settlement, to plant the blue gum tree, and to build a hospital and church, only partly accomplished its task, and other commissions have succeeded it. In 1878–79 a survey was taken for a railway from Lorenzo Marques to the Transvaal (see *Bol. da Soc. de Geogr. de Lisboa*, 1880), and the completion of this enterprise will make the settlement (which already possesses the best harbour on the African coast between the Cape and Zanzibar) a place of considerable importance. It became a regular port of call for the steamers of the British India Steam Navigation Company in 1879, and for those of the Donald Currie line in 1880. Since 1879 it is also a station on the telegraph line between Aden and South Africa. Both Germany and England maintain consular agents in the settlement.

See DELAGOA BAY, vol. vii. p. 40; and Lobo de Bulhaes, *Les Colonies portugaises* (Lisbon, 1878).

LORETO, a city in the province and circondario of Ancona, Italy, is situated some 15 miles by rail south-west from Ancona on the Ancona-Foggia railway, 16 miles north-east from Macerata, and 3 from the sea. It lies upon the right bank of the Musone, at some distance from the railway station, on a hill-side commanding splendid views from the Apennines to the Adriatic. The city itself consists of little more than one long narrow street, lined with booths for the sale of rosaries, medals, crucifixes, and similar objects, the manufacture of which is the sole industry of the place. The population in 1871 was only 1241; but, when the suburbs Montereale, Porta Marina, and Casette are included, the population is given as 4755, that of the commune being 8083. The number of pilgrims is said to amount to about 500,000 annually. The principal buildings, occupying the four sides of the piazza, are the college of the Jesuits, the Palazzo Apostolico (designed by Bramante), and the architecturally insignificant cathedral church of the Holy House (Chiesa della Casa Santa). The handsome façade of the church was erected under Sixtus V., who fortified Loreto and gave it the privileges of a town (1586); his colossal statue stands in the middle of the flight of steps in front. Over the principal doorway is a life-size bronze statue of the Virgin and Child by Girolamo Lombardo; the three superb bronze doors executed under Paul V. (1605–21) are also by Lombardo, his sons, and his pupils. The richly decorated campanile, by Vanvitelli, is of great height; the principal bell, presented by Leo X. in 1516, weighs 11 tons. The interior of the church has mosaics by Domenichino and Guido Reni, a beautiful bronze font and other works of art; but the chief object of interest is the Holy House itself, which occupies a central place. It is a plain brick building, measuring 28 feet by 12½, and 13½ feet in height; it has a door on the north side and a window on the west; and a niche contains a small black image of the Virgin and Child, in Lebanon cedar, and richly adorned with jewels. St Luke is alleged to have been the sculptor; its workmanship suggests the latter half of the 15th century. Around the Santa Casa is a lofty marble screen, designed by Bramante, and executed under Popes Leo X., Clement VII., and Paul III., by Andrea Sansovino, Girolamo Lombardo, Bandinelli, Guglielmo della Porta, and others. The four sides represent the Annunciation, the Nativity, the Arrival of the Santa Casa at Loreto, and the Nativity of the Virgin respectively. The treasury of the church contains a large variety of rich and curious votive offerings.

The legend of the Holy House, by which Loreto became what has been not inappropriately called the Christian Mecca, seems to have sprung up, how is not exactly known, at the close of the crusading period. It is briefly referred to in the *Italia Illustrata* of Flavius Blondus, secretary to Popes Eugenius IV., Nicholas V., Calixtus III., and Pius II. (*ob.* 1464); it is to be read in all its fulness in the "Redemptoris mundi Matris Ecclesiæ Lauretana historia," by a certain Teremannus, contained in the *Opera Omnia* (1576) of Baptista Mantuanus. According to this narrative the house at Nazareth in which Mary had been born and brought up, had received the annunciation, and had lived during the childhood of Jesus and after His ascension, was converted into a church by the apostles, and worship continued to be held in it until the fall of the kingdom of Jerusalem. Threatened with destruction by the Turks, it was carried by angels through the air and deposited (1291) in the first instance on a hill at Tersato in Dalmatia (some miles inland from Zengg), where an appearance of the Virgin and numerous miraculous cures attested its sacredness, which was confirmed by investigations made at Nazareth by messengers from the governor of Dalmatia. In 1294 the angels carried it across the Adriatic to a wood near Recanati; from this wood (lauretum), or from the name of its proprietrix (Laureta), the chapel derived the name which it still retains ("sacellum gloriosæ Virginis in Laureto"). From this spot it was afterwards (1295) removed to the present hill, one other slight adjustment being required to fix it in its actual site. Bulls in favour of the shrine at Loreto were issued by Sixtus IV. in 1491 and by Julius II. in 1507, the last alluding to the translation of the house with some caution ("ut pie creditur et fama est"). The recognition of the sanctuary by subsequent pontiffs has already been alluded to. In the end of the 17th century Innocent XII. appointed a "missa cum officio proprio" for the feast of the Translation of the Holy House, and the Festum Translationis Almæ Domus Lauretanæ B. M. V. is still enjoined in the Spanish Breviary as a "duplex majus" (December 10). In the sixth lesson it is stated that "the house in which the Virgin was born, having been consecrated to the divine mysteries, was by the ministry of angels removed from the power of the infidels first to Dalmatia and afterwards to the Lauretan field during the pontificate of Celestine V. That it is the identical house in which the Word was made flesh and dwelt among men is attested by papal documents, by the veneration of all the world, by continued miracles, and by the grace of heavenly blessings."

LORIENT, capital of an arrondissement in the department of Morbihan, and of one of the five maritime prefectures of France, a military port and fortified place, stands on the right bank of the Scorff, at its confluence with the Blavet, in 47° 45′ N. lat. and 3° 31′ W. long., on the railway line from Nantes to Brest, at a distance of 117 miles from the former and 111 from the latter. The town, which is modern and regularly built, contains no buildings of special architectural or antiquarian interest; it derives all its importance from its naval establishments lining the right bank of the river, which include sail-making works, cooperages, and shops for all kinds of ship carpentry. The rope-work forms a parallelogram more than 1000 feet in length by 100 broad. The foundries, fitting shops, and smiths' shops are on an equally extensive scale, the forges numbering eighty-four. Of the graving docks the largest is 509 feet in length, about 98 in breadth, and more than 26 feet in depth below low-water mark. The Prée, an area of 40 acres reclaimed from the sea, contains boatbuilding yards, steam saw-mills, and wood stores; a floating bridge 900 feet long connects it with the shipbuilding establishments of Caudan, which occupy the peninsula formed by the confluence of the Scorff and the Blavet. Apart from its naval constructions, in which Lorient holds the first rank in France, it has an important place in the manufacture of marine artillery. Private industry is also engaged in engine making. The trade in fresh fish and sardines within the arrondissement reaches an annual value of 35 millions of francs. South from the town, also on the Scorff, is the harbour, which comprises a dry dock and a wet dock, measuring about 1650 feet by 200. The roadstead, formed by the estuary of the Blavet, is accessible to vessels of the largest size; the entrance, 3 or 4 miles south from Lorient, which is defended by numerous forts, is marked on the east by the peninsula of Gâvre (an artillery practising ground) and the fortified town of Port Louis; on the west are the fort of Loqueltas, and, higher up, the battery of Kernevel. In the middle of the channel is the granite rock of St Michel, occupied by a powder magazine. Opposite it, on the right bank of the Blavet, is the mouth of the river Ter, with fish and oyster breeding establishments, from which 10 millions of oysters are annually obtained. Above Lorient on the Scorff, here spanned by a suspension bridge, is Kerantrech, a pretty village surrounded by numerous country houses. The population of Lorient in 1876 was 35,165, including 6360 of the military and official class.

Lorient has taken the place of Port Louis as the port of the Blavet. The latter stands on the site of an ancient hamlet which was fortified during the wars of the League and handed over by Mercœur to the Spaniards. After the treaty of Vervins it was restored to France, and it received its name of Port Louis under Richelieu. Some Breton merchants trading with the Indies had established themselves first at Port Louis, but in 1628 they built their warehouses on the other bank. The Compagnie des Indes, created in 1664, took possession of these, giving them the name of Lorient. In 1745 the company, then at the acme of its prosperity, owned thirty-five ships of the largest class and many others of considerable size. The failure of the attempt of the English under Lestock against Lorient is still commemorated by the inhabitants by an annual procession on the first Sunday of October. The decadence of the company dates from 1753. In 1782 the town was acquired by purchase by Louis XVI., on the bankruptcy of its former owners, the Rohan-Guéméné family.

LORRAINE (Lotharingia, Lothringen) is geographically the extensive Austrasian portion of the realm allotted by the partition treaty of Verdun in August 843 to the emperor Lothair I., and inherited by his second son, King Lothair II., 855–869, from whose days the name *Regnum Lotharii* first arose. This border-land between the realms of the Eastern and Western Franks in its original extent took in most of the Frisian lowlands between the mouths of the Rhine and the Ems, and a strip of the right shore of the Rhine to within a few miles of Bonn. In the neighbourhood of Bingen it receded from the left shore of the river so as to exclude the dioceses of Worms and Spires, but to admit a certain connexion with Alsace. Towards the west it included nearly the whole territory which is watered by the rivers Moselle and Meuse, and spread over the dioceses of Cologne, Treves, Metz, Toul, Verdun, Liége, and Cambrai. Hence this artificial realm embraced, broadly speaking, almost all modern Holland and Belgium (with the exception of Flanders), part of the Prussian Rhine provinces, and what is still called Lorraine, partly French and partly German, divided, however, from Alsace and the Palatinate by the natural frontier line of the Vosges and the Haardt mountains. Its inhabitants were soon called *Hlotharii*, *Lotharienses*, *Lotharingi*. Lotharingia, as the designation of the country, hardly appears before the middle of the 10th century.

Up to this time Lorraine had belonged alternately to the eastern and the western kingdom ever since Louis the German and Charles the Bald divided the realm of Lothair II. more ethnographically by the treaty of Meersen, August 8, 870. After the deposition in 887 of the emperor Charles III., who for a short time appeared at the head of the three reunited realms, the country still remained distinct, though the invasions of the Northmen and feudal disintegration creeping in from the west vied to tear it to pieces. Yet the emperor Arnulf, after his success against the Scandinavians, restored some order, and made his son Zwentebulch king over that part of the empire in 894. But he never overcame the difficulties inherent in a country peopled by Franks, Burgundians, Almains, Frisians, and Scandinavians, speaking various Romance and Teutonic dialects, the western group being evidently attracted by the growth of a French, the eastern by that of a German nationality. King Zwentebulch quarrelled with certain powerful lords, offended mortally the bishops, especially that of Treves, and finally lost his life in battle on the 13th August 900. In the days of Louis the Child, the last of the eastern Carolings, there rose to ducal dignity Reginar Long-neck, count of Haspengau, Hennegau, or Hainault, who owned a number of fiefs and monasteries in the diocese of Liége. He found it profitable to adhere to Charles, king of the Western Franks, especially after Louis's death in 911. His son Gisilbert from 915 began to rule the Lotharingians likewise in opposition to Conrad I. and Henry I., who were the successors of Louis the Child, with the exception, however, of Alsace and the Frisian districts, which now separated, definitively to remain with the German kingdom. By the treaty of Bonn (921) the Lotharingian duchy was ceded formally to France, until Henry I., profiting by the disunion between Charles the Simple and his rivals, subdued Gisilbert and his dominion (925), and about 928 returned it to him with the hand of his daughter as a member of the German kingdom, though rather more independent than other duchies. Its western frontier now appears to have extended up to the Dutch Zealands.

Henry's son, the great Otto I., when his brother rebelled in conjunction with Eberhard and Gisilbert, the dukes of Franconia and Lotharingia, beat and annihilated these two vassals (939), and secured the latter country by a treaty with the French king Louis IV., who married Gisilbert's widow, entrusting it consecutively to his brother Henry, to a Duke Otto, and from 944 to Conrad the Red, his son-in-law. Chiefly with the help of the Lotharingians he invaded France in order to reinstate the king, who had been dethroned by his proud vassals. But a few years later, when Liudulf, the son of King Otto and the English Edith, and Duke Conrad, discontented with certain measures, rose against their father and lord, the ever-restless spirit of the Lotharingians broke out into new commotions. The stern king, however, suppressed them, removed both his son and his son-in-law from their offices, and appointed his youngest brother, the learned and statesmanlike Brun, archbishop of Cologne and chancellor of the realm, to be also duke or, as he is called, archduke of Lotharingia. Brun snatched what was still left of demesne lands and some wealthy abbeys like St Maximine near Treves from the rapacious nobles, who had entirely converted the offices of counts and other functionaries into hereditary property. He presided over their diets, enforced the public peace, and defended with their assistance the frontier lands of Germany against the pernicious influence of the death struggle fought between the last Carolings of Laon and the dukes of Paris. Quelling the insurrections of a younger Reginar in the lower or ripuarian regions, he admitted a faithful Count Frederick, who possessed much land in the Ardennes, at Verdun, and at Bar, to ducal dignity. Although the emperor, after Brun's early death, October 10, 965, took the border-land into his own hands, he connived, as it appears, at the beginning of a final division between an upper and a lower duchy,—leaving the first to Frederick and his descendants, while the other, administered by a Duke Gottfrid, was again disturbed by a third Reginar and his brother Lambert of Louvain. When Otto II. actually restored their fiefs to them in 976, he nevertheless granted the lower duchy to Charles, a son of the Caroling Louis IV., and his own aunt Gerberga. Henceforth there are two duchies of Lorraine, the official name applying originally only to the first, but the two dignitaries being distinguished as *Dux Mosellanorum* and *Dux Ripuariorum*, or later on *Dux Metensis* or *Barrensis* and *Dux Lovaniensis*, *de Brabantia*, *Bullionis*, or *de Limburg*. Both territories now swarmed with ecclesiastical and temporal lords, who struggled to be independent, and, though nominally the subjects of the German kings and emperors, frequently held fiefs from the kings and the grand seigneurs of France.

Between powerful vassals and encroaching neighbours the imperial delegate in the lower duchy could only be a still more powerful seigneur. But Duke Charles became the captive of the bishop of Laon, and died in 994. His son, Duke Otto, dying childless (1004), left two sisters married to the counts of Louvain and Namur. Between 1012 and 1023 appears Duke Gottfrid I., son of a count of Verdun, and supporter of the emperor Henry II., who, fighting his way against the counts of Louvain, Namur, Luxemburg, and Holland, is succeeded by his brother Gozelo I., hitherto margrave of Antwerp, who since 1033, with the emperor's permission, ruled also Upper Lorraine, and defended the frontier bravely against the incursions of Count Odo of Blois, the adversary of Conrad II. At his death (1046) the upper duchy went to his second son Gottfrid, while the eldest, Gozelo II., succeeded in the lower, until he died childless (1046). But Gottfrid II. (the Bearded), an energetic but untrustworthy vassal, rebelled twice in alliance with King Henry I. of France and Count Baldwin V. of Flanders against the emperor Henry V., who opposed a union of the duchies in such hands. Lower Lorraine therefore was given (1046) to Count Frederick of Luxemburg, after whose death (1065) it was nevertheless held by Gottfrid, who in the mean time, being banished the country, had married Beatrice, the widow of Boniface of Tuscany, and acted a prominent part in the affairs of Italy. As duke of Spoleto and champion of the Holy See he rose to great importance during the turbulent minority of Henry IV. When he died December 21, 1069, his son Gottfrid III., the Hunchbacked, succeeded in the lower duchy, who for a short time was the husband to Matilda of Canossa, the daughter of Boniface and Beatrice. Soon, however, he turned his back on Italy and the pope, joined Henry IV., fought with the Saxon rebels and Robert of Flanders, and in the end was miserably murdered by an emissary of the count of Holland, February 26, 1076. Conrad, the emperor's young son, now held the duchy nominally till it was granted 1088 to Gottfrid IV., count of Bouillon, and son of Ida, a sister of Gottfrid III., and Count Eustace of Boulogne, the hero of the first crusade, who died king of Jerusalem in 1100. After him Henry, count of Limburg, obtained the country; but, adhering to the old emperor in his last struggles, he was removed by the son in May 1106 to make room for Gottfrid V., the great-grandson to Lambert I., count of Lorraine, a descendant of the first ducal house, which had been expelled by Otto the Great. Nevertheless he joined his predecessor in rebellion against the emperor (1114), but returned to his side in the war about the see of Liége. Later on he opposed King Lothair III., who in turn supported Walram, son of Henry of Limburg, but died in peace with Conrad

III., January 15, 1139. His son Gottfrid VI. was the last duke of Lower Lorraine, and second duke of Brabant. Henceforth the duchy split definitely into that of Limburg, the inheritance of the counts of Verdun, and that of Louvain or Brabant, the dominion of the ancient line of the counts of Haspengau. Various fragments remained in the hands of the counts of Luxemburg, Namur, Flanders, Holland, Juliers, &c.

Upper Lorraine, a hilly table-land, is bordered on the east by the ridge of the Vosges, on the north by the Ardennes, and on the south by the table-land of Langres. Towards the west the open country stretches on into Champagne. The Meuse and the Moselle, the latter with its tributaries Meurthe and Saar, run through it from S.E. to N.W. in a direction parallel to the ridge of the Argonnes. In this country Duke Frederick was succeeded by his son and grandson till 1033. Afterwards Gozelo I. and Gottfrid the Bearded, Count Albert of Alsace and his brother or nephew Gerard, held the duchy successively under very insecure circumstances. The ducal territories were even then on all sides surrounded and broken in upon, not only by those of the three bishops, but also by the powerful counts of Bar. Moreover, when in 1070 a new dynasty was established in Theodoric, son of Count Gerard of Alsace, his brother Gerard of Vaudemont became the founder of a separate line. The former political and feudal ties still connected the duchy with the empire. The bishops were the suffragans of the archbishop of Treves, who rose to be one of the prince-electors. The dukes, however, descending from Theodoric in the male line, though much weakened by the incessant dilapidation of their property, for two centuries adhered generally to the emperor. Duke Simon I. was step-brother of the emperor Lothair III.; his son Matthew I. intermarried with the Hohenstaufen family. His son and grandsons appear traditionally on the side of Henry VI., Philip, Frederick II., and but rarely prefer the Welfish opponent. Later on Theobald II. and Frederick IV. supported Albert and Frederick of Austria against Louis the Bavarian. Yet during the same age French feudalism and chivalry, French custom and language, advanced steadily to the disadvantage of German policy and German idioms amongst knights and citizens. King Philip Augustus already promoted Frenchmen to the sees of Cambrai, Verdun, and Toul. Though remaining a fief of the empire, the duchy of Lorraine itself, a loose accumulation of centrifugal elements, was irresistibly attracted by its western neighbour, although the progress of French monarchy for a time was violently checked by the English invasion. Duke Rudolf, a great grandson of Rudolf of Hapsburg, died at Crécy among the French chivalry, like his brother-in-law the count of Bar. To his son John, who was poisoned at Paris (1391), Charles, called the Bold, succeeded, while his brother Frederick, who was slain at Agincourt, had annexed the county of Vaudemont by right of his wife. Charles, who died in 1431 without male issue, had bestowed his daughter Isabella in marriage on René, count of Anjou, and titular king of Naples, Sicily, and Jerusalem, and also a French vassal for fragments of the duchy of Bar, and the fiefs of Pont à Mousson and Guise. However, when he obtained by right of his wife the duchy of Lorraine, he was defeated by Anthony, the son of Frederick of Vaudemont. But by his daughter Iolanthe marrying Frederick II., Count Anthony's son and heir, the duchies of Lorraine and Bar were in the end united by René II. with the county of Vaudemont and its dependencies Aumale, Mayenne, and Elbœuf. In the meantime all these prospects were nearly annihilated by the conquests of Charles of Burgundy, who evidently had chosen Lorraine to be the keystone of a vast realm stretching from the North Sea to the Mediterranean. This new border empire, separating Germany from France, fell almost instantly to pieces, however, when the bold Burgundian lost his conquests and his life in the battle of Nancy, January 4, 1477. After this the duchy tottered on, merging ever more into the stream of French history, though its bishops were princes of the empire and resided in imperial cities. At the death of René II. (1508), his eldest son Anthony, who had been educated in the court of France, inherited Lorraine with its dependencies. The second, Claude, was first duke of Guise, and the third, John, alternately or conjointly with his nephew Nicolaus, bishop of Metz, Toul, and Verdun, better known as the cardinal of Lorraine. Still the old connexion reappeared occasionally during the French wars of the emperor Charles V. In 1525 the country was invaded by German insurgents, and Lutheranism began to spread in the towns. When Maurice, elector of Saxony, and the German princes rose against the emperor (1552), they sold the three bishoprics and the cities of Toul, Metz, and Verdun, as well as Cambrai, to King Henry II., and hailed him as imperial vicar and *vindex libertatis Germaniæ*. In vain did Charles V. lay siege to Metz for nearly three months; the town, already entirely French, was successfully defended by the duke of Guise. German heresy also lost its hold in these territories owing to the Catholic influence of the house of Guise, which ruled the court of France during an eventful period. Charles II., the grandson of Duke Anthony, who as a descendant of Charles the Caroling even ventured to claim the French crown against the house of Bourbon, had by his wife, a daughter of King Henry II., two sons. But Henry, the eldest, brother-in-law to Henry of Navarre, leaving no sons, the duchy at his death, July 31, 1624, reverted to his brother Francis, who, on November 26, 1625, resigned it in favour of his son Charles III., the husband of Duke Henry's eldest daughter. Siding against Richelieu with the house of Austria and Duke Gaston of Orleans, Charles, after being driven out by the French and the Swedes, resigned the duchy, January 19, 1634; and like the three bishoprics it was actually allotted to France by the peace of Westphalia. The duke, however, after fighting with the Fronde, and with Condé and Spain against Turenne and Mazarin, and quarrelling in turn with Spain, was nevertheless reinstated by the treaty of the Pyrenees (1659) under hard conditions. He had to cede the duchy of Bar, to raze the fortifications of Nancy, and to yield the French free passage to the bishoprics and Alsace. But, restless as ever, after trying to be raised among the princes of the blood royal in return for a promise to cede the duchy, he broke again with Louis XIV., and was expelled once more together with his nephew and heir Charles IV. Leopold. Both fought in the Dutch war on the German side in the vain hope of reconquering their country. When Charles IV. after his uncle's death refused to yield the towns of Longwy and Nancy according to the peace of Nimeguen, Louis XIV. retained the duchy, while its proprietor acted as governor of Tyrol, and fought the Turks for the emperor Leopold I., whose sister he had married. In the next French war he commanded the imperial troops. Hence his son Leopold Joseph, at the cost of Saarlouis, regained the duchy once more by the treaty of Ryswick (1697). This prince carefully held the balance between the contending parties, when Europe struggled for and against the Bourbon succession in Spain, so that his court became a sanctuary for pretenders and persecuted partisans. His second son Francis Stephen, by a daughter of Duke Philip of Orleans, and his heir since 1729, surrendered the duchy ultimately, owing to the defeat of Austria in the war for the Polish crown (1735). This being lost by Stanislaus Leszczynski, the father-in-law of Louis XV., the usufruct of Lorraine and a comfortable residence at Nancy were granted to the

Polish prince till his death (1766). And now for more than a century all Lorraine and Alsace up to the Rhine were French. Meanwhile Francis Stephen, since 1736 the husband of Archduchess Maria Theresa, had obtained in compensation the grand-duchy of Tuscany, where the last of the Medici died in 1737. He became his wife's coregent in the Austrian provinces (1740), and was elected king of the Romans and crowned emperor 1745, the ancestor of the present rulers of Austria. When in the recent Franco-German war both Strasburg and Metz were taken by the German troops after a gallant defence, the French had to submit in the peace of Frankfort, May 10, 1871, to the political and strategical decisions of the conquerors. Old German territory, all Alsace, and a portion of Lorraine, the upper valley of the Saar, the strong fortresses of Diedenhofen (Thionville) and Metz on the Moselle, with the surrounding districts, viz., the greater part of the Moselle and the Meurthe departments, where here and there German is still the language of the inhabitants, were the spoils of victory. They are now united and administered in all civil and military matters as an imperial province of the new German empire.

LORY, a word of Malayan origin signifying Parrot,[1] in general use with but slight variation of form in many European languages, is the name of certain birds of the order *Psittaci*, mostly from the Moluccas and New Guinea, which are remarkable for their bright scarlet or crimson colouring, though also, and perhaps subsequently, applied to some others in which the plumage is chiefly green. The "Lories" have been referred to a considerable number of genera, of which *Eclectus*, *Lorius* (the *Domicella* of some authors), *Eos*, and *Chalcopsittacus* may be here particularized, while under the equally vague name of "Lorikeets" may be comprehended the genera *Charmosyna*, *Loriculus*, and *Coriphilus*. By most systematists some of these forms have been placed far apart, even in different families of *Psittaci*, but Garrod has shown (*Proc. Zool. Society*, 1874, pp. 586–598, and 1876, p. 692) the many common characters they possess, which thus goes some way to justify the relationship implied by their popular designation. The latest and perhaps the most complete account of these birds is to be found in the first part of Count T. Salvadori's *Ornitologia della Papuasia e delle Molucche*, published at Turin in 1880, though he does not entirely accept Garrod's arrangement. Of the genus *Eclectus* the Italian naturalist admits five species, namely, *E. pectoralis* and *E. roratus*, (which are respectively the *polychlorus* and *grandis* of most authors), *E. cardinalis* (otherwise *intermedius*), *E. westermani*, and *E. cornelia*—the last two from an unknown habitat, though doubtless within the limits of his labour, while the first seems to range from Waigiou and Mysol through New Guinea, including the Kei and Aru groups, to the Solomon Islands, and the second is peculiar to the Moluccas and the third to Bouru, Amboyna, and Ceram. Still more recently Dr A. B. Meyer has described (*Proc. Zool. Society*, 1881, p. 917) what he considers to be another species, *E. riedeli*, from Cera or Seirah, one of the Tenimber group, of which Timor Laut is the chief, to the south-west of New Guinea.[2] Much interest has been excited of late by the discovery in 1873, by the traveller and naturalist last named, that the birds of this genus possessing a red plumage were the females of those wearing green feathers. So unexpected a discovery, which was announced by Dr Meyer on the 4th of March 1874, to the Zoological and Botanical Society of Vienna,[3] naturally provoked not a little controversy, for the difference of coloration is so marked that it had even been proposed to separate the Green from the Red Lories generically[4]; but now the truth of his assertion is generally admitted, and the story is very fully told by him in a note contributed to Gould's *Birds of New Guinea* (part viii., 1st October 1878), though several interesting matters therewith connected are still undetermined. Among these is the question of the colour of the first plumage of the young, a point not without important signification to the student of phylogeny.[5]

Though the name Lory has long been used for the species of *Eclectus*, and some other genera related thereto, some writers would restrict its application to the birds of the genera *Lorius*, *Eos*, *Chalcopsittacus*, and their near allies, which are often placed in a subfamily, *Loriinæ*, belonging to the so-called Family of *Trichoglossidæ*, or "Brush-tongued" Parrots. Garrod in the course of his investigations on the anatomy of *Psittaci* was led not to attach much importance to the structure indicated by the epithet "brush-tongued," stating (*Proc. Zool. Society*, 1874, p. 597) that it "is only an excessive development of the papillæ which are always found on the lingual surface." The birds of this group are very characteristic of the New-Guinea Subregion,[6] in which occur, according to Count Salvadori, ten species of *Lorius*, eight of *Eos*, and four of *Chalcopsittacus*; but none seem here to require any further notice,[7] though among them, and particularly in the genus *Eos*, are included some of the most richly-coloured birds to be found in the whole world; nor does it appear that more need be said of the so-called Lorikeets. (A. N.)

LOS ANGELES, a city of the United States, the capital of Los Angeles county, California, is situated in the lowland between the Sierra Madre and the Pacific, about 17 miles from the coast, on the west bank of a stream of its

[1] The anonymous author of a *Vocabulary of the English and Malay Languages*, published at Batavia in 1879, in which the words are professedly spelt according to their pronunciation, gives it "*looree*." Buffon (*Hist. Nat. Oiseaux*, vi. p. 125) states that it comes from the bird's cry, which is likely enough in the case of captive examples taught to utter a sound resembling that of the name by which they are commonly called. Nieuhoff (*Voyages par mer et par terre à differents lieux des Indes*, Amsterdam, 1682–92) seems to have first made the word "Lory" known (*cf.* Ray, *Synops. Avium*, p. 151). Crawfurd (*Dict. Engl. and Malay Languages*, p. 127) spells it "nori" or "nuri"; and in the first of these forms it is used, says Dr Finsch (*Die Papageien*, ii. p. 732), by Pigafetta. Aldrovandus (*Ornithologia*, lib. xi. cap. 1) noticed a Parrot called in Java "nor," and Clusius (*Exotica*, p. 364) has the same word. This will account for the name "noyra" or "noira" applied by the Portuguese, according to Buffon (*ut supra*, pp. 125–127); but the modern Portuguese seem to call a Parrot generally "Louro," and in the same language that word is used as an adjective, signifying bright in colour. The French write the word "Loury" (*cf.* Littré, *sub voce*). The Lory of colonists in South Africa is a TOURACOO (*q.v.*); and King Lory is a name applied by dealers in birds to the Australian Parrots of the genus *Aprosmictus*.

[2] There seems just a possibility of this, however, proving identical with either *E. westermani* or *E. cornelia*—both of which are very rare in collections.

[4] *Proc. Zool. Society*, 1857, p. 226.

[5] The chemical constitution of the colouring matter of the feathers in *Eclectus* has been treated by Dr Krukenberg of Heidelberg (*Vergl. physiol. Studien*, Reihe ii. Abth. i. p. 161, reprinted in *Mittheil. Orn. Vereines in Wien*, 1881, p. 83).

[6] They extend, however, to Fiji, Tahiti, and Fanning Island.

[7] Unless it be *Oreopsittacus arfaki*, of New Guinea, remarkable as the only Parrot known as yet to have fourteen instead of twelve rectrices.

own name. It lies 483 miles by rail south-south-east of San Francisco on the Southern Pacific Railroad, and is connected by branch lines with Wilmington, Santa Monica (both on the coast), and Santa Ana. As the centre of a fine orange and grape growing country, and a resort for invalids, Los Angeles is a place of some importance; and since the opening of the railways it has been in full prosperity, the old adobe buildings rapidly giving place to more substantial structures. Founded in 1781 by the Spaniards, it received the name "Town of the Queen of the Angels" (*Pueblo de la Reina de los Angeles*) as a tribute to the beauty and pleasantness of the spot. It was the capital of the Mexican state of California from 1836 to 1846, in which latter year it was captured by United States forces. The population has increased from 5728 in 1870 to 11,311 in 1880.

LOT, the ancestor of Moab and Ammon, was the son of Haran and grandson of Terah, and accompanied his uncle Abraham in his migration from Haran to Canaan. At Bethel[1] Lot separated from Abraham, and, while the uncle went on to Hebron, the nephew settled in the district of Sodom. When Jehovah was about to destroy Sodom and the other cities of the plain two divine messengers appeared, spent the night in Lot's house, and next morning led Lot, his wife, and his two unmarried daughters out of the city. His wife looked back and was changed to a pillar of salt,[2] but Lot with his two daughters escaped first to Zoar and then to the mountains east of the Dead Sea, where the daughters, supposing themselves the only survivors of the catastrophe that had destroyed their home, planned and executed an incest by which they became mothers. The sons were the ancestors of Ammon and Moab. Such is the outline of the Jahvistic history of Lot, which the priestly narrator epitomizes in a few words, the only statement peculiar to his narrative being that in Gen. xi. 27-32. The account of Chedorlaomer's invasion and of Lot's rescue by Abraham belongs to an independent source, the age and historical value of which has been much disputed. See on the one hand Ewald, *Geschichte*, vol. i., and Tuch in his *Genesis*, and in an essay originally published in *Z.D.M.G.*, vol. i., and reprinted in the second edition of his *Genesis*, and on the other hand the essay in Nöldeke, *Untersuchungen*, and Wellhausen, *ut supra*, p. 414.

The name Lot (לוֹט) signifies "a veil," which has led Goldzieher, *Mythologie*, p. 216 *sq.*, to the arbitrary hypothesis that the story of Lot and his daughters is a myth about the night. Lot and his daughters passed into Arabic tradition from the Jews. The daughters are named Zahy and Ra'wa by Mas'ûdy, ii. 139; but other Arabian writers give other forms.

LOT, a south-westerly department of central France, corresponding to what was formerly known as Quercy (the country of the Cadurci), a district of the old province of Guyenne, is situated between 44° 12′ and 45° 5′ N. lat., and between 1° and ·2° 12′ E. long., and is bounded on the N. by Corrèze, on the W. by Dordogne and Lot-et-Garonne, on the S. by Tarn-et-Garonne, and on the E. by Aveyron and Cantal. Its extreme length, from north-east to south-west, is about 52 miles, and its breadth from north-west to south-east 31 miles, with an area of 2013 square miles. It slopes towards the south-west, from a maximum altitude of 2560 feet on the borders of Cantal to a minimum of 213 feet at the point where the river Lot quits the department, through a wide geological range beginning with primary rocks (granite, gneiss, mica-schists), which are succeeded by lias, oolitic limestone (occupying the greater portion of the area), chalks, and finally by Tertiary formations. The Lot, which traverses it from east to west, is navigable for the whole distance (78 miles) with the help of locks; its principal tributary within the department is the Célé (on the right). In the north of the department the Dordogne has a course of 37 miles; among its tributaries are the Cère, which has its rise in Cantal, and the Ouysse, a river of no great length, but remarkable for the abundance of its waters. The streams in the south of Lot all flow into the Tarn. By the Dordogne and Lot the surface is divided into a number of limestone plateaus known by the name of "causses"; that to the north of the Dordogne is called the Causse de Martel; between the Dordogne and the Lot is the Causse de Gramat or de Rocamadour; south of the Lot is the Causse de Cahors. These "causses," owing to the rapid disappearance of the rain through the faults in the limestone, have for the most part an arid appearance, and their rivulets are generally mere dry beds; but their altitude (from 700 to 1300 feet, much lower therefore than that of the similar plateaus in Lozère, Hérault, and Aveyron) admits of the cultivation of the vine; they also yield a small quantity of maize, wheat, oats, rye, and potatoes, and some wood. The deep intervening valleys are full of verdure, being well watered by abundant springs supplied by drainage from the plateaux above. The climate is on the whole that of the Girondine region; the valleys are warm, and the rainfall is somewhat above the average for France. The difference of temperature between the higher parts of the department belonging to the central plateau and the sheltered valleys of the south-west is considerable. Of the entire area of the department 691,920 acres are arable, 222,402 are forest land, 168,038 are occupied by vineyards, 64,250 are heath, and 61,778 are meadow. Sheep are the most abundant kind of live stock; but pigs, horned cattle, horses, asses, and mules, and goats are also reared, as well as poultry in large quantities, and bees. Wine is the principal product of the department, the most valued being that of Cahors or Côte du Lot. It is used partly for blending with other wines and partly for local consumption. The north-east cantons supply large quantities of chestnuts; apples, cherries, and peaches are common, and the department also grows tobacco and supplies truffles. The iron, lead, and zinc deposits are unimportant. Marble, millstones, limestone, and clay are obtained to some extent, but phosphate of lime is the most valuable mineral product of Lot. The manufactures are inconsiderable; but there are numerous mills, and wool spinning and carding as well as cloth making, tanning, currying, brewing, and agricultural implement making are carried on to some extent. The exports consist of grain, flour, wine, brandy, live stock, nuts, truffles, prunes, tobacco, wood, phosphate of lime, leather, and wool. The population in 1876 was 276,512. The three arrondissements are Cahors, Figeac, and Gourdon; there are twenty-nine cantons and three hundred and twenty-three communes.

LOT-ET-GARONNE, a department of south-western France, made up of Agenais and Bazadais, two districts of the former province of Guyenne, and Condomois and Lomagne, formerly portions of Gascony, lies between 43° 50′ and 44° 45′ N. lat., and 1° 7′ E. and 8′ W. long., and is bounded on the W. by Gironde, on the N. by Dordogne, on the E. by Lot and Tarn-et-Garonne, on the S. by Gers, and on the S.W. by Landes; its extreme length from south-west to north-east is 62 miles, and it has an area of 2067 square miles. The Garonne, which traverses the department from south-east to north-west, divides it into two unequal parts; in that to the north the slope is from east to west, while in that to the south it is directly from south to north. A small portion in the south-west belongs

[1] In Gen. xii. 10 *sq.*, where Abraham's visit to Egypt is recorded, there is no mention of Lot, and Wellhausen (*Jahrb. f. D. Theol.*, 1876, p. 413) has made it probable that this episode is no part of the Jahvistic narrative, to which the history of Lot mainly belongs.

[2] Such a pillar in the neighbourhood of Usdum is described by Lynch, *Narrative*, p. 307. See also Robinson, *Bib. Res.*, 2d ed., ii. 108.

to the sterile region of the Landes; the valleys of the Garonne and of the Lot (its greatest affluent here) on the other hand are proverbial for their fertility. The wildest part is in the borders of Dordogne, where oak, chestnut, and beech forests are numerous; the highest point is also here (896 feet). The Garonne, where it quits the department, is only some 33 or 36 feet above the sea-level; it is navigable throughout, with the help of its lateral canal, as also are the Lot and Bayse with the help of locks. The Dropt, a right affluent of the Garonne in the north of the department, is also navigable in the lower part of its course. The climate is that of the Girondine region, the mean temperature of Agen being 56°·6 Fahr., or 5° above that of Paris; the rainfall (31·5 inches) is also above the average of France. Of the entire area 741,342 acres are arable, 210,047 are vineyard, 172,980 under wood, 85,254 natural meadow, and 56,836 waste. Horned cattle are the chief live stock; next in order come pigs, sheep, horses, asses, and mules, and a small number of goats. Poultry and bees are also reared. Its wines and its cereals are a great source of wealth to the department; in 1875 488,000 quarters of grain and 14,000,000 gallons of wine were produced. Potatoes, beetroot, pulse, and maize are also largely grown; next come rye, barley, meslin, and buckwheat. In 1877 7759 acres produced 5,838,849 lb of tobacco, worth upwards of two million francs. Colza, hemp, and flax are also extensively cultivated. The fruit harvest (nuts, chestnuts, apricots) is large and valuable, the prunes which take their name from Agen being especially in demand. The forests in the south-west supply pine wood and cork. The forges, high furnaces, and foundries of the department are important; brazier's ware is also produced; and there are workshops for the manufacture of agricultural implements and other machines. The making of plaster, lime, and hydraulic cement, of tiles, bricks, and pottery, of confectionery and other eatables, and brewing and distilling, occupy many of the inhabitants. At Tonneins there is a national tobacco manufactory, and the list of industries is completed by the mention of boatbuilding, cork cutting, hat and candle making, wool spinning, weaving of woollen and cotton stuffs, tanning, paper making, oil making, and flour and saw milling. In 1876 the population was 316,920 (1100 Protestants). The inhabitants speak a patois in which elegant and graceful works have been written, such as the poems of Jasmin (*q.v.*). The arrondissements are four,—Agen, Marmande, Nérac, and Villeneuve; and there are thirty-five cantons and three hundred and twenty-five communes.

LOTHAIR I., Roman emperor, eldest son of Louis the Pious, was born in 795. At a diet held at Aix-la-Chapelle in 817 he received Austrasia with the greater part of Germany, and was associated with his father in the empire, while separate territories were granted to his brothers Louis and Pippin. This arrangement being modified in favour of Louis's youngest son Charles (afterwards Charles the Bald), the three brothers repeatedly rebelled, and for a time Lothair usurped supreme power. After the death of Louis in 840, Lothair, as his successor, claimed the right to govern the whole empire. His brothers Louis and Charles (Pippin being dead) united against him, and in 841 he was defeated in the great battle of Fontenay. On the 11th of August 843 the war was brought to an end by the treaty of Verdun, by which Lothair was confirmed in the imperial title, but received as his immediate territory only Italy (which he had ruled from 822) with a long narrow district reaching past the Rhone and the Rhine to the North Sea. His subsequent reign was full of trouble, for many of his vassals had become virtually independent, and he was unable to contend successfully with the Norsemen and the Saracens. In 855, weary of the cares of government, he divided his kingdom among his sons, and retired to the monastery of Prüm, where he died on the 28th of September of the same year. As emperor he was succeeded by his son Louis II.

LOTHAIR THE SAXON, German king and Roman emperor, was originally count of Suplinburg. In 1106 he was made duke of Saxony by the emperor Henry V., against whom he afterwards repeatedly rebelled. After the death of Henry V. in 1125, the party which supported imperial in opposition to papal claims wished to grant the crown to Duke Frederick of Swabia, grandson of Henry IV. The papal party, however, headed by Archbishop Adalbert of Mainz, managed to secure the election of Lothair, who obtained their favour by making large concessions by which he was afterwards seriously hampered. In 1133 he was crowned emperor in Rome by Innocent II., whom he had supported in a disputed papal election. In later times the church pretended that he had done homage to the pope for the empire, but what he really received in fief was the hereditary territory of the Countess Matilda. Meanwhile he had been engaged in bitter strife with the Hohenstaufen family, from whom he had demanded the allodial lands which they had inherited from the emperor Henry V. Duke Frederick of Swabia, and his brother Conrad, had resisted these pretensions; and Conrad had even been crowned king in Milan. The quarrel was ultimately settled by the lands in dispute being granted in fief to the house of Hohenstaufen. In order to strengthen his position, Lothair had given his daughter Gertrude (a child of eleven) in marriage to Henry the Proud, duke of Bavaria, whom he made also duke of Saxony. Henry was further enriched by receiving the hereditary and imperial territories of the Countess Matilda, so that the Guelphs became by far the most powerful family in the empire. Lothair secured other important adherents by giving North Saxony (afterwards Brandenburg) to Albert the Bear, and Thuringia (which he took from Landgrave Hermann) to Count Louis. In his relations to the neighbouring populations Lothair acted with great vigour. The duke of Bohemia and the duke of Poland were compelled to do homage, and the margraviate of Meissen and the county of Burgundy he gave to two of his supporters, the former to Count Conrad of Wettin, the latter to Duke Conrad of Zähringen. The kingdom of the Abotrites he granted to the Danish king Cnut; and Cnut's successor Magnus was forced to accept it as a fief of the empire. In 1136 Lothair undertook a second expedition to Italy for the defence of Pope Innocent II. against Roger of Sicily, and after accomplishing his object he died on the 3d of December 1137, in an Alpine hut near Trent, on his way back to Germany. During his reign the papacy gained ground in its rivalry with the empire, but he displayed courage and resource in maintaining the rights of the crown against all his secular opponents.

See Gervais, *Politische Geschichte Deutschlands unter der Regierung der Kaiser Heinrich V. und Lothar III.*, 1841–42; Jaffé, *Geschichte des deutschen Reichs unter Lothar dem Sachsen*, 1843.

LOTHIAN, Lothene, Laodonia, a name whose origin is unknown,[1] now preserved in the three Scottish counties of East, West, and Mid Lothian—Haddington, Linlithgow, and Edinburgh (*q.v.*)—originally extended from the Forth to the Tweed. The Forth separated it from Celtic Alba, and the Tweed from the southern part of Bryneich (Bernicia). Its western boundaries appear to have been the Cheviots and the Lowthers. After the Anglo-Saxon migration it formed part of the Anglian kingdom of Northumberland, founded by Ida the Flame-bearer in 547, which in its

[1] Loth, son of Anna, the sister of Arthur, a Scottish consul and lord of Laudonia (Fordun, iii. 24), the Llew of the Arthurian legend (Skene, *Four Books of Wales*, chap. iv.), is, of course, an eponymus.

widest extent, under the powerful Northumbrian kings of the 7th century, reached from the Humber to the Forth. A different but allied branch of the Angles settled along the tributaries of the Tweed, and the Cheviot, Lowther, Moorfoot, and Pentland (Pictish) hills separated the colonists of southern Scotland from the British kingdom of Strath Clyde or Cumbria. The victories of Catræth (596) and Dægsastan (603) in the reign of Ethelfrith represent the close of the struggle which drove the British or Cumbrian Celts (Cymry) into the western hill country, afterwards known as Westmoreland and Cumberland, and the Picts to the north of the Forth and Clyde, so that Anglian Northumberland secured the former river as its northern boundary, and even for a time threatened to pass it. Edwin of Deira (617–33), the chief king of England in his time, probably founded Edinburgh, although its Celtic name Dun Eden has been thought by some to suggest a different derivation. Egfrid at the close of the 7th century established an Anglian bishop at Abercorn on the Forth, but was defeated and slain at Nechtansmere, or Dunnichen, in Forfarshire by the Pictish king Brude (685), and Trumwine the bishop at Abercorn was forced to retire to Whitby. In the 8th century the Northumbrian kings were engaged in a conflict with Mercia, and in 827 the supremacy of Egbert, the founder of the West Saxon monarchy, was acknowledged, although on the part of the Northumbrians the recognition must have been at first almost nominal, for it was not until more than a century later that Athelstan, by the victory of Brunanburg (937) over the allied Welsh, Scots, and Northumbrian Danes, really extended the boundaries of the Wessex kingdom over the greater part of Northumbria, which was reduced to an earldom by Edred in 954. Athelstan had in 934 ravaged Scotland north of the Forth, and must for a time have reduced Lothian, the northern district of Northumberland, but it does not appear that either he or any of his successors had real sovereignty over Lothian, which was left to the rule of Northumbrian earls, sometimes of Anglian and at other times of Danish race. Its population continued Anglian, as is proved by the fact that there are no Danish monuments and few Danish place names between the Tweed and the Forth. The Scottish Celts, like the English Anglo-Saxons, were during this period occupied with warding off the Danes and Norsemen, but about the middle of the 9th century Kenneth Macalpine united the Scottish and Pictish kingdoms, and fixed the capital at Scone. This monarch is said by the Pictish chronicle to have six times invaded Saxony (the name given by the Celts to the Anglo-Saxon territory), and to have burnt Dunbar and Melrose. The Anglians of Northumbria had been converted to Christianity by Paulinus in 627, and reconverted by a Celtic mission from Iona between 635 and 651 under Aidan, who planted a mission station—a southern Iona—on the Holy Island, and became first bishop of Lindisfarne. Cuthbert, one of his successors in this bishopric, which had become Anglian and conformed to the Roman ritual and discipline after the council of Whitby (664), has the credit of spreading the gospel in Lothian, where he had been first monk and then prior of the recently founded monastery of Melrose.

About the middle of the 10th century (954-62) Edinburgh was abandoned by the Northumbrian Angles and occupied by Indulph, son of Constantine, king of the Scots. According to John of Wallingford and Roger of Wendover, Edgar the West Saxon king ceded in 966 Lothian to Kenneth III., son of Malcolm I., on condition that he should do homage for it and give pledges not to deprive the people of that region of their ancient customs, and that they should still retain the name and language of the Angles. This cession, which is not in the older chronicles, has been matter of controversy between Freeman (*Norman Conquest*, i., note B, p. 610), who accepts the statement, and E. W. Robertson (*Scotland under her Early Kings*, i. 390) and Skene (*Celtic Scotland*, i. 370), who reject it upon what appear better grounds. But the dispute is of small importance, as it is admitted on the authority of Simeon of Durham that, whether or not it was then ceded on condition of homage, it was annexed to Scotland by conquest in 1018 in consequence of the victory at Carham by Malcolm the son of Kenneth over the Northumbrian earl Eadulf Ciudel,—"Hoc modo," says Simeon writing before 1129, "Lodonium adjectum est regno Scotiæ." Canute and William the Conqueror made temporary conquests of Scotland including Lothian, and homage of various kinds was rendered to them and other Norman monarchs, but there is no trace of any special homage for Lothian except in two dubious charters by Edgar to William Rufus, so that it seems certain that from the beginning of the 11th century it was an integral part of Scotland. Freeman, in his *Historical Geography*, styles it an English earldom, but it is never so called in any authentic record. While it was an integral part of Scotland its population was recognized as a distinct branch of the Scottish nation, and the men of Lothian are frequently separately named, as in the contemporary account of the Battle of the Standard (1138). It also retained its language, customs, and laws, which were those of the Angles of Northumbria. Although united in civil government to Scotland, Lothian, or at least many places in it, continued ecclesiastically subject to the see of Durham, which had succeeded that of Lindisfarne, until the beginning of the 12th century (Stubbs and Haddan, *Concilia*, ii. p. 161), but it then came under the bishop of St Andrews, and was divided into three rural deaneries, the Merse, Haddington, and Linlithgow, with an archdeacon of Lothian, who first distinctly appears under that name at the commencement of the 13th century.

The division of Scotland into shires was probably made by David I., and Lothian included the shires of Berwick or the Merse (the march or borderland, as English Mercia and Spanish Murcia), Roxburgh, and Edinburgh, which included the constabularies of Haddington and Linlithgow, afterwards erected into separate counties. Its principal burghs — Berwick, Roxburgh, and Edinburgh — formed along with Stirling the court of the four burghs, whose laws were collected by David I. ("Leges Quatuor Burgorum," *Act. Parl. Scot.*, i. 327), and whose meeting-place was Haddington, but the frequent occupation of Berwick and Roxburgh by the English caused Lanark and Linlithgow to be substituted, and the place of meeting to be changed to Stirling in 1368. The convention of royal burghs may be traced back to this court.

The independence of Scotland, including Lothian, though frequently disputed by the English sovereigns, was always maintained by the Scotch, except when surrendered by William the Lion as a prisoner by the treaty of Falaise 1174, cancelled by Richard I. in 1189. It was finally acknowledged by Edward I. in the treaty of Brigham, but after the death of the Maid of Norway this acknowledgment was repudiated, and it was only finally established by the war of independence, and definitely recognized in the treaty of Northampton in 1328.

By a singular but fortunate series of events, of which the first was the marriage of Malcolm Canmore with the Saxon princess Margaret, Lothian, the Anglian part of the Scottish kingdom, though its borderland, became its centre. Edinburgh, its chief town, was from that time a favourite residence of the court, and under the Stuart kings became the capital of the kingdom. Its language, the dialect of northern England, became the basis of the Lowland Scots, at first called Inglys or English, but afterwards Scotch, when Celtic, Erse, or Gaelic had ceased to be spoken in the lowland districts, in distinction from southern English. Its customary law, with additions prior to the war of independence of Norman feudal institutions from England, is the basis of those parts of the common law of Scotland which are not taken from Roman jurisprudence. And it was from Lothian that Anglo-Saxon and Anglo-Norman civilization radiated to the remotest parts of the Highlands and Islands. (Æ. M.)

LOTTERIES. The word lottery has no very definite signification. It may be applied to any process of determining prizes by lot, whether the object be amusement, or gambling, or public profit. In the Roman Saturnalia and in the banquets of aristocratic Romans the object was amusement; the guests received *apophoreta.* The same plan was followed on a magnificent scale by some of the emperors. Nero excited the people by giving such prizes as a house or a slave. Heliogabalus introduced an element of absurdity,—one ticket for a golden vase, another for six flies. This amusing custom descended to the festivals given by the feudal and merchant princes of Europe, especially of Italy; and it afterwards formed a prominent feature of the splendid court hospitality of Louis XIV. In the Italian republics of the 16th century the lottery principle was applied to encourage the sale of merchandise. The lotto of Florence and the seminario of Genoa are well known, and Venice established a monopoly and drew a considerable revenue for the state. The first letters patent for a lottery in France were granted by Francis I., and in 1656 the Italian Tonti (the originator of "Tontines") opened another for the building of a stone bridge between the Louvre and the Faubourg St Germain. The institution became very popular in France, and gradually assumed an important place in the Government finance. The parliaments frequently protested against it, but it had the support of Mazarin, and Pontchartrain by this means raised the expenses of the Spanish Succession War. Necker, in his *Administration des Finances*, estimates the public charge for lotteries at 4,000,000 livres per annum. There were also lotteries for the benefit of religious communities and charitable purposes. Two of the largest were the *Loteries de Piété* and *des Enfans Trouvés.* These and also the great *Loterie de l'École militaire* were practically merged in the *Loterie Royale* by the famous decree of 1776, suppressing all private lotteries in France. The financial basis of these larger lotteries was to take $\frac{5}{24}$ths for expenses and benefit, and return $\frac{19}{24}$ths to the public who subscribed. The calculation of chances had become a familiar science. It is explained in detail by M. Caminade de Castres in *Enc. Méth. Finances*, ii., *s. v.* "Loterie." The names of the winning numbers in the first drawing were (1) *extrait,* (2) *ambe,* (3) *terne,* (4) *quaterne,* (5) *quine.* After this there were four drawings called *primes gratuites.* The *extrait* gave fifteen times the price of the ticket; the *quine* gave one million times the price. These are said to be much more favourable terms than were given in Vienna, Frankfort, and other leading European cities at the end of the 18th century. There is no doubt that lotteries had a demoralizing effect on French society. They were denounced by the eloquent bishop of Autun as no better than the popular games of *belle* and *biribi*; they were condemned on financial grounds by Turgot; and Condillac compared them to the debasement of money which was at one time practised by the kings of France. The *Loterie Royale* was ultimately suppressed in 1836. Under the law of 29th May 1844 lotteries may be held for the assistance of charity and the fine arts. The Société du Credit Foncier, and many of the large towns, are permitted to contract loans, the periodical repayments of which are determined by lot. This practice, which is prohibited in Germany and England, resembles the older system of giving higher and lower rates of interest for money according to lot. Lotteries were suppressed in Belgium in 1830, but they still figure largely in the State budgets of Germany, Holland, Spain, and Italy.

In England the earliest lotteries sanctioned by Government were for such purposes as the repair of harbours in 1569, and the Virginia Company in 1612. In 1696 by the Act 10 & 11 Will. III. c. 17 lotteries, with the exception of the Royal Oak lottery, were prohibited as common nuisances, by which children, servants, and other unwary persons had been ruined. This prohibition was in the 18th century gradually extended to illegal insurances on marriages and other events, and to a great many games with dice, such as faro, basset, hazard, except backgammon and games played in the royal palace. In spite of these prohibitions, the Government from 1709 down to 1824 showed a bad example to the nation by annually raising considerable sums in lotteries authorized by Act of Parliament. The prizes were in the form of terminable or perpetual annuities. The £10 tickets were sold at a premium of say 40 per cent. to contractors who resold them in retail (sometimes in one-sixteenth parts) by "morocco men," or men with red leather books who travelled through the country. As the drawing extended over forty days, a very pernicious system arose of insuring the fate of tickets during the drawing for a small premium of 4d. or 6d. This was partly cured by the Little Go Act of 1802, 42 Geo. III. c. 119, directed against the itinerant wheels which plied between the state lotteries, and partly by Perceval's Act in 1806, which confined the drawing of each lottery to one day. From 1793 to 1824 the Government made an average yearly profit of £346,765. Cope, one of the largest contractors, is said to have spent £36,000 in advertisements in a single year. The English lotteries were used to raise loans for general purposes, but latterly they were confined to particular objects, such as the improvement of London, the disposal of Cox's museum, the purchase of Tomkin's picture gallery, &c. Through the efforts of Lyttleton and others a strong public opinion was formed against them, and in 1826 they were finally prohibited. An energetic proposal to revive the system was made before the select committee on metropolitan improvements in 1830, but it was not listened to. By a unique blunder in legislation, authority was given to hold a lottery under the Act 1 & 2 Will. IV. c. 8, which provides a scheme for the improvement of the city of Glasgow. These "Glasgow lotteries" were suppressed by 4 & 5 Will. IV. c. 37. The statute law in Scotland is the same as in England. At common law in Scotland it is probable that all lotteries and raffles, for whatever purpose held, may be indicted as nuisances. The art unions are supposed to be protected by a special statute.

The American Congress of 1776 instituted a national lottery. The scheme was warmly advocated by Jefferson and other statesmen, and before 1820 at least seventy Acts were passed by Congress authorizing lotteries for various public purposes, such as schools, roads, &c.,—about 85 per cent. of the subscriptions being returned in prizes. A sounder opinion now prevails on this subject in America.

The only systematic work on this subject is the *Critique hist. pol. mor. econ. et comm. sur les loteries anc. et. mod. spirituelles et temporelles des États et des Églises*, Amsterdam, 1697, 3 vols., by the Bolognese historian Gregorio Leti. The subject is also dealt with by J. Dessaulx in his work *De la passion du jeu depuis les anciens temps jusqu' à nos jours*, Paris, 1779. (W. C. S.)

LOTUS-EATERS (Greek Λωτοφάγοι) were a Libyan tribe known to the Greeks as early as the time of Homer. Herodotus (iv. 177) describes their country as in the

Syrtic district, and says that a caravan route led from it to Egypt. The lotus still grows there in great abundance. It is a prickly shrub, the jujube tree, bearing a fruit of a sweet taste, compared by Herodotus to that of the date; it is still eaten by the natives, and a kind of wine is made from the juice (see JUJUBE). Marvellous tales were current among the early Greeks of the virtues of the lotus, as we see in *Odys.*, ix. 84. When Ulysses comes to the coast many of his sailors eat the lotus and lose all wish to return home. The idea has been worked up by Tennyson in a very fine poem. This lotus must not be confounded with the Egyptian plant, a kind of water-lily that grows in the Nile. See Ritter, *Erdkunde*, i.; and Heeren, *Ideen*, ii., or in *Historical Researches*, &c.

LOTZE, RUDOLPH HERMANN, one of the most eminent philosophers of our age, was born May 21, 1817, in Bautzen, in the kingdom of Saxony, and died at Berlin 1st July 1881. The incidents of the life of a philosopher, especially if his career has been exclusively an academic one, are usually passed over as unimportant. In external events no life could be less striking than that of Lotze, who, moreover, was of a retiring disposition, and was forced through delicate health to seclude himself from even such external excitement and dissipation as the quiet university town of Göttingen, where he passed nearly forty years of his life, might afford. His interests on the contrary, as exhibited in his various writings, are most universal; and in a surprising degree he possessed the power of appreciating the wants of practical life, and the demands of a civilization so complicated as that of our age, so full of elements which have not yet yielded to scientific treatment. But, although in his teachings he rose more than most thinkers beyond the temporary and casual influences which surrounded him, it was significant for the development of his ideas that the same country produced him which gave to Germany Lessing and Fichte, that he received his education in the gymnasium of Zittau under the guidance of eminent and energetic teachers, who nursed in him a love and tasteful appreciation of the classical authors, of which in much later years he gave a unique example in his masterly translation of the *Antigone* of Sophocles into Latin, and that, himself the son of a physician, he went to the university of Leipsic as a student of philosophy and natural sciences, but enlisted officially as a student of medicine. He was then only seventeen. It appears that thus early Lotze's studies were governed by two distinct interests and emanated from two centres. The first was his scientific interest and culture, based upon mathematical and physical studies, under the guidance of such eminent representatives of modern exact research as E. H. Weber, W. Volckmann, and G. T. Fechner. The others were his æsthetical and artistic predilections, which were developed under the care of C. H. Weisse. To the former he owes his appreciation of exact investigation and a complete knowledge of the aims of science, to the latter an equal admiration for the great circle of ideas which had been cultivated and diffused through the teachings of Fichte, Schelling, and Hegel. But each of these aspects, which early in life must have been familiar to him, exerted on the other a tempering and modifying influence. The true method of science which he possessed forced him to condemn as useless the entire form which Schelling's and Hegel's expositions had adopted, especially the dialectic method of the latter, whilst his love of art and beauty, and his appreciation of moral purposes, revealed to him the existence beyond the phenomenal world of a world of values or worths into which no exact science could penetrate. It is evident how this initial position at once defined to him a variety of tasks which philosophy had to perform. First there were the natural sciences themselves only just emerging from an unclear conception of their true method,—especially those which studied the borderland of physical and mental phenomena, the medical sciences, pre-eminently that science which has since become so popular, the science of biology. Lotze's first essay was his dissertation *De futuræ biologiæ principibus philosophicis*, with which he gained (1838) the degree of doctor of medicine, after having only four months previously got the degree of doctor of philosophy. Then, secondly, there arose the question whether the methods of exact science sufficed to explain the connexion of phenomena, or whether for the explanation of this the thinking mind was forced to resort to some hypothesis not immediately verifiable by observation, but dictated by our higher aspirations and interests. And, if to satisfy these we were forced to maintain the existence of a world of moral standards, it was, thirdly, necessary to form some opinion as to the relation of these moral standards of value to the forms and facts of phenomenal existence. These different tasks, which philosophy had to fulfil, mark pretty accurately the aims of Lotze's writings, and the order in which they were published. But, though he laid the foundation of his philosophical system very early, in his *Metaphysik* (Leipsic, 1841) and his *Logik* (1843), and commenced lecturing when only twenty-two years old on philosophical subjects, in Leipsic, though he accepted in 1844 a call to Göttingen to fill the chair of philosophy which had become vacant through the death of Herbart, he did not proceed to an exhaustive development of his peculiar views till very much later, and only during the last decade of his life, after having matured them in his eminently popular lectures, did he with much hesitation venture to present his ideas in something like a systematic form. The two small publications just referred to remained unnoticed by the reading public, and Lotze became first known to a larger circle through a series of works which had the object of establishing in the study of the physical and mental phenomena of the human organism in its normal and diseased states the same general principles which had been adopted in the investigation of inorganic phenomena. These works were his *Allgemeine Pathologie und Therapie als mechanische Naturwissenschaften* (Leipsic, 1842, 2d ed. 1848), the articles "Lebenskraft" (1843) and "Seele und Seelenleben" (1846) in Rud. Wagner's *Handwörterbuch der Physiologie*, his *Allgemeine Physiologie des Körperlichen Lebens* (Leipsic, 1851), and his *Medizinische Psychologie oder Physiologie der Seele* (Leipsic, 1852). When Lotze came out with these works, medical science was still much under the influence of Schelling's philosophy of nature. The mechanical laws, to which external things were subject, were conceived as being valid only in the inorganic world; in the organic and mental worlds these mechanical laws were conceived as being disturbed or overridden by other powers, such as the influence of final causes, the existence of types, the work of vital and mental forces. This confusion Lotze, who had been trained in the school of mathematical reasoning, tried to dispel. The laws which govern particles of matter in the inorganic world govern them likewise if they are joined into an organism. A phenomenon a, if followed by b in the one case, is followed by the same b also in the other case. Final causes, vital and mental forces, the soul itself can, if they act at all, only act through the inexorable mechanism of natural laws. If a is to be followed by d and not by b, this can only be effected by the additional existence of a third something c, which again by purely mechanical laws would change b into d. As we therefore have only to do with the study of existing complexes of material and spiritual phenomena, the changes in these must be explained in science by the rule of mechanical laws, such as obtain everywhere in the world. and only by such. One of the results of these investigations was to extend the meaning of the word mechanism, and comprise under it all laws which obtain in the phenomenal world, not excepting the phenomena of life and mind. Mechanism was the unalterable connexion of every phenomenon *a* with other phenomena *b*, *c*, *d*, either as following or preceding it; mechanism was the inexorable form into which the events of this world are cast, and by which they are connected. The object of those writings was to establish the all-pervading rule of mechanism. But the mechanical view of nature is not identical with the materialistic. In the last of the above-mentioned works the question is discussed at great length how we have to consider mind, and the relation between mind and body; the answer is—we have to consider mind as an immaterial principle, its action, however, on the body and *vice versa* as purely mechanical, indicated by the fixed laws of a psycho-physical mechanism. These doctrines of Lotze—though pronounced with the distinct and reiterated reserve that they did not contain a solution of the philosophical question regarding the nature, origin, or deeper meaning of this all-pervading mechanism, neither an explanation how the action of external things on each other takes place nor yet of the relation of mind and body, that they were merely a preliminary formula of practical scientific value, itself requiring a deeper interpretation—these doctrines were nevertheless by many considered to be the last word of the philosopher who, denouncing the reveries of Schelling or the idealistic theories of Hegel, established the science of life and mind on the same basis as that of material things. Published as they were during the years when the modern school of German materialism was at its height,[1] these works of Lotze were counted among the opposition literature which destroyed the phantom of Hegelian wisdom and vindicated the independent and self-sufficing position of empirical philosophy. Even philosophers of the eminence of J. H. Fichte (the younger) did not escape this misinterpretation of Lotze's true meaning, though they had his *Metaphysik* and *Logik* to refer to, though he promised in his *Allgemeine Physiologie* (1851) to enter in a subsequent work upon the "bounding province between æsthetics and physiology," and though in his *Medicinische Psychologie* he had distinctly stated that his position was neither the idealism of Hegel nor the realism of Herbart, nor materialism, but that it was the conviction that the essence of everything is the part it plays in the realization of some idea which is in itself valuable, that the sense of an all-pervading mechanism is to be sought in this that it denotes the ways and means by which the highest idea, which we may call the idea of the good, has voluntarily chosen to realize itself.

The misinterpretations which he had suffered induced Lotze to publish a small pamphlet of a polemical character (*Streitschriften*, Leipsic, 1857), in which he corrected two mistakes. The opposition which he had made to Hegel's formalism had induced some to associate him with the materialistic school, others to count him among the followers of Herbart, the principal philosopher of eminence who had maintained a lifelong protest against the development which Kant's doctrines had met with at the hands of Fichte, Schelling, and Hegel. Lotze publicly and formally denied that he belonged to the school of Herbart, though he admitted that historically the same doctrine which might be considered the forerunner of Herbart's teachings might lead to his own views, viz., the monadology of Leibnitz.

When Lotze wrote these explanations, he had already given to the world the first volume of his great work, *Mikrokosmus* (vol. i. 1856, vol. ii. 1858, vol. iii. 1864; 3d ed., 1876–1880). In many passages of his works on pathology, physiology, and psychology Lotze had distinctly stated that the method of research which he advocated there did not give an explanation of the phenomena of life and mind, but only the means of observing and connecting them together; that the meaning of all phenomena, and the reason of their peculiar connexions, was a philosophical problem which required to be attacked from a different point of view; and that the significance especially which lay in the phenomena of life and mind would only unfold itself if by an exhaustive survey of the entire life of man, individually, socially, and historically, we gain the necessary data for deciding what meaning attaches to the existence of this microcosm, or small world of human life, in the macrocosm of the universe. This review, which extends, in three volumes, over the wide field of anthropology, beginning with the human frame, the soul, and their union in life, advancing to man, his mind, and the course of the world, and concluding with history, progress, and the connexion of things, ends with the same idea which was expressed in Lotze's earliest work,—*Metaphysik*. The view peculiar to him is reached in the end as the crowning conception towards which all separate channels of thought have tended, and in the light of which the life of man in nature and mind, in the individual and in society, had been surveyed. This view can be briefly stated as follows. Everywhere in the wide realm of observation we find three distinct regions,—the region of facts, the region of laws, and the region of standards of value and worth. These three regions are separate only in our thoughts, not in reality. To comprehend the real position we are forced to the conviction that the world of facts is the field in which, and that laws are the means by which, those higher standards of moral and æsthetical value are being realized; and such a union can again only become intelligible through the idea of a personal Deity, who in the creation and preservation of a world has voluntarily chosen certain forms and laws, through the natural operation of which the ends of His work are gained.

Whilst Lotze had thus in his published works closed the circle of his thought, beginning with a conception metaphysically gained, proceeding to an exhaustive contemplation of things in the light it afforded, and ending with the stronger conviction of its truth which observation, experience, and life could afford, he had all the time been lecturing on the various branches of philosophy according to the scheme of academical lectures transmitted from his predecessors. Nor can it be considered anything but a gain that he was thus induced to expound his views with regard to those topics, and in connexion with those problems, which were the traditional forms of philosophical utterance. His lectures ranged over a wide field: he delivered annually lectures on psychology and on logic (the latter including a survey of the entirety of philosophical research under the title *Encyclopädie der Philosophie*), then at longer intervals lectures on metaphysics, philosophy of nature, philosophy of art, philosophy of religion, rarely on history of philosophy and ethics. In these lectures he expounded his peculiar views in a stricter form, and during the last decade of his life he embodied the substance of those courses in his *System der Philosophie*, of which only two volumes have appeared (vol. i. *Logik*, 1st ed., Leipsic, 1874, 2d ed., 1880; vol. ii. *Metaphysik*, 1879). The third and concluding volume, which was to treat in a more condensed form the principal problems of practical philosophy, of philosophy of art and religion, did not appear. A small pamphlet on psychology, containing the last form in which he had begun to treat the subject in his lectures (abruptly terminated through his death) during the sum-

mer session of 1881, has been published by his son. Appended to this volume is a complete list of Lotze's writings, compiled by Professor Rehnisch of Göttingen.

To understand this series of Lotze's writings, it is necessary to start with his definition of philosophy. This is given after his exposition of logic has established two points, viz., the existence in our mind of certain laws and forms according to which we connect the material supplied to us by our senses, and, secondly, the fact that logical thought cannot be usefully employed without the assumption of a further set of connexions, not logically necessary, but assumed to exist between the data of experience and observation. These connexions of a real not formal character are handed to us by the separate sciences and by the usage and culture of everyday life. Language has crystallized them into certain definite notions and expressions, without which we cannot proceed a single step, but which we have accepted without knowing their exact meaning, much less their origin. In consequence the special sciences and the wisdom of common life entangle themselves easily and frequently in contradictions. A problem of a purely formal character thus presents itself, viz., this—to try to bring unity and harmony into the scattered thoughts of our general culture, to trace them to their primary assumptions and follow them into their ultimate consequences, to connect them all together, to remodel, curtail, or amplify them, so as to remove their apparent contradictions, and to combine them in the unity of an harmonious view of things, and especially to make those conceptions from which the single sciences start as assumptions the object of research, and fix the limits of their applicability. This is the formal definition of philosophy. Whether an harmonious conception thus gained will represent more than an agreement among our thoughts, whether it will represent the real connexion of things, and thus possess objective not merely subjective value, cannot be decided at the outset. It is also unwarranted to start with the expectation that everything in the world should be explained by one principle, and it is a needless restriction of our means to expect unity of method. Nor are we able to start our philosophical investigations by an inquiry into the nature of human thought and its capacity to attain an objective knowledge, as in this case we would be actually using that instrument the usefulness of which we were trying to determine. The main proof of the objective value of the view we may gain will rather lie in the degree in which it succeeds in assigning to every element of culture its due position, or in which it is able to appreciate and combine different and apparently opposite tendencies and interests, in the sort of justice with which it weighs our manifold desires and aspirations, balancing them in due proportions, nor sacrificing to a one-sided principle any truth or conviction which experience has proven to be useful and necessary. The investigations will then naturally divide themselves into three parts, the first of which deals with those to our mind inevitable forms in which we are obliged to think about things, if we think at all (metaphysics), the second being devoted to the great region of facts, trying to apply the results of metaphysics to these, specially the two great regions of external and mental phenomena (cosmology and psychology), the third dealing with those standards of value from which we pronounce our æsthetical or ethical approval or disapproval. In each department we shall have to aim first of all at views clear and consistent within themselves, but, secondly, we shall in the end wish to form some general idea or to risk an opinion how laws, facts, and standards of value may be combined in one comprehensive view. Considerations of this kind will naturally turn up in the two great departments of cosmology and psychology, or they may be delegated to an independent research under the name of religious philosophy. We have already mentioned the final conception in which Lotze's speculation culminates, that of a personal Deity, Himself the essence of all that merits existence for its own sake, who in the creation and government of a world has voluntarily chosen certain laws and forms through which His ends are to be realized. We may add that according to this view nothing is real but the living spirit of God and the world of living spirits which He has created; the things of this world have only reality in so far as they are the appearance of spiritual substance, which underlies everything. It is natural that Lotze, having this great and final conception always before him, works under its influence from the very beginning of his speculations, permitting us—as we progress—to gain every now and then a glimpse of that interpretation of things which to him contains the solution of our difficulties.

The key to Lotze's theoretical philosophy lies in his metaphysics, to the exposition of which important subject the first and last of his larger publications have been devoted. To understand Lotze's philosophy, a careful and repeated perusal of these works is absolutely necessary. The object of his metaphysics is so to remodel the current notions regarding the existence of things and their connexions with which the usage of language supplies us as to make them consistent and thinkable. The further assumption, that the modified notions thus gained have an objective meaning, and that they somehow correspond to the real order of the existing world which of course they can never actually describe, depends upon a general confidence which we must have in our reasoning powers, and in the significance of a world in which we ourselves with all the necessary courses of our thoughts have a place assigned to them in harmony with the whole. The object therefore of these investigations is opposed to two attempts frequently repeated in the history of philosophy, viz.:—(1) the attempt to establish general laws or forms, which the development of things must have obeyed, or which a Creator must have followed in the creation of a world (Hegel); and (2) the attempt to trace the genesis of our notions, and decide as to their meaning and value (modern theories of knowledge). Neither of these attempts is practicable. The world of many things surrounds us; our notions, by which we manage correctly or incorrectly to describe it, are also ready made. What remains to be done is, not to explain how such a world manages to be what it is, nor how we came to form these notions, but merely this—to expel from the circle and totality of our conceptions those abstract notions which are inconsistent and jarring, or to remodel and define them so that they may constitute a consistent and harmonious view. In this endeavour Lotze discards as useless and untenable many favourite conceptions of the school, many crude notions of everyday life. The course of things and their connexion is only thinkable by the assumption of many things the reality of which (as distinguished from their existence in our thoughts) can be conceived only as a multitude of relations. This, standing in relation to other things, gives to a thing its reality. And the nature of this reality again can neither be consistently represented as a fixed and hard substance nor as an unalterable something, but only as a fixed order of recurrence of continually changing events or impressions. But, further, every attempt to think clearly what those relations are, what we really mean, if we talk of a fixed order of events, forces upon us the necessity of thinking also that the different things which stand in relations or the different phases which follow each other cannot be merely externally strung together or moved about by some indefinable external power, in the form of some predestination or inexorable fate. The things themselves which exist and their changing phases must stand in some internal connexion; they themselves must be active or passive, capable of doing or suffering. This would lead to the view of Leibnitz, that the world consists of monads, self-sufficient beings, leading an inner life. But this idea involves the further conception of Leibnitz, that of a pre-established harmony, by which the Creator has cared to arrange the life of each monad, so that it agrees with that of all others. This conception, according to Lotze, is neither necessary nor thoroughly intelligible. Why not interpret at once and render intelligible the conception of everyday life originating in natural science, viz., that of a system of laws which governs the many things? But, in attempting to make this conception quite clear and thinkable, we are forced to represent the connexion of things as a universal substance, the essence of which we conceive as a system of laws which underlies everything and in its own self connects everything, but imperceptible, and known to us merely through the impressions it produces on us, which we call things. A final reflexion then teaches us that the nature of this universal and all-pervading substance can only be imagined by us as something analogous to our own mental life, where alone we experience the unity of a substance (which we call self) preserved in the multitude of its (mental) states. It also becomes clear that only where such mental life really appears need we assign an independent existence, but that the purposes of everyday life as well as those of science are equally served if we deprive the material things outside of us of an independence, and assign to them merely a connected existence through the universal substance by the action of which alone they can appear to us.

The universal substance, which we may call the absolute, is at this stage of our investigations not endowed with the attributes of a personal Deity, and it will remain to be seen by further analysis in how far we are able—without contradiction—to identify it with the object of religious veneration, in how far that which to metaphysics is merely a postulate can be gradually brought nearer to us and become a living power. Much in this direction is said by Lotze in various passages of his writings; anything complete, however, on the subject is wanting. Nor would it seem as if it could be the intention of the author to do much more than point out the lines on which the further treatment of the subject should advance. The actual result of his personal inquiries, the great idea which lies at the foundation of his philosophy, we know. It may be safely stated that Lotze would allow much latitude to individual convictions, as indeed it is evident that the empty notion of an absolute can only become living and significant to us in the same degree as experience and thought have taught us to realize the seriousness of life, the significance of creation, the value of the beautiful and the good, and the supreme worth of personal holiness. To endow the universal substance with moral attributes, to maintain that it is more than the metaphysical ground of everything, to say it is the perfect realization of the holy, the beautiful, and the good, can only have a meaning for him who feels within himself what real not imaginary values are clothed in those expressions.

We have still to mention that æsthetics formed a principal and favourite study of Lotze's, and that he has treated this subject also in the light of the leading ideas of his philosophy. See his essays *Ueber den Begriff der Schönheit*, Gottingen, 1845, and *Ueber Bedingungen der Kunstschönheit*, ibid., 1847 ; and especially his *Geschichte der Æsthetik in Deutschland*, Munich, 1868.

Lotze's historical position is of much interest. Though he disclaims being a follower of Herbart, his formal definition of philosophy and his conception of the object of metaphysics are similar to those of Herbart, who defines philosophy as an attempt to remodel the notions given by experience. In this endeavour he forms with Herbart an opposition to the philosophies of Fichte, Schelling, and Hegel, which aimed at objective and absolute knowledge, and also to the criticism of Kant, which aimed at determining the validity of all human knowledge. But this formal agreement involves material differences, and the spirit which breathes in Lotze's writings is more akin to the objects and aspirations of the idealistic school than to the cold formalism of Herbart. What, however, with the idealists was an object of thought alone, the absolute, is to Lotze only inadequately definable in rigorous philosophical language ; the aspirations of the human heart, the contents of our feelings and desires, the aims of art, and the tenets of religious faith must be grasped in order to fill the empty idea of the absolute with meaning. These manifestations of the divine spirit again cannot be traced and understood by reducing (as Hegel did) the growth of the human mind in the individual, in society, and in history to the monotonous rhythm of a speculative schematism ; the essence and worth which is in them reveals itself only to the student of detail, for reality is larger and wider than philosophy ; the problem, "how the one can be many," is only solved for us in the numberless examples in life and experience which surround us, for which we must retain a lifelong interest, and which constitute the true field of all useful human work. This conviction of the emptiness of terms and abstract notions, and of the fulness of individual life, has enabled Lotze to combine in his writings the two courses into which German philosophical thought had been moving since the death of its great founder, Leibnitz. We may define these courses by the terms esoteric and exoteric,—the former the philosophy of the school, cultivated principally at the universities, trying to systematize everything and reduce all our knowledge to an intelligible principle, losing in this attempt the deeper meaning of Leibnitz's philosophy ; the latter the philosophy of general culture, contained in the literature of the classical period, in the unsystematic writings of Lessing, Winkelmann, Goethe, Schiller, and Herder, who more or less expressed their indebtedness to Leibnitz. Lotze can be said to have brought philosophy out of the schoolroom into the market of life. By understanding and combining what was great and valuable in those divided and scattered endeavours, he has become the true successor of Leibnitz, and his philosophy will no doubt attain that universal celebrity which was attained by the monadology and the system of pre-established harmony.

The age in which Lotze lived and wrote in Germany was not one peculiarly fitted to appreciate the position he took up. Frequently misunderstood, yet rarely criticized, he was nevertheless greatly admired, listened to by devoted hearers, and read by an increasing circle. But no watchword of easy currency, no ready Shibboleth, attracts or helps to combine this increasing circle to the unity of a philosophical school. The real meaning of Lotze's teaching is reached only by patient study, and those who in a larger or narrower sense call themselves his followers will probably feel themselves indebted to him more for the general direction he has given to their thoughts, for the tone he has imparted to their inner life, for the seriousness with which he has taught them to consider even small affairs and practical duties, and for the indestructible confidence with which his philosophy permits them to disregard the materialism of science, the scepticism of shallow culture, the disquieting results of philosophical and historical criticism. It is not unlikely that the present phase of English thought will more easily assimilate the valuable elements of Lotze's philosophy, as indeed fragments and beginnings of a similar view exist already in English literature. Wherever his writings are widely read and appreciated, it will be on account of the great moral influence which his philosophy exerts in common with some systems of the past, but almost alone among the systems of the day. (J. T. M.)

LOUDUN, capital of an arrondissement in the department of Vienne, France, stands on an eminence of 320 feet, overlooking a fertile plain, 45 miles (by rail) south-west from Tours. It was formerly surrounded by walls, of which only two towers and a single gateway now remain. Of the old castle which was destroyed under Richelieu, and of which the site is now turned into a public promenade, a fine old rectangular donjon of the 12th century has been preserved ; at its base traces of Roman constructions have been found, with fragments of porphyry pavement, mosaics, and mural paintings. The Carmelite convent, now occupied by the Brethren of Christian Doctrine, was the scene of the trial of Urban Grandier, who was burnt alive for witchcraft in 1634 (see Bayle's *Dictionnaire*) ; the old Byzantine church of Sainte Croix, of which he was curé, is now used as a market. There are several curious old houses in the town. Lace making and candle making are the chief industries, and there is a considerable trade in grain and flour. Before the revocation of the edict of Nantes the inhabitants numbered, it is said, more than 12,000 ; in 1876 the population was 4522.

LOUGHBOROUGH, the second town in Leicestershire, England, on the Midland Railway, 11 miles from Leicester and 14 from Nottingham. In 1881 its three parishes had a population of 14,733. A large tract of meadow land lies between the town and the river Soar, which is connected with the town by two canals,—the Loughborough canal, formed in 1776, and the Leicester canal, opened in 1791. On the Charnwood Forest side of the town there were once extensive parks. The open fields in the lordship were enclosed in 1762. The town has an excellent market-place, and is in the centre of a rich agricultural district. Its malt was once of special note. The old parish church of All Saints stands on rising ground, and is a conspicuous object for many miles round ; the church itself (restored in 1862) is of the Decorated style, and dates from the 14th century ; the tower is Perpendicular. Emmanuel church was completed in 1837, and Holy Trinity in 1878. The Roman Catholic chapel was built in 1833, and the extensive Early English convent, since enlarged, in 1850. The town-hall and corn exchange, in the market-place, were erected in 1855, and the cemetery and its elegant church date from 1857. The grammar school is a Tudor structure, standing in some 15 acres of ornamental grounds and walks ; it owes its origin to Thomas Burton's charity, in 1495. The present buildings were erected in 1852, and the new scheme was devised under the Grammar School Act of 3 & 4 Vict. The girls' grammar school, in the Early English style, was erected in 1879. The other public buildings comprise a dispensary and infirmary (built at the cost of Mr and Miss Herrick in 1862), local board offices, police station, schools, and nonconformist chapels. There are several large hosiery factories. Lace was a staple trade until 1816 (see HEATHCOAT). Bell-founding was introduced in 1840, and Messrs Taylor cast here in 1881 the great bell for St Paul's, London ($17\frac{1}{2}$ tons). Iron-foundries, dye-works, and horticultural glass-works also provide employment.

The town is mentioned under the name of Lucteburne in Domesday Book. William the Conqueror gave the town and manor to Hugh Lupus, from whom they passed to the more famous Despensers. They were held by the Beaumonts from 1326 to 1464, when they passed into the Hastings family, returning to them, after several changes of ownership, in 1554. Lord Moira sold the manor in 1818, and the major part of the manorial rights have now been purchased by the local board. The title of Baron Hastings of Loughborough was given to Sir Edward Hastings in 1558, and to Colonel Henry Hastings in 1643. Alexander Wedderburn, when made lord chancellor, assumed the title of Lord Loughborough, in 1780.[1] John Cleaveland, the royalist poet, was born here in 1613 ; John Howe, the Puritan divine, in 1630 ; and Richard Pulteney, the botanist, in 1730.

See Thomas Pochin's *Historical Description*, 1770 (vol. viii. of *Bibliotheca Topographica Britannica*); Potter's *Walks Round Loughborough*; Wood's *Plan of Loughborough*, 1857 ; W. G. Dimock Fletcher's *Parish Registers*, 1873, *Rectors of Loughborough*, and *Historical Handbook*, 1881.

LOUIS I., Roman emperor (called "der Fromme," also "le Débonnaire"), was born in 778. He succeeded his father Charlemagne in 814, having in the previous year

[1] The present courtesy title borne by the eldest son of the earl of Rosslyn was taken from Loughborough in Surrey, in 1795.

been declared co-regent. At the beginning of his reign he excited high anticipations by the earnestness with which he attacked the abuses that had accumulated during the later years of Charlemagne's sovereignty. The licentiousness which prevailed at court he sternly suppressed; he punished counts who were proved to have misused their authority; and he sought to reform the manners both of the secular and of the regular clergy. The Saxons and the Frisians, who, although conquered, had never cordially accepted Frankish rule, were conciliated by mild and generous treatment. A period of trouble and confusion, however, was opened in 817, when Louis, anxious to establish the order of succession, declared his eldest son Lothair his successor, and made him co-regent, granting him Austrasia with the greater part of Germany. The younger sons of Louis, Pippin and Louis, received, the former Aquitania, the latter Bavaria, Bohemia, Carinthia, and the subject Slavonic and Avar territories. This arrangement was resented by Bernard, king of Italy, the emperor's nephew, who forthwith rebelled. He was soon captured, and condemned to the loss of his sight, while his kingdom was transferred to Lothair. After the death of Bernard, the emperor, who was a man of a gentle and sensitive temper, bitterly repented the harsh punishment which he had sanctioned, and, being further depressed by the death of his first wife, he proposed to resign the crown and retire to a monastery. He was induced to abandon this intention, and (in 819) to marry Judith, the beautiful daughter of Count Welf of Bavaria. In 829 he made a new division of the empire in favour of Charles (afterwards Charles the Bald), his son by his second wife. The three brothers, deeply dissatisfied, combined to declare war against him, and at Compiègne he was taken prisoner. The empress Judith was condemned to the cloister for alleged infidelity to her husband, and Louis was virtually deposed. Pippin and the younger Louis, suspecting that Lothair meant to usurp exclusive authority, changed their policy, and at a diet in Nimeguen the emperor was restored. Soon afterwards he provoked fresh disturbance by granting Aquitania, the territory of Pippin, to Charles, and in 833 the army of the three brothers confronted that of their father near Colmar. When Louis was negotiating with Pope Gregory IV., who had crossed the Alps in the hope of restoring peace, his troops were persuaded to desert him, and on the Lügenfeld ("the field of lies") he was obliged to surrender to his sons. The empress was sent to Italy, her son to the monastery of Prüm, and at Soissons Louis not only abdicated, but made public confession of his sins, a long list of which he read aloud. Again the arrogance of Lothair awoke the distrust of his brothers, and they succeeded in reasserting the rights of the emperor, whose sufferings had excited general sympathy. He went through the ceremony of coronation a second time, and Lothair found it necessary to confine himself to Italy. After the death of Pippin in 838 Louis proposed a scheme by which the whole empire, with the exception of Bavaria, would have been divided between Charles and Lothair, to whom the empress had been reconciled. The younger Louis prepared to oppose this injustice, and he was supported by the people of Aquitania in the interest of Pippin's sons. A diet was summoned at Worms to settle the dispute, but before it met the emperor died on an island in the Rhine near Mainz, on the 20th of June 840. He had capacities which might have made him a great churchman, but as a secular ruler he lacked prudence and vigour, and his mismanagement prepared the way for the destruction of the empire established by his father. His son Lothair I. succeeded to the imperial title.

See Funck, *Ludwig der Fromme*, 1832; and Simson, *Jahrbücher des Fränkischen Reiches unter Ludwig dem Frommen*, 1874-76.

LOUIS II., Roman emperor, grandson of the preceding, was born about 822 and crowned king of Lombardy in 844. From 849 he shared the imperial title with his father, Lothair I., being crowned at Rome by Leo IV. in 850. He succeeded to the undivided but almost entirely nominal dignity in 855. On the death of his childless brother, Lothair of Lorraine, in 869, the inheritance was seized and shared by his uncles Charles the Bald and Louis the German; the pope, however, espoused the cause of the emperor, crowning him king of Lorraine in 872. Louis II. died in 875, and the imperial crown was forthwith bestowed on Charles the Bald.

LOUIS III., Roman emperor, surnamed "The Blind," was the son of Boso, king of Provence, and, through his mother, grandson of the emperor Louis II. He was born about 880, called to the throne of Provence in 890, and crowned emperor in succession to Berengar I. at Rome in 901. In 905, while residing at Verona, he was surprised by his discrowned rival, blinded, and ultimately sent back to Provence, where he lived in inactivity and comparative obscurity until 929.

LOUIS THE CHILD, though he never actually received the imperial crown, is usually reckoned as the emperor Louis III. or Louis IV. He was the son of the emperor Arnulf, was born in 893, and succeeded to the throne of East Francia or Germany in 900, when he was six years of age. During his brief reign Germany was desolated by the Hungarians, who invaded the country year after year, defeating every force that ventured to oppose them. At the same time the kingdom was weakened by internal strife. The result of the prevailing anarchy was that the imperial constitution established by Charlemagne broke down, and Germany was gradually divided into several great duchies, the rulers of which, while acknowledging the supremacy of the king, sought to become virtually independent. Louis, the last of the Carolingian race in Germany, died in 911.

LOUIS IV. (or V.), "the Bavarian," German king and Roman emperor, was born in 1286. He was the son of the duke of Bavaria, and in 1314, after the death of the emperor Henry VII., was elected to the throne by five of the electors, the others giving their votes for Frederick, duke of Austria. This double election led to a civil war, in which Frederick was supported by the church and by many nobles, while the inhabitants of the great cities rallied round Louis. In 1322 Louis gained the battle of Mühldorf, taking Frederick prisoner; but the war still went on. Pope John XXII. excommunicated Louis in 1324; whereupon, wishing to bring the conflict to an end, Louis offered to liberate Frederick on condition that he would withdraw his claim to the throne, and restore the cities and imperial lands seized by his party in Swabia. Frederick, finding that the obstinacy of his brother, Duke Leopold, would render it impossible to fulfil these terms, returned to captivity; and Louis was so touched by his magnanimity that he proposed that they should share the responsibilities of government. The plan was tried but did not succeed, and was virtually abandoned before Frederick's death in 1330. In 1327 Louis had gone to defend his rights in Italy, where he was crowned emperor by Pope Nicholas V., whom he supported in opposition to Pope John XXII. Returning to Germany in the year of Frederick's death, he made peace with the house of Austria, but John XXII. refused to be conciliated, and his successor Benedict XII., acting in part under the influence of France, continued the struggle. Irritated by the revival of papal pretensions which no longer commanded respect in Germany, the electors met at Rhense, and on the 15th of July 1338, issued an important declaration to the effect that the emperor derived his right to the German and imperial crowns, not from the pope, but from the electors by whom he was appointed. As the representative of national independence, Louis might have made himself one of the most popular of the emperors, but he excited bitter jealousies by his grasping and unscrupulous disposition. By his marriage with Margaret, the sister of Count William of Holland, he secured Holland, Zealand, Friesland, and Hainault; and he obtained the mastery of Tyrol by separating the heiress, Margaret Maultasch, from her husband, a son of John, the powerful king of Bohemia, and making her the wife of his own son Louis, to whom (in 1322) he had granted the march of Brandenburg. The enemies he thus created were reinforced by Pope Clement VI., who not only excommunicated him again, but (in 1346) persuaded a party of the electors to appoint a new king. Their choice fell on Charles, margrave of Moravia, the son of King John of Bohemia, who at once made an unsuccessful attempt to recover Tyrol. The outbreak of a new civil war was prevented by the sudden death of Louis at a bear hunt near Munich, on the 11th of October 1347. The conflict between the papacy and the empire was practically closed during the reign of Louis, and he marked an epoch by his encouragement of the cities in opposition to the princes and nobles.

See Mannert, *Kaiser Ludwig IV.*, 1812; Fr. von Weech, *Kaiser Ludwig der Baier und König Johann von Böhmen*, 1860; and Döbner, *Die Auseinandersetzung zwischen Ludwig IV. dem Baier und Friedrich dem Schönen von Oesterreich*, 1875.

LOUIS THE GERMAN, son of the emperor Louis I., was born in 804. In the first partition of the empire in 817 he received Bavaria, Bohemia, Carinthia, and the subject territories on his eastern frontier. Displeased by later schemes of partition in favour of his half-brother Charles, he associated himself with his brothers Lothair and Pippin against the emperor, and he was in the field in defence of his rights when his father died. After the emperor's death in 840, Louis and Charles united against Lothair, whom they defeated in the battle of Fontenay, and in 843 Louis received by the treaty of Verdun the whole of Germany to the east of the Rhine, with Mainz, Spires, and Worms on the left bank. He was a wise and vigorous ruler, but his forces were inadequate to protect the northern part of his kingdom against the Norsemen, and he was not always successful in his wars with Slavonic tribes. In 858 he invaded West Francia, which he hoped to unite with East Francia, his own state; but Charles the Bald proved to be stronger than Louis had supposed, and he was obliged to retreat. When Lothair of Lorraine died in 869, his kingdom was seized by Charles, who caused himself to be crowned at Metz; but in the following year, by the treaty of Mersen, the eastern half of the country was ceded to Louis. Louis expected to receive the imperial crown after the death of the emperor Louis II. Charles, however, outwitted him, and Louis was attempting to avenge this supposed wrong when he died at Frankfort on August 28, 876. East Francia and West Francia were again united under Charles the Fat; but, as Louis was the first sovereign who ruled over the Germans, and over no other Western people, he is generally considered the founder of the German kingdom.

See Dümmler, *Geschichte des Ostfränkischen Reichs*, 1862.

LOUIS I., king of France, surnamed Le Débonnaire or the Pious. See FRANCE, vol. ix. p. 533; GERMANY, vol. x. p. 480; and LOUIS I., emperor, *supra*.

LOUIS II., surnamed Le Bègue or the Stammerer, the son of Charles I. ("The Bald") by Irmentrud of Orleans, and the grandson of Louis the Pious, was born on November 1, 846. On the death of his elder brother Charles, the second son of Charles the Bald, he was consecrated king of Aquitania in 867, and ten years afterwards he succeeded his father, being crowned by Hincmar of Rheims under the title of "king of the French, by the mercy of God and the election of the people" (December 8, 877). In the following year (September 7) he availed himself of the presence of Pope John VIII. at Troyes to obtain a fresh consecration. He died at Compiègne, after a feeble and ineffectual reign of eighteen months, on April 10, 879.

LOUIS III., son of the preceding by Ansgarde, daughter of Count Hardouin of Brittany, was born about the year 863, and in 879 was designated by his father sole heir to the French throne. It was decided among the nobles, however, that the inheritance should be divided between Louis and his younger brother Carloman, the former receiving Neustria, or all France north of the Loire, and the latter Aquitania and Burgundy. On the Loire and elsewhere the two brothers inflicted several defeats on the Northmen (879–881); but in 882 Louis succumbed to the fatigues of war, leaving his inheritance to Carloman.

LOUIS IV., surnamed D'Outremer (Transmarinus), son of Charles III. ("The Simple") and grandson of Louis II., was born in 921. In consequence of the disasters which befell his father in 922, Louis was taken by his mother Odgiva, sister of Athelstan, to England, where his boyhood was spent,—a circumstance to which he owes his surname. On the death of Raoul or Rodolph of Burgundy, who had been elected king in place of Charles, the choice of Hugh the Great, count of Paris, and the other nobles, fell upon Louis, who was accordingly brought over the Channel and consecrated in 936. His *de facto* sovereignty, however, was confined to the countship of Laon. In 939 he became involved in a struggle with Otto I. ("The Great") of Germany about Lorraine, which had transferred its allegiance to him; the victory remained at last with the emperor, who married his sister Gerberga to Louis. After the death of William Longsword, duke of Normandy, Louis endeavoured to strengthen his influence in the duchy by obtaining possession of the person of Richard the infant heir, but a series of intrigues resulted only in his own captivity at Rouen in 944, from which he was not released in the following year until he had agreed to surrender Laon to his powerful vassal Hugh the Great. By the interposition of Otto, the brother-in-law of Louis, Hugh, who for some years had effectually resisted both the carnal resources of the empire and the spiritual weapons of the church, was at last persuaded to restore Laon. The last years of this reign were marked by repeated Hungarian invasions of France. Louis died in 954, and was succeeded by his son Lothaire.

LOUIS V., Le Fainéant, son of Lothaire and grandson of Louis IV., the last of the Carolingian dynasty, was born in 966, succeeded Lothaire in March 986, and died in May 987. He was succeeded by Hugh Capet.

LOUIS VI., surnamed Le Gros, L'Éveillé, and Le Batailleur, the son of Philip I. of France and Bertha of Holland, was born about 1078, was associated with his father in the government in 1100, and succeeded him in 1108. For some account of his character, and of the events of his reign, see FRANCE, vol. ix. pp. 538, 539. He died on August 1, 1137.

LOUIS VII., Le Jeune and Le Pieux, son of Louis VI., was born in 1120, and was associated with his father on the death of his elder brother Philip in 1131, being crowned at Rheims on October 25 by Pope Innocent II. He succeeded to the undivided sovereignty in 1137, the news of his father's death reaching him as he was engaged at Poitiers in the festivities connected with his unlucky marriage to Eleanor of Aquitania. In 1141 he made an unsuccessful attempt to assert his rights as duke of Aquitania over the countship of Toulouse, and in 1142 he fell into a vehement quarrel with Pope Innocent II., who had presumed too much on the piety of the well brought-up young prince by appointing a nephew of his own to the archbishopric of Bourges. In the course of the contest Louis, who had been excommunicated, pursued the new archbishop into the territory of the count of Champagne, and stormed Vitry, in the sack of which the cathedral was burned, causing the death of three hundred persons who had taken refuge within its walls (1143). Louis, horror-struck, made peace with the pope and his secular adversary, but found that nothing less than a pilgrimage to the Holy Land would suffice to expiate his offence. The capture of Edessa and the massacre of the Christians in 1144 led to the preaching of the second crusade by St Bernard, and in 1147 the king, leaving the regency in the hands of the Abbé Suger and Raoul, count of Vermandois, set out for the East, accompanied by his queen, a large company of nobles, and twenty-four thousand men. The disastrous results of the expedition, personal, domestic, and public, have already been recorded in the article FRANCE (vol. ix. p. 540), where also his long struggle with Henry II. of England, which terminated only in 1178, is briefly described. In 1178 he made a pilgrimage to the tomb of St Thomas of Canterbury on behalf of his eldest son Philip Augustus, then dangerously ill, and in the following year he associated him with himself in the sovereignty. Louis died on September 18, 1180.

LOUIS VIII., surnamed Le Lion, born on September 5, 1187, was the son of Philip Augustus, whom he succeeded in July 1223. In 1200 he had married Blanche of Castile, the granddaughter of Henry II. of England, and in virtue of this connexion he received from the English barons in 1216 an offer of the crown, which he accepted. Landing in England in May, he achieved several military successes, but retired early in 1217; later in the same year he renewed the attempt to make good his claims, but finally quitted English soil in September. He next took charge of the war against the Albigenses with varying success; it continued after his accession to the throne, and ultimately proved fatal to him. He died, most probably of pestilence, shortly after the capture of Avignon, at Montpensier in Auvergne on November 8, 1226, and was succeeded by his son Louis IX.

LOUIS IX., SAINT (1215–1270). See FRANCE, vol. ix. pp. 542, 543. He was canonized by Boniface VIII. in 1297, and is commemorated in the Roman Catholic Church on August 25 or 26. He was succeeded by his son Philip III.

LOUIS X., Le Hutin, was the eldest son of Philip IV. (the Fair) and Joan of Navarre, and was born in 1289. He succeeded his mother in the kingdom of Navarre and countships of Champagne and Brie in 1305. Historians are not agreed as to the origin of the surname ("The Quarreller") by which he is known in France, but it seems with most probability to commemorate the wild and boisterous character of his youth. He succeeded his father in 1314, and died, after a short and unimportant reign of less than two years, in June 1316. He was succeeded by his brother Philip V.

LOUIS XI., son of Charles VII. and Mary of Anjou, was born at Bourges on July 3, 1423. His jealous, ambitious, and restless character early manifested itself in the attitude of opposition he assumed to his father's mistress Agnes Sorel, and in the part he took (1439) as leader of the "Praguerie," as the league formed by the nobles against the introduction of a standing army was called. Though pardoned by his father in 1440 after the failure of the attempt, he never thenceforward enjoyed any of his confidence. He distinguished himself in the years immediately following in several military expeditions, but finally settled (1446) in his apanage of Dauphiné, where he acted with great independence, until in 1456 Charles, irritated by the intrigues of his son, intimated his intention of himself resuming the government of that province. Not waiting the arrival of the army which had been sent to take possession, Louis fled for protection to his uncle the duke of Burgundy, who assigned him a pension and a residence at Nieppe near Brussels. The death of Charles on July 22, 1461, permitted his return to France, where he was crowned at Rheims as Louis XI. in the following month. For the leading events of the three periods of his reign the reader is referred to FRANCE, vol. ix. pp. 552, 553. He died at Plessis-lès-Tours on August 30, 1483, and was succeeded by his son Charles VIII.

LOUIS XII. was born at Blois in 1462. His father was Charles, duke of Orleans, the grandson of Charles V. and the cousin of Charles VII., who spent twenty-five years of captivity in England, and who still holds an honourable place on the roll of French poets. Louis himself was for three years (1487–90) the prisoner of his second cousin, Charles VIII., in the castle of Bourges, but afterwards seconded his ambitious schemes faithfully and well, and on his death (1498) succeeded him, taking the titles of king of France, Jerusalem, and the Two Sicilies, and duke of Milan. For the events of his reign see FRANCE, vol. ix. pp. 554, 555. He died on January 1, 1515, and was succeeded by Francis I.

LOUIS XIII., the son of Henry IV. and Mary de' Medici, was born at Fontainebleau on September 27, 1601, and succeeded his father on May 14, 1610, his mother meanwhile availing herself of the confusion caused by the assassination to seize the regency. For some years the affairs of the kingdom were directed by the council of regency in which the Florentine Concini, created Marquis d'Ancre and a marshal of France, was the most prominent figure. After the assassination of D'Ancre in 1617, Marshal Luynes, the favourite of the weak young king, held the reins of power for about four years; his death of camp fever in the end of 1621, in the course of the Huguenot campaign, left Louis free to assert his own independence, which he did by carrying on the war with some vigour until its termination in the peace of Montpellier (1622). In 1624 Richelieu entered the council of state, and guided the affairs of Louis and of France for the next eighteen years (see FRANCE, vol. ix. pp. 568–571). Louis, who died at St Germain-en-Laye on May 14, 1643, was married at the age of fourteen (December 1615) to Anne of Austria, daughter of Philip III. of Spain; but his eldest son, who succeeded him as Louis XIV., was not born until twenty-three years afterwards.

LOUIS XIV., surnamed Le Grand, the elder son of the preceding, was born at Saint-Germain-en-Laye on September 16, 1638, succeeded to the throne of France in his fifth year, was declared of age in September 1651, and was crowned on June 7, 1654. His marriage with the infanta Maria Theresa of Austria, daughter of the Spanish Philip IV., was solemnized at St Jean-de-Luz on June 9, 1660. On the death of Mazarin in 1661 Louis XIV. began his true reign, the leading events of which will be found recorded in the article FRANCE (vol. ix. p. 574–584). He died at Versailles on September 1, 1715. Of his legitimate children by Maria Theresa, only one, Louis the Dauphin (1661–1711), reached manhood; he was married to a Bavarian princess by whom he had three sons—Louis the Dauphin, duke of Burgundy, who was the father of Louis XV.; Philip, duke of Anjou, afterwards Philip V. of Spain; and Charles, duke of Berri.

LOUIS XV., great-grandson and successor of the preceding, born at Versailles on February 15, 1710, was the third son of Louis, duke of Burgundy. His father became dauphin in 1711, and died in 1712, and he himself succeeded to the throne of France on September 1, 1715. His majority was declared in February 1723, and on September 5, 1725 (his cousin, to whom he had been engaged since 1721, having been sent back to Spain), his marriage to Maria Leczinski of Poland, his senior by seven years, was solemnized at Fontainebleau. This union continued to subsist after a fashion until the queen's death in 1768; but the successive relations of the king with De Châteauroux, De Pompadour, and Du Barry are elements of much greater interest and importance to the student of his reign. His surname of "Le Bien-aimé" is said to date from August 1744, when he was seized with a dangerous illness at Metz; the people of Paris rushed in crowds to the churches to pray for his recovery, nor could they sleep, eat, or enjoy any amusement until the "well-beloved king" was out of danger. He died of small-pox on May 10, 1774, having been predeceased for some years by his only son Louis. His successor was his grandson Louis XVI. For his reign see FRANCE (vol. ix. pp. 584–593).

LOUIS XVI., third son of Louis the Dauphin, and grandson of Louis XV., was born at Versailles on August 23, 1754, was married to Marie Antoinette, archduchess of Austria, at Versailles, on May 16, 1770, succeeded his grandfather on May 10, 1774, and was beheaded on January 21, 1793. See FRANCE (vol. ix. pp. 593–604).

LOUIS XVII., titular king of France, the third son of Louis XVI. and Marie Antoinette, was born at Versailles on March 27, 1785, became dauphin in June 1789, was proclaimed king after the execution of his father, was recognized as such by the Governments of England and Russia, but died in captivity in the Temple, Paris, June 8, 1795.

LOUIS XVIII., brother of Louis XVI., was the fourth grandson of Louis XV., and was born at Versailles on November 17, 1755, receiving at his birth the title of count of Provence. During the earlier stages of the revolutionary struggle he showed considerable sympathy with the popular party, but in June 1791 he found it necessary to withdraw to Coblentz, and subsequently he took some part in the operations of the army of Condé. He was at Hamm in Westphalia when tidings of his brother's murder arrived, and lost no time in proclaiming the succession of his nephew Louis XVII., himself being recognized as regent. In June 1795 he succeeded to the regal title; after several years of involuntary wandering he found an asylum in England from October 1807 till April 1814, when he re-entered France. He only once left it again, during the "Hundred Days" (March to June 1815); his death took place at Paris on September 18, 1824. For his reign, see FRANCE (vol. ix. pp. 617–619). He was succeeded by his brother Charles X.

LOUIS-PHILIPPE, king of the French, was born at the Palais Royal, Paris, on October 6, 1773. His father was Louis-Philippe-Joseph, duke of Orleans, a descendant of the younger brother of Louis XIV., and by his mother he derived his origin from the Comte de Toulouse, the legitimized son of Louis XIV. and Madame de Montespan. At his birth he received the title of duke of Valois; and after 1785, when his father succeeded to the Orleans title, he himself bore that of duke of Chartres. In 1781 Madame de Genlis was appointed his "gouverneur." From 1789 onwards he manifested sincere sympathy with the new ideas then gaining currency, and in June 1791 he joined at Vendôme the regiment of dragoons of which he had been colonel since 1785. In 1792 he took part in the battles of Valmy and Jemmapes, holding high military rank under Kellermann and Dumouriez; in the following year he was present at the bombardment of Venloo and of Maestricht, and showed remarkable courage at Neerwinden. Proscribed along with Dumouriez, he entered upon a period of twenty-one years of exile from France, spent partly in Switzerland and other European countries, partly in the United States and in the Spanish American colonies. By the execution of his father he became duke of Orleans in 1793; and he was married to Marie Amélie, daughter of Ferdinand IV. of Naples, at Palermo, on November 25, 1809. In April 1814 he returned to Paris, where his old military rank and the property of his father were restored to him; the "Hundred Days" in 1815 condemned him to a renewed but much briefer exile; during the reign of Louis XVIII. he was regarded with some jealousy by the court on account of his liberal opinions, but enjoyed greater favour under Charles X.; immediately after the three days of July 1830 he was called to exercise the functions of "lieutenant-general of the kingdom," and on August 9 he accepted the title of king of the French. For his reign see FRANCE (vol. ix. p. 620–622). Escaping in disguise from Paris at the Revolution of 1848, he on March 3 reached England, where Claremont was his home until his death on August 26, 1850.

LOUISA (1776–1810), queen of Prussia, was born March 10, 1776, in Hanover, where her father, Duke Charles of Mecklenburg-Strelitz, was commandant. After the death of her mother, who was by birth a princess of Hesse-Darmstadt, she was entrusted to the care of a Fräulein von Wolzogen, and afterwards to that of her grandmother, the landgravine of Hesse-Darmstadt. During the period of the revolutionary wars, she lived for some time with her sister Charlotte, the wife of Duke Frederick of Saxe-Hildburghausen. In 1793 she met at Frankfort the crown prince of Prussia, afterwards King Frederick William III., who was so fascinated by her beauty, and by the nobleness of her character, that he asked her to become his wife. On April 24 of the same year they were betrothed, and on the 24th of December they were married. As queen of Prussia she commanded universal respect and affection, and nothing in Prussian history is more pathetic than the patience and dignity with which she bore the sufferings inflicted on her and her family during the war between Prussia and France. After the battle of Jena she went with her husband to Königsberg, and when the battles of Eylau and Friedland had placed Prussia absolutely at the mercy of France, she made a personal appeal to Napoleon at his headquarters in Tilsit, but without success. Early in 1808 she accompanied the king from Memel to Königsberg, whence, towards the end of the year, she visited St Petersburg, returning to Berlin on the 23d of December 1809. During the war Napoleon, with incredible brutality, attempted to destroy the queen's reputation, but the only effect of his charges in Prussia was to make her more deeply beloved. On the 19th of July 1810 she died in her husband's arms, while visiting her father in Strelitz. No other queen in modern times has been more sincerely mourned. She was buried in the garden of the palace at Charlottenburg, where a beautiful mausoleum, containing a fine recumbent statue by Rauch, was built over her grave. In 1840 her husband was buried by her side. The Louisa Foundation (Luisenstift) for the education of girls was established in her honour, and in 1814 Frederick William III. instituted the Order of Louisa (Luisenorden). On the 10th of March 1876 the Prussian people celebrated the hundredth anniversary of her birth, and it was then decided to erect a statue of Queen Louisa in the Thiergarten at Berlin.

LOUISIANA

Copyright, 1882, by Henry Gannett.

Plate I. LOUISIANA, one of the Southern States of the American Union, situated on the lower course and debouchement of the Mississippi river. It is bounded S. by the Gulf of Mexico, W. by Texas, N. by Arkansas, and E. by Mississippi. Its western boundary is a line through the middle of Sabine lake and river, as far north as the 32d parallel, whence it follows the meridian of the point of intersection of the river with that parallel. The northern boundary is the parallel of 33°. The eastern boundary is the mid-channel of the Mississippi river, as far south as the 31st parallel, whence it follows that parallel eastward to the middle of Pearl river, and passes down that stream to the Gulf. The area of the State, according to a late determination made by the Census Bureau, is 48,720 square miles, of which 1060 consist of land-locked bays, 1700 of inland lakes, and 540 of river surface, leaving 45,420 square miles as the total land area of the State.

Boundaries and extent.

Surface. The average elevation of the State is only 75 feet, and no part of it reaches 500 feet above sea-level. The most elevated portion is near its northern border. The surface is naturally divided into two parts—the upland, and the alluvial and coast swamp regions. Each of the larger streams, as well as a large proportion of the smaller ones, is accompanied by a belt of bottom land, of greater or less width, lying low as regards the stream, and liable to overflow at times of high water. These bottom lands form collectively what is known as the alluvial region. It extends in a broad belt down the Mississippi, from the mouth of the Ohio to the Gulf of Mexico, and up the Ouachita and its branches and the Red River, to and beyond the limits of the State. Its breadth along the Mississippi within this State ranges from 10 to 50 or 60 miles, and that along the Red River and Ouachita has an average breadth of 10 miles. Through its great flood-plain the Mississippi river winds upon the summit of a ridge formed by its own deposits. In each direction the country falls away in a succession of minor undulations, the summits of the ridges being occupied by the streams and bayous. Nearly all of this vast flood-plain lies below the level of high water in the Mississippi, and, were it not for the protection afforded by the levees, with which most of the course of the stream is lined, every considerable rise of its waters would inundate vast areas of fertile and cultivated land.

Stretching along the coast, and extending inland to a varying distance, ranging from 20 to 50 or even 60 miles, is a low, swampy region, the surface of which is diversified only by the slight ridges along the streams and bayous which traverse it, by occasional patches of slightly elevated prairie, and by live oak ridges. It is in and along the borders of this coast swamp region that most of the sugarcane and rice produced in the State are grown.

The low regions of Louisiana, including the alluvial lands and the coast swamps, comprise about 20,100 square miles, or nearly one-half the area of the State. The remainder consists of uplands of prairie and forest. The borders of these uplands are generally defined by lines of bluffs of no great height.

Rivers. The principal rivers are the Mississippi, which flows nearly 600 miles through and along the border of the State, the Red River, the Ouachita or Washita, Sabine, and Pearl, all which, excepting the last, are navigable at all stages of the water. Besides those streams which may properly be called rivers, the State is intersected by "bayous," several of which are of great importance both for navigation and for drainage. They may be characterized as secondary outlets of the rivers. Among them may be mentioned Achafalaya Bayou, Bayou la Fourche, and Bayou Bœuf. The signification of the name has, however, been extended, so that many rivers in this region, particularly if they have sluggish courses, are known as bayous. The alluvial portion of the State, particularly below the mouth of the Red River, is a perfect network of these bayous, which serve, in time of flood, to carry off the invading surplus waters.

The lakes of the State are mainly comprised in three classes. First come the lagoons of the coast, many of which are merely land-locked bays, whose waters are salt, and which rise and fall with the tides. Of this class are Pontchartrain, Borgne, Maurepas, and Sabine, and indeed all or nearly all those situated in the region of the coast swamps. These are simply parts of the sea which have escaped the filling-in process carried on by the great river and the lesser streams. A second class, large in numbers but small in area, is the result of "cut-offs" and other changes of channel in the Mississippi, and, to a small extent, in the Red River. The part of the river left by this change of channel becomes gradually isolated from the stream by the deposit of silt along the borders of the latter, thus changing what were formerly windings of the river into crescent-shaped lakes. A third class may be mentioned, namely, those upon Red River and its branches which are caused by the partial stoppage of the water by the "raft" above Shreveport. These are, of course, much larger at flood season than at other times, and, it may be added, have been much reduced in size by the cutting of a channel through the raft.

The climate of the State is semi-tropical; the mean annual temperature ranges from 60° to 75°, changing approximately with the latitude. The mean temperature of the hottest month is about 85°, while that of the coldest month ranges in different parts of the State from 45° to 60°. The temperature rarely, if ever, falls below 0° Fahr., while the heats of summer reach 105° in some parts. The rainfall is very heavy along the coast, exceeding 60 inches annually, but decreases inland, and is not more than 50 inches in the northern districts.

This large amount of moisture, together with the high temperature and the fertile soil, suffices to cover the greater part of the State, and particularly the alluvial regions and the coast swamps, with the most luxuriant sub-tropical vegetation, both arborescent and herbaceous. Much of the latter region is covered with lofty cypress trees, from which hang festoons of Spanish moss. The most common species of the alluvial regions and the drier portions of the coast swamps are live and other species of oaks, sweet gum, magnolia, the tulip tree, black walnut, pine, and cedar. Along the streams in the alluvial region are found willows, cotton-woods, basket oaks, and other species of similar habitat. For the beauty and fragrance of its flowers Louisiana is justly celebrated. Its bottom lands and its upland prairies are decked with them in tropical profusion. Prominent among them in abundance are roses, magnolias, jasmines, camellias, and oleanders. Most fruits common to a semi-tropical region are to be found here, either native or cultivated, such as oranges, olives, figs, peaches, and plums.

The forests cover a very considerable portion of the area of the State, and are destined in the future to form an important element of its wealth, although up to the present time the lumber interest has not been very extensively developed. The most valuable timber is that of the long-leaved pine (*Pinus australis*) and the short-leaved pine (*Pinus mitis*). These are mainly confined to the upland regions, being nowhere found in the alluvial or coast sections. The north-western part of the State is occupied by the short-leaved pine, while the long-leaved pine is found

mainly in large masses north and south of the Red River, and also in the east of the State.[1]

'auna. The native fauna of the State resembles in its general features that of the other Gulf States. Large quadrupeds are comparatively rarely met with, although occasionally there are seen black bears and wolves, and in the swamps an occasional panther. Smaller quadrupeds, such as raccoons, squirrels, wild cats, opossums, &c., are still common. Every bayou contains alligators; and reptiles of various species, such as turtles, lizards, horned toads, rattlesnakes, and moccasin snakes, are abundant. The avifauna of the State is varied and abundant, comprising eagles, vultures, hawks, owls, pelicans, cranes, turkeys, geese, partridges, ducks, &c., besides numberless smaller species, many of these, as in other parts of the world in the same latitude, being brilliant of plumage, but harsh of voice.

Jeology. The surface geology in its general outlines is very simple. The whole alluvial region and the coast swamps, besides a considerable portion of the prairie and pine flats bordering upon the lowlands, are of the most recent or Quarternary formations, while the remainder of the State, comprised mainly in the region west of the Ouachita and Calcasieu rivers, is Tertiary, with the exception of a few very small islands of the Cretaceous formation in the north-western part of the State.

Iinerals. In the Tertiary region are found small quantities of iron ore, and an indifferent brown coal. But the only important mineral product of the State is rock salt; the deposit upon Petite Anse Island, in the coast swamp region, has been extensively worked, and produces a very high quality of salt. In 1880 its production was 312,000 bushels.

Agriculture. The principal industry of the State is agriculture, and in that cotton takes the first place. Out of a total area of tilled land of two and a half million acres, more than one-third was planted in 1879 with cotton. The total production was 508,569 bales, an average of ·59 of a bale per acre. Louisiana stood seventh in the list of cotton-producing States, being exceeded by Mississippi, Georgia, Texas, Alabama, Arkansas, and South Carolina. The cotton crop is cultivated both in the alluvial and the upland regions. In the former there were raised in 1879 282,390 bales, on 364,790 acres, an average yield per acre of ·77 of a bale. In the latter region 498,080 acres were planted, giving a total yield of 225,385 bales, an average of ·45 of a bale per acre. The great depth and fertility of the alluvial soils are strikingly illustrated by these average yields. In the coast swamp region but little cotton is cultivated,—the total yield in these parishes, as reported by the census, being but 794 bales.

The production of other agricultural products, as given by the census of 1880, is as follows:—

Indian corn		Bush.	9,906,189
Oats		,,	229,840
Wheat		,,	5,034
Rye		,,	1,013
Sugar cane	Sugar	Hhds.	171,706
	Molasses	Gals.	11,696,248
Sweet potatoes		Bush.	1,318,110
Rice		lb	23,189,038
Tobacco		,,	55,954

Rice is cultivated almost entirely in the lower coast region, on the margin of the swamps, upon their prairie islands, and in the alluvial region south of Red River.

Communication. With the exception of its navigable streams, the State is not well supplied with the means of transportation. The only railroads of importance are—the Chicago, St Louis, and New Orleans, which connects New Orleans with Cairo, Illinois; the Louisiana and Texas Railroad (Morgans), which runs from New Orleans westward to Vermillionville, and thence northward to Cheneyville; the Louisiana Western Railroad, from Vermillionville to Orange in Texas; the New Orleans and Pacific Railroad, from New Orleans to Shreveport; and the Vicksburg, Shreveport, and Pacific Railroad, running from Delta to Monroe. Besides these there are several minor lines. The total length of railroad is 632½ miles, and the cost of construction $44,869,342. The gross returns for 1880 were $3,238,318, and the net returns $984,497.

Manufactures. Louisiana, like the other Southern States, has latterly made great advances in the manufacture of home products. In 1880 there were 120 looms and 6096 spindles, which used 1354 bales of raw cotton.

Banking. The banking interest is not extensive, as will be seen from the following statement, from the report of the comptroller of the currency in 1880:—

	Number.	Capital.
National banks	7	$2,875,000
State banks	3	2,723,698
Private bankers	8	53,333
Total	18	5,652,031

The number and circulation of newspapers and periodicals for 1880 are as follows:—

	Number.	Circulation.
Dailies	13	38,765
Weeklies, semi-weeklies, &c.	97	95,115
Monthlies	2	950

Population. According to the census of 1880, the population of the State was 939,946. This was divided nearly equally between the sexes, females being but slightly in excess. The proportion of the population which was of foreign birth was very small, being but 5·5 per cent., while in respect of race, the negro element outnumbered the whites, being 51·5 per cent. of the total population. The following table gives the number in each of the above classes:—

Male	468,754	White	454,954
Female	471,192	Coloured	483,655
Native	885,800	Chinese	489
Foreign	54,146	Indian	848

The following table exhibits the growth of the State in population since it became a portion of the United States:—

	Population.	Per Cent. of Increase.	Density of Population.		Population.	Per Cent. of Increase.	Density of Population.
1810	76,556	...	1·7	1850	517,762	46·9	11·4
1820	152,923	99·7	3·4	1860	708,002	36·7	15·6
1830	215,739	41·0	4·7	1870	726,915	2·6	16·0
1840	352,411	63·3	7·8	1880	939,946	29·3	20·6

The principal cities are New Orleans, with a population of 216,090; Shreveport, in the north-western corner, population 8009; and Baton Rouge, the State capital, 7197.[2]

Education. The State is fairly well provided with the means of education. School attendance, however, is not very general. Out of a population of 330,930 between the ages of six and sixteen, 78,528 were enrolled in public schools, and the estimated average attendance was 50,248, or less than one-sixth. There are in the State seven colleges, with 49 instructors and 786 students.

Administration. As in the other States of the Union, the government is distributed among the executive, legislative, and judicial departments. The executive is represented by the governor, lieutenant-governor, secretary of state, State treasurer, auditor of public accounts, attorney-general, and superintendent of instruction—all these offices being elective, and the period of incumbency four years. The legislative power is vested in a general assembly consisting of two branches, the lower one being the house of representatives and the upper one the senate. The members of the former body are elected every two years, and the number is by law never to exceed 120 nor be less than 90. The members of the senate are elected for four years. The number of senators is fixed at 36, and the senatorial districts are apportioned according to the population. The judicial power is vested in a supreme court, district and parish courts, and justices of the peace. The supreme court, except in cases specially provided for by law, has appellate jurisdiction only. It is composed of one chief justice and four associate justices. These are appointed by the governor, by and with the advice and consent of the senate, and hold office for a term of eight years. The State is divided by the legislature into judicial districts, in each of which there is a district court. The number of districts in the State cannot by law be less than twelve nor more than twenty. The district judges are elected by the voters of the district, and hold office for four years. Each parish has its own court. The parish judge is elected by the voters of the parish, and holds his office for two years. In addition to this each parish elects a certain number of justices of the peace with power to try minor cases. The State is divided into fifty-eight parishes (equivalent to counties), and each of these into a certain number of police jury wards which are designated by their numbers.

[1] Of these two species of trees, Professor Sargent, of the United States Census Bureau, estimates that there were standing on June 1, 1880, 26,558,000,000 feet of the long-leaved and 21,625,000,000 feet of the short-leaved species. The cut of the former for the census year was 61,882,000, and of the latter 22,709,000 feet, the total cut being but ·2 per cent. of the amount standing. There is every probability, however, that the rate of destruction will increase greatly in the future.

[2] The capital was removed from New Orleans to Baton Rouge in 1880.

Louisiana is represented in the National Congress by two senators who are chosen by the legislature of the State for a term of six years, and by six representatives who are chosen for a term of two years by the voters of the several representative districts.

Finance. The following table, compiled from the returns of wealth, debt, and taxation of the tenth United States census, shows the financial condition of the State in 1880.

Valuation (Assessed)—	
Real estate	$122,362,297
Personal property	37,800.142
Debt—	
State	23,437,640
Parish	1,107,951
Municipal	18,320,361
Taxation—	
State	1,171,084
Parish	710,573
Municipal	1,914,219

History. *History.*—The early history of the exploration of Louisiana forms one of the most interesting chapters in the annals of the country. It was first visited in 1541 by De Soto, of the Spanish Government service. This daring explorer, landing on the coast of Florida, made his way through the pathless forests and almost impassable swamps to the Mississippi, and even penetrated many leagues west of it, finally leaving his bones upon its shores. In 1673 Marquette and Joliet, starting from the settlements in Canada, descended the great river from northern Illinois to the mouth of the Arkansas. In 1682 La Salle descended the Mississippi, also starting from the French settlements in the Canadas. He navigated the river from the mouth of the Illinois to the Gulf. Returning to France, he originated a scheme for colonizing the country, and succeeded in obtaining from France the desired concessions, and in collecting a company of colonists, which set sail from Rochelle on the 24th of July 1684. Owing to the difficulty of obtaining correct longitudes at sea, the vessel missed the mouth of the Mississippi, and finally landed on the shore of Matagorda Bay, in Texas, where they established a colony. From this point La Salle started to make his way overland to Canada, but was treacherously murdered by his companions. Shortly after his death the colony disappeared.

The first successful attempt at settlement within the State was made by the French under the leadership of Iberville in 1700. The colony was located at a point on the Mississippi about 38 miles below the present site of New Orleans, now known as "Poverty Point." At first it was by no means prosperous, and it was only after the treaty of Utrecht that it appears to have gained ground. At that time there were not over five hundred Europeans in the whole territory of Louisiana as then constituted; the greater part were in what is now the State of Louisiana, the others being scattered at a few little posts along the Mississippi and Illinois rivers. Immediately after the treaty of Utrecht the king of France granted the whole territory of Louisiana to Antoine Crozat, ceding to him all the territories watered by the Mississippi and its tributaries below the mouth of the Illinois, with all the privileges of hunting, fishing, commerce, mining, &c., which might arise in this new territory. Crozat appointed Cadillac governor of the colony. Affairs, however, went badly under the new administration, and after a succession of governors, the whole district fell into the hands of John Law, the originator of the famous "Mississippi scheme." Desiring to control, among other commercial monopolies, the colony of Louisiana, Law found it an easy matter to obtain the charter and privileges from Crozat, who was only too glad to relinquish them in his favour. A company was formed under the name of the "Western Company." Grants made to it were for twenty-five years. Subscribers to the stock were allowed to pay three-fourths of the purchase money in the depreciated bonds of France, one-fourth only of the subscription being asked for in coin. Bienville, brother of Iberville, and a man possessing great influence in the colony, was appointed governor. One of his first acts was to found the city of New Orleans on its present site. During the year 1718 7 vessels were sent out with stores and emigrants, numbering in all about 1500 persons. The following year 11 ships were despatched, and 500 negroes from the Guinea coast were imported. In 1721 1000 white emigrants arrived, and 1367 slaves.

In the meantime the Western Company had obtained from the regent power to join with it the East India Company grants, and its name was changed to that of the India Company. This inflated scheme burst in due time, but the misfortunes of the company did not check the prosperity of the colony. The year 1721, which was that following the financial ruin of the former, witnessed the greatest immigration to the colony which it had ever received. The company retained its organization and its grant of Louisiana until 1732, when the province reverted to the crown. At that time the population of the colony was said to have been 5000 whites and 2000 slaves; but a census taken fifteen years later shows a population of only 4000 whites.

In 1762, by a secret treaty, the province was transferred from France to Spain. This treaty was not made public till a year and a half after it was signed, and Spain did not obtain possession until 1769. Meanwhile, in February 1763, by a treaty made between France and Spain on the one hand and Great Britain and Portugal on the other, the portion of Louisiana lying east of the Mississippi from its source to the river Iberville, and thence along the middle of the Iberville and the lakes Maurepas and Pontchartrain to the sea, was ceded to Great Britain. In this treaty, by implication, Louisiana was made to extend to the sources of the Mississippi, and this is the view commonly held. The province was governed by Spain till the year 1800, in the meantime making little or no progress owing to the narrow and oppressive policy pursued towards it by the home government. By the treaty of 1783 with Great Britain, the United States were placed in possession of the eastern bank of the Mississippi river, as far down as the 31st degree of latitude, while Spain held possession of the other bank, and had complete possession of the river below the 31st parallel.

From the time of the first settlement in the valley of the Mississippi and its tributaries, the importance of the river as a means of transportation to the seaboard, and the almost absolute necessity of possessing the country about its mouths, were recognized by the United States. As settlements increased in the valley and spread down the river, and as the hostile policy of Spain became more and more plainly developed, the feeling of the settlers became stronger against the restrictions of the Spanish Government. In 1800, however, Spain ceded the territory back to France, and in 1803 it was sold to the United States by Napoleon, in order to prevent it from falling into the hands of Great Britain. The price was 60,000,000 francs, with a stipulation that the United States should assume the claims of its citizens against France (French spoliation claims), which were estimated to amount to $3,750,000. The province which thus came into the possession of the United States was of vast though ill-defined territorial extent.

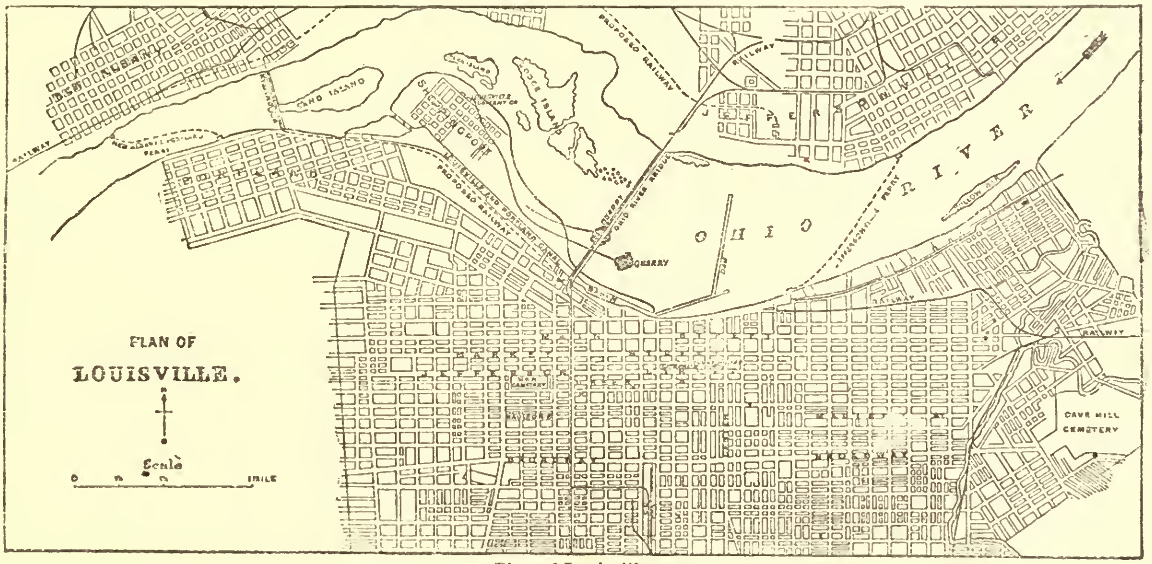
In 1804 nearly all of what is now the State of Louisiana was erected into a territory, under the name of Orleans. In 1810 this was increased by the addition of the south-eastern portion, east of the Mississippi river, and in 1812 it was admitted as a State under its present name, and with its present boundaries. During the war with Great Britain, which followed shortly after, a battle was fought for the possession of New Orleans, between the British forces under Pakenham and the American army under Jackson, in which the former were signally defeated. Up to 1860 the development of the State was very rapid, especially in the direction of agriculture and commerce.

Upon the outbreak of the civil war the State promptly joined its fortunes with the Southern Confederacy. Its act of secession from the Union was passed December 23, 1860, and from that time until the final suppression of the rebellion the State government was in the hands of the Confederates, although for the last two years of the war its territory was held in the main by the Federal forces. In the early part of the war the State suffered but little, but in April 1862 Admiral Farragut with a powerful fleet succeeded in passing Forts Jackson and St Philip, which defended the approaches to New Orleans, and captured the city, thus compelling the evacuation of the forts. The navigation of the Mississippi being secured by this means and by operations from the north, the State was at the mercy of the Federal Government. At the close of the war, on the reorganization of the State government, the administration fell into the hands of the ignorant negro classes led by unscrupulous whites, and an unfortunate state of affairs ensued, which was brought to an end only by the arbitrary and forcible assumption of power by the better elements of society. This occurred in 1877, and since that time the State has prospered markedly in all material respects. (H. G.)

LOUISVILLE, the sixteenth city of the United States in population, and the most important place in the State of Kentucky, is situated on the south bank of the Ohio river, in 38° 3′ N. lat. and 85° 30′ W. long. The river is here interrupted by a series of rapids which, except at high water, oblige the steamboat traffic to make use of the Louisville and Portland Canal (2½ miles long, constructed in 1833). The city, which has an area of 13 square miles, and a water front of 8 miles, occupies an almost level site about 70 feet above low-water mark. Its plan is regular and spacious, and, in the residential portions the houses, for the most part, have lawns and gardens in front. Among the public buildings of importance may be mentioned the city-hall, the court-house, the public library, the female high school, the industrial exhibition building, the Roman Catholic cathedral, and the State school for the blind.

From the time of the introduction of steam navigation upon the Ohio by Fulton in 1812, Louisville rapidly gained in importance as a centre of river trade. Owing to its position at the "falls of the Ohio," which obstruction long made necessary the transfer of goods at this point, the city became an important depôt of supplies for the cotton-growing States lying immediately to the south. The owners of plantations in those States devoted themselves wholly to the culture of cotton, and relied upon Kentucky for supplies of wheat, Indian corn, oats, and the like cereals, for the hempen bagging and rope used in baling the cotton, and for mules and horses, large droves of which were annually driven south from Louisville. The city was also for many years one of the principal points in the United States for pork-packing.

After the close of the civil war, the development of Kentucky, as of the South generally, entered new channels. Largely increased facilities of railway transportation, while bringing Louisville into more direct competition with Cincinnati, St Louis, and Chicago, resulted in a marked increase of both its commercial and manufacturing interests, notwithstanding the decline of the river trade. The extensive tobacco crop of Kentucky, with much of that grown in neighbouring States, now finds a market at Louisville, instead of at New Orleans as formerly; and it has become probably the largest market in the world for leaf tobacco, 68,300 hogsheads of which, of an aggregate value exceeding $5,000,000, were sold here during 1881. The manufacture of whisky is also important, this, with that of tobacco, paying to the Federal Government nearly $3,000,000 annually in revenue taxes, in the Louisville district. Pork-packing employs a capital of $2,520,000, and the tanning of leather $1,704,000, this industry being twenty times larger than before the war, and the product, especially of sole-leather, being in high demand. The manufacture of agricultural and mechanical implements employs $1,915,000 capital, the plough factories, which produce 125,000 ploughs annually, being among the largest in the United States. Steam-power is chiefly employed, the available water-power of the rapids having been neglected. The greater part of the coal consumed by the factories is brought down the Ohio from Pittsburg. The mountainous eastern portion of the State, rich in vast



Plan of Louisville.

deposits of both coal and iron, is now penetrated by several railroads, and others are being constructed, whose influence in developing this mineral wealth will add largely to the prosperity of the city.

The reports of the United States census of 1880 give the following summary of the industries of the city:—

	1860.	1870.	1880.
Number of establishments	436	801	1,191
Number of hands employed	7,396	11,589	21,937
Capital invested	$5,023,491	$11,129,291	$20,864,449
Wages paid	2,120,179	4,464,040	5,765,387
Value of material	7,896,891	10,369,556	22,362,704
Value of product	14,135,517	20,364,650	35,908,338

The Louisville and Nashville Railway, opened in 1859, controls, under one management, nearly 4000 miles of connected lines, reaching New Orleans, Pensacola, and Savannah. Various other lines contribute to make Louisville an important railway centre.

A bridge across the river, 5218⅔ feet long between abutments, with twenty-seven spans, and admitting the free passage of steamboats at high water, affords continuous railway transit, and connects the city with the thriving towns of New Albany (population 16,423) and Jeffersonville (population 9357), situated on the opposite bank of the Ohio, in the State of Indiana. A second railway bridge, having waggon-ways and foot-ways in addition, is now (1882) building.

Louisville is provided with adequate water-works, gas-works, &c. The famous Dupont artesian well, 2066 feet deep, has a flow of 330,000 gallons per day, with a force of ten horse-power, its water resembling slightly that of the Kissengen and Blue Lick (Ky.) springs. Although once regarded as unhealthy, the city has now an effective system of sewerage, and is in good sanitary condition.

The public school system is sustained at an annual expense of over $300,000, abundant separate provision being made for coloured children. There are four medical colleges, having a large attendance and reputation, and numerous private seminaries and schools. Among the newspapers published at Louisville the *Courier Journal* deserves mention both for its early connexion with George D. Prentice, and as a leading representative of the best order of American journalism. There are four other dailies (two English and two German), besides thirteen weekly sheets.

Louisville is a port of entry for foreign imports, which aggregate annually about $125,000. The city is governed by a mayor, elected every third year, with a board of aldermen and a common council, the former containing one, and the latter two representatives of each of the twelve wards. The population in 1830 was 10,341; in 1840, 21,210; in 1850, 43,196; in 1860, 68,033; in 1870, 100,753;

and in 1880 it was 123,758. This last total includes 20,905 persons of colour and 23,156 foreigners, the larger proportion of the latter being Germans.

It was in 1778 that Colonel George Rogers Clarke, on his way down the Ohio, left a company of settlers who took possession of Corn Island (no longer existing), near the Kentucky shore above the falls; and in the following year the first rude cluster of cabins appeared on the site of the present city. An Act of the Virginian legislature in 1780 gave the little settlement the rank of a town, and called it Louisville in honour of Louis XVI. of France, then assisting the American colonies in their struggle for independence. The rank of city was conferred by the Kentucky legislature in 1828.

LOULÉ, an old town of Portugal, in the district of Faro and province of Algarve, is beautifully situated in an inland hilly district about 5 miles to the north-west of the port of Faro. It is surrounded by walls and towers dating from the Moorish period, and the principal church is large and fine. The special industry of the place is basket-making. The population in 1878 was 14,862. The neighbouring church of Nuestra Senhora da Pietade is a favourite resort of pilgrims.

LOURDES, capital of a canton, and seat of the civil court of the arrondissement of Argelès, in the department of Hautes-Pyrénées, France, lies 12 miles by rail south-south-west of Tarbes, on the right bank of the Gave de Pau, and at the mouth of the valley of Argelès. It has grown up around what was originally a Roman castellum, and subsequently a feudal castle, picturesquely situated on the summit of a bare scarped rock. Near the town are marble quarries employing six hundred workpeople; and forty slate quarries give occupation to two hundred and sixty more. The pastures of the highly picturesque neighbourhood support the race of milch cows which is most highly valued in south-western France. The present fame of Lourdes is entirely associated with the grotto of Massavielle, where the Virgin Mary is believed in the Catholic world to have revealed herself repeatedly to a peasant girl in 1858; the spot, which is resorted to by multitudes of pilgrims from all quarters of the world, is now marked by a large church above the grotto, consecrated in 1876 in presence of thirty-five cardinals and other high ecclesiastical dignitaries. There is a considerable trade in rosaries and other "objets de piété," as well as in the wonder-working water of the fountain, for which a miraculous origin is claimed. Not far from the grotto of Massavielle are several other caves where prehistoric remains, going back to the Stone Age and the period of the reindeer, have been found. The population of Lourdes in 1876 was 5470.

LOUSE, a term applied indiscriminately in its broad sense to all epizoic parasites on the bodies of other animals. From a more particular point of view, however, it is strictly applicable only to certain of these creatures that affect the bodies of mammals and birds. The former may be considered as lice proper, the latter are commonly known as bird-lice (although a few of their number infest mammalia). Scientifically they are now generally separated into *Anoplura* and *Mallophaga*, although some authors would include all under the former term. In the article INSECTS it has been shown that modern ideas tend towards placing the *Anoplura* as degraded members of the order *Hemiptera*, and *Mallophaga* as equally degraded *Pseudo-Neuroptera*, according to the different formation of the mouth parts. Both agree in having nothing that can be termed a metamorphosis; they are active from the time of their exit from the egg to their death, gradually increasing in size, and undergoing several moults or changes of skin; but it should be remembered that many insects of the hemimetabolic division would scarcely present any stronger indications of metamorphoses were it not for the usual outgrowth of wings, which are totally wanting in the lice.

The true lice (or *Anoplura*) are found on the bodies of many mammalia, and, as is too well known, occasion by their presence intolerable irritation. The number of genera is few. Two species of *Pediculus* are found on the human body, and are known ordinarily as the head-louse (*P. capitis*) and the body-louse (*P. vestimenti*); some appear to recognize a third (*P. tabescentium*), particularly affecting persons suffering from disease, burrowing (at any rate when young) beneath the skin, and setting up what is termed "phthiriasis" in such a terrible form that the unhappy victims at length succumb to its attacks; to this several historical personages both ancient and modern are said to have fallen victims, but it is open to very grave doubts whether this frightful condition of things was due to other than the attacks of myriads of the ordinary body-louse. *P. capitis* is found on the head, especially of children. The eggs, laid on the hairs, hatch in about eight days, and the lice are full grown in about a month. Such is the fecundity of lice that it is asserted by Leeuwenhoek that one female (probably of *P. vestimenti*) may in the course of eight weeks witness the birth of five thousand descendants. Want of cleanliness undoubtedly favours their multiplication in a high degree, but it is scarcely necessary here to allude to the idea once existing, and probably still held by the very ignorant, to the effect that they are directly engendered from dirt. The irritation is caused by the rostrum of the insect being inserted into the skin, from which the blood is rapidly pumped up. Attempts have been made to prove that the head-louse (and, in a smaller degree, the body-louse) is liable to slight variation in structure, and also in colour, according to the races of men infested. This was probably first enunciated by Pouchet in 1841, and the subject received more extended examination by Andrew Murray in a paper published in the *Transactions of the Royal Society of Edinburgh* in 1861 (vol. xxii. pp. 567–577), who apparently shows that some amount of variation does exist, but there is yet need for further investigation. That lice are considered *bonnes bouches* by certain uncivilized tribes is well known. It would be out of place to discuss here the possible interpretation of the Biblical reference to "lice" (*cf.* Exodus viii. 16, 17). A third human louse is known as the crab-louse (*Phthirius pubis*); this disgusting creature is found amongst the hairs on other parts of the body, particularly those of the pubic region, but probably never on the head; although its presence may generally be looked upon as indicating dissolute association, it should not be regarded as always resulting therefrom, as it may be accidentally acquired by the most innocent. The louse of monkeys is now generally considered as forming a separate genus (*Pedicinus*), but the greater part of those infesting domestic and wild quadrupeds are mostly grouped in the large genus *Hæmatopinus*, and very rarely is the same species found on different kinds of animals; one species is found on the seal, and even the walrus does not escape, a new species (*H. trichechi*) having been recently discovered affecting the axillæ (and other parts where the skin is comparatively soft) of that animal.

The bird-lice (or *Mallophaga*) are far more numerous in species, although the number of genera is comparatively small. With the exception of the genus *Trichodectes*, the various species of which are found on mammalia, all infest birds (as their English name implies). As the mouth parts of these creatures are not capable of being extended into a sucking tube, but are clearly mandibulate, it appears probable that they feed more particularly on the scurf of the skin and feathers; nevertheless great irritation must be caused by their presence, for it is notorious that cage-birds, much infested, will peck themselves to such an extent as to cause death in their endeavours to get rid of the parasites. Several hundred species are already known. Sometimes two or three species (ordinarily of different genera) infest the same species of bird, and the same species of louse is not often found in different birds, unless those latter happen to be closely allied. But in aviaries and zoological gardens such cases do occasionally occur, as is natural under the circumstances. These are analogous to the occasional presence of the flea of the cat, dog, domestic fowl, &c., on man; temporary annoyance is caused thereby, but the conditions are not favourable for the permanent location of the parasites. Notwithstanding the marked preference shown by a special kind of bird-lice for a special host, there is also a marked preference shown by the individual species of certain genera or groups of lice for allied species of birds, which bears upon the question of the possible variation of human lice according to the race infested.

Literature.—The following works are the most important:—Denny, *Monographia Anoplurorum Britanniæ*, London, 1843; Giebel, *Insecta Epizoa* (which contains the working-up of Nitzsch's posthumous materials), Leipsic, 1874; Van Beneden, *Animal Parasites*, London, 1876; Piaget, *Les Pédiculines*, Leyden, 1880; Mégnin, *Les Parasites et les Maladies Parasitaires*, Paris, 1880.

LOUTH, a maritime county in the province of Leinster, Ireland, is bounded on the N.E. by Carlingford Bay and the county of Down, E. by the Irish Sea, S.W. by Meath, and N.W. by Monaghan and Armagh. It is the smallest county in Ireland, the area comprising 202,124 acres, or 316 square miles.

The greater part of the surface is undulating, with occasionally lofty hills; and in the north-east, on the borders of Carlingford Bay, there is a range of mountains approaching 2000 feet in height. Many of the hills are finely wooded, and towards the sea-coast the scenery, in the more elevated districts, is strikingly picturesque. The northern mountains are composed of felspathic and pyroxenic rocks. The lower districts rest chiefly on clay-slate and limestone. With the exception of the promontory of Clogher Head, which rises abruptly to a height of 180 feet, the sea-coast is for the most part low and sandy. The narrow and picturesque bay of Carlingford is navigable beyond the limits of the county, and the bay of Dundalk stretches to the town of that name and affords convenient shelter for a harbour. The principal rivers are the Fane, the Lagan, the Glyde, and the Dee, which all flow eastwards. None of these are navigable, but the Boyne, which forms the southern boundary of the county, is navigable for large vessels as far as Drogheda.

Agriculture.—In the lower regions the soil is a very rich deep mould, admirably adapted both for cereals and green crops. The higher mountain regions are covered principally with heath. Agriculture generally is in an advanced condition, and the farms are for the most part well drained.

In 1880 there were 97,954 acres, or nearly one-half of the total area, under tillage, while 74,944 were pasture, 4585 plantations, and 24,135 waste. The total number of holdings in 1880 was 8216, of which 1294 were less than 1 acre in extent. No less than 5340 were below 15 acres in extent, and of these 2486 were between 5 and 15 acres. The following table shows the areas under the principal crops in 1855 and 1881:—

	Wheat.	Oats.	Other Cereals.	Potatoes.	Turnips.	Other Green Crops.	Flax.	Meadow and Clover.	Total.
1855	9,674	38,530	22,028	12,010	9,235	2,548	190	17,286	111,501
1881	3,382	26,543	20,620	11,356	9,906	1,696	1,307	22,581	97,391

Between 1855 and 1881 horses have diminished from 12,133 to 10,810, of which 7394 are used for agricultural purposes. The number of cattle has increased only slightly, from 32,107 to 34,739, of which 8728 are milch cows. Sheep in 1855 numbered 31,712, and 33,362 in 1881. Pigs in 1881 numbered 10,471, and poultry 241,446. According to the last return the land was divided among 1279 proprietors, who possessed 200,287 acres, with an annual rateable value of £209,090, or 20s. 10d. per acre. Of the owners, 45 per cent. possessed less than 1 acre, and the average size of the properties was 156 acres. The largest proprietors were Lord Clermont, 20,369 acres; Viscount Masserene, 7193; A. H. Smith Barry, 6239; Colonel J. C. W. Fortescue, 5262; and Lord Bellew, 5109.

Manufactures and Trade.—Sheetings and coarse linen cloth are manufactured in some places. Many of the inhabitants are engaged in deep-sea fishing, and there is a very valuable oyster fishery in Carlingford Bay. At Newry, Drogheda, and Dundalk a considerable coasting trade is carried on.

Railways.—The county is intersected from north to south by the Dundalk and Belfast line, and the Irish North-Western line passes westwards from Dundalk to Enniskillen.

Administration and Population.—The county includes 6 baronies, 64 parishes, and 674 townlands. It is in the north-eastern circuit. Assizes are held at Dundalk, and quarter sessions at Ardee, Drogheda, and Dundalk. There are ten petty sessions districts within the county and a portion of one. It includes portions of the three poor-law unions of Ardee, Drogheda, and Dundalk. With the exception of Drogheda, which is in the Dublin military district, the county is in the Belfast military district; and there are barracks at Dundalk. Besides the two members at present returned by the county, and one member by each of the boroughs of Drogheda and Dundalk, Louth in the Irish parliament was represented by an additional member for each of the boroughs of Drogheda and Dundalk, and by two members for each of the boroughs of Ardee, Carlingford, and Dunleer. The principal towns are Drogheda (14,662) and Dundalk (12,294). In 1760 the population was estimated at 67,572, which in 1841 had increased to 128,347, but in 1851 had diminished to 108,018, in 1871 to 84,021, and in 1881 to 78,228, of whom 38,241 were males and 39,987 females. From 1st May 1851 to 31st December 1881, the number of emigrants was 33,521, a percentage of 37·2 of the average population during that period. The marriage rate to every 1000 of estimated population in 1880 was 3·4, the birth rate 23·5, and the death rate 21·4.

History and Antiquities.—In the time of Ptolemy, Louth was inhabited by the Voluntii. Subsequently it was included in the principality of Orgial or Argial, which comprehended also the greater part of Meath, Monaghan, and Armagh. A subordinate territory which included Louth was known as *Hy-Conal* and *Machuire-Conal.* The chieftain of the district was conquered by John de Courcy in 1183, and in 1210 that part of the territory now known as Louth was made shire ground by King John, and peopled by English settlers. Until the time of Elizabeth it was included in Ulster.

In the county there are a large number of antiquarian remains of special interest. There are ruins of Druidical altars at Balrighan and Carrick Edmond, and of a Druidical temple at Ballinahatrey near Dundalk. The round tower at Monasterboice is in very good preservation, and there are remains of another at Dromiskin. The most remarkable cromlechs are those on Killin Hill and at Ballymascanlan. At Killin Hill there is an extraordinary fort called *Faghs-na-ain-eighe*, or "the one night's work"; and near Ballymascanlan is Castle Rath, surrounded by lesser raths, and having a remarkable tumulus in its vicinity. About 2 miles from Dundalk there is a very ancient structure, the origin of which has been much discussed. Near Balrighan there is a curious artificial cave. A large number of spears, swords, axes of bronze, gold ornaments, and other relics of antiquity have been discovered. There are a great number of Danish and other old forts. Originally there are said to have been no fewer than twenty religious houses within the county. Of these there are interesting remains at Carlingford; at Faughart, where is also to be seen St Bridget's stone and pillar; at Mellifont, the architecture of which is specially beautiful and elaborate; and at Monasterboice, where there are two crosses, one of which, St Boyne's, is the most ancient and most finely decorated in Ireland.

LOUTH, a municipal borough and market-town of Lincolnshire, England, is pleasantly situated on the river Lud, and on a branch of the Great Northern Railway, 25 miles east-north-east of Lincoln. By means of a canal, completed in 1763, at a cost of £28,000, there is water communication with Hull. The town is about a mile in length, and is well built and paved. The church of St James, completed about 1516, in the Later English style, with a spire 288 feet in height, is one of the finest ecclesiastical buildings in the county. There are an Edward VI. grammar school, which is richly endowed, a commercial school founded in 1676, and a national school. The other public buildings include a town-hall, a corn exchange, and a market-hall. In the vicinity are the ruins of a Cistercian abbey, founded in 1139. The industries include the manufacture of carpets, tanning, iron-founding, brewing, malting, lime burning, and rope and brickmaking.

The population, which in 1851 was 10,467, had increased in 1871 to 10,500, and in 1881 to 10,690.

Louth is a corruption of *Ludd*, the ancient name of the river Lud. It received a charter of incorporation from Edward VI. In 1536 the town took part in the "Pilgrimage of Grace," on which account the vicar was executed at Tyburn. Alfred and Charles Tennyson were educated at the grammar school, and their little volume entitled *Poems by Two Brothers* was published by a Louth bookseller, whose shop still exists.

LOUVAIN, a town of Belgium in the province of Brabant, 18 miles east of Brussels, on the Liége and Cologne Railway, and on the river Dyle. The population in 1880 was 34,700. Louvain possesses some fine specimens of Gothic art,—the town-hall, which displays a wealth of decorative architecture almost unequalled on the Continent, and the collegiate church of St Pierre, with some fine sculptures and panels by Quentin Matsys. The general aspect of the town to the casual observer is dull and cheerless; the newer portions, extending between the town-hall and station, consist of broad streets of monotonous regularity, while the old mediæval quarter, despite its historic interest, is somewhat dingy and lifeless. Louvain has a market for corn and cattle as well as for cloth wares; wood carving is also carried on; but the chief industry of the locality is brewing, the Louvain beer, a lemon-coloured frothy beverage, being held in high repute in the country. In the world of science Louvain holds honourable rank, having a celebrated university, an academy of painting, a school of music, extensive bibliographic collections, a museum of natural history, and a botanical garden. The university, a stronghold of the Roman Catholic faith, was first instituted in 1425, and soon grew famous among the learned of all nations. In the 15th and 16th centuries not less than six thousand students flocked thither yearly, and it became the nursery of many illustrious men. Swept away for a time by the first French Revolution, it was re-established in 1835; and, though less conspicuous than in bygone ages, and more generally confined to the instruction of the youth of Belgium, it is yet of considerable importance in the country as the only Catholic university, and one of the main supports of the Conservative party.

Like Bruges and many other Flemish towns, Louvain was at one time a great and flourishing city, with a population of 200,000 souls, and one of the principal markets of the Continent. The turbulent spirit of the people, their frequent outbreaks against their rulers, and in particular the massacre of the patricians in 1378, were the chief causes of its decline. Duke Wenceslaus of Brabant, in a spirit of revenge after the last-mentioned rising, imposed so heavy taxes upon the people that they emigrated in large numbers. A hundred thousand weavers left the country, carrying abroad, mainly to England, the secrets of their trade; and from that period the material prosperity of Louvain has steadily diminished.

LOUVIERS, capital of an arrondissement in the department of Eure, France, is pleasantly situated, in a green valley surrounded by wooded hills, on the Eure (here divided into many branches), 71 miles west-north-west from Paris, and some 13 miles from Rouen and Evreux. The old part of the town, built of wood, stands on the left bank of the river; the more modern portions, in brick and hewn stone, on the right. There are several good squares, and the place is surrounded by boulevards. The Gothic church of Notre Dame has a fine square tower, recently restored, and a portal which ranks among the richest and most beautiful works of the kind produced in the 15th century; it contains several interesting works of art. The chief industry of Louviers is the cloth and flannel manufacture. There are also nineteen wool-spinning mills, five fulling mills, and important thread factories; and paper-making, tanning, currying and tawing, dyeing, and bleaching are also carried on. The town has a court of first instance, a tribunal of commerce, chambers of manufactures and agriculture, and a council of prudhommes. The population in 1876 was 10,973.

Louviers was originally a villa of the dukes of Normandy; its cloth-making industry first arose in the beginning of the 13th century. It changed hands once and again during the Hundred Years' War, and from Charles VII. it received extensive privileges, and the title of Louviers le Franc for the bravery of its inhabitants in driving the English from Pont de l'Arche, Verneuil, and Harcourt. It passed through various troubles successively at the period of the "ligue du bien public" under Louis XI., in the religious wars (when the parliament of Rouen sat for a time at Louviers), and in the wars of the Fronde. Its industries nevertheless developed steadily; before the Revolution its production of cloth amounted to 3000 pieces annually, in 1837 the number had risen to 15,000, and it is still greater now.

LOUVOIS, François Michel le Tellier, Marquis de (1641–1691), the great war minister of Louis XIV., was born at Paris on January 18, 1641. His father, Michel le Tellier, sprung from a bourgeois family of Paris, but had attached himself to the parlement of Paris, and married the niece of the chancellor Aligre. He won the favour of De Bullion, the superintendent of finances, and through him obtained the intendancy of Piedmont, where he made the acquaintance of Mazarin. He was Mazarin's right hand through the troublous times of the Fronde, and was the medium of communication between him and the queen, when the cardinal was in nominal disgrace at Brühl. He had been made secretary of state in 1643, and on the death of Mazarin was continued in his office. Like Colbert and unlike Fouquet he recognized the fact that Louis intended to govern, and by humouring his master's passion for knowing every detail of personnel and administration he gained great favour with him. He married his son to a rich heiress, the Marquise de Courtenvaux, and soon began to instruct him in the management of state business. The young man speedily won the king's confidence, and in 1666 was made secretary of state for war in his father's room. His talents were perceived by the great Turenne in the short war of the Devolution (1667–68), who gave him instruction not so much in the art of war as in the art of providing armies. The peace of Aix-la-Chapelle signed, Louvois devoted himself to the great work of organizing the French army. The years between 1668 and 1672, says Camille Rousset, "were years of preparation, when Lionne was labouring with all his might to find allies, Colbert to find money, and Louvois soldiers for Louis." Louvois's work was not the least important of the three. Till then armies were either bodies of free lances collected round a particular general and looking to him for pay, or a sort of armed militia, who looked on soldiering as an interlude, not a profession. Louvois understood the new condition of things, and organized a national standing army. In his organization, which lasted almost without a change till the period of the French Revolution, the leading points must be noted. First among them was the almost forcible enrolment of the nobility and gentry of France, which St Simon so bitterly complains of, and in which Louvois carried out part of Louis's measures for curbing the spirit of independence by service in the army or at court. Then must be mentioned his elaborate hierarchy of officers, the grades of which with their respective duties he established for the first time, and his new system of drill, perfected by Martinet. Besides the army itself, he organized for its support a system of payment and commissariat, and a hospital system, which made it more like a machine, less dependent on the weather, and far superior to the old German system. Further, with the help of Vauban he formed a corps of engineers, and lastly, to provide the deserving with suitable reward, and encourage the daring, he reorganized the military orders of merit, and founded the Hôtel des Invalides at Paris. The success of his measures is to be seen in the victories of the great war of 1672–1678, in which his old instructor Turenne was killed. After the peace of Nimeguen in 1678, Louvois was high in favour, his father Michel le Tellier had been made chancellor, and his only opponent Colbert was in growing disfavour. The ten years of peace between 1678 and 1688 were distinguished in French history by the rise of Madame de Maintenon, the capture of Strasburg, and the revocation of the edict of Nantes, in all of which Louvois bore a prominent part. The surprise of Strasburg in 1681 in time of peace, in pursuance of an order of the chamber of reunion, was not only planned but executed by Louvois and Monclar, and after the revocation of the Edict of Nantes he claims the credit of inventing the dragonnades. Colbert died in 1683, and had been replaced by Le Pelletier, an adherent of Louvois, in the controller-generalship of finances, and by Louvois himself in his ministry for public buildings, which he took that he might be the minister able to gratify the king's two favourite pastimes, war and buildings. Louvois was able to superintend the successes of the first years of the war of 1688, but died suddenly of apoplexy after leaving the king's cabinet on July 16, 1691. His sudden death caused a suspicion of poison, and struck everybody with surprise. "He is dead," writes Madame de Sevigné, "that great minister, that important man, who held so grand a position, and whose *Moi* spread so far, who was the centre of so much." "Tell the king of England," said Louis the next day, "that I have lost a good minister, but that his affairs and mine will go none the worse for that." He was very wrong; with Louvois the organizer of victory was gone. Great war ministers are far rarer than great generals. French history can only point to Carnot as his equal, English history only to the elder Pitt. The comparison with Carnot is an instructive one: both had to organize armies out of old material on a new system, both had to reform the principle of appointing officers, both were admirable contrivers of campaigns, and both devoted themselves to the material well-being of the soldiers. But in private life the comparison will not hold; Carnot was a good husband, an upright man, and a broad minded thinker and politician, while Louvois married for money and lived openly with various mistresses, most notoriously with the beautiful Madame de Courcelles, used all means to overthrow his rivals, and boasted of having revived persecution in his horrible system of the dragonnades.

The principal authority for Louvois's life and times is Camille Rousset's *Histoire de Louvois*, 4 vols., 1862–63, a gr at work founded on the 900 volumes of his despatches at the Depôt de la Guerre. Saint Simon from his class prejudices is hardly to be trusted, but Madame de Sevigné throws many bright side-lights on his times. *Testament Politique de Louvois* (1695) is spurious.

LOVAT, Simon Fraser, Baron, a famous Jacobite intriguer, executed for the part which he took in the rebellion of 1745, was born about the year 1676, and was the second son of Thomas, afterwards twelfth Lord Lovat. He was educated at King's College, Aberdeen, and there seems reason to believe that he was there no negligent student, as his correspondence afterwards gives abundant proof, not only of a thorough command of good English and idiomatic French, but of such an acquaintance with the Latin classics as to leave him never at a loss for an apt quotation from Virgil or Horace. Whether Lovat ever felt any real principle of loyalty to the Stuarts or was actuated throughout merely by what he supposed to be self-interest it is difficult to determine, but that he was a born traitor and deceiver there can be no doubt. One of his first acts on leaving college was to recruit three hundred men from his clan to form part of a regiment in the service of William and Mary, in which he himself was to hold a command,—his object being, as he unhesitatingly avows, to have a body of well-trained soldiers under his influence, whom at a moment's notice he might carry over to the interest of King James. Among other wild outrages in which he was engaged about this time was a rape and forced marriage committed on the widow of a previous Lord Lovat with the view apparently of securing his own succession to the estates; and it is a curious instance of his plausibility and power of influencing others that, after being subjected by him to the most horrible ill-usage, the woman is said to have ultimately become seriously attached to him. A prosecution for his violence, however, having been instituted against him by Lady Lovat's family, Simon found it prudent to retire first to his native strongholds in the Highlands, and afterwards to France, where he at length found his way in July 1702 to the court of St Germains. One of his first steps towards gaining influence there seems to have been to announce his conversion to the Catholic faith. He then proceeded to put the great project of restoring the exiled family into a practical shape. Hitherto nothing seems to have been known among the Jacobite exiles of the efficiency of the Highlanders as a military force. But Lovat, who was of course well acquainted with their capabilities, saw that, as they were the only part of the British population accustomed to the independent use of arms, they could be at once put in action against the reigning power. His plan therefore was to land five thousand French troops at Dundee, where they might reach the north-eastern passes of the Highlands in a day's march, and be in a position to divert the British troops till the Highlands should have time to rise. Immediately afterwards five hundred men were to land on the west coast, seize Fort William or Inverlochy, and thus prevent the access of any military force from the south to the central Highlands. The whole scheme affords strong indication of Lovat's sagacity as a military strategist, and it is observable that his plan is that which was continuously kept in view in all the future attempts of the Jacobites, and finally acted on in the last outbreak of 1745. The advisers of the Pretender seem to have been either slow to trust their astute coadjutor or slow to comprehend his project. At last, however, he was despatched on a secret mission to the Highlands to sound those of the chiefs who were likely to rise, and to ascertain what forces they could bring into the field. He very soon found, however, that there was little disposition to join the rebellion, and he then made up his mind to secure his own safety by revealing all that he knew to the Government of Queen Anne. Having by this means obtained a pardon for all his previous crimes, he was sent back to France to act as a spy on the Jacobites. On returning to Paris suspicions soon got afloat as to his proceedings, and in the end he was committed close prisoner in the castle of Angoulême, where he remained for nearly ten years, or till November 1714, when he made his escape to England. For some twenty-five years after this he was chiefly occupied in lawsuits for the recovery of his estates and the re-establishment of his fortune, in both of which objects he was successful. The intervals of his leisure were filled up by Jacobite and Anti-Jacobite intrigues, in which he seems to have alternately, as suited his interests, acted the traitor to both parties. But he so far obtained the confidence of the Government as to have secured the appointments of sheriff of Inverness and of colonel of an independent company. His disloyal practices, however, soon led to his being suspected; and he was deprived of both his appointments. When the rebellion of 1745 broke out, Lovat acted with his characteristic duplicity. He represented to the Jacobites—what was probably in the main true—that though eager for their success his weak health and advanced years prevented him from joining the standard of the prince in person, while to the Lord President Forbes he professed his cordial attachment to the existing state of things, but lamented that his headstrong son, in spite of all his remonstrances, had insisted on joining the Pretender, and succeeded in taking with him a strong force from the clan of the Frasers. The truth was that the poor lad was most unwilling to go out, but was compelled by his father to do so. Lovat's false professions of fidelity did not of course long deceive the Government, and after the battle of Culloden he was obliged to retreat to some of the wildest recesses of the Highlands, after seeing from a distant height his proud castle of Dounie delivered to the flames by the royal army. Even then, however, broken down by disease and old age, carried about on a litter and unable to move without assistance, his mental resources did not fail him; and in a conference with several of the Jacobite leaders he proposed that they should raise a body of three thousand men, which would be enough to make their mountains impregnable, and at length force the Government to give them advantageous terms. The project, though by no means a chimerical one, was not carried out, and Lovat, after enduring incredible hardships in his wanderings, was at last arrested on an island in Loch Morar close upon the west coast. He was conveyed in a litter to London, and after a trial of five days sentence of death in "the ordinary brutal form peculiar to England" was pronounced upon him on the 19th of March 1747. His execution took place on the 9th of April following. His conduct to the last was dignified and even cheerful,—his humour, his power of sarcasm, and his calm defiance of fate never deserting him. Just before submitting his head to the block he repeated the line from Horace—

"Dulce et decorum est pro patria mori."

LOVE-BIRD, a name somewhat indefinitely bestowed, chiefly by dealers in live animals and their customers, on some of the smaller short-tailed Parrots, from the remarkable affection which examples of opposite sexes exhibit towards each other, an affection popularly believed to be so great that of a pair that have been kept together in captivity neither can long survive the loss of its partner. By many systematic ornithologists the little birds thus named, brought almost entirely from Africa and South America, have been retained in a single genus, *Psittacula*, though those belonging to the former country were by others separated as *Agapornis*. This separation, however, was by no means generally approved, and indeed it was not easily justified, until Garrod (*Proc. Zool. Society*, 1874, p. 593) assigned good anatomical ground, afforded by the structure of the carotid artery, for regarding the two groups as distinct, and thus removed what had seemed to be the almost unintelligible puzzle presented by the geographical distribution of the species of *Psittacula* in a large sense, though Professor Huxley (*op. cit.*, 1868, p. 319) had indeed already suggested one way of meeting the difficulty. As the genus is now restricted, only one of the six species of *Psittacula* enumerated in the *Nomenclator Avium* of Messrs Sclater and Salvin is known to be found outside of the Neotropical Region, the exceptional instance being the Mexican *P. cyanopygia*, and not one of the seven recognized by the same authors as forming the very nearly allied genus *Urochroma*. On the other hand, of *Agapornis*, from which the so-called genus *Poliopsitta* can scarcely be separated, five if not six species are known, all belonging to the Ethiopian Region, and all but one, *A. cana* (which is indigenous to Madagascar, and thence has been widely disseminated), are natives of Africa. In this group probably comes also *Psittinus*, with a single species from the Malayan Subregion. These Old-World forms are the "Love-birds" proper; the others scarcely deserve that designation, and still less do certain even smaller Parrots, the very smallest indeed of the Order *Psittaci*, included in the genera *Cyclopsitta* and *Nasiterna*, which are peculiar to the Australian Region, though on account of their diminutive size they may here be just mentioned by name, but their real affinity remains to be determined. (A. N.)

LOVELACE, Richard (1618–1658), English poet, was born in 1618. On the father's side he was a scion of a Kentish family, and inherited a tradition of military distinction, maintained by successive generations from the time of Edward III. His mother's family was legal; her grandfather had been chief baron of the exchequer. Lovelace's fame has been kept alive by a few songs and the romance of his career, and his poems are commonly spoken of as careless improvisations, and merely the amusements of an active soldier. But the unhappy course of his life gave him more leisure for verse-making than opportunity of soldiering. Before the outbreak of the civil war in 1642 his only active service was in the bloodless expedition which ended in the Pacification of Berwick in 1640. By that time he was one of the most distinguished of the company of courtly poets gathered round Queen Henrietta, and influenced as a school by contemporary French writers of *vers de société*. Lovelace had probably a more serious and sustained poetical ambition than any of them. He wrote a comedy, *The Scholar*, when he was sixteen, and a tragedy, *The Soldier*, when he was one and twenty. From what he says of Fletcher, it would seem that this dramatist was his model, but only the spirited prologue and epilogue to his comedy have been preserved. When the rupture between king and parliament took place, Lovelace was committed to the Gatehouse at Westminster for presenting to the Commons a petition from Kentish royalists in the king's favour. It was then that he wrote his most famous song, "To Althæa from Prison." He was liberated on bail of £40,000,—a sign of his importance in the eyes of the parliament,—and throughout the civil war was a prisoner on parole, with this security in the hands of his enemies. His only active service was after 1646, when he raised a regiment for the French king, and took part in the siege of Dunkirk. Returning to England in 1648, he was again thrown into prison. During this second imprisonment, he collected and revised for the press a volume of occasional poems, many if not most of which had previously appeared in various publications. The volume was published in 1649 under the title of *Lucasta*, his poetical name—contracted from *Lux Casta*—for Lucy Sacheverell, a lady who married another during his absence in France, on a report that he had died of his wounds at Dunkirk. The last ten years of Lovelace's life were passed in obscurity. His fortune had been exhausted in the king's interest, and he is said to have been supported by the generosity of more fortunate friends. He died, according to Aubrey, "in a cellar in Longacre." A volume of Lovelace's *Posthume Poems* was published in 1659 by one of his brothers. They are of very inferior merit to his own collection.

The world has done no injustice to Lovelace in neglecting all but a few of his modest offerings to literature. But critics often do him injustice in dismissing him as a gay cavalier, who dashed off his verses hastily and cared little what became of them. It is a mistake to class him with Suckling; he has neither Suckling's easy grace nor his reckless spontaneity. We have only to compare the version of any of his poems in *Lucasta* with the form in which it originally appeared to see how fastidious was his revision. In many places it takes time to decipher his meaning. The expression is often elliptical, the syntax inverted and tortuous, the train of thought intricate and discontinuous. These faults—they are not of course to be found in his two or three popular lyrics, "Going to the Wars," "To Althæa from Prison," "The Scrutiny"—are, however, as in the case of his poetical master, Donne, the faults not of haste but of over-elaboration. His thoughts are not the first thoughts of an improvisatore, but thoughts ten or twenty stages removed from the first, and they are generally as closely packed as they are far-fetched. Lovelace is not named by Johnson among the "metaphysical poets," but in elaboration of workmanship as well as in intellectual force he comes nearer than any other disciple to the founder of the school. His most far-fetched conceits are worth the carriage, and there is genuine warmth in them. The wine of his poetry is a dry wine, but it is wine, and not an artificial imitation. His career as a dramatist was checked by the suppression of the stage; if he had been born thirty years earlier or thirty years later, Fletcher or Congreve would have had in him a powerful rival. The most recent edition of his poems is that by W. C. Hazlitt, in 1864.

LOVER, SAMUEL (1797–1868), novelist, artist, song-writer, and musician, was born in Dublin in 1797. His father was a member of the stock exchange. Lover began life as an artist, and was elected an academician of the Royal Hibernian Society of Arts—a body of which he afterwards became secretary. He acquired repute as a miniature painter; and a number of the local aristocracy sat to him for their portraits. His love for music showed itself at a very early age. At a dinner given to the poet Moore in 1818 Lover sang one of his own songs, which elicited special praise from Moore. One of his best known portraits was that of Paganini, which was exhibited at the Royal Academy. He attracted attention as an author by his *Legends and Stories of Ireland* (1832), and was one of the first writers for the *Dublin University Magazine*. He went to London about 1835, where, among others, he painted Lord Brougham in his robes as lord chancellor. His varied gifts rendered him very popular in society; and he appeared often at Lady Blessington's evening receptions. There he sang several of his songs, which were so well received that he published them (*Songs and Ballads*, 1839). Some of them illustrated Irish superstitions, among these being "Rory O'More," "The Angel's Whisper," "The May Dew," and "The Four-leaved Shamrock." In 1837 appeared *Rory O'More, a National Romance*, which at once made him a great reputation as a novelist; he afterwards dramatized it for the Adelphi Theatre, London. In 1842 was published his best known work, *Handy Andy, an Irish Tale*. Meanwhile his multifarious pursuits had seriously affected his health; and in 1844 he gave up writing for some time, substituting instead public entertainments, called by him "Irish Evenings," illustrative of his own works and his powers as a musician and composer. These were very successful both in Great Britain and in America. In addition to publishing numerous songs of his own, Lover edited a collection entitled *The Lyrics of Ireland*, which appeared in 1858. He died on July 6, 1868. Lover was remarkable for his versatility; but his fame rests mainly on his songs and novels; the latter are full of sunny Irish humour, and teem with felicitous pictures of national life. Besides those already mentioned he wrote *Treasure Trove* (1844), and *Metrical Tales and Other Poems* (1860).

LOWELL, the twenty-seventh city in population of the United States, in Middlesex county, Massachusetts, at the junction of the Concord and Merrimack rivers, 26 miles north-west from Boston. It is often called the "Spindle City," and the "Manchester of America," because of the extent of its cotton manufacture. The principal source of its water-power is Pawtucket Falls in the Merrimack, and steam is employed as an auxiliary to the amount of 19,793 horse-power. The first cotton-mill was started in 1823, when the place was the village of East Chelmsford. In 1826 it was made a town, and named Lowell in memory of Francis Cabot Lowell, from whose plans it had been developed, but who died in 1817. It was incorporated as a city in 1836. It originally comprised 2885 acres, but by annexation from neighbouring towns its area has been increased to 7615 acres, or 11·8 square miles. The population, which in 1836 was 17,633, was 40,928 in 1870, and 59,485 in 1880 (males, 26,855; females, 32,630), and in 1882 was estimated at 64,000.

The following table shows the extent of the principal manufacturing companies in 1882:—

Company.	Established.	Looms.	Spindles.	Operatives.	Yards per Week.
Merrimack	1823	4,267	153,552	3,300	947,000
Hamilton	1825	1,597	59,816	1,387	364,000
Appleton	1828	1,228	45,000	820	285,000
Lowell	1828	392	24,750	1,700	48,000
Middlesex	1830	250	18,640	836	25,000
Tremont and Suffolk	1832	2,700	94,000	1,500	550,000
Lawrence	1833	2,360	100,000	2,130	425,000
Booth	1836	3,600	127,000	1,875	650,000
Massachusetts	1840	3,658	119,528	1,717	907,000

The capital invested is $17,300,000; number of mills, 153; spindles, 806,000; looms, 20,521; females employed, 12,809; males, 9750; yards per year, cotton 209,056,000, woollen 8,335,000, carpetings 2,700,000; shawls, 350,000; hosiery per year, 13,695,520 pairs; cotton consumed annually, 34,087 tons; clean wool, 11,750,000 ℔; yards cotton dyed and printed, 97,240,000; coal consumed, 80,000 tons. There are many secondary industries connected with the cotton manufacture, including the making of machinery, elastic and leather goods, tools, boilers, &c., and also a number of small factories for the production of cartridges, chemicals, wire cloth, paper, doors, sashes, blinds, and carriages. The Lowell machine-shop employs 1400 men in the manufacture of machinery, and consumes 9800 tons of iron and steel annually. Lowell has 90 public day schools, 6 evening and 4 technical schools, a reform school, and 2 parochial schools. The principal public buildings are the city-hall, court-house, Middlesex county jail, Green school-house, and St John's Hospital. There are 7 national banks with a total capital of $2,500,000, and 6 savings banks with deposits of $11,000,000. The religious congregations number 35, all but three of which own their places of worship. The two largest Roman Catholic churches, St Patrick's and the Church of the Immaculate Conception, are among the finest in the State. Seven railroads connect Lowell with the railroad system of the country. The benevolent institutions include a home for young women and children, and one for aged women, 2 orphanages, and 3 hospitals. There are 2 reading-rooms, 5 daily newspapers (one French), 6 weeklies, and 4 public libraries. Lowell was early famed for the high character of its operatives, who for some years published a periodical of considerable literary merit called *The Lowell Offering*, which was, it is believed, the only publication of the kind ever sustained by workpeople. Many of the young women rose to positions of prominence in American society, and at least one, Miss Lucy Larcom, is known to readers on both sides of the Atlantic by her contributions to leading magazines.

In 1843 Charles Dickens visited the place, and devoted a chapter of his *American Notes* to its praise. The manufacturers have from the first provided for the moral and social as well as the physical wellbeing of their operatives, so that labour troubles have been exceedingly rare in Lowell. The corporation boarding-houses are model dwellings for the workpeople. The first blood shed in the American civil war was that of two Lowell young men, Luther C. Ladd and A. O. Whitney, who were killed by a mob while their regiment was passing through the streets of Baltimore, on the way to the defence of Washington, April 19, 1861. In their honour a granite monument has been erected in Merrimack Street, and in the same enclosure is a bronze statue of Victory by the German sculptor Rauch to commemorate the triumph of the Northern cause.

The assessed valuation in May 1881 was $42,785,434 an increase of $3,108,035 since 1879); the net debt December 31, 1881, was $1,992,868, of which $1,565,539 was on account of the introduction of water in 1873.

Lowell is divided into six wards, and is governed by a mayor, a board of eight aldermen, and a common council of twenty-four members.

LOWESTOFT, a watering-place, seaport, and market-town of Suffolk, England, is picturesquely situated on a lofty declivity, which includes the most easterly point of land in England, 23 miles south-west of Norwich by rail. Previous to the opening of a railway, it was only a small fishing village, but since then it has risen to some importance as a seaport, while its picturesque situation, and its facilities for sea-bathing, have rendered it a favourite watering-place. The church of St Margaret, in the Later English style, with tower and spire, possesses a very ancient font. There are a town-hall, a county-hall, two foundation schools, a large general hospital, and a number of charities. Along the shore there is a fine esplanade, and a new park was opened in 1874. Two piers 1300 feet in length enclose a harbour of 20 acres, which is much used as a harbour of refuge. For the last five years the average value of the foreign and colonial imports has been over £100,000, and the exports have been valued at about £5000. The fisheries of Lowestoft are of some importance, and there are shipbuilding yards, oil and flour mills, and rope-works. The population of the urban sanitary district in 1871 was 15,246, and in 1881 it had increased to 19,597.

LOWICZ, a town of Russian Poland, on the Bzura river, in the government of Warsaw, 54 miles by rail west from the capital, on the line between Skiernewice and Bromberg. It has lately become a centre of manufacture and trade, and the population (6650 in 1872) is rapidly increasing. Its fairs are important as regards the trade in horses and cattle. In the immediate neighbourhood are situated the hamlet Liczcowice, which has a beetroot sugar factory, and the rich estates Nieboron and Villa Arcadia of the Radziwill family.

LOWTH, Robert (1710–1787), bishop of London, was born at Buriton, Hampshire, or, according to other authorities, in the Close of Winchester, on November 27, 1710. He was the younger son of Dr William Lowth (1661–1732), rector of Buriton, a man of considerable learning, author of *A Vindication of the Divine Authority and Inspiration of the Old and New Testaments* (1692), *Directions for the Profitable Reading of the Holy Scriptures* (1708–26), and *A Commentary on the Prophets* (4 vols., 1714). Robert was educated on the foundation of Winchester College, and in 1730 was elected to a scholarship at New College, Oxford, where he took his degree of M.A. in 1737. In 1741 he was appointed professor of poetry, and it was in this capacity that he delivered the *Prælectiones Academicæ de Sacra Poesi Hebræorum*, afterwards published in 1753. Bishop Hoadly appointed him in 1744 to the rectory of Ovington, Hampshire, in 1750 to the archdeaconry of Winchester, and in 1753 to the rectory of East Woodhay, also in Hampshire. In 1754 he received the degree of doctor of divinity from his university, and in the following year he went to Ireland along with the duke of Devonshire, then lord-lieutenant, as first chaplain. Soon afterwards he declined a presentation to the see of Limerick, but accepted a prebendal stall at Durham and the rectory of Sedgfield. In 1758 he published his *Life of William of Wykeham*, which was followed in 1762 by *A Short Introduction to English Grammar*. In 1765, the year of his election into the Royal Societies of London and Göttingen, he engaged in a hot war of pamphlets with Warburton on a now obsolete question about the relations between the book of Job and the Mosaic economy; and (Gibbon being judge), "whatsoever might be the merits of an insignificant controversy, his victory was clearly established by the silent confession of Warburton and his slaves." In June 1766 Lowth was promoted to the see of St David's, whence about four months afterwards he was translated to that of Oxford, where he remained till 1777, when he became bishop of London. This last appointment he continued to hold until his death, having declined the archbishopric of Canterbury in 1783. In 1778 appeared his last work, *Isaiah, a new Translation, with a Preliminary Dissertation, and Notes, Critical, Philological, and Explanatory.* He died at Fulham on November 1787.

The *Prælectiones* exercised a great influence both in England and on the Continent. Their chief importance lay in the idea of looking at the sacred poetry as poetry, and examining it by the standards applied to profane literature. Lowth's æsthetic criticism was that of the age, and is now in great part obsolete, a more natural method having been soon after introduced by Herder. The principal point in which Lowth's influence has been lasting is his doctrine of poetic parallelism, and even here his somewhat mechanical classification of the forms of Hebrew sense-rhythm, as it should rather be called, is open to serious objections. The *Prælectiones* reached a second edition in 1763, and were republished with notes by J. D. Michaelis in 1770; both text and notes were translated by G. Gregory (1787; 4th ed., 1839). The Oxford edition of the original (1821) contains additions by Rosenmüller, Richter, and Weiss. The editions of Lowth's *Isaiah* have been numerous (13th ed., 1842), but the book is now much less read than the *Prælectiones*. A volume of *Sermons and other Remains*, with memoir by Hall, was published in 1834, and there is a comparatively recent edition of the *Popular Works* of Robert Lowth, 3 vols., 1843.

LOYALTY ISLANDS, a group in the South Pacific, about 60 miles east of New Caledonia, consisting of Uvea or Uea (the northmost), Lifu, Toka and several small islands, and Mare or Nengone. They are coral islands of comparatively recent elevation, and in no place rise more than 250 feet above the level of the sea. Lifu, the largest, is about 50 miles in length by 25 in breadth. Enough of its rocky surface is covered with a thin coating of soil to enable the natives to grow yams, taro, bananas, &c., for their support; cotton thrives well, and has even been exported in small quantities, but there is no space available for its cultivation on any considerable scale. Fresh water, rising and falling with the tide, is found in certain large caverns, and, in fact, by sinking to the sea-level a supply may be obtained in any part of the island. The population, about 7000, is on the decrease. The island called Nengone by the natives and Mare by the inhabitants of the Isle of Pines is about 80 miles in circumference, and contains about 6000 souls. Uvea, the most recent part of the group, consists of a circle of about twenty islets enclosing a lagoon 20 miles in width; the largest is about 30 miles in length, and in some places 3 miles wide, and the next largest is about 12 miles in length. The inhabitants, numbering about 2500, export considerable quantities of cocoa-nut oil.

The Loyalty islanders are classed as Melanesian; the several islands have each its separate language, and in Uvea the one tribe uses a Samoan and the other a New Hebridean form of speech. Captain Cook passed to the east of New Caledonia without observing the Loyalty group; but it was discovered soon afterwards, and Dumont D'Urville laid down the several islands in his chart. For many years after their discovery the natives had a bad repute as dangerous cannibals. Christianity was introduced into Mare by native teachers from Rarotonga and Samoa; missionaries were settled by the London Missionary Society at Mare in 1854, at Lifu in 1859, and at Uvea in 1865; Roman Catholic missionaries also arrived from New Caledonia; and in 1864 the French, considering the islands a dependency of that colony, formally instituted a commandant. An attempt was made by this official to put a stop to the English missions by violence; but the report of his conduct led to so much indignation in Australia and in England that the emperor Napoleon, on receipt of a protest from Lord Shaftesbury and others, caused a commission of inquiry to be appointed, and free liberty of worship to be secured to the Protestant missions. A new persecution of the Christians in Uvea, during 1875, called forth a protest on the part of the English Government, and matters appear to have since improved.

See W. Gill, *Gems from the Coral Islands*, new edition, 1871; S. Macfarlane, *Story of the Lifu Mission*, 1873.

LOYOLA, Ignatius de, St. Inigo, the youngest son of Beltran de Loyola, was born in 1491 at the castle of Loyola, the family seat, situated on the river Urola, about a mile from the town of Azpeitia, in the province of Guipuzcoa, Spain. He died at Rome on July 31, 1556, was beatified by Paul V. in 1609, and canonized along with Francis Xavier by Gregory XV. on March 13, 1623, the bull being published by Urban VIII. on August 6. His festival (duplex) is observed on July 31. See Jesuits.

LOZÈRE, a department of south-eastern France, but belonging to the great central plateau, is composed of almost the whole of Gévaudan and of some parishes of the old dioceses of Alais and Uzès, districts all formerly included in the province of Languedoc. It lies between 44° 6′ and 44° 58′ N. lat., and between 2° 58′ and 4° E. long., and is bounded on the N.W. by Cantal, on the N.E. by Haute-Loire, on the E. by Ardèche, on the S.E. by Gard, and on the S.W. by Aveyron, having an extreme length of 65 miles, an extreme breadth of 50, and an area of 1996 square miles. Lozère is mountainous throughout, and its average elevation makes it the highest of all the French departments. It has three distinct regions—the Cevennes to the south-east, the "causses" to the south-west, and the mountain tracts which occupy the rest. The Cevennes, forming the watershed between the Garonne and Loire basins to the west and that of the Rhone to the east, begin (within Lozère) with Mount Aigoual, which rises to a height of more than 5100 feet; parallel to this are the mountains of Bougès, a range between the rivers Tarn and Tarnon, bold and bare on its southern face, but falling gently away with wooded slopes toward the north. To the north of the Tarn is the range of Lozère, including the peak of Finiels, the highest point of the department (5584 feet). Further on occurs the broad marshy plateau of Montbel, from which the water drains southward to the Lot, northwards to the Allier, eastward by the Chassezac to the Ardèche. From this plateau extend the mountains of La Margeride, a long series of undulating granitic table-lands partly clothed with woods of oak, beech, and fir, and partly covered with pastures, to which the flocks are brought up from lower Languedoc in summer. The highest point (Mount de Randon) is 5098 feet. Adjoining the Margeride hills on the west is the volcanic range of Aubrac, an extensive pastoral district where horned cattle take the place of sheep; the highest point is 4826 feet. The "causses" of Lozère, having an area of about 483 square miles, consist of extensive calcareous tracts, fissured and arid, but separated from each other by deep and well-watered gorges, whose freshness and beauty are in pleasant contrast with the desolate aspect of the plateaus. The "causse" of Sauveterre, between the Lot and the Tarn, ranges from 3000 to 3300 feet in height; that of Méjean has nearly the same average altitude, but has peaks some 1000 feet higher. Between these two "causses" the Tarn flows through a series of landscapes which are among the most picturesque and grand in France. The Lot and the Tarn, the two most important tributaries of the Garonne, both have their sources in this department, as also have the Allier, the two Gardons, which unite to form the Gard, the Cèze, and the Chassezac with its affluent the Altier. The climate of Lozère varies greatly with the locality. The mean temperature of Mende, the capital, is below that of Paris; that of the mountains is always low, but in the "causses" the summer is scorching and the winter severe; in the Cevennes the climate becomes mild enough at their base (656 feet) to permit the growth of the olive. Rain falls in violent storms, causing disastrous floods. On the Mediterranean versant there are 78·7 inches, in the Garonne basin 45·5, and in that of the Loire only 27·95. The general character of the department is pastoral; only one-fourth of the area is occupied by arable land; 91,500 acres are meadow, 155,700 wood, and 90,000 chestnut plantation. The number of sheep (which is doubled in summer) is 300,000; there are 50,000 head of cattle; and pigs, goats, horses, asses, and mules are also reared. Bees are also kept, and, among the Cevennes, silkworms. The export of chestnuts from the Cevennes is considerable. Rye is the chief cereal; but oats, wheat, meslin, barley, and many potatoes are also grown. Great care is bestowed on cultivation in the valleys adjoining the Ardèche; fruit trees and leguminous plants are irrigated by small canals ("béals") on terraces which have been made or are maintained with much labour. The department yields argentiferous lead (Villefort), slates, and mineral waters, among which those of Bagnols are most frequented. The exportation of its antimony, manganese, marble, and lithographic stones is undeveloped as yet. The tufa of Mende is well adapted for building purposes. The manufactures are unimportant. The population in 1876 was 138,319, having decreased by 5000 since 1801, and by a still greater number since the end of the 17th century. There are about 20,000 Protestants. The arrondissements are three (Mende, Florac, and Marvejols), the cantons twenty-four, and the communes one hundred and ninety-six.

LÜBECK, a free city of Germany, situated in 53° 52′ N. lat. and 10° 41′ E. long., on a gentle ridge between the rivers Trave and Wakenitz, 10 miles S.W. of the mouth of the former, and 40 miles by rail N.E. of Hamburg. Old Lübeck, the chief emporium of the Slav inhabitants of Wagria (East Holstein), stood on the left bank of the Trave, where it is joined by the river Schwartau, and was ultimately destro ed in 1138. Five years later Count Adolphus II. of Holstein founded new Lübeck, a few miles farther up, on the peninsula Buku, where the deep current of the Trave is joined on the right by the Wakenitz, the broad emissary of the Lake of Ratzeburg. A most excellent harbour, well sheltered against pirates, it became almost at once a successful competitor for the commerce of

the Baltic. Its foundation coincided with the beginning of the general advance of the Low German tribes of Flanders, Friesland, and Westphalia along the southern shores of the great inland sea,—the second great emigration of the colonizing Saxon element. In 1140 Wagria, in 1142 the country of the Polabes (Ratzeburg and Lauenburg), had been annexed by the Holtsætas (the Transalbingian Saxons). From 1166 onwards there was a Saxon count at Schwerin. Frisian and Saxon merchants from Soest, Bardewieck, and other localities in Lower Germany, who already navigated the Baltic and had their factory in the distant isle of Gothland, settled in the new town, where Wendish speech and customs never entered. About 1157 Henry the Lion, duke of Saxony, forced his vassal, the count of Holstein, to give up Lübeck; and in 1163 he removed thither the tottering episcopal see of Oldenburg (Stargard), founding at the same time the dioceses of Ratzeburg and Schwerin. He issued the first charter to the citizens, and deliberately constituted them a free Saxon community having its own magistrate, an inestimable advantage over all other towns of his dominions. He invited the traders of the towns and realms of the north to visit his new market free of toll and custom, provided his subjects were promised similar privileges in return. From the very beginning the king of Denmark granted them a settlement for their herring fishery on the coast of Schoonen. Adopting the statutes of Soest in Westphalia as their code, Saxon merchants exclusively ruled the city. In concurrence with the duke's reeve they recognized only one right of judicature within the town, to which nobles as well as artisans had to submit. Under these circumstances the population grew rapidly in wealth and influence by land and sea, so that, when Henry was attainted by the emperor, who had come in person to besiege Lübeck, Barbarossa, "in consideration of its revenues and its situation on the frontier of the empire," fixed by charter, dated September 19, 1188, the limits, and enlarged the liberties, of the free town. Evil times, however, were in store when the Hohenstaufen dynasty became more and more involved in its Italian projects. In the year 1201 Lübeck was conquered by Waldemar II. of Denmark, who prided himself on the possession of such a city. But in 1223 it regained its liberty, after the king had been taken captive by the count of Schwerin. In 1226 it was incorporated as an independent city of the empire by Frederick II., and took an active part with the enemies of the Danish king in the victory of Yornhövd, 1227. The citizens, distinguished by the firmness and wisdom with which they pursued their objects, and fully conscious that they were the pioneers of civilization in the barbarian regions of the north-east, repelled the persistent encroachments of their dynastic neighbours alike in Holstein and in Mecklenburg. On the other hand their town, being the principal emporium of the Baltic by the middle of the 13th century, acted as the firm ally of the Teutonic knights in Livonia. Generation after generation of crusaders embarked to found new cities and new sees of Low German speech among alien and pagan races; and thus in the course of a century the commerce of Lübeck had fully supplanted that of Westphalia. In close connexion with the Germans at Wisby, the capital of Gothland, and at Riga, where they had a house from 1231, the people of Lübeck with their armed vessels scoured the sea between the Trave and the Neva. They were encouraged by papal bulls in their brave contest for the rights of property in wrecks, and for the protection of shipping against pirates and slave-hunters. Before the close of the century the statutes of Lübeck were adopted by most Baltic towns having a German population, and Wisby raised her protest in vain that the city on the Trave had become the acknowledged court of appeal for nearly all these cities, and even for the German settlement in Russian Novgorod. In course of time more than a hundred places were embraced in this relation, the last vestiges of which did not disappear until the beginning of the 18th century. Hitherto only independent merchants, individual Westphalian and Saxon citizens, had flocked together at so many out-lying posts. From about 1299 Lübeck presided over a league of cities, Wismar, Rostock, Stralsund, Greifswald, and some smaller ones, commonly called the Wendish towns. A Hansa of towns became heir to a Hansa of traders simultaneously on the eastern and the western sea, after Lübeck and her confederates had been admitted to the same privileges with Cologne, Dortmund, and Soest at Bruges and in the Steelyards of London, Lynn, and Boston. Such progress of civic liberty and federal union held its own, chiefly along the maritime outskirts of the empire, rather against the will of king and emperor. Nevertheless Rudolf of Hapsburg and several of his successors issued new charters to Lübeck. Charles IV., who, like his son after him, deliberately opposed all confederacies of the Franconian and Swabian towns in Upper Germany, surrendered to the municipal government of Lübeck the little that remained of imperial jurisdiction by transferring to them the chief responsibility for preserving the public peace within the surrounding territories. Under these circumstances the citizens, like independent members of the empire, stood valiantly together with their sister towns against encroaching princes, or joined the princes against the lawless freebooters of the nobility. As early as 1241 Lübeck, Hamburg, and Soest had combined to secure their common highways against robber knights. Solemn treaties to enforce the public peace were concluded in 1291 and 1338 with the dukes of Brunswick, Mecklenburg, and Pomerania, and the counts of Holstein. From Lübeck families, the descendants of Low German immigrants with a certain admixture of patrician and even junker blood, arose a number of wise councillors, keen diplomatists, and brave warriors to attend almost incessantly the many diets of the league, to decide squabbles, petty or grave, of its members, to interfere with shrewd consistency when the authorities in Flanders, or king and parliament in England, touched their ancient commercial privileges, to take the command of a fleet against the kings of Norway or Denmark. Though the great federal armament against Waldemar IV., the destroyer of Wisby, was decreed by the city representatives assembled at Cologne in 1367, Lübeck was the leading spirit in the war which ended with the surrender of Copenhagen and the glorious peace concluded at Stralsund on 24th May 1370. Her burgomaster, Brun Warendorp, who commanded in person the combined naval and land forces, died bravely in harness. In 1368 the seal of the city, a double-headed imperial eagle (which in the 14th century took the place of the more ancient ship), was expressly adopted as the common seal of the confederated towns (*civitates maritimæ*), some seventy of which had united to bear the brunt of the strife. By and by, however, towards the end of the 15th century, the power of the Hanseatic League began slowly to decline, owing to the rise of Burgundy in the west, of Poland and Russia in the east, and the emancipation of the Scandinavian kingdom from the fetters of the union of Calmar. Still Lübeck, even when nearly isolated, strove manfully to preserve its predominance in a war with Denmark (1501–12), supporting Gustavus Vasa in Sweden, lording it over the north of Europe during the years 1534 and 1535 in the person of Jürgen Wullenwever, the democratic burgomaster, who professed the most advanced principles of the Reformation, and engaging with Sweden in a severe naval war (1563–70). Before the end of the century the old privileges of the London Steelyard were definitely suppressed by Elizabeth. As early as 1425 the regular shoals of herring, a constant source of early wealth, began to forsake the Baltic waters. Later on, by the discovery of a new continent, general commerce was diverted into new directions. Finally, with the Thirty Years' War, misfortunes and ruin came thick. The last Hanseatic diet met at Lübeck in 1630, shortly after Wallenstein's unsuccessful attack on Stralsund; and from that time merciless sovereign powers stopped free intercourse on all sides. Danes and Swedes battled for the possession of the Sound and its heavy dues. The often changing masters of Holstein and Lauenburg abstracted much of the valuable landed property of the city and of the chapter of Lübeck. Still, towards the end of the 18th century, there were signs of improvement. Though the Danes temporarily occupied the town in 1801, it preserved its freedom and gained some of the chapter lands when the imperial constitution of Germany was broken up by the Act of February 25, 1803. Trade and commerce prospered marvellously for a few years. But in November 1806, when General Blücher, retiring from the catastrophe of Jena, had to capitulate in the vicinity of Lübeck, the town was taken and sacked by the enemy. Napoleon annexed it to the empire in December 1810. But it rose against the French, March 19, 1813, was reoccupied by them till the 5th December, and was ultimately declared a free and Hanse town of the German Confederation by the Act of Vienna, June 9, 1815. The Hanseatic League, however, having never been officially dissolved, Lübeck still enjoyed its traditional connexion with Bremen and Hamburg. In 1853 they sold their common property, the London Steelyard. Till 1866 they enlisted by special contract their military contingents for the German Confederation. Down to the year 1879 they had their own court of appeal at Lübeck. The town, however, joined the Prussian Customs Union as well as the North German Union in 1866, profiting by the final retirement from Holstein and Lauenburg of the Danes, whose interference had prevented as long as possible a direct railroad between Lübeck and Hamburg.

Lübeck through many changes in the course of eight centuries has preserved its republican government. At the first rise of the town, justice was administered to the inhabitants by the *vogt* (reeve) of the count. Simultaneously with the incorporation by Henry the Lion, who presented the citizens with the privileges of mint, toll, and market of their own, there appears a magistracy of six persons, elected probably by the reeve from the *schöffen* (*scabini*, *probi homines*). The members of the town council had to be freemen, born in lawful wedlock, in the enjoyment of free property, and of unstained repute. Vassals or servants of any lord and tradespeople were excluded. A third of the number had annually to retire for a year, so that two-thirds formed the sitting, the other third the reposing council. By the middle of the 13th century there were two burgomasters (*magistri burgensium*, *magistri civium*, *proconsules*). Meanwhile the number of magistrates (*consules*) had largely increased, but was indefinite, ranging from twenty to forty and upwards. The council appointed its own officers in the various branches of the administration,—chancellor, chaplain, surgeon, *stadesscrivere* (recorders), notaries, secretaries, marshal, constable, keeper of the ordnance, messengers, watchmen. In the face of so much self-government the *vogt* by and by vanished completely. He is by no means to be confounded with the *rector*, a neighbouring prince, whom the Lübeckers occasionally adopted as their honorary guardian. There were three classes of inhabitants—full freemen, half freemen, guests or foreigners. People of Slav origin being considered unfree, all intermarriage with them tainted the blood. Hence nearly all surnames point to Saxon, especially Westphalian, and even Flemish descent.

Since the end of the 13th century the city has been entered by the same gates and traversed by the same streets as at the present day. Stately churches of the Gothic order in glazed brick rose slowly,—last not least St Mary's or *Die Rathskirche* close to the *Rathhaus* (town-hall) and the spacious market-place with its long rows of booths and the pillory. Within its precincts is the *Dom* (cathedral) dedicated to St Nicholas, the patron saint of navigators; in Protestant times down to 1803 the secularized chapter was generally presided over by a prince of the ducal house of Gottorp. There were magnificent convents of the Dominicans, the Franciscans, and the nuns of St Clara. The population, when the city and the Hansa were in full power about 1400, can scarcely have been under 80,000. But such prosperity was not obtained by foreign commerce alone, though this was the principal occupation of the upper classes:—the *Junker* or *Zirkel* company, a sort of patriciate (since 1379); the merchant company, also patricians, but mostly "rentiers"; the "nations" of the *Bergenfahrer*, *Schonenfahrer*, *Novgorodfahrer*, *Rigafahrer*, *Stockholmfahrer*. From the very beginning various tradespeople and handicraftsmen had settled in the town, all of them freemen, of German parentage, and with property and houses of their own. Though not eligible for the council, they shared to a certain extent in the self-government through the aldermen of each corporation (*amt*, officium, guild), of which some appear as early as the statutes of 1240, and many more arise and disappear in course of time under authority of the council and the guidance of certain police magistrates (*wetteherren*). A number still exist, and own their old picturesque gable houses. The rolls of nearly all have been kept most carefully. Naturally there arose much jealousy between the guilds and the aristocratic companies, which exclusively ruled the republic. After an attempt to upset the merchants had been suppressed in 1384, the guilds succeeded under more favourable circumstances in 1408. The old patrician council left the city to appeal to the Hansa and to the imperial authorities, while a new council, elected chiefly from the guilds, with democratic tendencies, took their place. In 1416, however, there was a complete restoration, owing to the interference of the confederated cities and of two kings of the Romans, Rupert and Sigismund. The aristocratic government was expelled a second time when democracy and religious sectarianism got the upper hand under the dictatorship of Wullenwever, till the old order of things was once more re-established in 1535. Nevertheless the mediæval church had been finally supplanted by the Lutheran Reformation, and the tendency to increase the political privileges of the commonalty appeared again and again. In the constitution of 1669, under the pressure of a great public debt, the seven upper companies yielded to (8) the *Gewandschneider* (merchant tailors), (9) the grocers, (10) the brewers, (11) the mariners, and (12) the combined four great guilds, viz., the smiths, bakers, tailors, and shoemakers, a specified share in the financial administration. Nevertheless they continued to choose the magistrates by co-optation among themselves. Three of the four burgomasters and two of the senators, however, henceforth had to be graduates in law. Their constitution, set aside only during the French ascendency, has subsequently been slowly reformed. From 1813 senatorial and civic deputies joined in the administration of an annual budget of income, expenditure, and public debt. But the reform committee of 1814, of which the object was to substitute for the rule of the old companies a wider participation of the citizens in their common affairs (most of the learned professions, many proprietors, and the suburban population being without any representation), had made very little progress, when under the pressure of the events of the year 1848 a representative assembly of one hundred and twenty members, elected by universal suffrage, obtained a place beside the senatorial government. By the constitution of the 29th December 1851 the senate, for which all citizens above thirty years of age are eligible, has at present fourteen members. Eight must be taken from the learned professions, of whom six have to be lawyers, while of the rest five ought to be merchants. Every second year the offices and departments are redistributed, to be in most cases administered conjointly with deputies of the assembly. The president of the senate, chosen for two years, retains the old title of burgomaster. The members of the assembly, which participates in all public affairs, are elected for six years, and must be summoned at least six times a year, while a committee of thirty members meets every fortnight simultaneously with the periodical sessions of the senate. These truly democratic institutions have been scarcely at all modified by the resuscitation of the German empire under the king of Prussia. But evidently the ancient republic has lost some important attributes of a sovereign state by giving up its own military contingent, its right of levying customs, its coinage, its postal dues, its judicature, to the new national empire. On the other hand, it has preserved its municipal self-government and its own territory, the inhabitants of which now enjoy equal political privileges with the citizens. The territory, of about 5½ German square miles (116 Eng. sq. m.), partly extends towards the mouth of the river Trave, where the borough of Travemünde has been the property of Lübeck since 1329, and partly consists of numerous villages, manors, farms, and corn, pasture, and forest lands scattered over the adjoining portions of the duchies of Holstein and Lauenburg. The manor and borough of Bergedorf on the Elbe, 1½ German square miles, long held by Lübeck in common with Hamburg, was ceded to the latter by treaty of 1st July 1867. The lands which remain to Lübeck are thinly peopled, for, according to the census of 1875, of the total of 56,912 inhabitants 44,799 lived in Lübeck itself. The vast majority, 55,693, are Lutheran Protestants, whose service continues in the magnificent city churches, the cathedral, two parishes at Travemünde, and the four country parishes. A celebrated high school (gymnasium) is situated in the spacious buildings of St Catharine, formerly the house of the Franciscans. The charitable institutions enjoy a large, well-administered property, chiefly the lands of the monastery of St John and the hospital of the Holy Ghost. Since 1789 there has existed a "Gesellschaft zur Beförderung Gemeinnütziger Thätigkeit," with a branch union for the history and the antiquities of Lübeck, which has collected a valuable museum and promotes important historical publications, the materials of which are kept in the most unique municipal archives in existence. The income and expenditure of the Lübeck budget of 1881 balance with 2,739,382 marks; the public debt amounts to 23,804,913 marks.

The manufactures of the town are numerous, but not large or important (woollen, linen, cotton, and silk goods, leather wares, hardware, tobacco, and preserves). The commerce, on the other hand, is considerable, the chief exports being corn, cattle, wool, timber, and iron; while wines, silks, cottons, hardware, colonial products, and dye-stuffs are imported. There is regular steamship communication with Copenhagen and the Baltic ports, and four lines of railway converge in Lübeck. Since the deepening of the Trave (1850-54) sea-going ships can come up to Lübeck itself; formerly they required to unload at Travemünde. In 1878 the local shipping of Lübeck amounted to 46 vessels of 10,223 aggregate tonnage (27 steamers, 1504 horse-power, 6463 tons). In 1877 2302 vessels (981 steamers) with a tonnage of 301,910 entered, and 2332 vessels (979 steamers) with a tonnage of 307,567 cleared the port.

LUBLIN, a town of Russian Poland, capital of the province of same name, 60 miles south-east of Warsaw, on the Bistrzyca, a tributary of the Wieprz. It is the most important town of Poland after Warsaw and Lodz. It has an old citadel, many churches, and several educational and charitable institutions, and it is the see of a bishop. Lublin is one of the chief centres of the manufacture of thread-yarn and of linen and hemp goods (to the value of more than £250,000), as well as of woollen stuffs; there is also an active trade in corn and cattle. The three annual fairs have a certain importance for the neighbouring district. The population in 1873 was 28,900, and is rapidly increasing.

The date of the foundation of Lublin is unknown, but it was in existence in the 10th century, and has a church which is said to have been built in 986. During the time of the Jagellons it was the most important city between the Vistula and the Dnieper, having 40,000 inhabitants (70,000 according to other authorities), and keeping in its hands all the trade with Podolia, Volhynia, and Red Russia. Indeed, the present town is surrounded with heaps of ruins, which prove that it formerly covered a much larger area. But it was frequently destroyed by the inroads of Tartars and Cossacks. In 1568 and 1569 it was the seat of the stormy convention at which the union between Poland and Lithuania was decided. In 1702 another convention was held in Lublin, in favour of Augustus II. and against Charles XII., who carried the town by assault, giving it over to his army to be plundered, and stayed for six weeks at Jacobowice, the estate of Prince Lubomirsky, in the immediate neighbourhood. In 1831 Lublin was taken by the Russians after a battle. The whole surrounding country is rich in historical reminiscences of the struggle of Poland for independence.

LUBRICANTS are fluids which are interposed between solid machine surfaces that are required to slide on each other. The object is to lessen the friction, which is injurious both in wearing away the surfaces, and thus destroying the fit between them, and in dissipating and rendering useless part of the energy transmitted through the machine. The difference between the wear on unlubricated and that on lubricated surfaces is so serious that a comparison between the cost of lubrication and the money saving in avoidance of repairs is superfluous. But the difference in wear when two different lubricants are used is not very great, and the proper choice between the two lubricants depends on a comparison of their cost with the amount of working power they save from dissipation. If the price of oil per gallon, inclusive of wages for its application to the journals, &c., be p; if, in order to lubricate as well as can be done with this oil any one working surface or set of such surfaces, it is necessary to use the fraction g of a gallon of oil per hour; if, with the use of this quantity of the oil, there is still wasted in friction at these surfaces H horse-power; and if the cost in fuel, water, wages, repairs, &c., of the working energy is P per hour per horse-power; then the money loss per hour caused by the friction is $pg + \text{PH}$. By comparing the values of this quantity for two oils, it can be determined which it is more advantageous to use. Of the commonly used oils, the higher priced are much more efficient as lubricants. If two oils of which the same amount requires to be used have the prices p_1 and p_2, and allow H_1 and H_2 horse-power to be wasted, then the money advantage to be gained per hour by using the first (the higher priced) rather than the second is $\text{P}(\text{H}_2 - \text{H}_1) - (p_1 - p_2)g$. This is positive if

$$\frac{\text{H}_2 - \text{H}_1}{g} > \frac{p_1 - p_2}{\text{P}}.$$

If this inequality is found *not* to be true in any special comparison, then the cheaper oil should be used. P varies from $\frac{3}{4}$d. to over $1\frac{1}{2}$d., according to the class of engine and boiler and to the good or bad management of the works, while $p_1 - p_2$, in comparing the extremes of cheap and expensive commercial lubricants, amounts to 2s. 6d. or more.

To compare the advantages of using a larger or smaller amount of the same oil, let g_1 and g_2 be the quantities used, and the resulting wastes of horse-power be H_1 and H_2. Then the use of the larger quantity g_1 will be economical if

$$\text{P}(\text{H}_2 - \text{H}_1) - p(g_1 - g_2) > 0\,; \quad \text{or} \quad \frac{\text{H}_2 - \text{H}_1}{g_1 - g_2} > \frac{p}{\text{P}}.$$

Considering the meaning of this inequality in the two cases of a high-priced and of a low-priced oil, in the former case $\frac{p}{\text{P}}$ has a larger value, while $\frac{\text{H}_2 - \text{H}_1}{g_1 - g_2}$ has also a larger value than in the latter case. In both cases this latter fraction decreases with increase of g_1; but it decreases more rapidly in the case of a high-priced than in that of a low-priced oil, because the former is a better lubricator. Thus with the dearer oil the limit beyond which it is uneconomical to increase the consumption of oil is reached sooner than with the cheaper, and it follows that of the cheaper oils it is best to use a large quantity, while of the dearer a smaller amount is what is most usefully employed. If the law according to which H varies with g be found for any oil, by experiment or otherwise, then the exact most economical quantity can be found by differentiating $pg + \text{PH}$ with respect to g, and equating the differential coefficient to zero; thus

$$\frac{d\text{H}}{dg} = -\frac{p}{\text{P}},$$

when $\frac{d\text{H}}{dg}$ is expressed in terms of g, gives this most economical value of g. An example of the actual values of the quantities involved in these formulas is given by an experiment by Van Cleve on a journal 6 inches in diameter by 7 inches long, in which the coefficient of friction was found to be about ·077, and there was wasted 3·4 horse-power when ·023 of a gallon was used per hour.

Of the animal oils and fats suitable for lubrication those commonly used are sperm, lard, neats-foot, tallow, and common whale oil. Of vegetable oils olive, cotton-seed, and rape-seed are extensively employed, the first mostly in those countries where the olive is grown, and generally in the pure condition, while the last two are more used for mixing with higher class and more expensive oils. Various fish oils are also much used, and mineral oils now form a large proportion of the many lubricating compositions that are in use. For machinery where considerable pressure is exerted between the bearing surfaces the mineral oils are too thin, or, as it is termed, are too wanting in "body" to be quite suitable without being mixed with an animal or vegetable oil. Unless a lubricant has considerable "body" it is quickly pressed out of the bearing, and an unnecessarily rapid supply has to be provided. The same oil may be used several times over, and several ingenious designs of bearings for rotating shafts, such as Player Brothers' or Taylor & Challen's, whereby the shaft itself as it runs round continually pumps up again to the top of the bearing the oil that has once been used, have been very successful in practice. If an automatic arrangement of this sort is not employed, the oil dripping from the bearing should be collected in a pan and used again to fill the oil-cups. The oil gets gradually worn out as a lubricant by becoming filled with dirt, partly the dust of the atmosphere and partly the minute iron and brass dust that is continually rubbed off the bearing surfaces. Oils that have been used two or three times can be to a certain extent repurified by washing in a solution of carbonate of soda or potash and chloride of calcium in boiling water. But it must not be supposed that with repurification an oil may be used an indefinite time as a lubricant. A large portion of it is actually evaporated by the heat caused by the friction at the journal, and the unevaporated portion seems to undergo some chemical change injurious to its lubricating properties. Vegetable oils are peculiarly rich in volatile constituents, and it is this fact probably, even more than the greater cheapness of mineral oils, that has led to the largely increased use of the latter in the lubrication of machinery.

The quality of an oil may be tested by chemical analysis; by measurement of density and viscosity; by observation of the temperature necessary for ignition in the atmosphere, or, as it is called, the "flashing" temperature; by observation of the succession of figured patterns produced when a single drop of the oil is let fall upon the surface of pure water in a clean dish; by the measurement of the temperatures to which a journal rises when running at different speeds and under different pressures, and when supplied with a given amount of the lubricant per minute; and by the measurement of the coefficient of friction at the same journal with varying speeds of rotation and pressures. The last two methods of test are the most interesting and directly useful from a mechanical point of view, *i.e.*, considering the oil as a lubricant simply.

The machine designed and used by Professor Thurston of the Stevens Institute of technology is the best that has yet been constructed to carry out these tests. In it a spindle is revolved in horizontal bearings by a belt from the main shaft of the workshop of the Institute. On the overhanging end of this spindle is formed a journal from which is hung a heavily-weighted rod. The bearings in this rod by which it hangs on the journal are of brass, and the two halves are pressed down upon the journal with any desired pressure by means of a spiral spring placed in the centre of the rod. The weight of this pendulum prevents it revolving along with the spindle, but the friction at the journal deflects the pendulum from the vertical through an angle whose sine is a measure of the frictional effort. There is also inserted in the bearings a thermometer by which the effect of the friction in increasing the temperature is observed. With this machine Professor Thurston has obtained extremely interesting results regarding the variation of the coefficient of friction with temperature, pressure, and velocity of rubbing. These are summarized as follows. With great intensity of pressure and low velocity, the friction increases as the temperature is raised; but for each low velocity the rate of increase of friction with temperature becomes slower as the pressure diminishes, and becomes zero at a certain limit of pressure which is higher the higher the velocity is. With high velocities the variation of friction with temperature is in the opposite direction within the limits of pressure commonly used. Again at a given temperature and a given pressure the friction first decreases very rapidly with increase of velocity, and then above a certain limit of velocity increases again slowly with further increase of velocity. The limit of velocity at which the direction of variation changes from negative to positive does not appear to depend on the intensity of pressure, but the change occurs at much lower velocity-limits with low than with high temperatures. Thirdly, with a given temperature and a given velocity the coefficient of friction, *i.e.*, the ratio of friction to normal pressure, at first decreases rapidly with increase of pressure at low pressures, and then at higher pressures increases again with the pressure. This law seems to hold for all temperatures and all velocities; but how the limit of pressure at which the variation changes in direction is altered by alteration of temperature and velocity is not as yet certainly determined.

It is thus seen that the variation of friction at lubricated journals is extremely complicated, and has no resemblance to the simple law of constant proportionality between the friction and the normal pressure which until lately was commonly believed to hold good for unlubricated flat surfaces. This simple law is really true for many unlubricated surfaces and through a tolerably wide range of conditions, but is not true for all such surfaces, or under all, and especially extreme, conditions of pressure, velocity, and temperature.

Professor Thurston has endeavoured to represent these results in algebraic formulæ, but the number of his experiments seems hardly sufficient to establish any general mathematical law which will be true under all circumstances, and the particular formulæ which he has adopted give values differing very considerably from those given by some of his experiments.

The friction at a lubricated journal depends really much more on the viscosity of the lubricant than on the frictional properties of either of the solids, which never come in contact when the lubrication is carefully attended to. The layer of oil immediately in contact with either solid probably does not move at all relatively to the solid. The rubbing, therefore, in all probability takes place between two surfaces, or rather between an indefinitely large number of pairs of surfaces, of oil. The viscosity of the oil, which hinders this relative motion, is, however, very likely affected by the adhesive force between the solid and liquid surfaces, because, especially if the intensity of bearing pressure be great and the film of lubricant consequently very thin, some at least of the liquid motion will take place within the sphere of action of the cohesive forces.

It is of the greatest importance in order to secure economy in the use of lubricants to maintain the supply to each journal at a constant uniform rate. To effect this, numberless "automatic lubricators" have been invented. The common syphon oil-cup is very efficient so long as the rate of working is steady; but the supply does not automatically vary with the requirements. The "needle" lubricator allows the oil to flow down to the journal through a small straight tube in which is placed a wire which nearly blocks up the tube. When the wire is motionless the dimensions of the space between the wire and the tube are capillary, and no oil flows. When the shaft runs, however, its surface scraping on the end of the wire throws it into continual vibration, and this allows a slow stream of oil to pass downwards which is automatically regulated in accordance with the speed of revolution. The necessity of very perfect lubrication of the cylinders of gas engines, which run at a high speed and at a high temperature, has led to the adoption by Messrs Crossley Brothers of an extremely neat and perfect arrangement. A small crank on the end of a spindle, driven at a rate proportional to that of the engine, has suspended from the crank pin a short wire pendulum. At the lower part of the revolution this pendulum dips into a basin of oil and lifts a drop from it. In the upper half of the circular motion, the wire is dragged over a little scraper extending over the open mouth of a pipe. This scrapes the drop off the pendulum, and the drop falls from the scraper into the tube, along which it flows to the surface to be lubricated. The number of drops is thus accurately proportioned to the speed of the engine, and the size of drop can be varied by using smaller or larger wire for the pendulum.

Table of Coefficients of Friction on Cast-Iron Journals at Temperature 70° F. and Velocity 750 Feet per Minute (from Thurston).

Name of Oil.	Pressure in lb per sq. in.			
	8.	16.	32.	48.
Natural Summer Sperm	·17	·16	·10	·12
" Winter "	·25	·14	·09	·08
Bleached " "	·19	·16	·12	·10
Natural Summer Whale	·20	·14	·11	·09
Winter Lard	·24	·16	·14	·10
Extra Neatsfoot	·22	·16	·12	·11
Tallow	·18	·15	·09	·12
Olive	·17	·16	·17	·09
Refined Cotton Seed	·21	·14	·12	·11
Rape Seed	·18	·16	·12	·11
Menhaden	·25	·12	·10	·12
Kerosine	·23	·17	·13	·17
Paraffin	·26	·18	·13	·22

Other mineral oils than the kerosine and paraffin give a smaller coefficient. For mineral oils generally the lowest coefficient appears to occur at from 30 to 40 lb pressure per square inch. The supply of oil in the experiments was intermittent, and must have been insufficient for the best lubrication.

Table of Coefficients of Friction between Steel Journals and Bronze Bearings lubricated with Sperm Oil, and run at different Pressures, Velocities, and Temperatures (from Thurston).

Temperature, Degrees Fahr.	Velocity in feet per minute.													
	30.				100.				250.		500.		1200.

110	·010	·004	·006	·094	·004	·002	·003	·063	·005	004	·006	·005	·007	·009
90	005	·003	·004	·094	·004	·002	·003	·063	·007	·005	·007	·006	010	·015

The journal upon which the above results were obtained was $1\frac{1}{4}$ inches in diameter and $1\frac{1}{2}$ inches long. With a larger journal the results would probably not be exactly the same. (R. H. S.*)

LUCAN. Marcus Annæus Lucanus, the most eminent Roman poet of the silver age, grandson of the rhetorician Seneca and nephew of the philosopher, was born at Corduba, November 3, 39 A.D. His father, Lucius Annæus Mela, had amassed great wealth as imperial procurator for the province. In a memoir by an anonymous grammarian, who may have abridged Suetonius, Lucan is said to have been taken to Rome at the age of eight months, to have displayed remarkable precocity, and to have incurred the displeasure of Nero by overcoming him in a poetical contest. The latter statement seems to be founded upon a misapprehension of a passage in Statius's *Genethliacon Lucani*; but it is certain that Nero, whether from jealousy, as Tacitus affirms, or on account of the republican spirit of Lucan's poetry, forbade him to recite in public, and that his indignation made him an accomplice in the conspiracy of Piso, 65 A.D. Upon the discovery of the plot he is alleged to have endeavoured to purchase safety by impeaching his own mother ("hoping," says his translator Gorges quaintly, "that this impiety might be a means to procure pardon at the hands of an impious prince"). The statement, however, of Tacitus, that letters were forged in his name to implicate his father, warrants the suspicion that the evidence against his mother may also have been fabricated. Failing to obtain a reprieve, he caused his veins to be opened, and expired with great courage, repeating a passage from his *Pharsalia* descriptive of the death of a wounded soldier ("Lucan by his death approved," Shelley's *Adonais*). His father was involved in the proscription, his mother escaped, and his widow Polla Argentaria survived to receive the homage of Statius under Domitian.

Besides his principal performance, Lucan's works included juvenile poems on the descent of Orpheus and the ransom of Hector, an unfinished tragedy on the subject of Medea, and numerous miscellaneous pieces. The *Carmen ad Pisonem* sometimes attributed to him is now more commonly ascribed to Saleius Bassus. His minor works have perished, but all that the author wrote of the *Pharsalia* has come down to us. It would probably have concluded with the battle of Philippi, but breaks off abruptly as Cæsar, beset by foes, is about to plunge into the harbour of Alexandria. This incompleteness should not be left out of account in the estimate of its merits, for, with two capital exceptions, the faults of the *Pharsalia* are such as revision might have mitigated or removed. No such pains, certainly, could have amended the deficiency of unity of action, or supplied the want of a legitimate protagonist. The *Pharsalia* follows history with inevitable servility, and is rather a metrical chronicle than a true epic. If it had been completed according to the author's design, Pompey, Cato, and Brutus must have successively enacted the part of nominal hero, while the real hero is the arch enemy of liberty and Lucan, Cæsar. Yet these defects, though glaring, are not fatal or peculiar to Lucan. The real hero of *Paradise Lost*, it has been repeatedly observed, is no other than Satan; and Shakespeare himself succeeded no better than Lucan in preserving unity of action when he wrote his *Julius Cæsar*. The false taste, the strained rhetoric, the ostentatious erudition, the tedious harangues and far-fetched or commonplace reflexions so frequent in this singularly unequal poem, are faults much more irritating, but they are also faults capable of amendment, and which the writer might not improbably have removed. As pointed out by Dean Merivale, the bombastic style of composition which prevailed under Nero yielded to a more sober taste under the Flavian dynasty; and the lapse of time would have contributed to mellow the poet's immaturity and chasten the ardour of temperament which made him essay great themes "ante annos Culicis Maroniani." Great allowance should also be made for the difficulties the highest genius must encounter when emulating predecessors who have already carried art to its last perfection, and thus necessitated to choose between mere imitation and a conscious effort after originality. Lucan's temper could never have brooked the former course; his versification, no less than his subject, is entirely his own; he avoids all resemblance to his great predecessor with a persistency which can only have resulted from deliberate purpose, while largely influenced by the declamatory school of his grandfather and uncle. Hence his partiality for finished antithesis, contrasting strongly with his generally breathless style and turbid diction. Quintilian sums up both aspects of his genius with pregnant brevity, "Ardens et concitatus et sententiis clarissimus," adding with equal justice, "Magis oratoribus quam poetis annumerandus." Lucan's oratory, however, frequently rises into the region of poetry, especially where it sets forth ideas essentially sublime, and impressive in the mere statement. Such are the apotheosis of Pompey at the beginning of the ninth book, and the passage in the same book where Cato, in the truest spirit of the Stoic philosophy, refuses to consult the oracle of Jupiter Ammon. The exordium of the poem, and the portraits of Cæsar and Pompey, are examples of oratory blazing up into poetry, as a wheel takes fire by friction. In some cases Lucan's rhetoric is frigid, hyperbolical, and out of keeping with the character of the speaker, as in Cæsar's address to his legions before Pharsalia; in general, however, it may be said that the more he is of an orator or a moralist the more he is of a poet. If this denotes that his genius was not essentially and in the truest sense poetical, the same may be said of Dryden and Pope; and it at least proves him to have been in harmony with the living forces of his age, in which rhetoric was a note of culture and philosophical humanitarianism a growing idea, while poetry, though widely cultivated, was becoming more and more a mere ornamental accomplishment. This is not the case with Lucan; his theme has a genuine hold upon him; in the age of Nero he celebrates the republic as a poet with the same energy with which in the age of Cicero he might have defended it as an orator. But for him it might almost have been said that the Roman republic never inspired a Roman poet.

Lucan never speaks of himself, but his epic speaks for him. The author of the *Pharsalia* must have been endowed with no common ambition, industry, and self-reliance, an enthusiastic though narrow and aristocratic patriotism, and a faculty for appreciating magnanimity in others which is at least some presumption that he possessed it himself. He probably bore a strong family resemblance to his uncle Seneca; but the only personal trait positively known to us is his conjugal affection, a characteristic of Seneca also.

Lucan, together with Statius, was preferred even to Virgil in the Middle Ages. So late as 1493 his commentator Sulpitius writes:—"Magnus profecto est Maro, magnus Lucanus; adeoque prope par, ut quis sit major possis ambigere." Shelley and Southey, in the first transport of admiration, thought Lucan superior to Virgil; Pope, with more judgment, says that the fire which burns in Virgil with an equable glow breaks forth in Lucan with sudden, brief, and interrupted flashes. In general, notwithstanding the enthusiasm of isolated admirers, Lucan has been unduly neglected, but he has exercised an important influence upon one great department of modern literature by his effect upon Corneille, and through him upon the classical French drama.

The most celebrated editions of Lucan are those by Oudendorp (1728), Burmann (1740), and Weber (1829). Bentley's emendations are brilliant, but unsafe. The most elaborate criticism is that in Nisard's *Études sur les Poëtes Latins de la Décadence*, stern to the poet's defects and unkind to his deserts. Dean Merivale has some excellent observations in his *History of Imperial Rome*, chaps. liv. and lxiv. Brebeuf's French version is celebrated. Christopher Marlowe, a kindred spirit, translated the first book of the *Pharsalia* into English, and there are other old versions by Sir Ferdinand Gorges and Thomas May. The latter's supplement is one of the best examples of modern Latin versification. Gorges's translation is in octosyllabic verse, and very curious. The standard English version, by Rowe, is one of the most successful translations in our language. It is somewhat too diffuse, but as a whole reproduces the vehemence and animation of the original with a spirit that leaves little to be desired. (R. G.)

LUCANIA, in ancient geography, was the name given to a province of Southern Italy, extending from the Tyrrhenian Sea on the west to the Gulf of Tarentum on the east, while to the north it adjoined Campania, Samnium, and Apulia, and to the south was separated by a comparatively narrow isthmus from the province of Bruttium, which forms the southern extremity of Italy. It thus comprised the modern province of the Basilicata, together with the greater part of the Principato Citeriore and a small portion of Calabria. The precise limits were the river Silarus on the north-west, which separated it from Campania, and the Bradanus, which flows into the Gulf of Tarentum, on the north-east; while the two little rivers Laus and Crathis, flowing from the ridge of the Apennines to the sea on the west and east, marked the limits of the province on the side of Bruttium.

Almost the whole of the province thus limited is occupied by the rugged masses of the Apennines, which in this part of Italy can hardly be said to constitute a range of mountains so much as a group of lofty masses, huddled together in a very irregular manner. The main ridge, however (if it be taken as determined by the watershed), approaches much more nearly to the western sea than to the Gulf of Tarentum, and is continued from the lofty knot of mountains immediately on the frontiers of Samnium, nearly due south, till it approaches within a few miles of the Gulf of Policastro, and thenceforward is separated from the sea by only a narrow interval till it enters the province of Bruttium. Just within the frontier of Lucania rises the very lofty group of Monte Pollino, the highest summit of which attains to an elevation of above 7000 feet, the greatest that is found in the southern Apennines. Towards the east the mountains descend by a much more gradual slope to the Gulf of Tarentum, constituting long ridges of hills which subside by degrees to the strip of plain that immediately adjoins the shores of the gulf. This narrow strip is somewhat wider from the mouth of the Bradanus to that of the Siris, and again expands to a considerable extent at the mouth of the Crathis, but between the two a group of rugged hills descends quite to the sea, and forms the headland of Roseto. The consequence of this constitution is that while the rivers which flow to the Tyrrhenian Sea are of comparatively little importance, those that descend towards the Gulf of Tarentum have much longer courses, and attain to a considerable magnitude. Of these the most important are—the Bradanus (still called Bradano), which rises near Potentia, and enters the gulf just to the north of the ruins of Metapontum; the Casuentus (Basiento), which has a course almost exactly parallel with the preceding; the Aciris or Agri; and the Siris or Sinno. The Crathis, which forms at its mouth the southern limit of the province, belongs almost wholly to Bruttium, but it receives a tributary, the Sybaris (Coscile), which flows from the mountains of Lucania. The only considerable stream on the western side of Lucania is the Silarus or Sele, which constitutes its northern boundary, and has two important tributaries in the Calor or Calore, and the Tanagrus, which joins it from the south, after flowing through one of those trough-like upland valleys so characteristic of the Apennines.

The province of Lucania was so called from the people of that name, by whom it was conquered about the middle of the 5th century B.C. Previous to that period it was included under the general name of Œnotria, which was applied by the Greeks to the whole of the southernmost portion of Italy. The mountainous regions of the interior were occupied by the tribes known as Œnotrians and Chones, while the coasts on both sides were occupied by Greek colonies, which attained to great power and prosperity, and doubtless exercised a kind of protectorate over the interior also. (See GRÆCIA MAGNA.) The Lucanians were a Sabellian race, an offshoot of the Samnites of Central Italy, who pressed downwards towards the south until they gradually conquered the whole country (with the exception of the Greek towns on the coast) from the borders of Samnium and Campania to the southern extremity of Italy. Subsequently, however, the inhabitants of the peninsula which forms the extreme south (now known as Calabria) broke out into insurrection, and under the name of Bruttians succeeded in establishing their independence, after which the Lucanians became confined within the limits already described. After this time we find them engaged in hostilities with the Tarentines, and with Alexander, king of Epirus, who was called in by that people to their assistance, 326 B.C. It was immediately after this that they first entered into relations with Rome, with which they were sometimes in alliance, but more frequently engaged in hostilities, during the long-continued wars of the Romans with the Samnites. On the landing of Pyrrhus in Italy (281 B.C.) they were among the first to declare in his favour, and in consequence found themselves exposed to the full brunt of the resentment of Rome when the departure of Pyrrhus left his allies at the mercy of the victorious Romans. It was not, however, till after several campaigns that they were reduced to complete subjection (272 B.C.). Notwithstanding this lesson, the Lucanians again espoused the cause of Hannibal during the Second Punic War (216 B.C.), and their territory became the theatre of war during several successive campaigns, and was ravaged in turn by both contending armies. It is clear that the country never recovered the effects of these disasters, and under the Roman government Lucania fell into a state of complete decay, to which the Social War (90–88 B.C.) appears to have given the finishing stroke. In the time of Strabo the Greek cities on the coast, once so rich and flourishing, had fallen into utter insignificance, and the few towns of the interior were poor places of no importance. A large part of the province was given up to pasture, and the mountains of the interior were covered with vast forests, which abounded in wild boars, bears, and wolves.

The towns on the east coast, adjoining the Gulf of Tarentum, were—Metapontum, a few miles south of the Bradanus; Heraclea, at the mouth of the Aciris; and Siris, on the river of the same name. Close to its southern frontier stood Sybaris, which was destroyed in 510 B.C., but subsequently replaced by Thurii, founded within a few miles of the same site. On the west coast stood Posidonia, known under the Roman government as Pæstum, immediately south of the Silarus; below that came Elea or Velia, Pyxus, called by the Romans Buxentum, and Laus, near the frontier of the province towards Bruttium. Of the towns of the interior, none of which ever attained to any importance, the most considerable was Potentia, still called Potenza, and now the capital of the Basilicata. To the north, near the frontier of Apulia, were Acheruntia and Bantia; while due south from Potentia was Grumentum, and still farther in that direction were Nerulum and Muranum. In the upland valley of the Tanagrus were Atina, Forum Popilii, and Consilinum; Eburi (Eboli) and Volceii (Buccino), though to the north of the Silarus, were also included in Lucania.

For administrative purposes under the Roman empire, Lucania was always united with Bruttium. The two together constituted the third region of Augustus. (E. H. B.)

LUCARIS, CYRILLUS (*c.* 1572-1638). See GREEK CHURCH, vol. xi. p. 158.

LUCAS OF LEYDEN (*c.* 1494–1533) was born at Leyden, where his father Hugh Jacobsz gave him the first lessons in art. He then entered the painting-room of Cornelis Engelbrechtszen of Leyden, and soon became known for his capacity in making designs for glass, engraving copper-plates, painting pictures, portraits, and landscapes in oil and distemper. According to Van Mander he was born in 1494, and painted at the age of twelve a Legend of St Hubert, for which as many florins were paid to him as he numbered years. He was only fourteen when he finished a plate representing Mohammed taking the life of a friar, and at fifteen he produced a series of nine plates for a Passion, a Temptation of St Anthony, and a Conversion of St Paul. The list of his engravings in 1510, when, according to Van Mander, he was only sixteen, includes a celebrated Ecce Homo, Adam and Eve expelled from Paradise, a herdsman and a milkmaid with three cows, and a little naked girl running away from a barking dog. It will be seen to what a variety of tastes the youthful artist was asked to cater. Whatever may be thought of the tradition embodied in Van Mander's pages as to the true age of Lucas of Leyden, there is no doubt that, as early as 1508, he was a master of name as a copper-plate engraver, and had launched his boat in the current which in those days led to wealth and to fame. The period of the great masters of etching, which had not yet come for Holland, was being preceded by the period of the great masters in the use of the graver. It was the time when art readily found its patrons amongst the large public that could ill afford to buy pictures, yet had enough interest in culture to wish to educate itself by means of prints. Lucas of Leyden became the representative man for the great public of Holland as Dürer became the representative man for the great public of Germany; and a rivalry grew up between the two engravers, which came to be so close that on the neutral market of Italy the products of each were all but evenly quoted. Vasari devoted almost equal attention to both, affirming indeed that Dürer surpassed Lucas as a designer, but that in the use of the graver they were both unsurpassed, a sentence which has not been reversed by the criticism of our day. But the rivalry of the two artists was friendly. About the time when Dürer visited the Netherlands Lucas came to Antwerp, which then flourished greatly as an international mart for productions of the pencil and the graver, and it is thought, not without reason, that he was the master who took the freedom of the Antwerp guild in 1521 under the name of Lucas the Hollander. In the diary which Dürer faithfully kept during his travels in the Low Countries, we find that at Antwerp he met Lucas, who asked him to dinner, and that Dürer accepted the invitation, and was much surprised at the smallness of the Dutchman's stature. But he valued the art of Lucas at its true figure, and exchanged the Dutchman's prints for eight florins' worth of his own. In course of time Lucas rose to more than a competence. In 1527 he made a tour of the Netherlands, giving dinners to the painters of the guilds of Middleburg, Ghent, Malines, and Antwerp. He was accompanied during the trip by Mabuse, whom he imitated in his style as well as in his love of rich costume. But festive cheer and banquets disagreed with Lucas. On his return home he fell sick and remained ailing till his death in 1533, and when he died he did so with the firm belief that poison had been administered to him by some envious comrade.

As an engraver Lucas of Leyden deserves his reputation. He has not the genius, nor had he the tact, of Dürer; and he displays more cleverness of expression than skill in distribution or refinement in details. But his power in handling the graver is very great, and some of his portraits, especially his own, are equal to anything that was done by the master of Nuremberg. Much that he accomplished as a painter has been lost, because he worked a good deal upon cloth in distemper. But some pictures have been preserved which fairly manifest the influences under which he became productive. In 1522 he painted the Virgin and Child with the Magdalen and a kneeling donor, now preserved in the gallery of Munich. His manner was then very much akin to that of Mabuse. The Last Judgment in the town-hall, now the town-gallery of Leyden, is composed on the traditional lines of Cristus and Memling, furnished with monsters in the style of Jerome Bosch, and figures in the stilted attitudes of the South German school; the scale of colours in yellow, white, and grey is at once pale and gaudy; the quaintest contrasts are produced by the juxtaposition of alabaster flesh in females and bronzed skin in males, or black hair by the side of yellow, or rose-coloured drapery set sharply against apple-green or black, yet some of the heads are painted with great delicacy and modelled with exquisite feeling. Dr Waagen gave a most favourable opinion of a triptych now at the Hermitage at St Petersburg, executed, according to Van Mander, in 1531, representing the blind man of Jericho healed by Jesus Christ in the presence of the apostles. Here too the great German critic observed the union of faulty composition with great finish and warm flesh-tints with a gaudy scale of harmonies. The same defects and qualities will be found in such specimens of the master's art as are still preserved in public collections, amongst which may be mentioned the Card Party at Wilton House, the Penitent St Jerome in the gallery of Berlin, and the hermits Paul and Anthony in the Lichtenstein collection at Vienna.

A few days before his death Lucas van Leyden was informed of the birth of a grandson, firstborn of his only daughter Gretchen. Gretchen's fourth son Jean de Hoey followed the profession of his grandfather, and became well known at the Parisian court as painter and chamberlain to the king of France, Henry IV.

LUCCA, a city of Northern Italy, the chief town of a province, an archiepiscopal see, and the seat of a court of assize, lies 13 miles by rail north-east of Pisa, in 43° 50' N. lat. and 10° 28' E. long. Situated 50 feet above the level of the sea, in the valley of the Serchio, the city looks out for the most part on a horizon of hills and mountains. The fortifications—pierced by four gates—were commenced in 1504 and completed in 1645, and long ranked among the most remarkable in the peninsula. The city has a well-built and substantial appearance, its chief attraction lying in the numerous churches, which belong in the main to a well-marked basilican type, and present richly decorated exteriors, fine apsidal ends, and quadrangular campaniles. The cathedral or church of St Martin was begun in 1063 by Bishop Anselm; but the great apse with its tall columnar arcades is probably the only remnant of the early edifice. The west front, "built during the first forty years of the 13th century, consists of a vast portico of three magnificent arches, and above them three ranges of open galleries covered with all the devices of an exuberant fancy." The ground plan is a Latin cross, the nave being 273 feet in length and 84 feet in width, and the transepts 117 feet in length. In the nave is a little octagonal temple or chapel built (1484) by Matteo Civitali, which serves as a shrine for the most precious of the Lucchese relics, a cedar-wood crucifix, carved, according to the legend, by Nicodemus, and miraculously conveyed to Lucca in 782. The Sacred

Countenance (*Volto Santo*), as it is generally called, because the face of the Saviour is considered a true likeness, is only shown thrice a year. The beautiful tomb of Maria Guinigi is described by Ruskin, *Modern Painters*, ii. The church of Saint Michael, founded in the 8th century, and built of marble within and without, has a lofty and magnificent western façade (1188)—an architectural screen rising much above the roof of the church. St Frediano or Frigidian dates originally from the 7th century; the front (of the 13th century) occupies the site of the ancient apse; in one of its chapels is the tomb of Santa Zita, patroness of servants and of Lucca itself. San Giovanni (originally of the 12th century), San Romano (rebuilt in the 17th century, by Vincenzo Buonamici), and Santa Maria Forisportam (of the 13th century) also deserve to be mentioned. Among the secular buildings are the old ducal palace, begun in 1578 by Ammanati, and now the residence of the prefect and seat of the provincial officers and the public picture gallery; the Palazzo Pretorio, or former residence of the podestà, now the seat of the civil and correctional courts; the palace, erected in the 15th century by a member of the great Guinigi family, and now serving as a poor-house; and the 16th century palace of the Marquis Guidiccioni, now used as a depository for the archives. The principal market-place in the city (*Piazza del Mercato*) has taken possession of the arena of the ancient amphitheatre, the arches of which can still be seen in the surrounding buildings. Besides the academy of sciences just mentioned, which dates from 1584, there are several institutions of the same kind—a royal philomathic academy, a royal academy of arts, and a public library of 50,000 volumes. The silk manufacture, which was introduced at Lucca about the close of the 11th century, and in the early part of the 16th became for a time the means of subsistence for 30,000 of its inhabitants, now gives employment (in reeling and throwing) to only about 1500. The bulk of the population is engaged in agriculture. In 1871 the city had 21,286 inhabitants. The commune has increased from 61,175 in 1834 to 68,063 in 1881.

Lucca (Latin, *Luca*) is probably a place of Ligurian origin. First mentioned as the place to which Sempronius retired (218 B.C.) before the victorious Hannibal, it passes out of sight again till 177, when it became the seat of a Roman colony. In the time of Julius Cæsar it is frequently heard of as a town in his province of Cisalpine Gaul and Liguria, to which he repaired for consultation with his political associates. By Augustus it was transferred to Etruria. Though plundered and deprived of part of its territory by Odoacer, Lucca appears as an important city and fortress at the time of Narses, and under the Lombards it was the residence of a duke or marquis and had the privilege of a mint. The dukes gradually extended their power over all Tuscany, but after the death of the famous Matilda the city began to constitute itself an independent community, and in 1160 it obtained from Welf VI., duke of Bavaria and marquis of Tuscany, the lordship of all the country for 5 miles round. Internal discord afforded an opportunity to Uguccione della Faggiola to make himself master of Lucca in 1314; but the Lucchese expelled him two years afterwards, and handed over their city to Castruccio, under whose masterly tyranny it became "for a moment the leading state of Italy." Occupied by the troops of Louis of Bavaria, sold to a rich Genovese Gherardo Spinola, seized by John, king of Bohemia, pawned to the Rossi of Parma, sold to the Florentines, surrendered to the Pisans, nominally liberated by the emperor Charles IV., and governed by his vicar, Lucca was subjected to endless vicissitudes, but managed, at first as a democracy, and after 1628 as an oligarchy, to maintain "its independence alongside of Venice and Genoa, and painted the word Libertas on its banner till the French Revolution." In the beginning of the 16th century one of its leading citizens, Francesco Burlamacchi, made a noble attempt to give political cohesion to Italy, but perished on the scaffold (1548); his statue by Ulisse Cambi was erected on the Piazza San Michele in 1863. As a principality formed in 1805 by Napoleon in favour of his sister Elisa and her husband Baciocchi, Lucca was for a few years wonderfully prosperous. It was occupied by the Neapolitans in 1814; from 1816 to 1847 it was governed as a duchy by Maria Luisa, queen of Etruria, and her son Charles Louis; and it afterwards formed one of the divisions of Tuscany.

The bishops of Lucca, who can be traced back to 347, gradually acquired a variety of exceptional marks of distinction, such as the pallium in 1120, and the archiepiscopal cross from Alexander II.; and at length in 1726 Benedict XIII. raised their see to the rank of an archbishopric, without suffragans.

See *Memorie per servi. e alla storia del ducato di Lucca*, published by the Lucca Academy; Mazzarosa, *Storia di Lucca*, Lucca, 1833; Repetti, *Dizionario della Toscana*, Florence, 1835; Freeman, *Hist. and Arch. Sketches*, London, 1876.

LUCCA, BATHS OF (BAGNI DI LUCCA, formerly BAGNO A CORSENA), a commune of Italy in the province of Lucca, containing a number of famous watering-places. They are situated in the valley of the Lima, a tributary of the Serchio; and the district is known in the early history of Lucca as the Vicaria di Val di Lima. Ponte Serraglio (16 miles to the north of Lucca) is the principal village; but there are warm springs and baths also at Villa, Docce Bassi, Bagno Caldo, &c. Bagno a Corsena is mentioned in 1284 by Guidone da Corvaia, a Pisan historian (Muratori, vol. xxii.); and by the 16th century the waters had attained great celebrity. Fallopius, who gave them credit for the cure of his own deafness, sounded their praises in 1569; and they have been more or less in fashion since. The temperature of the water varies from 96° to 133° Fahr.; in all cases it gives off carbonic acid gas, and contains lime, magnesium, and sodium products. In the village of Bagno Caldo there is a considerable hospital, constructed largely at the expense of Nicholas Demidoff in 1826. The population of the commune was 11,000 in 1881.

LUCENA, a town of Spain, in the province of Cordova, 37 miles south-south-east from that city, and 11 miles by road south-east from the Aguilar station of the Cordova-Malaga Railway. It is pleasantly situated on the Cascajar, a minor tributary of the Genil, in a district that produces oil, wine, and cereals in great abundance, and affords excellent pasture. The parish church, which is large but not otherwise remarkable, dates from the beginning of the 16th century. The chief industries are the manufacture of hardware and pottery, bronze lamps being a specialty of Lucena, and also the large earthenware jars (*tinajas*) used throughout Spain for the storage of oil and wine. There is considerable trade in the produce of the neighbourhood, and the horse mart is famous throughout Andalusia. The population in 1877 was 19,540. Lucena was taken from the Moors early in the 14th century; it was in the attempt to recapture it that King Abu 'Abdallah (Boabdil) of Granada was taken prisoner in 1483.

LUCERA, a city of Italy, in the province of Foggia, on a hill in the midst of the Apulian plain, lies 10 miles west-north-west of Foggia. Although a busy and flourishing place, with 14,014 inhabitants in 1871, Lucera is mainly of historical interest. The cathedral, erected on the ruins of the magnificent mosque, is a fine Romanesque building with Gothic features; and the castle, whose imposing ruins still crown the hill to the north of the town, was formerly the grandest of all the strongholds possessed by the Hohenstaufen emperors to the south of the Alps.

By a Greek tradition the foundation of Luceria was assigned to Diomede, and the statue in its temple of Minerva passed as the authentic Palladium; but the place would seem to be really of Oscan rather than Daunian origin. The Romans were marching to the relief of Luceria when they suffered the defeat at the Caudine Forks; they effected its capture in 320 B.C.; and when they recovered it in 314 they slew a great part of the inhabitants, and introduced a powerful body of colonists. During the Second Punic War the city was the headquarters of the Apulian campaigns. It continued to exist as a place of some mark down through the empire, and is mentioned by Pliny as a colony. Destroyed (663 A.D.) by the emperor Constans, who had recovered it from the Lombards, it was shortly after restored, and in 1227 it was raised to more than its former prosperity by Frederick II., who settled there a great body of his Saracen followers from Sicily, and thus increased its population to about 77,000. The Mohammedan colony, however, was brought to ruin by the hostility of Charles I. and II. of Anjou. Previous to 1806 Lucera was the administrative centre of the two provinces Basilicata and Molise. See W. Lang, in *Im Neuen Reich*, Dec. 1877.

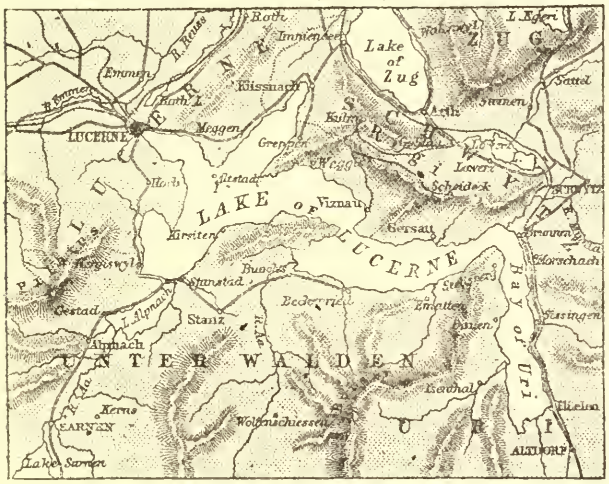
LUCERNE (German, *Luzern*), a canton of Switzerland lying north-west of the central mass of the Swiss Alps, having the canton of Aargau to the north, Bern to the west and south, and the small cantons of Zug, Schwyz, and Unterwalden on the east and south-east sides. Like most of the Swiss cantons its form is very irregular, and it includes, besides a part of the Lake of Lucerne, the Lakes of Sempach and Baldegg, and several smaller sheets of water. To this circumstance is probably due the discrepancy in the various estimates of the area, which range from 498 to 585 square miles. The greater part of its territory lies in the low hilly region of north-western Switzerland, most of which is under cultivation; but it has one considerable valley, the Entlebuch, enclosed by mountains, several of which exceed 5000 feet in height, which is devoted to pasturage. The only considerable mountain in the canton is the Pilatus, a steep jagged ridge with numerous peaks, the highest of which is 7290 feet above the sea, forming the boundary between this and the canton of Unterwalden. The only river is the Reuss, which issues from the lake at the town of Lucerne, but soon turns abruptly to the north-east, and passes the boundary of the canton. Of many smaller streams that water its surface, the most important is the Little Emme, which drains the Entlebuch and its tributary valleys. The soil is moderately fertile, and produces good crops of cereals, but the vine is grown only in a few exceptionally favourable situations. Some of the higher valleys, especially the Entlebuch, are mainly devoted to pasture, and furnish cheese and butter in considerable quantities, of which the surplus is exported. The population in December 1880 was 134,806, of whom all but 5634 were Roman Catholics. The language is exclusively German, and the people belong to the Teutonic stock. Excepting the inhabitants of the town of Lucerne, they are mainly employed in agriculture. The men of the Entlebuch, leading a pastoral life and little exposed to intercourse with strangers, have preserved more of the original simplicity of manners and costume than is now often found elsewhere in Switzerland. They are famed for their strength and skill in wrestling and other athletic exercises, as may be seen at the *Schwingfeste*, still frequently held in that district.

Like the rest of northern Switzerland, Lucerne was subject to the house of Austria until 1332, when its people joined the league of the forest cantons, Uri, Schwyz, and Unterwalden, thus forming the fourth in date of the confederation. They bore their share in the brilliant victory of Sempach, fought in 1386 near the village of that name, and in 1402 acquired the Entlebuch by purchase from the Austrian duke. The government was until the end of the 18th century an oligarchy in the hands of a few families, but in 1798 the French invasion substituted democratic institutions. These, with several changes all tending to give more complete power to the people, have continued to the present time. The constitution now in force dates from the 17th February 1869, and is based on the principle which prevails throughout the whole of Switzerland, that the sovereign power is vested exclusively in the people, but may be exercised either directly or through delegates elected by universal suffrage. Lucerne formerly sent a contingent of 1734 men to the federal army, but according to the latest return the number of men belonging to the canton on the rolls (in 1879) was 5176. In 1846 Lucerne took a leading part in the formation of the *Sonderbund*, a league of several of the Catholic cantons to oppose forcible resistance to the decree of the federal government for the expulsion of the Jesuits from Switzerland. In the brief campaign that ensued in the following year, the forces of the Sonderbund were utterly routed, and after a few days the conflict ceased. Since that date the canton seems to have enjoyed complete internal tranquillity. Lucerne has produced a fair proportion of men who have distinguished themselves in science, literature, philosophy, and art. Among many others whose reputation is confined to their own country, the names of the naturalists Cappeler and Lange, the historians Etterlin and Balthasar, and the philosopher Troxler have acquired more permanent reputation.

LUCERNE, the chief town of the Swiss canton of that name, stands on both banks of the Reuss, where that river issues from the north-west end of the chief arm of the lake of Lucerne. The position of the town is singularly beautiful. Beyond the lower hills, rich with planting and cultivation, which slope towards the shores of the lake and the river, loftier summits of very varied form rise in the background. Most prominent of these is the many-peaked Pilatus, only about 7 miles distant, while the double summit of the Mythen, at the opposite end of the lake, is flanked by other less imposing summits, amongst which the Righi draws attention, owing to the fame of its panoramic view. The picturesque aspect of the town is much enhanced by the ancient walls, now partly removed, and the circular or octagonal towers which surround it. One of these, called the Wasserthurm, rising from the water's edge, is said to have served as a lighthouse (*lucerna*), and to have originated the name of the town and canton. The town appears to owe its origin to a Benedictine monastery which stood on the site of the present Hofkirche. The buildings which clustered round gradually increased, until, early in the 14th century, the walls were erected for protection, and bridges were carried across the river. The Rathhaus, which is the seat of the cantonal Government, is an ancient building adorned with wood carving and quaint pictures. In a large hall are preserved the portraits of the chief magistrates (*Schultheissen*) from the earliest times to the year 1814. The libraries of Lucerne are said to possess the most complete and important collection of documents connected with the history of Switzerland during the Middle Ages. The town library, now in the museum, contains about 12,000 volumes, and is especially rich in manuscript chronicles. The cantonal library, reckoned at over 80,000 volumes, with many incunabula, was chiefly formed from the libraries of suppressed monasteries. Other curious books are to be found in the library of the Capuchins at Wesemlin outside the town.

Besides two modern bridges which span the river, there are two wooden causeways, roofed over, and passable only on foot, which anciently served the wants of the inhabitants; a third, the longest of all, was removed in the progress of modern improvements. Of those remaining, the more ancient, called the Mühlbrücke, was adorned with illustrations of the "Dance of Death," a favourite subject with German and Swiss mediæval artists; though much injured by time, they are still visible. The other wooden bridge—the Kapellbrücke—is decorated with numerous paintings representing events in Swiss history and in the lives of Saints Leodegar and Mauritius, the patrons of the city. The principal church, which has little architectural merit, possesses a fine organ. Along with various religious and charitable institutions which seem fully adequate to the wants of the population, a museum has been opened of late years which, among various other objects, contains an interesting archæological collection, going back to the prehistoric period, and including relics of historical interest, such as trophies taken on the field of Sempach, formerly preserved in the arsenal. The town contains one object of genuine artistic interest—the colossal lion designed to commemorate the men of the Swiss guard who fell in the defence of the Tuileries in Paris on the 10th August 1792. The idea, which might easily have led an inferior artist into extravagance and vulgarity, was well suited for the simple and manly genius of Thorwaldsen, who supplied the model; and, although the execution is necessarily somewhat rude, the effect is touching and impressive. In an architectural point of view the most notable part of the town is the wide quay formed on land reclaimed from the lake in 1852, planted on one side with trees, and on the other showing a succession of those great hotels which everywhere in Switzerland have been built to accommodate and to tempt the strangers who annually resort to the country. This constant flow of visitors has led to a large increase of population; that of Lucerne, which twenty years before was little over 10,000, was 17,850 at the census of 1880. (J. B.)

LUCERNE, Lake of, the name given by foreigners to the Vierwaldstättersee, or lake of the four forest cantons of Switzerland. Only a small portion of its shores lie within the canton of Lucerne, but the name has been taken from the most considerable town which it approaches. Lying on the north-west side of the Alps of central Switzerland, this lake has extraordinary interest for the physical geographer, for the lover of natural scenery, and for all who feel sympathy with the story of Swiss independence. Like most of the other Alpine lakes, it lies altogether among the *Voralpen*, or outer ranges of the Alps, but is remarkable for the extreme irregularity of its form, which suggests problems of much difficulty to the orographer. The great majority of the Alpine lakes occupy depressions or excavations in a single line of valley; and, so far as their form is concerned, the facts appear to be equally reconcilable with the views of those geologists who believe the lake basins to have been hollowed out by great glaciers as with those



Plan of Lake of Lucerne.

which refer their origin to disturbances of relative level, and restrict the action of the ancient glaciers to a secondary part in the result. The Lake of Lucerne, however, appears to occupy portions of four different valleys, orographically distinct, and connected only by narrow and tortuous channels. Commencing at its eastern extremity, we have the portion called the Bay of Uri, which at its southern end receives the considerable stream of the Reuss, bearing down the drainage of the Alps adjoining the pass of St Gotthard. This extends from south to north about 8 miles, with an average breadth of less than 2 miles, enclosed between steep limestone mountains rising from 4000 to 5000 feet above its surface. At the north end of the Bay of Uri a low tract, only a few miles in width, divides the shore of the lake from the little Lake of Lowerz, and another similar tract divides the latter from the Lake of Zug, so that it seems natural to conclude that if the Bay of Uri had been excavated by ice action it would have retained its original direction and carried the waters of the Reuss to the Lake of Zug. In point of fact the channel of the lake is bent abruptly westward round the promontory of Treib, and extends in the same direction nearly 10 miles, with the local designation of Buochsersee. But this channel is closed at its western end by a low neck of land, and the passage for navigation is through a narrow strait, less than half a mile wide, which connects the Buochsersee, lying south of the Bürgenstein and the Vitznauerstock, with a third basin occupying the bottom of the valley which lies north of those ridges. Proceeding westward along this latter portion of the lake, we find two deep bays, several miles in length, opening on either hand, while a third extends somewhat north of west to the town of Lucerne. The bay on the left hand, opening towards the south-west, is called the Alpnachersee, while that on the opposite or north-east side is the Bay of Küssnacht. At the central point where these meet it is seen that they lie in a continuous line of valley extending from the Brünig Pass to the Lake of Zug, as the Bay of Küssnacht is separated from the latter only by a low isthmus. Those who refuse to regard glaciers as the chief agents in the excavation of lake basins ask how it can be supposed that a glacier from the valley of the Reuss could have accomplished the hollowing out of the middle portions of the lake, and further inquire whether the glacier from the valley of Sarnen, which is supposed to have excavated the bays of Alpnach and Küssnacht, should not have also cleared away the isthmus between the latter and the Lake of Zug, leading the drainage of the lake in that direction. The question as to the true origin of lake basins in the Alps cannot be satisfactorily discussed until their forms have been determined by numerous and accurate soundings, and this has as yet been done for the Lake of Como alone. The greatest depth hitherto measured in the Lake of Lucerne is 1040 feet, but no connected series of soundings appear to have as yet been made. The mean height of the surface above the sea-level is 1437 feet, or 68 feet higher than the Lake of Zug.

The irregularity of its form is the chief cause of the unequalled variety which characterizes the scenery of the Lake of Lucerne, but the geological structure of the mountains that enclose it much enhances the effect. Its eastern portion lies amid the Secondary limestone rocks which are everywhere in the Alps marked by sharp peaks and ridges and precipitous crags; the middle part is enclosed by great masses of Tertiary conglomerate, called in Switzerland Nagelfluhe, which constitutes such mountains as the Righi and the Bürgenstein, showing steep faces with gently sloping summits; while the western extremity is surrounded by swelling hills richly planted and dotted with bright looking hamlets or solitary farm-houses. The forests which once covered the greater part of this region, and give the local designation to the four original cantons of Switzerland, have been extensively thinned, but enough yet remain to add another element to the charms of the scenery. Vineyards with their formal rows of stakes are scarcely seen on the shores of the lake, but orchards surround most of the houses, and the walnut grows to great perfection. Lucerne is the only town on the lake. Altdorf, the chief town of Uri, stands nearly 2 miles from the head of the Bay of Uri, and Schwyz, capital of the canton of that name, is more than 3 miles from the shore; but since the introduction of steam navigation several of the villages on its coast have largely increased in population.

Modern scepticism has thrown doubt upon many of the details in the popular history of the origin of Swiss independence; but it is certain that the shores of this lake nurtured the men who commenced the heroic efforts that secured freedom for their country. Here, at the beginning of the 14th century, in an age when nearly all Europe was in the hands of feudal oppressors, a handful of mountaineers drove out the local tyrants and levelled their strong holds, and a few years later, on the fields of Morgarten and Sempach, confronted and put to flight the chivalry of Austria. The man who can visit unmoved the Grütli, the spot, overlooking the Bay of Uri, consecrated by popular tradition as the scene of the first meeting of the confederates on the night of the 7th October 1307, must be devoid of all sense of the sublime in natural scenery and of the heroic in human action. (J. B.)

LUCIA, or Lucy, St, was a noble Christian virgin of Syracuse, who lived in the reign of Diocletian. Her mother, having been miraculously cured of an illness at the sepulchre of St Agatha in Catania, was persuaded by Lucia to distribute all her wealth to the poor. The youth to whom the daughter had been betrothed forthwith denounced her to Paschasius the prefect, who ordered that she should be taken away and subjected to shameful outrage. But it was found that no force which could be applied was able to move her from the spot on which she stood; even boiling oil and burning pitch had no power to hurt her, until at last she was slain with the sword. Such in substance is the narrative of the appropriate lessons given in the Roman Breviary for the festival of St Lucia on December 13 (duplex); a later legend represents her as having plucked out her eyes when they threatened to become a snare to her lover, and as having had them afterwards restored to her more beautiful than before. In art she is represented as suffering martyrdom, as bearing her eyes on a salver, or as carrying a flaming lamp in her hand; in the last case she is the type of celestial light or wisdom (comp. Dante, *Inf.*, ii.; *Purg.*, ix.; *Par.*, xxxii.). She is invoked in cases of eye-disease, and is also regarded as the patroness of the labouring poor.

LUCIAN, one of the principal essay-writers (λογογράφοι) and satirists of the post-Christian era, the silver age of Greek literature, was born at Samosata on the Euphrates in northern Syria.[1] We have no indication of the precise date of his birth, but it is probable that he flourished about or after the middle of the 2d century, as he mentions Marcus Aurelius and his war with the German Marcomanni and Quadi (170–74 A.D.) in his *Alexander* (§ 43). He tells us in the *Somnium* or *Vita Luciani*, § 1, that his means being small he was at first apprenticed to his maternal uncle, a statuary, or rather sculptor of the stone pillars called Hermæ.[2] When a schoolboy he had been in the habit of scraping the wax from his tablets and using it for moulding or modelling little figures of dogs, horses, or men.[3] Having made an unlucky beginning by breaking a marble slab, and having been well beaten for it, he absconded and returned home. Here he had a dream or vision of two women, representing Statuary and Literature. Both plead their cause at length, setting forth the advantages and the prospects of their respective professions; but the youth chooses Παιδεία, and decides to pursue learning. For some time he seems to have made money as a ῥήτωρ, following the example of Demosthenes, on whose merits and patriotism he expatiates in the dialogue *Demosthenis Encomium*. It is clear from his numerous writings that he was very familiar with the rival schools of philosophy, and he must have well studied their teachings; but he lashes them all alike, the Cynics, perhaps, being the chief object of his derision.[4] A large number of philosophers, both ancient and contemporary, are mentioned by name, nearly always in ridicule or disparagement. Lucian was not only a sceptic; he was a scoffer and a downright unbeliever. He felt that men's actions and conduct always fall far short of their professions, and therefore he concluded that the professions themselves were worthless, and a mere guise to secure popularity or respect. Of Christianity he shows some knowledge, and it must have been somewhat largely professed in Syria at the close of the 2d century.[5] In the *Philopatris*, though the dialogue so called is generally regarded as spurious, there is a statement of the doctrine of the Trinity,[6] and the "Galilæan who had ascended to the third heaven" (§ 12), and "renewed" (ἀνεκαίνισεν) by the waters of baptism, may possibly allude to St Paul. The doctrines of the Λόγος and the "Light of the world," and that God is in heaven making a record of the good and bad actions of men,[7] seem to have come from the same source, though the notion of a written catalogue of human actions to be used in judgment was familiar to Æschylus and Euripides.

As a satirist and a wit Lucian stands without a rival. In these respects he may be said to occupy in prose literature the unique position which Aristophanes holds in Greek poetry. But whether he is a mere satirist, who laughs while he lashes, or a misanthrope, who hates while he derides, is not very clear. In favour of the former view it may be said that the two main objects of his ridicule are mythology and the sects of philosophy; in favour of the latter, his bitter exposure of imposture and chicanery in the *Alexander*, and the very severe attacks he makes on the "humbug" of philosophy,[8] which he everywhere assails with the most acrimonious and contemptuous epithets.

As a writer Lucian is fluent, easy, and unaffected, and a close follower of the best Attic models, such as Plato and the orators. His style is simpler than Plutarch's, and some of his compositions, especially the *Dialogues of the Gods* (pp. 204–287) and *of the Marine Deities* (288–327), and, above all, the *Dialogues of the Dead* (329–454), are models of witty, polished, and accurate Greek composition. Not less clever, though rather lax in morality, are the ἑταιρικοὶ διάλογοι (pp. 280–325), which remind us somewhat of the letters of Alciphron. The sarcasms on the popular mythology, the conversations of Pluto, Hermes, Charon, and others of the powers in Hades, show a positive disbelief of any future state of existence. The model Lucian followed in these dialogues, as well in the style as in the sparkling and playful repartee, was the Platonic conversations, founded on the drama, of which the dialogue may be called the prose representative. Aristotle never adopted it, perhaps regarding it as beneath the true dignity of philosophy. The dialogue, in fact, was revived and improved by Lucian,[9] the old traditions of the λογοποιοί and λογογράφοι, and above all, the immense influence of rhetoric as an art, having thrown some discredit on a style of composition which, as introduced by Plato, had formed quite a new era in Greek prose composition. For rhetoric loved to talk, expatiate, and declaim, while dialectic strove to refute by the employment of question and answer, often in the briefest form.

In his language, as tested by the best classical models, Lucian is at once elegant and correct. But he occasionally indulges in idioms slightly solecistic, as in the use of κἂν

---

[1] He mentions it only once, in the treatise πῶς δεῖ ἱστορίαν συγγράφειν, where he speaks of τὴν ἐμὴν πατρίδα τὰ Σαμόσατα (§ 24). In *Piscator* (§ 18), he speaks of himself as Σύρος τῶν Ἐπευφρατιδίων.

[2] The words ἄριστος ἑρμογλύφος εἶναι δοκῶν (§ 3) are probably satirical, and really mean φαῦλος, "second-rate," for it is clear that he disliked his uncle.

[3] *Ibid.*, § 2.

[4] Hence Diogenes is made to say in *Piscator*, § 23, ὑπὲρ ἅπαντας ὕβρισμαι, sc. πρὸς Λουκιάνου. In βίων πρᾶσις (p. 551) the same philosopher asserts that "any one will be looked up to and get a reputation if only he has impudence and abuse." At the auction Diogenes is valued at *twopence* (§ 11). That Lucian had practised in law courts, and turned his eloquence afterwards against the philosophers, is asserted in *Piscat.*, § 25.

[5] In the *Alexandrus* (§ 25) we are told that the province of Pontus, due north of Syria, was "full of Christians."

[6] § 12, ὑψιμέδοντα Θεὸν μέγαν ἄμβροτον οὐρανίωνα, υἱὸν Πατρὸς, Πνεῦμα ἐκ πατρὸς ἐκπορευόμενον, ἓν ἐκ τριῶν καὶ ἐξ ἑνὸς τρία, a passage which bears on the controverted procession "a Patre Filioque."

[7] *Ibid.*, § 13. Æsch., *Eum.*, 265, δελτογράφῳ δὲ πάντ᾽ ἐπωπᾷ φρενί.

[8] At p. 792 Hermotimus says to Lycinus (who must be assumed to represent Lucian himself), ὑβριστὴς ἀεὶ σὺ, καὶ οὐκ οἶδ᾽ ὅ τι παθὼν μισεῖς φιλοσοφίαν καὶ ἐς τοὺς φιλοσοφοῦντας ἀποσκώπτεις. In *Icaromenippus* (§ 5) he says he always guessed who were the best physical philosophers "by their sour-faced looks, their paleness of complexion, and the length of their beards." See also *ibid.*, § 29.

[9] He says (speaking as Σύρος in *Bis accusatus*, § 34) that he found dialogue somewhat out of repute from the too numerous questions (*i.e.*, employed by Plato), and brought it up to a more human and natural standard, substituting banter and repartee for dialectic quibbles and close logical reasoning.

(*καὶ ἂν*) with a future or even an imperative, *μὴ* in place of *οὐ*, the particle *ἂν* misplaced or wrongly added, and a subjunctive mood instead of an optative.[1] Nevertheless, he evinces a perfect mastery over a language as wonderful in its inflexions as in its immense and varied vocabulary; and it is a well-merited praise of the author to say that to a good Greek scholar the pages of Lucian are almost as easy and as entertaining as an English or French novel. In this respect they form a contrast with the somewhat "crabbed" style of Plutarch, many of whose moral treatises are by no means easy reading.

Of course Greek, like every other language, is progressive, and the notion of fixing it to any given period as absolutely the best is quite arbitrary. We shall not be surprised at finding in Lucian some forms and compounds which were not in use in the time of Plato or Demosthenes. Thus, he has *ὑπερείδεις* for *ὑπερορᾷς* (p. 99), *πεπεμμένος* as the participle of the perfect passive of *πέμπω* (p. 240), *ἐνσέσεικε* the perfect of *ἐνσείω* (p. 705), to which a purist would object; and there are occasional tendencies to Latinism which can hardly surprise us. From a writer living under Roman rule we may expect some Latin words in his vocabulary, as Σακέρδως for *Sacerdos*, and Roman names like Μάγνος, Κελσός, Κέληρ (*Celer*), Ῥουτιλλίανος, &c. In the *Lexiphanes* a long passage is read from a treatise composed in words of the strangest and most out-of-the-way form and sound, on hearing which Lucian pretends to be almost driven crazy (p. 342). His own sentiments on the propriety of diction are shown by his reproof to Lexiphanes (§ 24), "if anywhere you have picked up an out-of-the-way word, or coined one which you think good, you labour to adapt the sense of it, and think it a loss if you do not succeed in dragging it in somewhere, even when it is not really wanted." The free use of such a vocabulary[2] even in satire shows Lucian's intimate knowledge of the spurious bombast which had begun to corrupt the classic dialect.

Lucian founded his style, or obtained his fluency, from the successful study of rhetoric, by which he appears to have made a good income from composing speeches which attracted much attention.[3] At a later period in life he seems to have held a lucrative office in Egypt. When he "all but had one foot in Charon's boat" (he says in *Apologia*, § 1), "he lent his neck to be bound by a golden collar." This office was to register the actions and verdicts of the law courts,—he was a kind of "Master of the Rolls," who had the custody of the state documents, and received his salary directly from the king (*ibid.*, § 12). He speaks of the emoluments as *οὐ σμικρὸς μισθὸς ἀλλὰ πολυτάλαντος*. We do not know the date of Lucian's death, but he may have lived till about 200 A.D.

The extant works of this writer are so numerous that of some of the principal only a short sketch can be given. To understand them aright we must remember that the whole moral code, the entire "duty of man," was included, in the estimation of the pagan Greek, in the various schools of philosophy. As these were generally rivals, and the systems they taught were more or less directly antagonistic, truth presented itself to the inquirer, not as one, but as manifold. The absurdity and the impossibility of this forms the burden of all Lucian's writings. He could only form one conclusion, viz., that there is no such a thing as truth.

One of the best written and most amusing treatises of antiquity is Lucian's *True History*, which forms a rather long narrative in two books. It is composed, he says in a brief introduction, not only as a pastime and a diversion from severer studies, but avowedly as a satire (*οὐκ ἀκωμῳδήτως*, p. 71) on the poets and logographers who have written so many marvellous tales, *πολλὰ τεράστια καὶ μυθώδη*. He names Ctesias and Homer; but Hellanicus and Herodotus, perhaps other *λογοποιοί* still earlier, appear to have been in his mind.[4] The only true statement in his *History*, he wittily says (p. 72), is that it contains nothing but lies from beginning to end.

The main purport of the story is to describe a voyage to the moon. He set out, he tells us, with fifty companions, in a well-provisioned ship, from the "Pillars of Hercules," intending to explore the western ocean. After eighty days rough sailing they came to an island on which they found a Greek inscription, "This was the limit of the expedition of Heracles and Dionysus"; and the visit of the wine-god seemed attested by some miraculous vines which they found there. After leaving the island they were suddenly carried up, ship and all, by a whirlwind into the air, and on the eighth day came in sight of a great round island shining with a bright light (p. 77), and lying a little above the moon. In a short time they are arrested by a troop of gigantic "horse-vultures" (*ἱππόγυποι*), and brought as captives to the "man in the moon," who proves to be Endymion. He is engaged in a war with the inhabitants of the sun, which is ruled by King Phaethon, the quarrel having arisen from an attempt to colonize the planet Venus (Lucifer). The voyagers are enlisted as "Moonites," and a long description follows of the monsters and flying dragons engaged in the contest. A fight ensues, in which the slaughter is so great that the very clouds are tinged with red (p. 84). The long description of the inhabitants of the moon is extremely droll and original, and has often been more or less closely imitated. After descending safely into the sea, the ship is swallowed by a huge "sea serpent" more than 100 miles long. The adventures during the long confinement in the creature's belly are most amusing; but at last they sail out through the chinks between the monster's teeth, and soon find themselves at the "Fortunate Islands." Here they meet with the spirits of heroes and philosophers of antiquity, on whom the author expatiates at some length. The tale comes to an abrupt end with an allusion to Herodotus in the promise that he "will tell the rest in his next books." The story throughout is written in easy and elegant Greek, and shows the most fertile invention.

Another curious and rather long treatise is entitled Λούκιος ἢ ὄνος. The authorship is regarded as doubtful; the style, as it seems to us, does not betray another hand. Parts of the story are coarse enough; the point turns on one Lucius visiting in a Thessalian family, in which the lady of the house was a sorceress. Having seen her changed into a bird by anointing herself with some potent drug, he resolves to try a similar experiment on himself, but finds that he has become an ass, retaining, however, his human senses and memory. The mistake arose from his having filched the wrong ointment; however, he is assured by the attendant, Palæstra, that if he can but procure roses to eat, his natural form will be restored. In the night a party of bandits break into the house and

---

[1] Thus in p. 591, *προελόμενοι τινα ἐξ ἁπάντων ὅστις ἄριστα κατηγορῆσαι ἂν δοκῇ*, either *ὅστις ἂν ἄριστα δοκῇ* or *ὅστις ἄριστα ἂν δοκοίη* is required by the laws of Attic Greek.

[2] In describing a banquet Lexiphanes says (§ 7), *ποτήρια δὲ ἔκειτο παντοῖα ἐπὶ τῆς δελφινίδος τραπέζης, ὁ κρυψιμέτωπος καὶ τρυηλὶς μεντορουργὴς εὐλαβῆ ἔχουσα τὴν κέρκον καὶ βομβύλιος καὶ δειροκύπελλον καὶ γηγενῆ πολλὰ οἷα Θηρικλῆς ὤπτα, εὐρυχαδῆ τε καὶ ἄλλα εὔστομα, τὰ μὲν Φωκαῆθεν, τὰ δὲ Κνιδόθεν, πάντα μέντοι ἀνεμοφόρητα καὶ ὑμενόστρακα.*

[3] *Bis accusat.* (§ 27), where Rhetoric declares she had enriched him, *προῖκα οὐ μικρὰν ἐπεσενεγκαμένη πολλοὺς καὶ θαυμασίους λόγους.*

[4] In p. 127 he says that he saw punished in Hades, more severely than any other sinners, writers of false narratives, among whom were Ctesias of Cnidus and Herodotus. Yet in the short essay inscribed *Herodotus*, p. 831, he wishes it were possible for him to imitate the many excellencies of that writer.

carry off the stolen goods into the mountains on the back of the unfortunate donkey, who gets well beaten for stumbling on the rough road. Seeing, as he fancies, some roses in a garden, he goes in quest of them, and again gets beaten as a thief by the gardener (p. 585). After many adventures with the bandits, he attempts to run away, but is caught. A council is held, and he is condemned to die along with a captive girl who had essayed to escape on his back. Suddenly, however, soldiers appear, and the bandits are arrested (p. 595). Again the ass escapes "to the great and populous city of Berœa in Macedonia" (p. 603). Here he is sold to a strolling conjurer, afterwards to a market-gardener; and both experiences are alike painful. Again he passes into the possession of a cook, where he gets fat and sleek on food more suited to his concealed humanity than the hard fare he has of late lived upon (p. 614). At last, during an exhibition in the theatre, he sees some roses being carried past, and, making a successful rush to devour them, he recovers his former shape. "I am Lucius," he exclaims to the wondering president of the exhibition, "and my brother's name is Caius. It was a Thessalian witch that changed me into a donkey." Thus all ends well, and he returns safe to his country. Droll and graphic as many of the adventures are, they but too clearly show the profligate morals of the age.

The treatise *On the Syrian Goddess* (Mylitta, the moon-goddess, the Semitic Venus) is written in the Ionic dialect in imitation perhaps of the style of Herodotus, though the resemblance is by no means close. The writer professes to be an Assyrian (p. 452), and to describe the wonders in the various temples of Palestine and Syria; he descants on the eunuchs of Syria and the origin of the self-imposed privation of manhood professed and practised by the Galli. The account of the temples, altars, and sacrifices is curious, if really authentic; after the manner of Pausanias it is little more than a list, with the reasons in most cases added, or the origin of the custom explained.

De Morte Peregrini is a narrative of one Proteus, a Cynic, who after professing various doctrines, and among them those of Christianity, ended his own life by ascending a burning pyre (p. 357).[1] The founder of the Christian religion is described (p. 334) as "the man who had been crucified (or fixed to a stake, ἀνασκολοπισθέντα) in Palestine," and as one "still worshipped for having introduced a new code of morals into life." The zeal of the early converts is shown by their flocking to the prison when Proteus had been arrested, by the sympathy conveyed from distant cities of Asia (p. 336), by contributions of money for his support, and by their total indifference to life; for "the poor wretches have persuaded themselves that they will live for ever." The founder of the religion, "that first lawgiver of theirs," says Lucian, "made them believe that they are all brothers when once they have abjured the gods of Greece and worshipped the crucified man who is their teacher, and have begun to live according to his laws" (p. 337).

Bis accusatus is a dialogue commencing with a satire on the folly of the popular notion that the gods alone are happy. Zeus is represented as disproving this by enumerating the many and heavy duties that fall to their lot in the government of the world, and Hermes remarks on the vast crowds of philosophers of rival sects, by whose influence the respect and worship formerly paid to the gods have seriously declined. A trial is supposed to be held under the presidency of the goddess Δίκη, between the Academy, the Porch, the schools of the Cynics and Epicureans, and Pleasure, Revelry, Virtue, Luxury, &c., as variously impugned or defended by them. Then Conversation and Rhetoric come before the court, each having an action for defamation to bring against Syrus the essayist, who of course is Lucian himself (p. 823). His defence is heard against the charges of both, and in both cases he is triumphantly acquitted. This essay is brilliant from its clever parodies of Plato and Demosthenes, and the satire on the Socratic method of arguing by short questions and answers.

The *Lover of Lying* (Φιλοψευδής) discusses the reason why some persons seem to take pleasure in falsehood for its own sake, and when there is nothing to be gained by it. Under the category of lying all mythology (*e.g.*, that of Homer and Hesiod) is included, and the question is asked, why the hearers of such stories are amused by them? Quack remedies, charms, and miraculous cures are included among the most popular kinds of falsehood; witchcraft, spiritualism, exorcism, expulsion of devils, spectres, are discussed in turn, and a good ghost story is told in p. 57. An anecdote is given of Democritus, who, to show his disbelief in ghosts, had shut himself up in a tomb, and when some young men, dressed up with death's heads, came to frighten him at night, and suddenly appeared to him while he was engaged in writing, he did not even look up, but called out to them, "Stop your joking" (p. 59). This treatise, a very interesting one, concludes with the reflexion that truth and sound reason are the only remedies for vain and superstitious terrors.

The dialogue *Navigium seu Vota* (Πλοῖον ἢ εὐχαί) gives an apparently authentic account of the measurements and fittings of an Egyptian ship which has arrived with a cargo of corn at the Piræus, driven out of its course to Italy by adverse winds. The full length is 180 feet, the breadth nearly 50, the depth from deck to the bottom of the hold 43 feet. The "wishes" turn on a party of friends, who have been to see the ship, declaring what they would most desire to possess. One would have the ship filled with gold, another a fine house with gold plate; a third would be a "tyrant" with a large force devoted to his interests; a fourth would like to make himself invisible, enter any house that he pleased, and be transported through the air to the objects of his affection. After hearing them all, the first speaker, Lycinus (Lucian), says that he is content with the privilege of laughing heartily at the vanity of human wishes, especially when they are those of professed philosophers.

The dialogue between Philo and Lycinus, *Convivium seu Lapithæ*, is a very amusing description of a banquet, at which a party of dignified philosophers quarrelled over their viands at a marriage feast, and came to blows. The style is a good imitation of Plato, and the scene reminds one of the "clients' dinner" in the fifth satire of Juvenal. One of the party is so irritated by taunts that he flings a goblet half full of wine at the head of another, who retorts by spitting in the face of the aggressor (p. 441). Matters come to a climax by the attempt of one of the guests, Zenothemis, to secure for himself a fatter fowl which had been served to his next neighbour Hermon. Each seizes his bird and hits the other with it in the face, at the same time pulling his beard. Then a general fight ensues, and serious wounds are inflicted. The story is, of course, a satire on philosophy, the favourite topic of a writer who believed neither in gods nor in men.

The *Piscator*, a dialogue between Lucian, Socrates, Pythagoras, Empedocles, Plato, and others, commences with a general attack on the author as the enemy of philosophy. Socrates proposes that the culprit should be tried, and that Philosophia should assist in the prosecution. Lucian declares that he does not know where such a person lives, long as he has been looking for her (§ 11). She is found at last, but declares Lucian has never disparaged

[1] It is open to controversy whether he was not a martyr at the stake.

her, but only impostors and pretenders under her name (§ 15). He makes a long defence (pp. 598–606), abusing the philosophers in the sort of language in which some schools of theologians abuse the monks of the Middle Ages (§ 34). The trial is held in the Acropolis of Athens, and the sham philosophers, dreading a verdict against them, throw themselves from the rock. A Cynic flings away his scrip in the hurry, and on examination it is found to contain, not books or loaves of bread, but gold coins, dice, and fragrant essences (§ 44). The title of *Fisherman* is given to this witty treatise, because at the end Lucian baits his hook with a fig and a gold coin, and catches gluttonous strollers in the city while seated on the wall of the Acropolis.

The *Voyage Home* (Κατάπλους) opens with the complaint that Charon's boat is kept waiting for Hermes, who soon appears with his troop of ghosts to be ferried over the infernal river. Among them is a τύραννος, one Megapenthes, who, as his name is intended to express, mourns greatly over the life he has just left. Amusing appeals are made by other souls for leave to return to life, and even bribes are offered to the presiding goddess of destiny, but Clotho is, of course, inexorable. The moral of the piece is closely like that of the parable of Dives and Lazarus: the rich and prosperous bewail their fate, while the poor and afflicted find rest from their troubles, and have no desire to return to them. The τύραννος here is the man clothed in purple and fine linen, and Lucian shows the same bitter dislike of tyrants which Plato and the tragic writers display. The heavy penalty is adjudged to Megapenthes that he may ever remember in the other world the misdeeds done in life.

The *Sale of Lives* is an auction held by Zeus to see what price the lives of philosophers of the rival sects will bring. A Pythagorean, who speaks in the Ionic, first undergoes an examination as to what he can teach, and this contains an enumeration of the doctrines usually ascribed to that sect, including metempsychosis. He is valued at 7s. 6d., and is succeeded by Diogenes, who avows himself the champion of truth, a cosmopolitan (§ 8), and the enemy of pleasure. Socrates brings two talents, and is purchased by Dion, tyrant of Syracuse (§ 19). Chrysippus, who gives some specimens of his clever quibbles,[1] is bought for fifty pounds, Aristotle for nearly a hundred, while Pyrrho the sceptic (or one of his school), who professes to "know nothing," brings four pounds, "*because* he is dull and stupid and has no more sense than a grub" (§ 27). But the man raises a doubt, "whether or not he has really been bought," and refuses to go with the purchaser till he has fully considered the matter.

Timon is a very amusing and witty dialogue. The misanthrope, once wealthy, has become a poor farm-labourer, and reproaches Zeus for his indifference to the injustice of man. Zeus declares that the noisy disputes in Attica have so disgusted him that he has not been there for a long time (§ 9). He tells Hermes to conduct Plutus to visit Timon, and see what can be done to help him. Plutus, who at first refuses to go, is persuaded after a long conversation with Hermes, and Timon is found by them digging in his field (§ 31). Poverty is unwilling to resign her votary to wealth; and Timon himself, who has become a thorough misanthrope, objects to be made rich again, and is with difficulty persuaded to turn up with his mattock a crock of gold coins. Now that he has once more become rich, his former flatterers, who had long left him, come cringing with their congratulations and respects, but they are all driven off with broken heads or pelted with stones. Between this dialogue and the *Plutus* of Aristophanes there are many close resemblances.

Hermotimus (pp. 739–831) is one of the longer dialogues, Hermotimus, a student of the Stoic philosophy for twenty years (§ 2), and Lucian (Lycinus) being the interlocutors. The long time—forty years at the least—required for climbing up to the temple of virtue and happiness, and the short span of life, if any, left for the enjoyment of it, are discussed. That the greatest philosophers do not always attain perfect indifference, the Stoic *ultimatum*, is shown by the anecdote of one who dragged his pupil into court to make him pay his fee (§ 9), and again by a violent quarrel with another at a banquet (§ 11). Virtue is compared to a city with just, and good, and contented inhabitants; but so many offer themselves as guides to the right road to virtue that the inquirer is bewildered (§ 26). What is truth, and who are the right teachers of it, still remains undetermined. The question is argued at length, and illustrated by a peculiar custom of watching the pairs of athletes and setting aside the reserved combatant (πάρεδρος) at the Olympian games by the marks on the ballots (§§ 40–43). This, it is argued, cannot be done till all the ballots have been examined; so a man cannot select the right way till he has tried all the ways to virtue. But to know the doctrines of all the sects is impossible in the term of a life (§ 49). To take a taste of each, like trying a sample of wine, will not do, because the doctrines taught are not, like the crock of wine, the same throughout, but vary or advance day by day (§ 59). A suggestion is made (§ 68) that the searcher after truth should begin by taking lessons in the science of discrimination, so as to be a good judge of truth before testing the rival claims. But who is a good teacher of such a science? (§ 70). The general conclusion of this well-argued inquiry is that philosophy is not worth the pursuit. "If I ever again," says Hermotimus, "meet a philosopher on the road, I will shun him as I would a mad dog."

The *Alexander* or *False Prophet* is a severe exposure of a clever rogue who seems to have incurred the personal enmity of Lucian (pp. 208–265). Born at Abonoteichus in Bithynia, a town on the southern shore of the Euxine, he is denounced as having filled all the Roman province of Asia with his villainy and plundering. Handsome, clever, and unprincipled, he had been instructed in the arts of imposture by one of the disciples of Apollonius of Tyana. Trusting to the natural credulity of Asiatics (§ 9), he sets up an oracle in his native town, having buried some brazen tablets which pretended that Æsculapius would be worshipped in a temple there. A long account is given of the frauds and deceptions of this pretended hierophant, and the narrative ends with his treacherous attempt to drown Lucian off the coast of Amastris by a secret order given to the pilot,—a design which was frustrated by the honesty of the man (§ 56).

The *Anacharsis* is a dialogue between Solon and the Scythian philosopher, who has come to Athens on purpose to learn the nature of the Greek institutions. Seeing the young men performing athletic exercises in the Lyceum, he expresses his surprise at such a waste of energy and the endurance of so much useless pain. This gives Socrates an opportunity of descanting at length on training as a discipline, and emulation as a motive for excelling. Love of glory, Solon says, is one of the chief goods in life. The argument is rather ingenious and well put; the style reminds us of the minor essays of Xenophon.

In all, one hundred and twenty-four extant treatises of Lucian (excluding about fifty epigrams and two iambic poems of no great merit) are considered genuine. We have given a brief account of

[1] *E.g.*, § 25, "A stone is a body; a living creature is a body; you are a living creature; therefore you are a stone." Again: "Is *every* body possessed of life?" "No." "Is a stone possessed of life?" "No." "Are *you* a body?" "Yes." "A *living* body?" "Yes." "Then, if a living body, you are not a stone."

some of the longest and best, but many others, *e.g.*, *Prometheus*, *Menippus*, *Life of Demonax*, *Toxaris*, *Zeus Tragœdus*, *The Dream or the Cock*, *Icaromenippus* (an amusing satire on the physical philosophers), are of considerable literary value. The excellent edition of C. Jacobitz, in the Teubner series, which is furnished with a very complete index, places the text in the student's hand in a much more satisfactory state than has yet fallen to the lot of Plutarch in his *Opera Moralia*. (F. A. P.)

LUCIAN, the martyr, was born, like the famous heathen writer of the same name, at Samosata. His parents, who were Christians, died when he was in his twelfth year. In his youth he studied under Macarius of Edessa, and after receiving baptism he adopted a strictly ascetic life, and devoted himself with zeal to the continual study of Scripture. Settling at Antioch, he became a presbyter, and, while supporting himself by his skill as a swift writer, became celebrated as a teacher, pupils crowding to him from all quarters, so that he is regarded as the founder of the famous theological school of Antioch. He did not escape suspicion of heresy, and is represented as the connecting link between Paul of Samosata and Arius. Indeed, on the deposition of the former, he was excluded from ecclesiastical fellowship by three successive bishops of Antioch, while the latter seems to have been among his pupils (Theodoret, *H. E.*, i. 3, 4). He was, however, restored before the outbreak of persecution, and the reputation won by his high character and learning was confirmed by his courageous martyrdom. He was carried to Nicomedia before the cruel Maximin, and persisting in his faith perished 312 A.D., under torture and hunger, which he refused to satisfy with food offered to idols. His remains were conveyed to Drepanum in Bithynia, and under Constantine the town was founded anew in his honour with the name of Helenopolis, and exempted from taxes by the emperor (327 A.D., see *Chron. Pasch.*, Bonn ed., p. 527). Here, on the day after Epiphany 387 A.D. (the day on which his martyrdom was commemorated), Chrysostom delivered the panegyrical homily from which, with notices in Eusebius (*H. E.*, ix. 6), Theodoret (*loc. cit.*), and the other ecclesiastical historians, the life by Jerome (*Vir. Ill.*, cap. 77), but especially from the account by S. Metaphrastes (cited at length in Bernhardy's notes to Suidas, *s.v.* νοθεύει), the facts above given are derived. See also, for the celebration of his day in the Syriac churches, Wright, *Cat. of Syr. MSS.*, p. 283.

Jerome says, "Feruntur eius de Fide libelli et breves ad nonnullos epistolæ"; but only a short fragment of one epistle remains (*Chron. Pasch.*, p. 516). The authorship of a confession of faith ascribed to Lucian and put forth at the semi-Arian synod of Antioch (341 A.D.) is questioned. Lucian's most important literary labour was his edition of the Septuagint corrected by the Hebrew text, which, according to Jerome (*Adv. Ruf.*, ii. 77), was in current use from Constantinople to Antioch. That the edition of Lucian is represented by the text used by Chrysostom and Theodoret, as well as by certain extant MSS., such as the Arundelian of the British Museum, was proved by F. Field (*Prol. ad Origenis Hexapla*, cap. ix.), who points out that Lucian filled up lacunæ of the Septuagint text as compared with the Hebrew from the other Greek translations, that his method was harmonistic, and that he sometimes indulged in paraphrastic additions and other changes. Before the publication of Field's *Hexapla*, Lagarde had already directed his attention to the Antiochian text (as that of Lucian may be called). See his *Symmicta* (ii. 142), and *Ankündigung einer neuen Ausg. d. gr. Uebersetzung des A. T.* (1882), in which an edition of this recension is promised, and the means for effecting it described. The accomplishment of this task may be looked to as the first step in the process of tracing backwards the history of the Septuagint.

From a statement of Jerome in his preface to the gospels it seems probable that Lucian had also a share in fixing the Syrian recension of the New Testament text, but of this it is impossible to speak with certainty. Compare the introductory volume of Westcott and Hort's *New Testament*, p. 138.

LUCIFER, bishop of Cagliari (hence called *Calaritanus* or rather *Caralitanus*), an ardent supporter of the cause of Athanasius, after the unfavourable result of the synod of Arles in 353 volunteered to go to the court and endeavour to obtain a new and impartial council; he was accordingly sent by Pope Liberius, along with Pancratius the presbyter and Hilarius the deacon, but did not succeed in preventing the condemnation of Athanasius, which was renewed at Milan in 355. For his own persistent adherence to the orthodox creed he was banished to Germanicia in Commagene; he afterwards lived at Eleutheropolis in Palestine, and finally in the upper Thebaid. His exile came to an end with the publication of Julian's edict in 362. From 363 until his death in 371 he lived at Cagliari in a state of voluntary separation from ecclesiastical fellowship with his former friends Eusebius of Vercelli, Athanasius, and the rest, on account of their mild decision at the synod of Alexandria in 362 with reference to the treatment of those who had unwillingly Arianized under the persecutions of Constantius. The Luciferian sect thus founded did not continue to subsist long after the death of its leader. It is doubtful whether it ever formulated any distinctive doctrine; certainly it developed none of any importance. The memory of Lucifer is still cherished in Sardinia; but, although popularly regarded there as a saint, he has never been canonized.

The controversial writings of Lucifer, dating from his exile, are chiefly remarkable for their passionate zeal and for the boldness and violence of the language addressed to the reigning emperor, whom he did not scruple to call the enemy of God and a second Saul, Ahab, and Jeroboam. Their titles, in the most probable chronological order, are *De non parcendis in Deum delinquentibus*, *De regibus apostaticis*, *Ad Constantium Augustum pro Athanasio libri ii.*, *De non conveniendo cum hæreticis*, and *Moriendum esse pro Filio Dei*. Their quotations of Scripture are of considerable value to the critical student of the Latin text before Jerome. They were first collected and edited by Tilius (Paris, 1586), and afterwards reprinted in the *Bibliotheca Patrum* (1618); the best edition is that of the brothers Colet (Venice, 1778).

LUCILIUS. Among the early Roman poets, of whose writings only fragments have been preserved, Lucilius was second in importance to Ennius. If he did not, like the epic poet of the republic, touch the imagination of his countrymen, and give expression to their highest ideal of national life, he exactly hit their ordinary mood, and expressed the energetic, critical, and combative temper which they carried into political and social life. He was thus regarded as the most genuine literary representative of the pure Roman spirit. The reputation which he enjoyed in the best ages of Roman literature is proved by the terms in which Cicero and Horace speak of him. Persius, Juvenal, and Quintilian vouch for the admiration with which he was regarded in the first century of the empire. The popularity which he enjoyed in his own time is attested by the fact that at his death in 102 B.C., although he had filled none of the offices of state, he received the honour of a public funeral.

His chief claim to distinction is his literary originality. He alone among Roman writers established a new form of composition. He may be called the inventor of poetical satire, as he was the first to impress upon the rude inartistic medley, known to the Romans by the name of *satura*, that character of aggressive and censorious criticism of persons, morals, manners, politics, literature, &c., which the word satire has ever since denoted. In point of form the satire of Lucilius owed nothing to the Greeks. It was a legitimate development of an indigenous dramatic entertainment, popular among the Romans before the first introduction of the forms of Greek art among them; and it seems largely also to have employed the form of the familiar epistle which circumstances had developed among them about the time when Lucilius flourished. But the style, substance, and spirit of his writings were apparently as original as the form. He seems to have commenced his poetical career by ridiculing and parodying the conventional language of epic and tragic poetry, and to have used in his own writings the language commonly employed in the social intercourse of educated men. Even his frequent use of Greek words, phrases, and quotations, reprehended by Horace, was probably taken from the actual practice of men, powerfully stimulated by the new learning, who found their own speech as yet inadequate to give free expression to the new ideas and impressions which they derived from their first contact with Greek philosophy, rhetoric, and poetry. Further, he not only created a style of his own, but, instead of taking the substance of his writings from Greek poetry, or from a remote past, he treated of the familiar matters of daily life, of the personal interests and peculiarities of himself or his contemporaries, of the politics, the wars, the government of the provinces, the administration of justice, the fashions and tastes, the eating and drinking, the money-making and money-spending, the scandals and vices, the airs and affectations, which made up the public and private life of Rome in the last quarter of the second century before our era. This he did in a singularly frank, independent, and courageous spirit, with no private ambition to serve, or party cause to advance, but with an honest desire to expose the iniquity or incompetence of the governing body, the sordid aims of the middle class, and the corruption and venality of the city mob. There was nothing of stoical austerity or of rhetorical indignation in the tone in which he treated the vices and follies of his time. His character and tastes were much more akin to those of Horace than of either Persius or Juvenal. But he was what Horace was not, a thoroughly good hater; and he lived at a time when the utmost freedom of speech and the most unrestrained indulgence of public and private animosity were the characteristics of men who took a prominent part in affairs. Although Lucilius took no active part in the public life of his time, he regarded it in the spirit, not of a recluse or a mere student of books, but of a man of the world and of society, as well as a man of letters. His ideal of public virtue and private worth had been formed by intimate association with the greatest and best of the soldiers and statesmen of an older generation.

The dates assigned by Jerome for his birth and death are 148 and 103 or 102 B.C. But it is impossible to reconcile the first of these dates with other facts recorded of him. We learn from Velleius that he served under Scipio at the siege of Numantia in the year 134 B.C. We learn from Horace that he lived on the most intimate terms of friendship with Scipio and Lælius, and that he celebrated the exploits and virtues of the former in his satires. Fragments of those books of his satires which seem to have been first given to the world (books xxvi.–xxix.) clearly indicate that they were written in the lifetime of Scipio. Some of these bring the poet before us as either corresponding with, or engaged in controversial conversation with, his great friend. One line—

> "Percrepa pugnam Popilli, facta Corneli cane—"

in which the defeat of M. Popillius Lænas, in 138 B.C., is contrasted with the subsequent success of Scipio, bears the stamp of having been written while the news of the capture of Numantia was still fresh. It is in the highest degree improbable that Lucilius served in the army at the age of fourteen; it is still more unlikely that he could have been admitted into the familiar intimacy of Scipio and Lælius at that age. It seems a moral impossibility that between the age of fifteen and nineteen—*i.e.*, between 133 B.C. and 129 B.C., the year of Scipio's death—he could have come before the world as the author of an entirely new kind of composition, and one which, to be at all successful, demands especially maturity of judgment and experience. It may further be said that the well-known words of Horace, in which he characterizes the vivid portraiture of his life, character, and thoughts, which Lucilius bequeathed to the world,

> "quo fit ut omnis
> Votiva pateat veluti descripta tabella
> Vita senis,"[1]

lose much of their force unless *senis* is to be taken in its ordinary sense,—which it cannot be if Lucilius died at the age of forty-six. Two explanations have been given of the error. One is that, from a similarity in the names of the consuls for the years 180 and 148 B.C., Jerome had confused the one year with the other, and thus that the date of the birth of Lucilius must be thrown back thirty-two years. He would thus have been nearly fifty when he served at Numantia, and when he first began to write satire. But the terms which Horace applies to the intimacy of Lucilius and Scipio, such as "discincti ludere," indicate the relations of an older to a much younger man; and the verve and tone of his satires are those of a man not so far advanced in years as he would have been if born in the year 180 B.C. A simpler explanation of the error is supported by Mr Munro, in the *Journal of Philology*, No. xvi. He supposes that Jerome must have written the words "anno xlvi" for "anno lxiv" or "lxvi"; which would make the birth of Lucilius eighteen or twenty years earlier than that usually assigned. Lucilius would thus have been about thirty-three or thirty-five years of age when he served at Numantia, and two or three years older when he gave his first satires to the world. As he lived for about thirty years longer, and as he seems to have continued the composition of his satires during most of what remained of his life, and as it was his practice to commit to them all his private thoughts, the words of Horace would naturally and truthfully describe the record of his observation and experience between the age of thirty-five and his death. His birthplace was Suessa Aurunca in Campania, from which circumstance Juvenal describes him as "magnus Auruncæ alumnus." He belonged to the equestrian order, a fact indicated by Horace's notice of himself as "infra Lucili censum." He was granduncle to Pompey, on the mother's side. Though not himself belonging to any of the great senatorian families, he was in a position to associate with them on equal terms, and to criticize them with independence. And this circumstance contributed to the boldness, originality, and thoroughly national character of his literary work. Had he been a "semi-Græcus," like Ennius and Pacuvius, or of humble origin, like Plautus, Terence, or Accius, he would scarcely have ventured, at a time when the senatorian power was strongly in the ascendant, to revive the rôle which had proved disastrous to Nævius; nor would he have had the intimate knowledge of the political and social life of his day which fitted him to be its painter. Another circumstance determining the bent of his mind to satire was the character of the time in which he began the work of his life. The origin of Roman political and social satire is to be traced to the same disturbing and disorganizing forces which led to the revolutionary projects and legislation of the Gracchi.

The remains of Lucilius extend to about eleven hundred lines. But much the largest number of his fragments are unconnected lines, preserved by late grammarians, as illustrative of peculiar verbal usages. He was, for his time, a voluminous as well as a very discursive writer. He left behind him thirty books of satires, and there is reason to believe that each book, like the books of Horace and Juvenal, was composed of different pieces. The order in which they were known to the grammarians was not that in which they were written. The earliest in order of composition were probably

[1] "And so it happens that the whole life of the old man stands clearly before us, as if it were represented on a votive picture."

those numbered from xxvi. to xxix., which were written in the trochaic and iambic metres that had been employed by Ennius and Pacuvius in their *Saturæ*. In these he made those criticisms on the older tragic and epic poets of which Horace and other ancient writers speak. In them too he speaks of the Numantine War as recently finished, and of Scipio as still living. Book i., on the other hand, in which the philosopher Carneades, who died in 128 B.C., is spoken of as dead, must have been written after the death of Scipio. With the exception of books xxvi.–xxix., and one satire in which he seems to have made an experiment in the unfamiliar elegiac metre, all the satires of Lucilius were written in hexameters. So far as an opinion can be formed from a number of unconnected fragments, he seems to have written the trochaic tetrameter with a smoothness, clearness, and simplicity which he never attained in handling the hexameter. The longer fragments produce the impression of great discursiveness and carelessness, but at the same time of considerable force. The words of Horace, "fluere lutulentum," seem exactly to express the character of his style. He appears, in the composition of his various pieces, to have followed no settled plan, but to have treated everything that occurred to him in the most desultory fashion, sometimes adopting the form of dialogue, sometimes that of an epistle or an imaginary discourse, and often to have spoken in his own name, giving an account of his travels and adventures, or of amusing scenes that he had witnessed, or expressing the results of his private meditations and experiences. Like Horace he largely illustrated his own observations by personal anecdotes and fables. The fragments clearly show how often Horace has imitated him, not only in expression, but in the form of his satires (see for instance i. 5 and ii. 2), in the topics which he treats of, and the class of social vices and the types of character which he satirizes. For students of Latin literature, the chief interest of studying the fragments of Lucilius consists in the light which they throw on the aims and methods of Horace in the composition of his satires, and, though not to the same extent, of his epistles. But they are important also as materials for linguistic study; and they have a considerable historical value as throwing light on the feeling, temper, circumstances, and character of a most interesting time, of which there is scarcely any other contemporary record.

The best edition of the *Fragments* is that of L. Müller (1872). A collection of them by Lachmann has appeared since his death. The emendation of these fragments still employs the ingenuity of both German and English scholars. Important contributions to the subject have been made by Mr Munro in the *Journal of Philology*. (W. Y. S.)

LUCIUS, the name of three popes.

LUCIUS I., whose pontificate of about eight months (253-54) fell between those of Cornelius and Stephen I., had been one of the presbyters who accompanied Cornelius when he withdrew from Rome. After his own election also he appears to have lived for some time in exile, but ultimately to have been permitted to return. No facts of his official life have been recorded, but he is referred to in several letters of Cyprian as having been in agreement with his predecessor Cornelius in preferring the milder view on the question as to how the penitent lapsed should be treated. The manner of his death is uncertain; according to some accounts he was decapitated. In the *Catalogus Liberianus* and in the *Catalogus Corbeiensis* he is said to have been pope for more than three years; but there can be no doubt of the correctness of the statement of Eusebius, that his pontificate was of less than eight months' duration. Like all the early popes he has been canonized in the Church of Rome; and he is commemorated as a martyr on March 4.

LUCIUS II. (Gherardo de Caccianimici), a Bolognese, succeeded Celestine II. on March 4, 1144. Soon after his accession the people of Rome chose a patrician, for whom they claimed the temporal sovereignty; Lucius at the head of the oligarchical party appealed to arms, and perished in an attempt to storm the Capitol on February 25, 1145. He was succeeded by Eugenius III.

LUCIUS III. (Ubaldo Allucingoli), a native of Lucca, was bishop of Ostia and Velletri when he was chosen to succeed Alexander III. on September 1, 1181. For six months he lived at Rome, but in March 1182 he was driven forth by rebellion, and resumed his abode at Velletri; he afterwards lived at Anagni, and finally at Verona. While at the last-named place he pronounced sentence of excommunication against the Cathari, Paterines, Humiliati, Waldensians, and Arnoldists in 1184; but "left the papal thunders to their own unaided effects." He died at Verona on November 25, 1185, and was succeeded by Urban III.

LÜCKE, GOTTFRIED CHRISTIAN FRIEDRICH (1791-1855), theologian, was born on August 24, 1791, at Egeln near Magdeburg, where his father was a merchant, received his early education at the Magdeburg gymnasium, and studied theology at Halle and Göttingen (1810-13). In 1813 he became repetent at Göttingen, and in 1814 he received the degree of doctor in philosophy from Halle; in 1816 he removed to Berlin, where he became licentiate in theology, and qualified as "privatdocent." He soon became intimate with Schleiermacher and De Wette, and was associated with them in 1818 in the redaction of the *Theologische Zeitschrift*. Meanwhile his lectures and publications (among the latter a *Grundriss der Neutestamentlichen Hermeneutik*, 1816) had brought him into considerable repute, and he was appointed professor extraordinarius in the new university of Bonn in the spring of 1818; in the following autumn he became professor ordinarius. From Bonn, where he had Augusti, Gieseler, and Nitzsch for colleagues, he was called to Göttingen to succeed Stäudlin in 1827. Here he remained, declining all further calls elsewhere, as to Erlangen, Kiel, Halle, Tübingen, Jena, and Leipsic, until his death, which occurred on February 14, 1855.

Lücke, who was one of the most learned, many-sided, and influential of the so-called "mediation" school of evangelical theologians, is now known chiefly by his principal work, an *Exposition of the Writings of St John*, of which the first edition, in four volumes, appeared in 1820-32; it has since passed through two new and improved editions (the last volume of the third edition by Bertheau, 1856). He is one of the most intelligent maintainers of the Johannine authorship of the Fourth Gospel; in connexion with this thesis he was one of the first to argue for the early date and non-apostolic authorship of the Apocalypse.

LUCKENWALDE, a busy little town of Prussia, in the province of Brandenburg, district of Potsdam, lies on the river Nuthe and on the Berlin and Anhalt Railway, 30 miles to the south-west of Berlin. Its cloth and wool manufactories are among the most extensive in Prussia, and it also contains cotton-printing works, dye-works, machine shops, and numerous other industrial establishments. The population in 1880 was 14,706. The site of Luckenwalde was occupied in the 12th century by a Cistercian monastery, but the village did not spring up till the reign of Frederick the Great. It was made a town in 1808.

LUCKNOW, a district of Oudh, in the division or commissionership of Lucknow,[1] under the jurisdiction of the lieutenant-governor of the North-Western Provinces, India, lying between 26° 30′ and 27° 9′ 30″ N. lat., and between 80° 36′ and 81° 15′ 30″ E. long., is bounded on the N. by Hardoi and Sítápur districts, on the E. by Bára Bánki, on the S. by Rái Bareli, and on the W. by Unao. The general aspect of the country is that of an open champaign, well studded with villages, finely wooded, and in parts most fertile and highly cultivated. In the vicinity of rivers, however, stretch extensive barren sandy tracts (*bhúr*), and there are many large sterile wastes of saline efflorescence (*usár*). The country is an almost dead level throughout, the average slope, which is from north-west to south-east, being less than a foot per mile. The principal rivers are the Gumti and the Sái, with their

[1] Lucknow division lies between 26° 9′ and 27° 21′ 5″ N. lat. and between 80° 5′ and 81° 54′ E. long., comprises the three districts of Lucknow, Unao, and Bára Bánki, and has an area of 4480 square miles, of which 2520 are returned as under cultivation. The population in 1869 was 2,838,106, viz., 2,449,763 Hindus, 383,260 Mohammedans, 4309 Europeans, and 784 Eurasians.

tributaries. The former enters the district from the north, and, after passing Lucknow city, turns to the east and enters Bára Bánki. The Sái forms the south-west boundary of the district, running almost parallel with the Gumti.

The census of 1869 returned the population of the district at 970,625. Recent changes and transfers to and from other districts have, however, taken place. Allowing for these, Lucknow contains (according to the census of 1869) a population of 789,465 persons (416,960 males and 372,505 females), spread over an area of 965 square miles. Hindus number 614,276; Mohammedans, 167,184; Christians, 4982; the remainder being made up of unclassified prisoners and jail officials. Four towns contain a population exceeding 5000 inhabitants, viz., Lucknow city, Amethi (7182), Kakori (8220), Malihábád (8026). The estimated area under cultivation is returned at 547 square miles. Three harvests are reaped in the year, viz., the *rabí* in spring, comprising wheat, barley, gram, peas, *gujai* (a mixture of wheat and barley), and *birra* (a mixture of barley and gram); the *kharíf* in the rainy season, comprising rice, millets, *sánwán*, *mandwá*, *kákun*, and Indian corn; and the *henwat* in the autumn, consisting of *joar*, *bájra*, *másh*, *múng*, *moth*, *masúr*, and *lobia*. In addition, there are valuable crops of tobacco, opium, cotton, spices, and vegetables. Irrigation is carried on by means of rivers, tanks, and wells. The cultivators are almost all deeply in debt, and under advances of seed grain from their landlords. Wages have remained stationary in the country, but have decreased in the city owing to its diminished wealth and population since the departure of the Oudh court. The price of food, on the other hand, has materially risen of late years. When not paid in grain, an ordinary agricultural labourer receives about 1½d. a day. Artisans, such as smiths and carpenters, receive 4½d. a day for work in their own villages, or 6d. a day if called away from their homes. Famines have occurred in Lucknow in 1769, 1784–86, and 1837, and severe scarcities in 1861, 1865–66, 1869, and 1873—all caused by drought. The district is well provided with communications by road, river, and railway. Three imperial lines of road branch out south, east, and north to Cawnpur, Faizábád, and Sítápur, metalled and bridged throughout, and comprising, exclusive of the roads in Lucknow city and cantonments, a length of about 500 miles. There are also seven principal local lines of road. River communication is not much used. The line of railway is comprised in the Oudh and Rohilkhand railway system. The entire length of railway communication is 52 miles. Manufactures are mainly confined to Lucknow city. In the country towns are a few weavers, dyers, bangle-makers, brass-workers, and potters. Cotton weaving has greatly declined since the introduction of European piece-goods. The principal imports are food-stuffs, piece-goods, arms, hardware, glass, crockery, and salt; while muslins, embroidery, cotton prints, brass vessels, lace, tobacco, &c., are exported. The district is administered by a deputy commissioner, aided by a magistrate in charge of the city, and a second in the cantonments, one or two assistant commissioners, three extra-assistant commissioners, three *tahsildárs*, and four honorary magistrates. Besides, there are a civil judge and a small-cause court judge, who have no criminal or revenue powers. The total imperial and local revenue of Lucknow district in 1871–72 amounted to £162,926, and the expenditure to £70,534; the Government land revenue was £70,580. Excluding Lucknow city, the schools consist of one Anglo-vernacular middle class, five vernacular middle class, and seventy-one primary schools. The prevailing endemic diseases are fevers, skin diseases, and bowel complaints. Cholera is seldom absent. Small-pox is also an annual visitant. The average annual rainfall is 37·6 inches, and the mean annual temperature 78°·8 Fahr.

Lucknow, capital of the above district, and of the province of Oudh, in 26° 52′ N. lat., 80° 58′ E. long., is distant from Cawnpur 42 miles, from Benares 199 miles, and from Calcutta 610 miles, and has an area of 13 square miles. It ranks fourth in size among Indian cities, being only surpassed by the presidency capitals of Calcutta, Madras, and Bombay. It stands on both banks of the Gumti, mostly on the western side, the river being spanned by four bridges, two of them built by native rulers and two since the British annexation in 1856. Viewed from a distance, the city presents a picture of unusual magnificence and architectural splendour, which fades on nearer view into something more like the ordinary aspect of a crowded Oriental town. From the new bridge across the Gumti, the city seems to be embedded in trees. High up the river the ancient stone bridge of Asaf-ud-daulá crosses the stream. To its left rise the walls of the Machí Bháwan fort, enclosing the Lachman *tílá* (Lachman's hill), the earliest inhabited spot in the city, from which it derives its modern name. Close by, the immense Imámbára, or mausoleum of Asaf-ud-daulá, towers above the surrounding buildings. Farther in the distance, the lofty minarets of the Jamá Masjíd or "cathedral mosque" overlook the city; while nearer again, on the same side of the river, the ruined walls of the residency, with its memorial cross, recall the heroic defence made by the British garrison in 1857. In front, close to the water's edge, the Chattar Manzil palace, a huge and irregular pile of buildings, crowned by gilt umbrellas, glitters gaudily in the sunlight; while to the left, at some little distance, two mausoleums flank the entrance to the Kaisar Bágh, the last of the overgrown palaces built by the exiled dynasty of Oudh. Still more picturesque panoramas may be obtained from any of the numerous towers and cupolas which abound in every quarter. But a nearer examination shows that Lucknow does not correspond in its interior arrangements to its brilliant appearance from a little distance. Nevertheless, many of its streets are broader and finer than those of most Indian towns; and the clearance effected for military purposes after the mutiny has been instrumental in greatly improving both the aspect and the sanitary condition of the city. A glacis half a mile broad surrounds the fort; and three military roads, radiating from this point as a centre, cut right through the heart of the native quarter, often at an elevation of some 30 feet above the neighbouring streets. Three other main roads also branch out from the same point, one leading across the bridge, and the others along the banks of the Gumti. The residency crowns a picturesque eminence, the chief ornament of the city, containing, besides many ruined walls, an old mosque and a magnificent banyan tree. An artificial mound rises near at hand, its sides gay with parterres of flowers, while in the rear, half hidden by the feathery foliage of gigantic bamboos, the graveyard covers the remains of some 2000 Europeans, who perished in 1857. The cantonments lie 3 miles to the south-east of the city.

The population of Lucknow, including the cantonments, was returned by the census of 1869 at 284,779. The native civil population consisted of 273,126, viz., 161,739 Hindus and 111,387 Mohammedans. There were also 3648 native soldiers, 4222 Europeans, 760 Eurasians, and 3023 prisoners and jail officials. The traffic of Oudh flows southwards through Lucknow to Cawnpur. Large quantities of grain and timber come in from the trans-Gogra districts to the north, while raw cotton, iron, and imported goods from the south and east are sent in exchange. In 1869–70 goods to the value of nearly three quarters of a million sterling paid taxes at the octroi office. The chief municipal taxable articles are food stuffs, *ghí*, *gúr* or molasses, sugar, spices, oilseeds, and tobacco; besides a large quantity of European manufactured articles brought into the town. Of the total municipal revenue in 1870–71 (£20,018), £16,230 was derived from octroi. Lucknow muslins and other textile fabrics have a high reputation. Gold and silver brocade, however, forms the leading manufacture. It is used for the numerous purposes of Indian pomp, and has a considerable market even in Europe. The gorgeous needlework embroidery upon velvet and cotton, with gold thread, thread and coloured silks, furnishes employment to many hands. Lucknow jewellery, once very famous, has declined since the departure of the native court. Glass work and moulding in clay still maintain their original excellence. A Kashmiri colony has introduced a small manufacture of shawls. The Oudh and Rohilkhand Railway, with its branches, has a central station in Lucknow, and gives direct communication with Benares, Bareilly, and Cawnpur, as well as connecting with the great trunk lines to Calcutta, Bombay, and the Punjab. Before the amalgamation of Oudh with the North-Western Provinces in 1877, Lucknow formed the residence of the chief commissioner and his staff, and it still ranks as the headquarters of officials whose authority extends over the whole province. The principal medical institutions are the King's hospital, Balrampur hospital, Government dispensary and lunatic asylum. The leading educational establishments are the Canning college, Martinière college, Ward's institution, Loretto convent, and a number of schools under the charge of the Church of England and American missions.

History.—The most interesting event in the modern history of Lucknow is the siege during the mutiny of 1857–58. Symptoms of disaffection occurred as early as April 1857, and Sir Henry Lawrence immediately took steps to meet the danger by fortifying the residency and accumulating stores. On the night of the 30th May the expected insurrection broke out; the men of the 71st regiment of native infantry, with a few from the other regiments, began to burn the bungalows of their officers, and to murder the inmates, but were dispersed by the European force and fled towards Sítápur. Though the city thus remained in the hands of the British, the symptoms of disaffection amongst the remaining native troops were unmistakable, and on June 11 the military police and native cavalry broke into open revolt, followed on the succeeding morning by the native infantry. On the 20th news of the fall of Cawnpur arrived; and on the 29th occurred the failure of Lawrence's attack upon the advancing enemy, in consequence of which the British troops fell back on Lucknow, abandoned the Machi Bháwan, and concentrated all their strength upon the residency. The siege of the enclosure began upon July 1. Three unsuccessful assaults were made by the mutineers on July 20, August 10, and August 18; but meanwhile the British within were dwindling away. On September 5 news of the relieving force under Outram and Havelock reached the garrison, and on the 22d the relief arrived at the Alambágh, a walled garden on the Cawnpur road held by the enemy in force. Havelock stormed the Alambágh, and on the 25th fought his way with continuous opposition through the narrow lanes of the city. On the 26th he arrived at the gate of the residency enclosure, and was welcomed by the gallant defenders within. The sufferings of the besieged had been very great; but even after the first relief it became clear that Lucknow could only be temporarily defended till the arrival of further reinforcements should allow the garrison to cut its way out. Night and day the enemy kept up a continual firing against the British position, while Outram, who had reassumed the command which he yielded to Havelock during the relief, retaliated by frequent sorties. Throughout October the garrison continued its gallant defence, and a small party, shut up in the Alambágh, and cut off unexpectedly from the main body, also contrived to hold good its dangerous post. Meanwhile Sir Colin Campbell's force had advanced from Cawnpur, and arrived at the Alambágh on the 10th of November. The Alambágh, the Dílkusha palace, south-east of the town, the Martinière, and the Sikandra Bágh, the chief rebel stronghold, were successively carried in the course of the six following days, and the second relief was successfully accomplished. Even now, however, it remained impossible to hold Lucknow, and Sir Colin Campbell determined, before undertaking any further offensive operations, to return to Cawnpur with his army, escorting the civilians, ladies, and children rescued from their long imprisonment in the residency, with the view of forwarding them to Calcutta. On the morning of the 20th November the troops received orders to march for the Alambágh; and the residency, the scene of so long and stirring a defence, was abandoned for a while to the rebel army. Outram with 3500 men held the Alambágh until the commander-in-chief could return to recapture the capital. The rebels in great strength again surrounded the greater part of the city, for a circuit of 20 miles, with an external line of defence. On the 2d of March 1858 Sir Colin Campbell found himself free enough in the rear to march once more upon Lucknow. He first occupied the Dílkusha, and posted guns to command the Martinière. On the 5th Brigadier Franks arrived with 6000 men; Outram's force then crossed the Gumti, and advanced from the direction of Faizábád, while the main body attacked from the south-east. After a week's hard fighting, March 9–15, the rebels were completely defeated, and their posts captured one by one.

LUCRETIUS (T. Lucretius Carus), more than any of the great Roman writers, has acquired a new interest in the present day. This result is due, not so much to a truer perception of the force and purity of his style, of the majesty and pathos of his poetry, or of the great sincerity of his nature, as to the recognition of the relation of his subject to many of the questions on which speculative curiosity is now engaged. It would be misleading to speak of him, or of the Greek philosophers whose tenets he expounds, as anticipating the more advanced scientific hypotheses of modern times. But it is in his poem that we find the most complete account of the chief effort of the ancient mind to explain the beginning of things, and to understand the course of nature and man's relation to it. Physical philosophy in the present day is occupied with the same problems as those which are discussed in the first two books of the *De Rerum Natura*. The renewed curiosity as to the origin of life, the primitive condition of man, and his progressive advance to civilization finds an attraction in the treatment of the same subjects in the fifth book. The old war between science and theology, which has been revived in the present generation, is fought, though with different weapons, yet in the same ardent and uncompromising spirit throughout the whole poem, as it is in the writings of living thinkers. In comparing the controversies of the present day with those of which we find the record in Lucretius, we are reminded of the poet's own description of the war of elements in the world,—

> "Denique, tantopere inter se cum maxima mundi
> Pugnent membra, pio nequaquam concita bello,
> Nonne vides aliquam longi certaminis ollis
> Posse dari finem?" [1]

But this concurrence with the stream of speculation in the present day is really the least of his permanent claims on the attention of the world. His position both among ancient and modern writers is unique. No one else combines in the same degree the contemplative enthusiasm of a philosopher, the earnest purpose of a reformer and moral teacher, and the profound pathos and sense of beauty of a great poet. He stands alone among his countrymen as much in the ardour with which he observes and reasons on the processes of nature as in the elevation of feeling with which he recognizes the majesty of her laws, and the vivid sympathy with which he interprets the manifold variety of her life. It would have been an instructive study to have traced some connexion between his personal circumstances and the intellectual and moral position which he holds. We naturally ask what influence of teachers in Rome or Athens first attracted him to this study and observation of natural phenomena, what early impressions or experience gave so sombre a colouring to his view of life, how far the delight, so strange in an ancient Roman, which he seems to find in a kind of recluse communion with nature, and the spirit of pathetic or indignant satire in which he treats the more violent phases of passion and the more extravagant modes of luxury, was a recoil from the fascination of pleasures in which his contemporaries and equals freely indulged. We should like also to know how far the serene heights which he professed to have attained procured him exemption from or alleviation of the actual sorrows of life. But such questions, suggested by the strong interest which the impress of personal feeling and character stamped on the poem awakens in the reader, can only be raised; there are no ascertained facts by which they can be settled. There is no ancient poet, with the exception of Homer, of whose history so little is positively known. Unlike Catullus, Horace, Virgil, Cicero, Tacitus, and nearly all the great Roman writers, he is absolutely silent on the subject of his own position and fortunes. Nor is this silence compensated by any personal reference to him in the works of his two eminent contemporaries by whom the social life of their age is so amply illustrated, Cicero and Catullus, although it is certain that each of them read his poem almost immediately after it was given to the world. The great poets of the following ages were influenced by his genius, but they tell us nothing as to his career. So consistently does he seem to have followed the maxim of his master, "Pass through life unnoticed," and to have realized, in the midst of the excited political, intellectual, and social life of the last years of the republic, the ideal of those "who do not wish to be known even while living." [2]

Our sole information concerning his life is found in the brief summary of Jerome, written more than four centuries after the poet's death. Scholars are now agreed that in these summaries, added to his translation of the Eusebian

[1] "In fine, as the mightiest members of the world are battling fiercely together in an unhallowed feud, seest thou not that some end of the long warfare may be reached by them?"

[2] Quoted from Pliny by M. Martha in *Le Poëme de Lucrèce*.

Chronicle, Jerome followed, often carelessly and inaccurately, the accounts contained in the lost work of Suetonius *De Viris Illustribus.* But that work was written about two centuries after the death of Lucretius; and, although it is likely that Suetonius used the information transmitted by earlier grammarians, there is nothing to guide us to the original sources from which the tradition concerning the life of Lucretius was derived. The strange character of the story which has been transmitted to us, and the want of any support to it from external evidence, oblige us to receive it with a certain reserve.

According to this account the poet was born in the year 94 B.C.; he became mad ("in furorem versus") in consequence of the administration of a love-philtre; and after composing several books in his lucid intervals, which were subsequently corrected by Cicero, he died by his own hand in the forty-fourth year of his age. The statement of Donatus in his life of Virgil, a work also based on the lost work of Suetonius, that Lucretius died on the 15th of October 55 B.C., the same day on which Virgil assumed the *toga virilis*, is inconsistent either with the date assigned for the poet's birth or with the age at which he is said to have died. A single mention of the poem (which from the condition in which it has reached us may be assumed to have been published posthumously) in a letter of Cicero's, written early in 54 B.C., is confirmatory of the date given by Donatus as that of the poet's death. Similar errors in chronology are common in the summaries of Jerome; and, where there is an inconsistency between the date assigned for the birth of any author and the age at which he is said to have died (as, for instance, in the case of Catullus), there are grounds for believing that the error lies in the first date. Taking the statements of Donatus and of Jerome together, we may consider it probable that Lucretius died in the October of 55 B.C., in the forty-fourth year of his age, and that he was born either late in the year 99 B.C. or early in the year 98 B.C. He would thus be about seven years younger than Cicero, a year or two younger than Julius Cæsar, about the same age as Memmius, to whom the poem is dedicated, and about fifteen years older than Catullus and Calvus, the younger poets of his generation, from whom he is widely separated both by his more archaic style and rhythm and by the greater seriousness of his art and the more earnest dignity of his character. The other statements of Jerome have been questioned or disbelieved on the ground of their intrinsic improbability. They have been regarded as a fiction invented in a later time by the enemies of Epicureanism, with the view of discrediting the most powerful work ever produced by any disciple of that sect. It is more in conformity with ancient credulity than with modern science to attribute a permanent tendency to derangement to the accidental administration of any drug, however potent. A work characterized by such strength, consistency, and continuity of thought is not likely to have been composed "per intervalla insaniæ." Donatus, in mentioning the poet's death, gives no hint of the act of suicide. The poets of the Augustan age, who were deeply interested both in his philosophy and his poetry, are entirely silent about the tragical story of his life. Cicero, by his professed antagonism to the doctrines of Epicurus, by his inadequate appreciation of Lucretius himself, and by the indifference which he shows to other contemporary poets, seems to have been neither fitted for the task of correcting the unfinished work of a writer whose genius was so distinct from his own, nor likely to have cordially undertaken such a task.

Yet these considerations do not lead to the absolute rejection of the story as a pure invention of a hostile and uncritical age. The evidence afforded by the poem rather leads to the conclusion that the tradition contains some germ of fact. We need not attach any importance to the supposed efficacy of the love-philtre in producing mental alienation, nor are we called upon to think of Lucretius as one liable to recurring fits of insanity, in the ordinary sense of the word. But it is remarkable, as was first observed by Mr Munro, his English editor, that in more than one passage of his poem he writes with extraordinary vividness of the impression produced both by dreams and by waking visions. It is true that the philosophy of Epicurus put great stress on these, as affording the explanation of the origin of supernatural beliefs. But the insistence with which Lucretius returns to the subject, and the horror with which he recalls the effects of such abnormal phenomena, suggest the inference that he himself may have been liable to such hallucinations, which are said to be consistent with perfect sanity, though they may be the precursors either of madness or of a state of despair and melancholy which often ends in suicide.[1] Other passages in his poem, as, for instance, the lines

> "Nos agere hoc autem, et naturam quærere rerum,
> Semper et inventam patriis exponere chartis,"[2]

where he describes himself as ever engaged, even in his dreams, on his task of inquiry and composition, produce the impression of an unrelieved strain of mind and feeling, which may have ended in some extreme reaction of spirit, or in some failure of intellectual power, from the consciousness of which he may, in accordance with examples which he himself quotes, have taken refuge in suicide. But the strongest confirmation of the existence of some germ of fact in the tradition is found in the unfinished condition in which the poem has reached us. The subject appears indeed to have been fully treated in accordance with the plan sketched out in the introduction to the first book. But that book is the only one which is finished in style and in the arrangement of its matter. In all the others, and especially in the last three, the continuity of the argument is frequently broken by passages which must have been inserted after the first draft of the arguments was written out. Thus, for instance, in his account of the transition from savage to civilized life, he assumes at v. 1011 the discovery of the use of skins, fire, &c., and the first beginning of civil society, and proceeds at 1028 to explain the origin of language, and then again returns, from 1090 to 1160, to speculate upon the first use of fire and the earliest stages of political life. These breaks in the continuity of the argument show what might also be inferred from frequent repetitions of lines which have appeared earlier in the poem, and from the rough workmanship of passages in the later books, that the poem could not have received the final revision of the author, and must have been given to the world by some editor after his death. Nor is there any great difficulty in believing that that editor was Cicero. It is not necessary to press the meaning of the word "emendavit" as applied to the task fulfilled by him. Cicero certainly was incapable of "improving" any of the poetry of Lucretius, and the slight mention which he makes of the poem in a letter to his brother ("the poem of Lucretius is, as you describe it, a work not of much genius but of much art"[3]) seems to imply that he was not very capable of appreciating it. But other motives, besides appreciation of the poet's genius or sympathy with his doctrines, may have induced

[1] *Cf. Fortnightly Review*, September 1878.

[2] "While I seem to be ever busily plying this task, to be inquiring into the nature of things, and to be expounding my discoveries by writings in my native tongue."

[3] The reading is so uncertain that it is doubtful whether it is the claim of genius or of art that Cicero refuses to concede. Some interpretations of the passage imply that he conceded both.

him to undertake a task which has not been very successfully performed. It may be remarked further that scepticism as to statements about their lives is less warranted in the case of the great Roman than of the great Greek writers, from the fact that the work of criticism went on at Rome contemporaneously with the progress of original creation, and that the line of grammarians and commentators by whom these statements were transmitted continued unbroken almost from the first beginning of Latin literature.

We find in the instance of nearly all the other Latin poets, even of the most obscure among them, that their birthplace has been recorded, and it has often been remarked that Latin poetry was an Italian and provincial rather than a purely Roman product. From the absence of any claim on the part of any other district of Italy to the honour of having given birth to Lucretius it is inferred that he was an exception to the rule, and was of purely Roman origin. No writer certainly is more purely Roman in personal character and in strength of understanding. He seems to speak of Rome as his native state in such expressions as "patriai tempore iniquo," "patrii sermonis egestas," and "patriis chartis." His silence on the subject of Roman greatness and glory as contrasted with the prominence of these subjects in the poetry of men of provincial birth such as Ennius, Virgil, and Horace, may be explained by the principle that the familiarity of long-inherited traditions had made the subject one of less wonder and novelty to him. The Lucretian *gens* to which he belonged was one of the oldest of the great Roman houses, nor do we hear of the name, as we do of other great family names, as being diffused over other parts of Italy, or as designating men of obscure or servile origin. It seems from the evidence of the name, confirmed by the tone in which he writes, as probable as any such inference can be that Lucretius was a member of the Roman aristocracy, belonging either to a senatorian or to one of the great equestrian families, living in easy circumstances, and familiar with the spectacle of luxury and artistic enjoyment which the great houses of Rome and the great country houses in the most beautiful parts of Italy presented. If the Roman aristocracy of his time had lost much of the virtue and of the governing qualities of their ancestors, they showed in the last years before the establishment of monarchy a taste for intellectual culture which might have made Rome as great in literature as in arms and law, if the republic could have continued. The discussions which Cicero puts in the mouth of Velleius, Cotta, &c., indicate the new taste for philosophy developed among members of the governing class during the youth of Lucretius; and we hear of eminent Greek teachers of the Epicurean sect being settled at Rome at the same time, and living on terms of intimacy with them. The inference that Lucretius belonged to this class, and shared in the liberal culture which it received, is confirmed by the tone in which he addresses Memmius, a man of an eminent senatorian family, and of considerable oratorical and poetical accomplishment, to whom the poem is dedicated. His tone to Memmius is quite unlike that in which Virgil or even Horace addresses Mæcenas. He addresses him as an equal; he expresses sympathy with the prominent part his friend played in public life, and admiration for his varied accomplishment, but on his own subject claims to speak to him in the tones of authority.

Although our conception of the poet's life and circumstances is necessarily vague and meagre, yet his personal force is so remarkable and so vividly impressed on his poem, and his language bears so unmistakably the stamp of sincerity, that we seem able to form a consistent idea of his tastes and habits, his sympathies and convictions, his moral and emotional nature. If we know nothing of the particular experience which determined his passionate adherence to the Epicurean creed and his attitude of spiritual and social isolation from the ordinary course of Roman life and belief, we can at least say that the choice of a contemplative life was not the result of indifference to the fate of the world, or of any natural coldness or even calmness of temperament. In some of his most powerful poetry, as in the opening lines of the second and of the third books, we can mark the strong recoil of a humane and sensitive spirit from the horrors of the reign of terror which he witnessed in his youth, and from the anarchy and confusion which prevailed at Rome during the later years of his life; while his vivid realization of the pains and disappointments of passion, of the unsatisfying nature of all violent emotion, and of the restlessness and weariness of life which excessive luxury entails, suggest at least the inference that he had not been through his whole career so much estranged from the social life of his day as he seems to have been in his later years. Passages in his poem attest his familiarity with the pomp and luxury of city life, with the attractions of the public games, and with the pageantry of great military spectacles. But much the greater mass of the illustrations of his philosophy scattered through the poem indicate that, while engaged in its composition, and in the studies preparatory to it, he must have lived in the country or by the sea-shore, and that he must have passed much of his time in the open air, exercising at once the keen observation of a naturalist and the contemplative vision of a poet. He shows a fellow feeling with the habits and moods of the animals associated with human toil and adventure. He seems to have found a pleasure, more congenial to the modern than to the ancient temperament, in ascending mountains or wandering among their solitudes (vi. 469, iv. 575). References to companionship in these wanderings, and the well-known description of the charm of a rustic meal (ii. 29) enjoyed with comrades amid beautiful scenery and in fine weather, speak of kindly sociality rather than of any austere separation from his fellows.

Other expressions in his poem (*e.g.*, iii. 10, &c.) imply that he was an ardent student of books, as well as a sympathetic observer of outward phenomena. Foremost among these were the writings of his master Epicurus; but he had also an intimate knowledge and appreciation of the philosophical poem of Empedocles, and at least an acquaintance with the works of Democritus, Anaxagoras, Heraclitus, Plato, and the Stoical writers. Of other Greek prose writers he knew Thucydides and Hippocrates; while of the poets he expresses in more than one passage the highest admiration of Homer, whom he has imitated in several places. Next to Homer Euripides is most frequently reproduced by him. There is an evident struggle between the impulses of his imaginative temperament, prompting him to recognize the supremacy of the great masters in art and poetry, and the influence of the teaching of Epicurus, in accordance with which the old poets and painters of Greece are condemned as the authors and propagators of false ideas both of nature and the gods. But his poetical sympathy was not limited to the poets of Greece. For his own countryman Ennius he expresses an affectionate admiration; and he imitates his language, his rhythm, and his manner in many places. The fragments of the old tragedian Pacuvius and of the satirist Lucilius show that Lucretius had made use of their expressions and materials. In his studies he was attracted by the older writers, both Greek and Roman, in whose masculine temperament and understanding he recognized an affinity with his own. He had a most enthusiastic admiration for genius, especially when exercised in the investigation and discovery of truth. His devotion to Epicurus seems at first sight more difficult to explain than his enthusiasm for Empedocles or Ennius. Probably he found in his calmness of temperament, in his natural or acquired indifference to all violent emotion, even in his want of imagination, a sense of rest and of exemption from the disturbing influences of life which the passionate heart of the poet denied himself; while in his physical philosophy he found both an answer to the questions which perplexed him and an inexhaustible stimulus to his intellectual curiosity. The combative energy, the sense of superiority, the spirit of satire, characteristic of him as a Roman, unite with his loyalty to Epicurus to render him not only polemical but intolerant and contemptuous in his tone toward the great antagonists of his system, the Stoics, whom, while constantly referring to them, he does not condescend even to name. With his admiration of the genius of others he combines a strong sense of his own power. He is quite conscious of the great importance and of the difficulty of his task; but he feels his own ability to cope with it. He has the keenest capacity for intellectual pleasure, and speaks of the constant charm which he found both in the collection of his materials and in the exercise of his art. If his mind was overstrained by the incessant devotion to his task of which he speaks, he allows no expression of fatigue or discouragement to escape from him. The ardour of study, the delight in contemplative thought, the "sweet love of the muses," the "great hope of fame," all combined to bear him buoyantly through all the difficulties and fatigues of his long and lonely adventure.

It is more difficult to infer the moral than the intellectual characteristics of a great writer from the personal impress left by him on his work. Yet it is not too much to say that there is no work in any literature that produces a profounder impression of sincerity. No writer shows a juster scorn of all mere rhetoric and exaggeration. This is one of the main causes of the spell which the poem exercises over us. By no Stoic even could the doctrine of independence of the world, and of the superiority of simplicity over show and luxury, be more forcibly and consistently inculcated. No one shows truer courage, not marred by irreverence, in confronting the great problems of human destiny, or greater strength in triumphing over human weakness. No one shows a truer humanity and a more tender sympathy with natural sorrow. In reverence for the sanctities of human affection, Virgil alone is his equal, nor is it an unlikely surmise that it was to the power of this sentiment, and the influence which it had on his relation with others, that he owed the *cognomen* of "Carus"[1] or the "beloved."

The peculiarity of the poem of Lucretius, that which makes it unique in literature, is that it is a reasoned system of philosophy, written in verse. The subject was chosen and the method of exposition adopted, not primarily with the idea of moving and satisfying the imagination, but of communicating truth. The prosaic title *De Rerum Natura*, a translation of the Greek περὶ φύσεως, implies the subordination of the artistic to a speculative motive. As in the case of nearly all the great works of Roman literary genius, the form of the poem was borrowed from the Greeks. The rise of speculative philosophy in Greece was coincident with the beginning of prose composition, and many of the earliest philosophers gave their thoughts to the world in the prose of the Ionic dialect; others however, and especially the writers of the Greek colonies in Italy and Sicily, expounded their systems in continuous poems composed in the epic hexameter. These writers flourished in the beginning and first half of the 5th century B.C.,—the great awakening time of the intellectual, imaginative, and artistic faculties of the ancient world. The names most famous in connexion with this kind of poetry are those of Xenophanes and Parmenides, the Eleatics, and that of Empedocles of Agrigentum. The last was less important as a philosopher, but greater than the others both as a poet and a physicist. On both of these grounds he had a greater attraction to Lucretius. The fragments of the poem of Empedocles show that the Roman poet regarded that work as his model. In accordance with this model he has given to his own poem the form of a personal address, he has developed his argument systematically, and has applied the sustained impetus of epic poetry to the treatment of some of the driest and abstrusest topics. Many ideas and expressions of the Sicilian have been reproduced by the Roman poet; and the same tone of impassioned solemnity and melancholy seems to have pervaded both works. But Lucretius, if less original as a thinker, was probably a much greater poet than Empedocles. With the speculative enthusiasm of the Greeks he combines, in a remarkable measure, the Italian susceptibility to the charm of nature, and the greater humanity of feeling which belongs to a more advanced stage of human history. But what chiefly distinguishes him from his Greek prototypes is that his purpose is rather ethical than purely speculative. He shares with them the delight in inquiry and discovery; but the zeal of a teacher and reformer is more strong in him than even the intellectual passion of a thinker. His speculative ideas, his moral teaching, and his poetical power are indeed interdependent on one another, and this interdependence is what mainly constitutes their power and interest. But of the three claims which he makes to immortality,—

> "Primum quod magnis doceo de rebus, et artis
> Religionum animum nodis exsolvere pergo,
> Deinde quod obscura de re tam lucida pango
> Carmina musæo contingens cuncta lepore,—"[2]

that which he himself regarded as supreme was the second,—the claim of a liberator of the human spirit from the cramping bonds of superstition.

This purpose is announced by him over and over again, as for instance at the beginning of the argument in the first, second, third, and sixth books. The main idea of the poem is the irreconcilable opposition between the truth of the laws of nature and the falsehood of the old superstitions. But it is not merely by the intellectual opposition between truth and falsehood that he is moved. The happiness and the dignity of life are regarded by him as absolutely dependent on the acceptance of the true and the rejection of the false doctrine. The ground of his extravagant eulogies of Epicurus is that he recognized in him the first great champion in the war of liberation, and in his system of philosophy he believed that he had found the weapons by which this war could be most effectually waged. Following in his footsteps, he sets before himself the aim of finally crushing that fear of the gods and that fear of death resulting from it which he regards as the source of all the human ills. Incidentally he desires also to purify the heart from other violent passions which corrupt it and mar its peace. But the source even of these—the passions of ambition and avarice—he finds in the fear of death; and that fear he resolves into the fear of eternal punishment after death.

The selection of his subject and the order in which it is treated are determined by this motive. Although the title

[1] *Cf.* Martha, *Le Poëme de Lucrèce*, p. 28

[2] "First, by reason of the greatness of my argument, and my purpose to set free the mind from the close drawn bonds of superstitions; next, because on so dark a theme I write such lucid verse, casting over all the charm of poesy."

of the poem implies that it is a treatise on the "whole nature of things," the aim of Lucretius is not to treat exhaustively the whole of natural science, recognized in the Epicurean system, but only those branches of it which are necessary to clear the mind from the fear of the gods and the terrors of a future state. In the two earliest books, accordingly, he lays down and largely illustrates the first principles of being with the view of showing that the world is not governed by capricious agency, but has come into existence, continues in existence, and will ultimately pass away in accordance with the primary conditions of the elemental atoms which, along with empty space, are the only eternal and immutable substances. These atoms are themselves infinite in number but limited in their varieties, and by their ceaseless movement and combinations during infinite time and through infinite space the whole process of creation is maintained. In the third book he applies the principles of the atomic philosophy to explain the nature of the mind and vital principle, with the view of showing that the soul perishes with the body. In the fourth book he discusses the Epicurean doctrine of the "simulacra," or images, which are cast from all bodies, and which act either on the senses or immediately on the mind, in dreams or waking visions, as affording the explanation of the belief in the continued existence of the spirits of the departed. The fifth book, which has the most general interest, professes to explain the process by which the earth, the sea, the sky, the sun, moon, and stars, were formed, the origin of life, and the gradual advance of man from the most savage to the most civilized condition. All these topics are treated with the view of showing that the world is not itself divine nor directed by divine agency. The sixth book is devoted to the explanation, in accordance with natural causes, of some of the more abnormal phenomena, such as thunderstorms, volcanoes, earthquakes, &c., which are special causes of supernatural terrors.

It would be impossible, within the limits of this article, to give any detailed account or criticism of an argument which is carried on, with the interruption only of occasional episodes, in which the moral teaching of the poet is enforced, through a poem extending to between six and seven thousand lines. Readers who are especially interested in the science of Lucretius will find the subject clearly treated in chapter v. of Lange's *History of Materialism.* The consecutive study of the argument produces on most readers a mixed feeling of dissatisfaction and admiration. They are repelled by the dryness of much of the matter, the unsuitableness of many of the topics discussed for poetic treatment, the arbitrary assumption of premisses, the entire failure to establish the connexion between the concrete phenomena which the author professes to explain and these assumptions, and the erroneousness of many of the doctrines which are stated with dogmatic confidence. On the other hand they are constantly impressed by his power of reasoning both deductively and inductively, by the subtlety and fertility of invention with which he applies analogies, by the clearness and keenness of his observation, by the fulness of matter with which his mind is stored, and by the consecutive force, the precision, and distinctness of his style, when employed in the processes of scientific exposition. The first two books enable us better than anything else in ancient literature to appreciate the boldness and, on the whole, the reasonableness of the ancient mind in forming hypotheses on great matters that still baffle the investigations of science. The third and fourth books give evidence of acuteness in psychological analysis; the fourth and sixth of the most active and varied observation of natural phenomena; the fifth of original insight and strong common sense in conceiving the origin of society and the progressive advance of man to civilization. But the chief value of Lucretius as a thinker lies in his firm grasp of speculative ideas, and in his application of them to the interpretation of human life and nature. It is in this application that the most powerful interest of his poetry lies. All phenomena, moral as well as material, are contemplated by him in their relation to one great organic whole, which he acknowledges under the name of "Natura dædala rerum," and the most beneficent manifestations of which he seems to symbolize and almost to deify in the "Alma Venus," whom, in apparent contradiction to his denial of a divine interference with human affairs, he invokes with prayer in the opening lines of the poem. In this conception of nature are united the conceptions of law and order, of ever-changing life and interdependence, of immensity, individuality, and all-pervading subtlety, under which the universe is apprehended both by his intelligence and his imagination.

Nothing can be more unlike the religious and moral attitude of Lucretius than the old popular conception of him as an atheist and a preacher of the doctrine of pleasure. It is true that he denies the two bases of all religion, the doctrines of a supernatural government of the world and of a future life. But his arguments against the first are really only valid against the limited and unworthy conceptions of divine agency involved in the ancient religions; his denial of the second is prompted by his vivid realization of all that is meant by the arbitrary infliction of eternal torment after death. His war with the popular beliefs of his time is waged, not in the interests of licence, but in vindication of the sanctity of human feeling. The great and cardinal line of the poem,

"Tantum religio potuit suadere malorum,"

is elicited from him as his protest against the wicked and impious sacrifice of Iphigenia by the hand of her father. But in his very denial of a cruel, limited, and capricious agency of the gods, and in his imaginative recognition of an orderly, all-pervading, all-regulating power,—the "Natura dædala rerum,"—we find at least a nearer approach to the higher conceptions of modern theism than in any of the other imaginative conceptions of ancient poetry and art, unless we include the hymn of Cleanthes among the utterances of poets. But his conception even of the ancient gods and of their indirect influence on human life is more worthy than the popular one. They are conceived of by him as living a life of eternal peace and exemption from passion, in a world of their own; and the highest ideal of man is, through the exercise of his reason, to realize an image of this life,

"Ut nil impediat dignam dis degere vitam."

Although they are conceived of as unconcerned with the interests of our world, yet influences are supposed to emanate from them which the human heart is capable of receiving and assimilating. The effect of unworthy conceptions of the divine nature is that they render a man incapable of visiting the temples of the gods in a calm spirit, or of receiving the emanations "divinæ nuntia pacis" in peaceful tranquillity.

"Nec delubra deum placido cum pectore adibis,
Nec de corpore quæ sancto simulacra feruntur
In mentis hominum divinæ nuntia pacis
Suscipere hæc animi tranquilla pace valebis." [1]

It is in no iconoclastic spirit that he regards even the temples and solemn rites of the gods, except when he finds the acts of worship tainted with "the foul stain of super-

[1] "Nor wilt thou approach the temples of the gods with a calm spirit, nor wilt thou be able, in tranquil peace of heart, to receive those images which are borne from their holy bodies into the minds of men, carrying tidings of the divine peace" (vi. 75–78).

stition." Thus he describes with a grave solemnity of feeling the procession of the image of Cybele through the cities of men, and acknowledges the beneficent influence of the truths symbolized by that procession. The supposed "atheism" of Lucretius proceeds from a more deeply reverential spirit than that of the majority of professed believers in all times.

His moral attitude is also far removed from that either of ordinary ancient Epicureanism or ordinary modern materialism. Though he acknowledges pleasure to be the law of life,—"dux vitæ dia voluptas,"—yet he is far from regarding its attainment as the end of life. What man needs is not enjoyment, but "peace and a pure heart."

"At bene non poterat sine puro pectore vivi."

The victory to be won by man is the triumph over fear, ambition, passion, luxury. With the conquest over these nature herself supplies all that is needed for happiness. Self-control and renunciation are the lessons which he preaches with as much fervour and as real conviction as any of the preachers of Stoicism. "Great riches consist in living plainly with a contented spirit"—

"Divitiæ grandes homini sunt vivere parce
Æquo animo."

As was mentioned above, it is uncertain whether the short criticism of Cicero ("Lucretii poemata," &c.) concedes to Lucretius the gifts of genius or the accomplishment of art. Readers of a later time, who could compare his work with the finished works of the Augustan age, would, if they refused his claim to the full possession of the two necessary constituents of the greatest poets, have certainly disparaged his art rather than his power. But with Cicero it was different. He greatly admired, or professed to admire, the genius of the early Roman poets, while he shows that indifference to the poetical genius of his younger contemporaries which men who have formed their taste for poetry in youth, and whose own intellectual interests have been practical and political, often do to the new ideas and new modes of feeling which an original poet brings into the world. On the other hand, as one who had himself written many verses in his youth, and as one of the greatest masters of style who have ever lived, he could not have been insensible to the immense superiority in rhythmical smoothness which the hexameter of Lucretius has over that of Ennius and Lucilius. And no reader of Lucretius can doubt that he attached the greatest importance to artistic execution, and that he took a great pleasure, not only in propelling "the long roll of his hexameter" to its culminating break at the conclusion of some weighty paragraph, but also in producing the effects of alliteration, assonance, &c., which are so marked a peculiarity in the style of Plautus and the earlier Roman poets. He allows his taste for these tricks of style, which, when used with moderation by writers of a more finished sense of art such as Virgil and even Terence, have the happiest effect, to degenerate into mannerism. And this is the only drawback to the impression of absolute spontaneity which his style produces. But those who recognize in him one of the most powerful and original poetical forces which have appeared in the world feel, when they compare him with the greatest poets of all times, that he was unfortunate in living before the natural rudeness of Latin art—the "traces of the country," which continued to linger "in rude Latium" down to the time of Horace—had been successfully grappled with. His only important precursors in serious poetry were Ennius and Lucilius, and, though he derived from the first of these an impulse to shape the Latin tongue into a fitting vehicle for the expression of elevated emotion and imaginative conception, he could find in neither a guide to follow in the task he set before himself. He had thus, in a great measure, to discover the way for himself, and to act as the pioneer to those who came after him. The difficulty and novelty of his task enhances our sense of his power. His finest passages are thus characterized by a freshness of feeling and enthusiasm of discovery, as of one ascending, alone and for the first time, the "pathless heights of the Muses."[1] But the result of these conditions and of his own inadequate conception of the proper limits of his art is that more than in the case of any other work of genius his best poetry is clogged with a great mass of alien matter, which no treatment in the world could have made poetically endurable. If the distinction suggested by a brilliant living poet and critic between the Titans and the Olympians of literature be a valid one, it is among the former certainly that Lucretius is to be classed.

The genius of Lucretius, as of all the greatest poets, does not reveal itself as any mere isolated or exceptional faculty, but as the impassioned and imaginative movement of his whole moral and intellectual being. It is the force through which the sincerity and simplicity, the reverence, the courage, the whole heart of the man have found an outlet for themselves. It is also the force from which both his speculative and his observant faculty derive their most potent impulse. His poetical style is as simple, sensuous, and passionate as that of the poets who reproduce only the immediate appearances and impressions of the world of nature and of human feeling. But it assumes a more majestic and elevated tone from the recognition of the truth that the beauty of the world, the unceasing life and movement in nature, the destructive as well as the beneficent forces of the elements, the whole wonder and pathos of human existence, are themselves manifestations of secret invisible agencies and of eternal and immutable laws.

The fullest account of the MSS. and of the various editions of Lucretius, and of the influence which he exercised on the later poets of Rome, is to be found in the introductions to the critical and explanatory notes of Mr Munro's edition of the poet, a work recognized as the most important contribution to Latin scholarship made in England during the present century. For scholars that edition contains all that is needed for the full understanding of the author. For those who are not classical scholars, the work of C. Martha, *Le Poëme de Lucrèce*, may be recommended, as containing an interesting and eloquent estimate of the genius of the poet, and of his moral, religious, and scientific position. Among recent English works on the author, an essay, by Professor Veitch, and one by Mr J. A. Symonds, are especially good. The subject is also discussed at length in chaps. xi.-xiv. of the *Roman Poets of the Republic*, by Professor Sellar. (W. Y. S.)

LUCULLUS. The Luculli appear in Roman history shortly after the close of the second Punic war. They belonged to the Licinian "gens," a plebeian house which became noted for its special ability in amassing wealth. By far the most famous of its members was Lucius Licinius Lucullus, surnamed Ponticus from his victorious campaigns in Asia Minor against one of the most formidable enemies Rome ever encountered, the great Mithridates, king of Pontus. His father had held an important military command in Sicily, but on his return to Rome he was considered to have acquitted himself so discreditably that he was prosecuted on a charge of bribery and corrupt practices, and was condemned to exile. His mother was Cæcilia, of the family of the Metelli, and was the sister of the distinguished Metellus Numidicus. The career of Lucullus coincides with the first half of the 1st century B.C. It appears that he was rather senior to Pompey, who was born in 106 B.C. We hear of him when quite a young man as making a determined though unsuccessful attempt to avenge his father's downfall on the author of the prosecution, and this won him credit and popularity. Early in life he attached himself to the party of Sulla, and to that party

[1] "Avia Pieridum peragro loca, nullius ante
Trita solo."

he remained constant to his life's end. Sulla's favourable notice was secured by good military service in the so-called Social War, which finally completed the subjugation of Rome's Italian allies and in fact of the whole peninsula. In 88 B.C. came the great Mithridatic war in the East, with the direction of which Sulla was charged. In that year the young Lucullus went with him as his quæstor to Greece and Asia Minor, and, while Sulla was besieging Athens, he raised a fleet and drove Mithridates out of the Mediterranean. He won a brilliant victory off Tenedos, and it seems probable that, had he been as faithful to Rome as he was to Sulla and his party, he might have ended a perilous war. But, like many of his contemporaries, Lucullus was too much of a party man to be a genuine patriot.

In 84 B.C. peace was concluded with Mithridates, and the great king had to cede the Greek islands and a large part of his Asiatic possessions, and was practically reduced to the position of a mere Roman dependant. Sulla returned to Rome, while Lucullus remained in Asia, and by a series of wise and generous financial reforms laid the foundation of the future wealth and prosperity of the province. The result of his policy was that he stood particularly well with the provincials, but unfortunately for himself made a host of enemies among the powerful class which farmed the public revenue. He was in Asia till 80 B.C., and then returned to Rome as curule ædile, in which capacity he exhibited together with his colleague, his brother Marcus, games which were long remembered by the citizens of Rome for their exceptional magnificence. We may infer that thus early in life he had found the means of acquiring an immense fortune, which throughout his whole career it was his delight lavishly to display. Soon afterwards he was elected prætor, and was next appointed to the province of Africa, where again he won a good name as a just and considerate governor. In the year 74 B.C. he became consul, with Aurelius Cotta as his colleague. An attempt was made at this time by a leader of the democratic party to repeal the legislation of Sulla, and its failure appears to have been mainly due to the strenuous efforts of Lucullus.

The East was now again unsettled, and Bithynia, which had been bequeathed to Rome by its king Nicomedes, was threatened by Mithridates. The new province with the command of the fleet fell to Cotta, but Lucullus was called to lead the armies of Rome against this dangerous enemy. In 74 B.C. he was in Asia at the head of a force of about 30,000 foot and 2000 horse. The king of Pontus was already on Roman ground in Bithynia, and Cotta was shut up in Chalcedon on the Propontis by a vast host of 150,000 men. The enemy's fleet had forced its way into the harbour, and had burnt all the Roman vessels lying at anchor. The advance of Lucullus, however, forced the king to raise the siege and retire along the sea-coast, till he halted before the strong city of Cyzicus, the key of Asia, as it was called, built on an island at a little distance from the mainland, with which it was connected by a bridge. All the attempts of Mithridates on the place were foiled by a gallant defence, and it was not long before Lucullus took up a threatening position in the rear of his army, which cut off all his land communications and left him only master of the sea. Bad weather and violent storms and scant supplies soon drove the king from the walls of Cyzicus, and his vast army was dispersed without having had the chance of fighting a single pitched battle. His fleet too, which as yet had had the command of the Ægean, was soon afterwards destroyed by Lucullus, and thus his whole power for offensive warfare had completely collapsed. He himself withdrew into his own proper territory, and all that the Roman general had to fear was that he might baffle pursuit by a flight eastward into the remote wilds of Armenia. However, in the autumn of 73 B.C., Lucullus pushed into the heart of Pontus far beyond the Halys, the limit of the famous Scipio's advance eastward, and continued his onward march, regardless of the murmurs of his weary soldiery, to Cabeira or Neocæsarea (now Niksar), where the king had gone into winter quarters with a vague hope that his son-in-law, Tigranes, the powerful king of Armenia, and possibly even the Parthians, might, for their own sakes, come to his aid against a common foe. It was by a very toilsome march through difficult roads that the Roman army at last reached Cabeira, to find themselves confronted by a greatly superior force. But the troops of Mithridates were no more a match for the Roman legionaries than were the Persians for Alexander, and a large detachment of his army was decisively cut up by one of Lucullus's lieutenant-generals. The king decided on instant retreat, but the retreat soon became a disorderly flight, and Lucullus, seizing the moment for attack, annihilated his enemy, Mithridates himself escaping with difficulty over the mountain range between Pontus and Cappadocia into Lesser Armenia. He found a sort of refuge in the dominions of Tigranes, but he was in fact detained as a prisoner rather than received as an honoured friend and ally.

Pontus thus, with the exception of some of the maritime cities, such as Sinope, Heraclea, and Amisus, which still clung to the king under whom they had enjoyed a free Greek constitution, became Roman territory. Two years were occupied in the siege and capture of these strongholds, while Lucullus busied himself with a general reform of the administration of the province of Asia. His next step was to demand the surrender of Mithridates and to threaten Tigranes with war in the event of refusal. He had indeed no direct authority from the home government to attempt the conquest of Armenia, but he may well have supposed that in invading the country he would be following out Sulla's policy, and securing Rome in the East from a serious danger. Nor was it unnatural that there should be a fascination in the idea of winning renown in the distant and almost unknown regions beyond the Euphrates. In the spring of the year 69 B.C., at the head of only two legions, which, it appears, by no means liked the hardships of the expedition, he marched through Sophene, the south-western portion of Armenia, crossed the Tigris, and pushed on to the newly-built royal city, Tigranocerta, situated on one of the affluents of that river. A motley host, made up out of the tribes bordering on the Black Sea and the Caspian, hovered round his small army, but failed to hinder him from laying siege to the town. On this occasion Lucullus showed consummate military capacity, contriving to maintain the siege and at the same time to give battle to the enemy with a force which must have been inferior in the ratio of something like one to twenty. According to his own account he put the Armenians to rout with a loss of five Roman soldiers, leaving 100,000 dead on the field of battle. The victory before the walls of Tigranocerta was undoubtedly a very glorious one for the arms of Rome, and it resulted in the dissolution of the Armenian king's extensive empire. There might now have been peace but for the interference of Mithridates, who for his own sake pressed Tigranes to renew the war and to seek the aid and alliance of Parthia. The Parthian king, however, was disposed to prefer a treaty with Rome to a treaty with Armenia, and desired simply to have the Euphrates recognized as his western boundary. Mithridates next appealed to the national spirit of the peoples of the East generally, and endeavoured to rouse them to a united effort against Roman aggression. He hoped to crush his enemy amid the mountains of Armenia, and indeed the position of Lucullus was highly critical. The home government was for recalling him, and seemed to think little of his splendid successes; and his little army, which one might have been supposed would have been proud of their general, was on the verge of mutiny. One can hardly understand how under such circumstances Lucullus should have persisted in marching his men northwards from Tigranocerta over the high table-land of central Armenia, with the enemy's cavalry and innumerable mounted archers hanging on his columns, in the hope of reaching the distant Artaxata on the Araxes. The vexation of his troops broke out into an open mutiny, which compelled him to recross the Tigris into the Mesopotamian valley. Here, on a dark tempestuous night, he surprised and stormed Nisibis, the capital of the Armenian district of Mesopotamia, and in this city, which yielded him a rich booty, he found satisfactory winter quarters.

Meantime Mithridates was again in Pontus, and the Roman forces which had been left there were soon overwhelmed. In one disastrous engagement at Ziela the Roman camp was taken and the army slaughtered to a man. Lucullus was still thwarted by the mutinous spirit of his troops, and after all his brilliant achievements he was obliged to pursue his retreat into Asia Minor with the full knowledge that Tigranes and Mithridates were the unresisted masters of Pontus and Cappadocia. The work of eight years of war was undone. Commissioners sent from Rome to settle the affairs of the East had to report to the senate that a large part of Asia Minor was in the enemy's hands. In the year 66 B.C. Lucullus was recalled, and superseded in his command by Pompey.

He had indeed fairly earned by his brilliant victories the honour of a triumph, but he had powerful enemies at Rome, and charges of maladministration, to which no doubt his immense wealth gave no unreasonable colour, caused it to be deferred for three years. In 63 B.C., however, it was celebrated with extraordinary magnificence. By this time Lucullus seems to have felt that he had done his work. He had little taste for the increasingly turbulent political contests of the time, and, with the exception of occasional appearances in public life, he gave himself up to elegant luxury, with which, however, he combined a sort of dilettante pursuit of philosophy, literature, and art. Cicero, who was on terms of close intimacy with him, always speaks of him with enthusiasm and in terms of the highest praise. Lucullus is with him a *vir fortissimus et clarissimus*, and a man too of the highest and most refined intellectual culture. As a provincial governor, in his humane consideration for the conquered and his statesmanlike discernment of what was best suited to their circumstances, he was a man after Cicero's own heart. In this respect he reminds us of the younger Pliny. Very possibly Cicero may have spoken too flatteringly of him, but we cannot think his praise was altogether undeserved.

As a soldier, considering what he achieved and the victories he won with but small forces under peculiarly unfavourable conditions, he must have been a man of no ordinary capacity. It is true that he does not seem to have had the confidence of his troops to the extent to which a great general ought to possess it, and it is just possible that he may have erred on the side of an excessive aristocratic hauteur, which to his men may have looked like a selfish indifference to their hardships. But it is also possible that out of a strict regard to the lives and property of the provincials he may have been too strict a disciplinarian for the taste of the soldiers. Some of his unpopularity, it is pretty certain, was due to the restraints which he had put on the rapacity of the capitalists, who thought themselves aggrieved if they could not make rapid and enormous fortunes by farming the revenue of the rich provinces of the East. We can hardly doubt that with very decided aristocratic feeling and thorough devotion to his political party Lucullus combined much generous uprightness and kindliness of heart.

His name calls up before the mind visions of boundless luxury and magnificence, and among the Roman nobles who revelled in the newly acquired riches of the East Lucullus, it is certain, stood pre-eminent. His park and pleasure grounds in the immediate vicinity of the capital were the wonder and admiration of his own and of the succeeding age. Pompey is said to have styled him the Roman Xerxes, in allusion, not only to his splendour, but also to the costly and laborious works to be seen in his parks and villas at Tusculum, near Naples, where rocks and hills had been pierced at an almost infinite expense. On one of his luxurious entertainments he is said to have spent upwards of £2000. Far the most pleasing trait in his character is the liberal patronage which he gave more especially to Greek philosophers and men of letters, and the fact that he collected a vast and valuable library, to which such men had free access. On the whole we may take Lucullus to have been a man who in many respects rose above his age, and was a decidedly favourable specimen of a great Roman noble.

Of his latter years but little is recorded. He had, as we have seen, almost wholly retired from public life. It appears that he sank into a condition of mental feebleness and imbecility some years before his death, and was obliged to surrender the management of his affairs to his brother Marcus. The usual funeral panegyric was pronounced on him in the Forum, and the people would have had him buried by the side of the great Sulla in the Campus Martius, but he was laid at his brother's special request in his splendid villa at Tusculum.

The best account of Lucullus's campaign in the East is to be found in Mommsen's *History of Rome*, bk. v. chap. 2. Our knowledge of him is drawn mainly from Plutarch, Appian's *Mithridatic War*, the epitomes of the lost books of Livy, and very frequent allusions to him in Cicero's works. (W. J. B.)

LUDDITES, The, were organized bands of rioters for the destruction of machinery, who made their first appearance in Nottingham and the neighbouring midland districts of England about the end of 1811. The origin of the name is curious, and is given as follows in the *Life of Lord Sidmouth* (vol. iii. p. 80). In 1779 there lived in a village in Leicestershire a person of weak intellect, called Ned Lud, who was the butt of the boys of the village. On one occasion Lud pursued one of his tormentors into a house where were two of the frames used in the stocking manufacture, and, not being able to catch the boy, vented his anger on the frames. Afterwards, whenever any frames were broken, it became a common saying that Lud had done it. It is curious also that the leader of the riotous bands took the name of General Lud. The Luddite riots arose out of the severe distress caused by commercial depression and the consequent want of employment. They were specially directed against machinery because of the widespread prejudice that its use directly operated in producing a scarcity of labour. Apart from the prejudice, it was inevitable that the economic and social revolution implied in the change from manual work to work by machinery should give rise to great misery by upsetting all the old industrial habits and arrangements. The riots began at Nottingham, in November 1811, with the destruction of stocking and lace frames, and, continuing through the winter and following spring, spread into Yorkshire and Lancashire. They were met by severe repressive legislation,—a notable feature in the opposition to it being Lord Byron's speech in the House of Lords, the first which he delivered there. In 1816 the rioting was resumed, through the fearful depression that followed on the European peace, aggravated by one of the worst of recorded harvests, when wheat rose from 52s. 6d. to 103s. a quarter (in Yorkshire it was more than a guinea a bushel), when the corn was still green in October, and the potato crop was a failure. In that year, though the centre of the rioting was again in Nottingham, it extended over almost the whole kingdom, and took more decidedly the form of a general discontent and seditious restlessness. The rioters were also thoroughly organized. While part of the band with extraordinary quickness and thoroughness destroyed the machinery in the houses, sentinels were posted to give warning of the approach of the military and police; and all had generally disappeared before the least risk of discovery. Under the influence of vigorous repressive measures, and especially of reviving prosperity, the spirit of rioting ere long died out.

See the *Annual Register* for the years concerned; *Life of Lord Sidmouth*, by the Hon. George Pellew, dean of Norwich, vol. iii.; and Spencer Walpole, *History of England*, vol. i.

LUDHIÁNA, a district in the lieutenant-governorship of the Punjab, India, lying between 30° 33′ and 31° 1′ N. lat. and between 75° 24′ 30″ and 76° 27′ E. long., is bounded on the N. by the Sutlej river, on the E. by Umballa (Ambála) district, on the S. by Patiála, Nábha, and Maler Kotla states, and on the W. by Firozpur district. The surface of Ludhiána consists for the most part of a broad plain, without hills or rivers, and stretching northward from the native borders to the ancient bed of the Sutlej. The soil is composed of a rich clay, broken by large patches of shifting sand. On the eastern edge, towards Umballa, the soil improves greatly, the clay being here surmounted by a bed of rich mould, suitable for the cultivation of cotton and sugar-cane. Towards the west the sand occurs in union with the superficial clay, and forms a light friable soil, on which cereals form the most profitable crop. Even here, however, the earth is so retentive of moisture that good harvests are reaped from fields which appear to the eye mere stretches of dry and sandy waste, but are covered, after the autumn rains, by waving sheets of wheat and millet. These southern uplands descend to the valley of the Sutlej by an abrupt terrace, which marks the former bed of the river. The principal stream has now shifted to the opposite side of the valley, leaving a broad alluvial strip, 10 miles in width, between its ancient and its modern bed. The Sutlej itself is here only navigable for boats of small burden. A branch of the Sirhind Canal, now in course of construction, will irrigate a large part of the western *parganás*. At present irrigation is almost entirely confined to wells. The district is singularly bare of trees.

The census of 1868 returned a total population of 583,245 persons (319,342 males and 263,903 females), spread over an area of 1359 square miles, inhabiting 879 villages and towns, and 151,934 houses. Hindus numbered 219,371; Mohammedans, 206,603; Síkhs, 95,463; and "others," 61,858. In ethnical classification the Játs rank first, both in number (205,304) and in agricultural importance; they form one-third of the total population, and nearly two-thirds of the cultivating class. The Gújars come next with 30,009 persons. Rájputs number 23,961, and cluster thickly in the fertile strip along the bank of the Sutlej. Though they hold the richest portion of the district, they are but careless and improvident cultivators. Bráhmans number 21,165, but their social importance is small, and they own but a single village. The mercantile classes are represented by 15,251 Kshattriyas and 8174 Banias. There are also 5549 Kashmirís, employed in weaving shawls and woollen goods. Four towns were returned in 1868 as containing upwards of 5000 inhabitants, viz., Ludhiána, 39,983; Ráikot, 9165; Jagráon, 7096; and Machiwára, 6062. Ludhiána is a flourishing agricultural district in spite of the general unpromising appearance of its soil, a result mainly attributable to the untiring diligence of its Ját cultivators. Almost all the available land has been brought under the plough, and in many villages no waste land is left for pasturage, the cattle being fed from cultivated produce. Under *rabí* or spring crops there were in 1872–73 198,279 acres of wheat, 30,620 of barley, 162,649 of gram, and 576 of poppy. The *kharíf* or rain crops comprised 129,589 acres of *joár*, 49,047 of Indian corn, 55,293 of *moth*, and 15,894 of cotton. In spite of their industrious habits, many of the peasantry are deeply in debt, and the rate of interest is high. Most of the land is held by tenants-at-will. Agricultural labourers are paid in grain; in the towns, unskilled labour is paid at the rate of from 3d. to 4½d. per diem. Ludhiána is comparatively free from danger of actual famine, though it suffers much from drought. The exports, of which the annual value is estimated at £377,120, are chiefly confined to grain, cotton, wool, saltpetre, and indigo; the principal imports (£365,552) are English goods, spices, and red madder dye. Manufactures include shawls, *pashmína* cloth, stockings, gloves, cotton goods, furniture, carriages, and firearms. Eight large silk factories and upwards of four hundred private silk-looms give employment to over three thousand persons. Communication is afforded by the Sind, Punjab, and Delhi Railway, which runs through the centre of the district, and by several lines of good metalled roads.

The administrative staff of the district comprises a deputy commissioner, with an assistant and two extra assistants, a small-cause court judge, and three *tahsíldárs*, besides the usual medical and constabulary officers. The total revenue in 1872–73 was £103,795, of which £85,215 was contributed by the land tax. Education in 1873 was afforded by 184 schools, of which 68 were in receipt of Government grants in aid; the total number of enrolled pupils was 6733. In the upland portion of the district the atmosphere is dry and healthy; in the Sutlej valley, however, the air is extremely noxious after the rainy season floods, and fever prevails often in an epidemic form; ophthalmia is also common. The mean temperature in 1872 was 87°·59 Fahr. in May, 85°·67 in July, and 54°·85 in December, the maximum being 117°, and the minimum 31°. The average annual rainfall is 28 inches.

History.—Though the present town of Ludhiána dates no farther back than the 15th century, other cities in the district can claim a much greater antiquity. At Sunet, close to the modern station, are ruins of an extensive brick-built town, whose greatness had already passed away before the period of Mohammedan invasion; and the old Hindu city of Máchiwára is of still earlier date, being mentioned in the *Mahábhárata*. During the Mussulman epoch, the history of the district is bound up with that of the Ráis of Ráikot, a family of converted Rájputs, who received the country as a fief under the Sayyid dynasty, about the year 1445. The town of Ludhiána was founded in 1480 by two of the Lodí race (then ruling at Delhi), from whom it derives its name, and was built in great part from the prehistoric bricks of Sunet. The Lodís continued in possession until 1620, when it again fell into the hands of the Ráis of Ráikot. Throughout the palmy days of the Mughal empire the Ráikot family held sway, but the Sikhs took advantage of the troubled period which accompanied the Mughal decadence to establish their supremacy south of the Sutlej. Several of their chieftains made encroachments on the domains of the Ráis, who were only able to hold their own by the aid of George Thomas, the famous adventurer of Hariána. In 1806 Ranjít Sinh crossed the Sutlej and reduced the obstinate Mohammedan family, and distributed their territory amongst his own co-religionists. Since the British occupation of the Punjab Ludhiána has grown in wealth and population, but its history has been uneventful.

LUDHIÁNA, the chief town and headquarters station of Ludhiána district, is situated on the south bank of the old bed of the Sutlej, 8 miles from the present bed of the river, in 30° 55′ 25″ N. lat. and 75° 53′ 30″ E. long. The population in 1868 was 39,983, viz., Mohammedans, 27,860; Hindus, 10,208; Síkhs, 45; Christians, 79; "others," 1791. The Kashmirís retain their hereditary skill as weavers of shawls and *pashmína* cloth, the value of the quantity exported in 1871–72 being returned at £13,350. Shawls of the soft Rámpur wool, cotton cloths, scarfs, turbans, furniture, and carriages also form large items in the thriving trade of the town. Since the opening of the railway Ludhiána has become a great central grain mart, having extensive export transactions both with the north and south. The American Presbyterian Mission has a church and school, with a small colony of native Christians. The town bears a bad reputation for unhealthiness.

LUDLOW, a municipal and parliamentary borough and market-town of Shropshire, England, is situated at the junction of the Teme and Corve on the borders of Herefordshire, 27 miles south-east from Shrewsbury and 10 north from Leominster. The old castle, on an eminence above the Teme, presents an imposing and massive appearance, the Norman towers and the greater part of the walls being still complete. The parish church of St Lawrence, a fine cruciform structure in the Gothic style, with a lofty central tower, dates from the reign of Edward III.; it was restored in 1859-60. The grammar school, founded in the reign of John, was incorporated by Edward I. The other principal public buildings are the guild-hall, the town-hall and market-house, and the public rooms, which include the assembly-rooms and a museum of natural history. Tanning and malting are carried on to a small extent, and there are also flour-mills. The population of the municipal borough (280 acres) in 1871 was 5087, and in 1881 5035. The population of the parliamentary borough (1371 acres) in the same years was 6203 and 6663.

Ludlow is said to have existed as a British town under the name of *Dinan*. After the Conquest it was granted to Roger de Montgomery, who is said to have been the founder of the castle. For some time the castle was a royal residence, and from the reign of Henry VIII. to that of William III. it was the seat of the council of the marches. In the reign of Charles I. it was garrisoned for the king, but it surrendered to the parliamentary forces in June 1646. The town had a charter of incorporation at a very early period, which was confirmed by Edward IV.

LUDLOW, Edmund (1620-1693), was born at Maiden Bradley, Wiltshire, in 1620, of an ancient and honourable family. He studied at Trinity College, Oxford (where he took his B.A. degree in 1636), and at the Temple. When the war broke out he engaged as a volunteer in the life guard of Lord Essex, consisting of one hundred gentlemen. His first essay in arms was at Worcester, his next at Edgehill. He was made governor of Wardour Castle in 1643, which place he surrendered on honourable terms after ten months' siege. On being exchanged soon afterwards, he engaged as major of Sir A. Haslerig's regiment of horse, in which capacity he did good service in the western counties. He was present at the second battle of Newbury, October 1644. In 1645 he was elected M.P. for Wilts in the room of his father Sir Henry Ludlow, and attached himself inflexibly to the republican party. In 1648 he was one of a committee of six who arranged the violent action known as Pride's Purge. He was one of the king's judges, and put his hand to the warrant for his execution. In January 1651 Ludlow was sent into Ireland as lieutenant-general of horse, holding also a civil commission. Here he spared neither health nor money in the public service. Ireton, the deputy of Ireland, died 27th November 1651, and for six months Ludlow held the chief place, which he then resigned to Fleetwood. Though disapproving of Cromwell's action in dissolving the Long Parliament, he maintained his employment, but when Cromwell was declared Protector he declined to acknowledge his authority, and was soon after recalled to England. He refused the Protector face to face when ordered to submit to his government, and in December 1655 retired to his own house in Essex. After Oliver Cromwell's death Ludlow was returned for the borough of Hindon, and took his seat in Richard's parliament in 1659. He sat also in the restored Rump, and was a member of its council of state and of the committee of safety after its second expulsion. He also held office for a short time in Ireland. After the Restoration, finding that his life was in danger, he left England, in September 1660, and travelled through France and Geneva, and thence to Vevey, then under the protection of the canton of Bern. There he spent the rest of his long life unmolested, to the great credit of the Government of that canton, which had also extended its protection to other regicides. He was, however, in constant danger from Cavalier assassins. He steadily refused during thirty years of exile to have anything to do with the desperate enterprises of republican plotters. But in 1689 he returned to England, hoping to be employed in Irish affairs. He was, however, known only as a regicide; and an address from the House of Commons was presented to William III. by Sir Edward Seymour, requesting the king to issue a proclamation for his arrest. Ludlow escaped again, and returned to Vevey, where he died in 1693, aged seventy-three, and where a monument raised to his memory by his widow is still to be seen in the church of St Martin. Over the door of the house in which he lived was placed the inscription "Omne solum forti patria, quia Patris." His memoirs, extending to the year 1688, were published in 1698-99 at Vevey.

LUDOLF, or Leutholf, Hiob (1624-1704), a learned Orientalist, was born at Erfurt on June 15, 1624. At an early age he manifested a passion for the acquisition of foreign tongues; and after exhausting the imperfect educational resources of his native place he went in 1645 to Leyden, where for upwards of a year he was the pupil of Erpenius, Golius, and other linguists. Having received an appointment as tutor, he afterwards travelled in France (where he became acquainted with Bochart at Caen) and in England, and in 1649 he was commissioned by the Swedish ambassador at the French court to go to Rome in quest of certain papers which had been lost, and which Queen Christina wished to recover. In this mission he was unsuccessful, but while in Italy he became acquainted with four Abyssinians, from whom he acquired his knowledge (at that time unique) of Ethiopic. In 1652 he entered the diplomatic service of the duke of Saxe-Gotha; in this he continued (acting also for some time as tutor to the young princes) until 1678, when he retired to Frankfort-on-the-Main. At the conferences held there in 1681 and 1682 he held a commission to act for the dukes of Saxony. In 1683 he visited England to promote a cherished scheme for establishing trade with Abyssinia, but his efforts were unsuccessful, chiefly through the bigotry of the authorities of the Coptic Church. Returning to Frankfort in 1684, he gave himself wholly to literary work, which he continued almost to his death on April 8, 1704. In 1690 he had the honour to be appointed president of the "Collegium Imperiale Historicum."

His works, of which a complete list will be found in Chauffepié's *Dictionnaire*, include *Historia Ethiopica* (fol. 1681), with *Commentarius ad Hist. Eth.* (1691), and *Appendix* (1693); *Grammatica Amharicæ Linguæ, quæ vernacula est Habessinorum*, 1698; *Lexicon Amharico-Latinum*, 1698; *Lexicon Ethiopico-Latinum*, of which the first edition was published in London in 1661, but with many inaccuracies for which Ludolf refused responsibility (a second edition appeared at Frankfort in 1699); *Grammatica Linguæ Ethiopicæ* (London, 1661; Frankfort, 1702). Ludolf holds a very high place among the older Orientalists, and his works on Ethiopic in particular continued to be the standard text-books till they were superseded by those of Dillmann.

LUDWIGSBURG, the second royal residence of Würtemberg, is situated 9 miles to the north of Stuttgart and 1½ miles from the Neckar. It was laid out at the beginning of last century by Duke Eberhard Ludwig as a rival to Stuttgart, and was greatly enlarged by Duke Charles, who resided there from 1764 to 1785. Constructed as the adjunct of a palace, the town bears the impress of its artificial origin, and its straight streets and spacious squares have a dull and lifeless appearance. Its main importance now consists in its being the chief military depôt of Würtemberg, as which it contains extensive barracks, a cannon foundry, an arsenal, and a military academy. The royal palace, one of the largest and finest in Germany, stands in a beautiful park, and contains a portrait-gallery and the burial vault of the sovereigns of Würtemberg. Among the other prominent buildings are four churches and several educational and charitable institutions. Ludwigsburg also carries on manufactures of organs, woollen and linen cloth, japanned tin-wares, picture frames, and chicory. In 1880 it contained 16,100 inhabitants, about one-fourth of whom belonged to the garrison. David Strauss, author of the *Life of Jesus*, was a native of Ludwigsburg. In the vicinity is the beautiful royal chateau of Monrepos, connected with the park of Ludwigsburg by a fine avenue of limes.

LUDWIGSHAFEN. See MANNHEIM.

LUGANO, a town of Switzerland, which divides with Locarno and Bellinzona the first rank in the canton of Tessin (Ticino). It stands on the shore of the lake of the same name, on a narrow strip of Swiss territory which projects into Lombardy and is everywhere close to the Italian frontier. The prosperity of the town is due to its position on the main line of land communication between Milan and the pass of the St Gotthard, and the facility of intercourse by land and water, whether for legitimate or contraband trade, between this outlying fragment of Switzerland and the rich region that surrounds it. The buildings are not remarkable, but the church of Santa Maria degli Angioli contains several important pictures by Luini, a native of the adjoining district. The monastery to which the church formerly belonged is now converted into a large hotel. During the struggle of the people of northern Italy to expel the Austrians from Lombardy, between the years 1848 and 1866, Lugano served as head-quarters for Mazzini and his followers. Books and tracts intended for circulation throughout Italy were produced there, and at the neighbouring village of Capolago, on a large scale, and the efforts of the Austrian police to check their circulation were completely powerless. The population is Italian in character and features, and the Italian tongue is exclusively spoken. On the quay is a statue of Tell by Vela, and there are other works by the same eminent sculptor, a native of the canton, in private grounds near the town. About 2 miles distant, and nearly due south, a steep hill—called Monte Salvatore—rises more than 2000 feet above the surface of the lake, and commands a fine panoramic view, limited in some directions by the higher mountains on the opposite side of the lake, but extending in one direction to Monte Rosa, and in another to the cathedral of Milan.

LUGANO, LAKE OF (sometimes called *Lago Ceresio* by the Italians, from the Roman name *Lacus Ceresius*), situated partly in Lombardy and partly in the Swiss canton Tessin or Ticino, takes its ordinary name from the town of Lugano, the only considerable place on its banks. Its form is very irregular, and has been compared to a sickle, a fish-hook, and various other objects. It lies altogether amidst the outer ranges of the Alps that divide the basin of the Ticino from that of the Adda, where the calcareous strata have been disturbed by the intrusion of porphyry and other igneous rocks. It is not connected with any considerable valley, but is fed by numerous torrents in various directions issuing from short glens in the surrounding mountains, and is drained by the Tresa, an unimportant stream that flows westward into the Lago Maggiore. The surface of the lake is 889 feet above the sea, and the form of its bed seems to be very irregular. In some parts soundings of more than 1000 feet have been taken, while in one place the lake is so shallow that a causeway half a mile in length, supporting the road and the railway, has been carried from shore to shore. The scenery is of a varied character: in great part, and especially in the north-east arm extending from Lugano to the Lombard village of Porlezza, the lake is enclosed between mountains that rise steeply to a height of some 2000 feet from the water's edge, while on its southern and western branches it is encompassed by gently swelling hills rich with the luxuriance of Italian vegetation.

LUGANSK, a town of Russia, in the government of Ekaterinoslaff, district of Slavianoserbsk, 300 miles to the eastward of the capital of the province, is connected by a branch with the railway between Kharkoff and Azoff, as well as with other towns and iron-works of the Donetz coal-mines district. It stands on the small river Lugan, 10 miles from its junction with the northern Donetz, in the Lugan mine district, of which it is the chief town. This district, which comprises the important coal-mines of Lisitchansk and the anthracite mines of Gorodische, occupies an area of about 110,000 acres on the banks of the Donetz river, and has a population of more than 15,000. Although it is mentioned in Russian history as early as the 16th century, and coal was discovered in it at the time of Peter I., it was not until 1795 that an Englishman, Gascoyne or Gaskoin, established its first iron-work for supplying the Black Sea fleet and the southern fortresses with guns and shot. This proved a failure, owing to the great distance from the sea, and the manufacture of supplies for the navy was suspended; but during the Crimean war the iron-works of Lugan again largely produced shot, shell, and gun-carriages. Since 1864 agricultural implements, steam-engines, and the various machinery required for beetroot sugar-works, distilleries, &c., have been the chief manufactures. The Lugan works, which employ about 1200 men, are the chief centre for smelting the ores of the neighbouring iron-mines. The town is the seat of the mining authorities for the district, and has a first-class meteorological and magnetic observatory. The 11,000 inhabitants of Lugansk also carry on a very active trade in cattle, tallow, wools, skins, linseed, wine, corn, and manufactured wares. The weekly fairs are much frequented. There are also in the town many tallow-melting works, and the smith trade is largely carried on.

LUGO, a maritime province of Spain, one of the four into which Galicia has since 1833 been divided, is bounded on the E. by Oviedo and Leon, on the S. by Orense, on the W. by Pontevedra and Coruña, and on the N. by the Atlantic. Its extreme length from north to south is about 98 miles, its breadth 58, and the area 3787 square miles. The coast, which extends for about 40 miles from the estuary of Rivadeo to Cape Vares, is extremely rugged and inaccessible, and few of the inlets that exist, except those of Rivadeo and Vivero, admit vessels of any size. The province, especially in the north and east, is mountainous in its character, being traversed by the great Cantabrian chain and its offshoots; the sierra by which it is separated from Leon attains in some places a height of 6000 feet. A large part of the area is drained by the Miño, which rises on the western slope of the Sierra de Meira, and follows a southerly direction until it is joined by the Sil; the latter for a considerable distance forms the southern boundary of the province. Of the rivers of the northern versant the most important are the Navia (which has its lower course through Oviedo), the Eo (for some distance the boundary between the two provinces), the Masma, the Oro, and the Landrobe. The Eume, one of the rivers of Coruña, and the Ulla, which separates that province from Pontevedra, both have their rise on the western slopes of Lugo. Some of the northern valleys even, in their lower portions, are fertile, and yield not only corn but fruit and wine, but the principal agricultural wealth is on the Miño and Sil, where rye, maize, wheat, legumes of various kinds, flax, hemp, and a little silk are produced. The hills are comparatively well wooded. Iron is found at Caurel and Incio, antimony at Castroverde and Cervantes, argentiferous lead at Riotorto; and there are quarries of granite, marble, and various kinds of slate and building stone. Linen and woollen cloths are manufactured, but to an insignificant extent, and the trade of the province is unimportant. The internal communications are still very imperfect. There is only one railway, that connecting Lugo with Coruña; but connexions with Leon (Brañuelas) and with Orense are in contemplation. The total population in 1877 was 410,387, being a decrease of 22,129 since 1860. There are ten towns with a population over 10,000—Chantada, Fonsagrada, Lugo, Mondoñedo, Monforte, Panton, Sarria, Saviñao, Villalba, and Vivero.

LUGO, the capital of the above province, stands on a small hill near the northern bank of the river Miño, at a height of 1930 feet above the level of the sea, 60 miles south-west from Coruña, and 353 north-west from Madrid, on the highway between these two cities. With the former it is continuously connected by rail. The form of the town, which is nearly quadrangular, is defined by a massive Roman wall, from 30 to 40 feet in height and 20 feet thick, with projecting semicircular towers which, prior to the civil war in 1809, were eighty-five in number; it now serves as a promenade, commanding an extensive and delightful prospect. The principal public places are the Plaza de la Constitucion, a spacious arcaded square, the Plaza de San Domingo, the Plaza del Hospital, and the busy Plaza del Campo, where fairs and markets are held. The most important of the public buildings is the Gothic cathedral on the south side of the town; it dates from the 12th century, but was modernized in the 18th, and possesses no special architectural merit. Other churches are those of the Capuchins and that of San Domingo; the only other buildings of note are the episcopal palace, the secondary school, the hospital, and the prison. The principal industries are tanning, and the manufacture of linen cloth and of cream of tartar; there is some trade in silk wares. About a mile to the south of the town, on the left bank of the Miño, are the famous hot sulphur baths of Lugo; the bathing house dates from 1847. The population of the ayuntamiento in 1877 was 18,909.

Lugo (*Lucus Augusti*) was made by Augustus the seat of a *conventus juridicus*. Its sulphur baths were even then well known. It suffered greatly in the 5th century, during the Moorish wars, and, more recently, during the war of independence. The bishopric dates from a very early period, and it is said to have acquired metropolitan rank in the middle of the 6th century; it is now suffragan to Santiago.

LUGOS, a market-town of Hungary, capital of the trans-Tisian county of Krassó, is situated on the Temes, and on the railway from Temesvár to Karánsebes, 32 miles east-south-east of the former, in 45° 41′ N. lat., 21° 53′ E. long. The two main portions of the town, separated by the river, and named respectively Német- (German) Lugos and Román- (Roumanian) Lugos, are connected by a wooden bridge 312 feet in length. Lugos is the seat of a Greek Catholic (Roumanian) bishopric, of royal and circuit courts of law, and of the usual bureaus of a county administration. The public and other buildings include Greek Orthodox, Greek Catholic, Roman Catholic, and Lutheran churches, a synagogue, a royal upper gymnasium (founded in 1823), a Minorite convent, an episcopal palace, the barracks, and the ruins of a castle. The surrounding country is mountainous and well-wooded, and produces large quantities of grapes and plums. In 1880 the population was 11,287, of whom 3476, chiefly Germans, were in Német-Lugos, and 7811, Roumanians, with a few Slavonians and Magyars, in Román-Lugos.

Lugos was once a strong fortress and of greater relative importance than at present. During the 16th and 17th centuries it suffered much at the hands of the Turks. At the close of the Hungarian revolutionary war (August 1849) it was the last resort of Kossuth and several other leaders of the national cause previous to their escape to Turkey.

LUINI, BERNARDINO, the most celebrated master of the Lombard school of painting founded upon the style of Leonardo da Vinci, was born at Luino, a village on the Lago Maggiore, towards 1465. He himself wrote his name as "Bernardin Lovino," but the spelling "Luini" is now very generally adopted. Few facts are known regarding the life of this illustrious and delightful painter, and it is only since a comparatively recent date that he has even been credited with the production of his own works, and with the fame thereto appertaining, as many of them had, in the lapse of years and laxity of attribution, got assigned to Leonardo. It appears that Luini studied painting at Vercelli under Giovenone, or perhaps under Lo Scotto. He reached Milan either after the departure of Da Vinci in 1500, or shortly before that event; it is thus left uncertain whether or not the two artists had any personal acquaintance, but Luini was at any rate in the painting-school established in Milan by the great Florentine. In the latter works of Luini a certain influence from the style of Raphael is superadded to that, far more prominent and fundamental, from the style of Leonardo; but there is nothing to show that he ever visited Rome. His two sons are the only pupils who have with confidence been assigned to him; and even this can scarcely be true of the younger, who was born in 1530, when Bernardino was well advanced in years, and was not far from the close of his career. Gaudenzio Ferrari has also been termed his disciple. One of the sons, Evangelista, has left little which can now be identified; the other, Aurelio, was accomplished in perspective and landscape work. There was likewise a brother of Bernardino, named Ambrogio, a competent painter. Bernardino, who hardly ever left Lombardy, had some merit as a poet, and is said to have composed a treatise on painting. The precise date of his death is unknown; he may perhaps have survived till about 1540. A serene, contented, and happy mind, naturally expressing itself in forms of grace and beauty, seems stamped upon all the works of Luini. The same character is traceable in his portrait, painted in an upper group in his fresco of Christ Crowned with Thorns in the Ambrosian library in Milan,—a venerable bearded personage. The only anecdote which has been preserved of him tells a similar tale. It is said that for the single figures of saints in the church at Saronno he received a sum of money equal to 22 francs per day, along with wine, bread, and lodging; and he was so well satisfied with this remuneration that, in completing the commission, he painted a Nativity for nothing.

Along with this natural sweetness of character, a dignified suavity is the most marked characteristic of Luini's works. They are constantly beautiful, with a beauty which depends at least as much upon the loving self-withdrawn expression as upon the mere refinement and attractiveness of form. This quality of expression appears in all Luini's productions, whether secular or sacred, and imbues the latter with a peculiarly religious grace—not ecclesiastical unction, but the devoutness of the heart. His heads, while extremely like those painted by Leonardo, have less subtlety and involution and less variety of expression, but fully as much amenity. He began indeed with a somewhat dry style, as in the Pietà in the church of the Passione; but this soon developed into the quality which distinguishes all his most renowned works; although his execution, especially as regards modelling, was never absolutely on a par with that of Leonardo. Luini's paintings do not exhibit an impetuous style of execution, and certainly not a negligent one; yet it appears that he was in fact a very rapid worker, as his picture of the Crowning with Thorns, painted for the College del S. Sepolcro, and containing a large number of figures, is recorded to have occupied him only thirty-eight days, to which an assistant added eleven. His method was simple and expeditious, the shadows being painted with the pure colour laid on thick, while the lights are of the same colour thinly used, and mixed with a little white. The frescos exhibit more freedom of hand than the oil pictures; and they are on the whole less like the work of Da Vinci, having at an early date a certain resemblance to the style of Mantegna, as later on to that of Raphael. Luini's colouring is mostly rich, and his light and shade forcible.

Among his principal works the following are to be mentioned. At Saronno are frescos painted towards 1525, representing the life of the Madonna—her Marriage, the Presentation of the Infant Saviour in the Temple, the Adoration of the Magi, and other incidents. His own portrait appears in the subject of the youthful Jesus with the Doctors in the Temple. This series—in which some comparatively archaic details occur, such as gilded nimbuses—was partly repeated from one which Luini had executed towards 1520 in S. Croce. In the Brera Gallery, Milan, are frescos from the suppressed church of La Pace and the Convent della Pelucca,—the former treating subjects from the life of the Virgin, the latter, of a classic kind, more decorative in manner. The subject of girls playing at the game of "hot-cockles," and that of three angels depositing St Catherine in her sepulchre, are particularly memorable, each of them a work of perfect charm and grace in its way. In the Casa Silva, Milan, are frescos from Ovid's *Metamorphoses*. The Monastero Maggiore of Milan (or church of S. Maurizio) is a noble treasure-house of Luini's art,—including a large Crucifixion, with about one hundred and forty figures; Christ Bound to the Column, between figures of Saints Catherine and Stephen, and the founder of the chapel kneeling before Catherine; the Martyrdom of this Saint; the Entombment of Christ; and a large number of other subjects. In the Ambrosian library is the fresco (already mentioned), covering one entire wall of the Sala della S. Corona, of Christ Crowned with Thorns, with two executioners, and on each side six members of a confraternity; in the same building the Infant Baptist Playing with a Lamb; in the Brera, the Virgin Enthroned, with Saints, dated 1521; in the Louvre, the Daughter of Herodias receiving the Head of the Baptist; in the Esterhazy Gallery, Vienna, the Virgin between Saints Catherine and Barbara; in the National Gallery, London, Christ Disputing with the Doctors. Many or most of these gallery pictures used to pass for the handiwork of Da Vinci. The same is the case with the highly celebrated Vanity and Modesty in the Sciarra Palace, Rome, which also may nevertheless in all probability be assigned to Luini. Another singularly beautiful picture by him, which seems to pass almost entirely unobserved by tourists and by writers, is in the Royal Palace in Milan—a large composition of Women Bathing. That Luini was also pre-eminent as a decorative artist is shown by his works in the Certosa of Pavia.

LUKE, whose name is traditionally attached to the Third Gospel, appears to have been one of the companions of Paul, being mentioned as such in Col. iv. 14, Philem. 24, and 2 Tim. iv. 11; even if, as some critics suppose, these epistles were not written by Paul himself, they are at any rate likely to have preserved the local colouring. Assuming, as is probable, that the same person is intended in all three passages, we gather (1) that Luke was not a born Jew, since in Col. iv. 11, "those who are of the circumcision" appear to be separated from those, among whom is Luke, who are mentioned afterwards (but there is nothing to determine the question, which has since been raised, whether he had been a Jewish proselyte or a Gentile), and (2) that he was a physician. There was an early belief, first mentioned by Irenæus, that he is spoken of, though not mentioned by name, in 2 Cor. viii. 18, as "the brother whose praise is in the gospel throughout all the churches"; and the subscription of that epistle in some MSS., and in the Peschito and other versions, embodies this belief. Of his birth and country nothing is positively known; but it is a possible inference from his name *Lucas*, which is a contraction of *Lucanus* (the full form occurs in some early MSS. of the Itala), that he was of Italian (Lucanian) descent.

From the time of Irenæus, whose testimony is soon followed by that of Clement of Alexandria, Tertullian, and Origen, this companion of Paul has generally been considered to be the author of the third canonical Gospel and of the Acts of the Apostles; but no other facts are mentioned by early writers as to his personal history, except such as may be gathered from the writings which are attributed to him. Tertullian, for example, speaks of him as "non apostolus sed apostolicus," and as "posterioris apostoli sectator" (*Adv. Marcion.*, 4, 2); and the Muratorian fragment says that he had not seen the Lord in the flesh. The most important of these biographical inferences are those which were made by Eusebius, who, translating, or mistranslating, παρηκολουθηκότι πᾶσι, in the preface to the Gospel, by "having accompanied all," *i.e.*, the "eyewitnesses and ministers of the word," infers that Luke was a companion not of Paul only but also of the other apostles, and, probably referring to Acts xiii. 1, says that he was "one of those from Antioch."[1] These inferences of Eusebius are further elaborated by Jerome, who adds, without quoting any authority, that he wrote the Gospel in Achaia or Bœotia (many MSS. have Bithynia), and the Acts at Rome.[2]

Those who accept this tradition of his having been the author of the Acts of the Apostles usually infer from the sections of that work in which the pronoun "we" is employed that he accompanied Paul on part of his second and third missionary journeys, and also on his voyage to Rome. The first of these sections begins with the apostle's determination to go into Macedonia, and ends when he has left Philippi (Acts xvi. 10–40); the second begins when the apostle returns to Philippi, and ends with his arrival at Jerusalem (Acts xx. 6–xxi. 18); the third begins with his sailing from Cæsarea, and ends with his arrival at Rome (Acts xxvii. 1-xxviii. 16). Even some of those who assign the greater part of the book to a much later date think that these sections may be extracts from an original diary of a companion of Paul, and that this companion may have been Luke. Others, however, think it improbable that Luke, without being specially mentioned either in them or elsewhere, should have accompanied Paul on his voyage to Rome, and assign these sections to Timothy, or Titus, or Silas (some have added the very improbable conjecture that Luke and Silas are the same person).

The other biographical details which are found in patristic literature, and which are not inferences from the New Testament, rest upon no certain evidence, and are frequently at variance not only with one another but also with earlier documents. It is sometimes stated that he was one of the seventy disciples; this statement is found in Epiphanius (*Hæres.*, li. 11), in pseudo-Origen (*De recta in Deum fide*, ed. De la Rue, vol. i. p. 806), in Gregory the Great (*Moral.* i. 1), and elsewhere; but it is inconsistent, not only with Tertullian and the Muratorian fragment, but also with the clear inference from the preface to the Gospel that its author was not himself an eyewitness of what he narrates. It is also stated that he was one of the two disciples who went to Emmaus (S. Greg. Magn., *Moral.* i. 1; Paul. Diacon., *Homil.* 59 *in Natali S. Lucæ*; and others); but this statement is discredited by the same facts as the preceding. Like all the other disciples whose names are mentioned in the New Testament, he is said to have gone forth as a preacher of the gospel; but statements vary widely as to the place in which he preached: Gregory of Nazianzus says Achaia; Epiphanius says Dalmatia, Gaul, Italy, and Macedonia; Œcumenius says Africa; later legends mention his having been at Enns in Austria (Hansiz, *Germ. Sacra*, vol. i. p. 15). And also, like most of the other early disciples, he is said not only to have preached the gospel but also to have suffered death for its sake. Gaudentius of Brescia says that this occurred at Patra in Achaia, and Nicephorus specifies as the manner of his martyrdom that he was hung on an olive tree. But elsewhere it is stated or implied that he died an ordinary death, either at Thebes in Bœotia (*Martyrol. Basil.*), or in Bithynia (Paulus Diaconus, Isidore of Seville, and the *Martyrologies* of Ado and Usuardi). Most traditions agree in stating that his body was transferred by Constantius to Constantinople ("Chron. Hieron.," ap. Mai, *Nov. Script. Coll*; Prosper Aquitanus, Paulus Diaconus, Nicephorus, and others), but its place of burial seems to have been forgotten, and Procopius (*De ædif. Justin.*, i. 4) mentions that it was discovered in Justinian's time in digging the foundations of a new

[1] Some have thought that, like the persons who are mentioned by Origen, *Comm. in Rom.*, chap. x. (vol. iv. p. 686, ed. De la Rue), Eusebius here confuses the two names Lucas and Lucius.

[2] *De Viris Illustr.*, chap. vii.; *Comm. in Matth.*, pref., vol. vii. p. 3

church; a subsequent tradition stated that it was afterwards removed to Italy, and in the 15th century Pius II. commissioned Cardinal Bessarion to decide upon a violent controversy between the Minorite monastery of S. Job at Venice and the Benedictine monastery of S. Giustina at Padua, each of which claimed to possess the perfect relics of the evangelist.

A late tradition represents Luke to have been a painter as well as a physician; the tradition first appears in a doubtful fragment of an author of doubtful date, Theodorus Lector (printed in H. Valois's edition of Theodoret, p. 618), who mentions that the empress Eudocia sent to Pulcheria, from Jerusalem to Constantinople, a picture of the Virgin painted by Luke. The same story is mentioned in an almost certainly spurious oration of John of Damascus (*Orat. in Constant. Copron.*, c. 6., vol. i. p. 618, ed. Le Quien); and the first certain authorities for the tradition are Symeon Metaphrastes and the *Menologium* of Basil the younger, both of which belong to the 10th century. That the tradition is not of much earlier growth is proved by the fact that, if it had existed, it could not fail to have been largely used in the iconoclastic controversy.

The martyrologies and calendars for the most part agree in fixing Luke's festival on October 18; but a doubt is expressed whether that day should be regarded as the anniversary of his birth or of the translation of his remains to Constantinople.

In Christian art he is usually symbolized by an ox (with reference to Ezekiel i. 10, Revelation iv. 7), on the significance of which symbol various statements were made by both Eastern and Western writers (some of them will be found quoted by Ciampini, *Vet. Monum.*, vol. i. 192). (E. HA.)

LUKE, Gospel of. See Gospels.

LUKOW, a town of Russian Poland, in the province of Siedlce, 60 miles by rail to the west of Brest-Litovsky. Owing to its situation on the railway and in the centre of a rich district, it is rapidly developing. The population is 11,050.

LUKOYANOFF, a district town in Russia, in the government of Nijni-Novgorod, 108 miles south-south-east of the chief town of the government, on the highway to Saratoff, at the sources of the Tesha river, tributary of the Oka. It is situated in a district where agriculture is carried on to a large extent, corn being sold to distilleries, and hemp exported, while the extensive forests furnish materials for the production of wooden wares. Wooden spoons, buckets, sledges, carts, implements for linen weaving, are made in large quantities by the peasants of the neighbouring villages, and exported to the steppe provinces of southern Russia; and there is also considerable trade in timber, felts, fishing nets, nails, &c. Population 9600.

LULLY, Giovanni Battista (1633-1687), was born in Florence, and joined in 1650, as a violinist, the orchestra of the French court. Though friendless and in a foreign country, his genius soon opened for him a road to honours and wealth. He was appointed director of music to King Louis XIV., and director of the Paris opera. The influence of his music was so great as to produce a radical revolution in the style of the dances of the court itself. Instead of the slow and stately movements, which had prevailed until then, he introduced lively and rhythmically quick ballets. Having found a congenial poet in Quinault, Lully composed twenty operas, which met with a most enthusiastic reception from a delighted public. He effected important improvements in the composition of the orchestra, into which he introduced several new instruments. Lully enjoyed the friendship of Molière, for some of whose best plays he composed illustrative music. His *Miserere*, written for the funeral of the minister Sequier, is a splendid work of genius; and very remarkable are also his minor sacred compositions. On his death-bed he wrote *Bisogna morire, peccatore.* Lully's right to be numbered among the most original and the best musicians is undoubted. His music is full of the most charming and enthralling forms of Italian melody; and the fact of its being even now performed, after the lapse of so many years, is proof sufficient of its inherent beauty and intrinsic worth.

LULLY, Raymond (1235-1315), the inventor of a fantastic system of logic by which Mohammedans should be converted to Christianity, was born at Palma, in the island of Majorca, in 1235. His father had been born at Barcelona, and belonged to a distinguished Catalonian family; but for his services in helping to recover the Balearic islands from the Saracens he was rewarded with a gift of land in the conquered territory, and the paternal estates descended to his enthusiastically-minded son. The younger Lully, however, showed at first but little of the speculative tendencies which he afterwards developed, and his early years were spent in the gaiety and even profligacy of a courtier in the service of James II., of Aragon, who appointed him grand seneschal of the isle. He married, but notwithstanding sought the reputation of a gallant, and was mixed up in more than one intrigue. Something, however, of the nature of a cancer, which attacked one of the objects of his passion, Signora Ambrosia,—such is the way in which we are asked to account for his "conversion,"—affected him so deeply that he abandoned in his thirty-second year his licentious life, and, having distributed the greater portion of his goods to his family and the poor, he withdrew to the retirement of a cell on Mount Randa, the only part of his property which he had reserved for himself. Visions of a crucified Saviour and like phenomena confirmed him in his devotion to the cause of Christ, and in the course of a nine years' retreat on Randa he came to regard himself as commissioned by God to refute the errors of Mohammed.

This missionary call became henceforth the actuating principle in Lully's life. To realize it, he went to Paris in his fortieth year, to prosecute the study of Latin and logic; and, with a view to becoming familiar with the language of the infidels, he engaged the services of an unlettered Arabian, who, finding that Lully was seeking to demolish the faith of Islam, attempted to assassinate his master. This need of acquiring a knowledge of the language of the church's adversary became itself now one of Lully's favourite ideas. In 1286 he began a series of visits, which he made to Rome to induce the supreme pontiff to found colleges for the study of Arabic; but the small success which would attend his efforts in this direction was foreshadowed by the death of Honorius (then pope) before he could attain an audience of him. Meanwhile Lully had become discontented with the methods of science commonly in use, and had set himself to construct his "great art," a method which, by mechanically presenting all the predicates which could attach to any subject, was adapted to answer any question on any topic, and would (its author imagined) by the cogency of its inferences necessarily convert the heathen. His natural enthusiasm respecting the consequences of this art were strengthened by revelations (as he judged them) of the co-operation of God in his designs, and he gave himself up, with the fervour of a divinely appointed missionary, to the work of spreading a knowledge of his "great art" in every country. He expounded it at Paris and Montpellier in 1286, and after a visit to Pope Nicholas, to solicit his help in founding linguistic colleges, and a serious illness at Genoa, brought on apparently by an isolated fit of nervous cowardice in face of the dangers he was going to encounter, he sailed to Tunis, to apply his new method to the errors of Mohammedanism. At Tunis his attacks upon the religion of the country led to his being cast into prison, and it was only by the mediation of a sheikh, who had been impressed by the earnestness of the Christian preacher, that he managed to escape to sea, not without the roughest treatment at the hands of the mob, and find his way to Naples.

A new influence was brought to bear on Lully's life at

Naples. He made the acquaintance of the alchemist Arnaud de Villeneuve, and acquired, we may believe, not only that skill in transmuting metals for which Lully himself became in popular tradition famous, but imbibed also something of that spirit which brought down the censure of the church on Villeneuve for maintaining that medicine and charity were more pleasing to God than religious services. For the next few years the scene of Lully's labours was continually changing. He made an unsuccessful attempt to interest Pope Boniface in the missionary colleges which he wished to see established, and similar appeals to the kings of France and Cyprus met with no more favourable a response. From Cyprus Lully proceeded (1306) to Bougiah in Africa, and repeated the experiences he had already had at Tunis. But, though Mohammedanism showed little disposition to welcome the "great art" and its author, the European world had meanwhile begun to show itself more favourably disposed towards Lully's projects. In 1297 he had received at Montpellier, from the general of the Franciscans, letters recommending him to the superiors of all Franciscan houses; and in 1309 his "art" was publicly approved by a decree of the university of Paris. Emboldened perhaps by such recognition, he appeared before the council of Vienne in southern France in 1311, and petitioned the assembled fathers to reduce the different and often-contending religious orders to one great order serving simply under Christ, and to meet Mohammedanism abroad and Averroism at home by founding colleges for the study of Arabic. Nothing would seem to have come directly of these petitions, but we may perhaps trace their result in some chairs of Syriac and Arabic which Clement V. instituted at Rome, and in a college for training Franciscans in Oriental languages which James of Aragon established in Majorca. Lully was now nearly eighty years of age, but his zeal in combating the foes of Christianity did not abate. He sailed again for Africa, and received the martyr's crown, which would seem to have become the ambition of his life. At Bougiah he again proclaimed the doctrines of the church, and his preaching raised such a tumultuous attack that although he managed to get on board a Genoese vessel, he succumbed during the voyage to the injuries he had received, and died in sight of his native town of Palma (1315).

During his lifetime Lully composed a vast number of treatises, some of which have never yet been printed. They were written partly in Latin, partly in Catalonian, Lully deserving mention as one of the first in mediæval times who tried to find a national expression for philosophy in the language of the country. Some of these works may be described as dealing with apologetic theology, *e.g.*, the *Liber de Gentili et Tribus Sapientibus*, in which a Jew, Christian, and Saracen explain the nature of their faith, or the *Disputatio Fidelis et Infidelis*; others again relate to dogmatic divinity, *e.g.*, *Liber de XIV. Articulis, De Deo et Jesu Christo*; a third class refer to particular questions of logic, *e.g.*, *De Prima et Secunda Intentione, Ars Inveniendi Particularia in Universalibus, De Venatione Medii*; and a large number are reputed to deal with questions of alchemy. But the "Great Art" of discovery itself is the subject of most of Lully's treatises. So it is with the *Ars Demonstrativa, Compendium Artis Demonstrativæ, Ars Universalis, Ars Inventiva Veritatis, De Auditu Cabbalistico, Ars Magna et Ultima.* And even when Lully is engaged with such treatises as the *Principia Medicinæ* or *Principia Juris* it is to the universal key of knowledge which the great art supplies that he invariably falls back.

The reasonableness and demonstrability of Christianity is the assumption underlying the exercise of this great method. Nothing, Lully holds, interferes more with the spread of Christianity than the attempt of its advocates to present its doctrines as undemonstrated and undemonstrable truths; the very difference between Christianity and Antichrist lies in the fact that the former can *prove* the truth of its beliefs; and the glory of the faith, repeats the *Liber Magnus Contemplationis*, is not that it maintains the indemonstrable but simply the supersensuous. The demonstration, however, which is wanted in the service of Christianity is not, Lully thinks, that of the ordinary logic; we require a method which will reason not only from effect to cause, or from cause to effect, but *per æquiparantiam*, and show that contrary attributes can coexist together in one subject. This method, however, must be real, not merely formal and subjective; it must deal not only with the second intentions, but rather with the first intentions, that is, the things themselves. The great art in fact goes beyond logic and metaphysic; as a universal topic it provides a universal art of discovery, and contains the formulæ to which every demonstration in every science can be reduced. This *ars investigandi*, however, turns out to be not so much a key to all possible knowledge as a tabulation of the different points of view from which propositions may be framed about various objects—a mechanical contrivance for finding out the different ways in which categories apply to things. Just, Lully thought, as by knowing the typical terminations of cases and tenses we could inflect and conjugate any word whatever, so by a knowledge of the different types of existence and their possible combinations as portrayed by his method we should possess implicitly a knowledge of the whole of nature.

The great art accordingly begins by laying down an alphabet according to which the nine letters from B to K stand for the different kinds of substances and attributes. Thus, in the series of substances, B stands for God, C angel, D heaven, E man, and so on; in the series of absolute attributes, B represents goodness, C greatness, D duration; or again, in the nine questions, B stands for *Utrum*, C for *Quid*, D for *De quo*. The manipulating of these letters in such a way as will show the relationship between different subjects and predicates constitutes accordingly the peculiarity of the "new art," this manipulation being effected by the help of certain so-called "figures." The construction of these figures varies somewhat in different parts of Lully's writings, but their general character is always the same. Circles and other mathematical figures divided into sections and marked by Lully's symbolical letters are so arranged, sometimes with the help of different colours, as to show the possible combinations of which the letters are capable. Thus for example one figure exhibits the possible combination of the attributes of God, another the possible conditions of the soul, and so on. These figures are fenced about by various definitions and rules, and their use is further specified by various "evacuations" and "multiplications" which show us how to exhaust and draw out *all* the possible combinations and sets of questions which the terms under consideration can admit. When so "multiplied," the fourth figure is, Lully himself says, that by which other sciences can be most easily and rapidly acquired; and it may accordingly be taken as no unfair specimen of Lully's method. This fourth figure then is simply an arrangement of three concentric circles (made of tin or pasteboard) each divided into nine sections B, C, D, &c., and so constructed that while the upper and smaller circle remains fixed, the two lower and outer revolve round it. Taking then the letters in the sense of the series which seems most fitted for the subject under discussion, we are enabled by making the outer circles revolve to find out the possible relationships between different conceptions and elucidate the agreement or disagreement which subsists between them, while, at the same time, we discover the intermediate terms (in the middle circle) by which they are to be connected or disconnected.

The weakness of Lully's art is the weakness of every system which pretends, as Bacon's also did, to equalize all intellects, and provide a method which will produce discovery as surely as compasses will construct a circle. But it would be unfair to say that Lully supposed that thinking and reasoning could be reduced to a mere rotation of pasteboard circles. The real value of his art lies not in being an *a priori* compendium of knowledge but a method of investigation—a tabulation of the different sides from which a question must be regarded, and in embodying the ideal which science puts before herself of finally bringing all conceptions into unity and correlation. It is easy, with the Port-Royal logic, to speak of Lully's art as merely enabling us "to talk without judgment of that which we do not know"; but in his conception of scientific method as tending to the glory of God and the good of man, in his departure from the school logic and his wish for a real interpretation of nature, in his conception of a universal method and his application of the vernacular languages to philosophy, he appears as a precursor of Bacon himself. And in his assertion of the place of reason in religion, in his demand that a *rational* Christianity should be presented to heathendom, in his missionary zeal and his project of linguistic colleges, Lully, with all his quixotic character, goes far beyond the ideas and the aspirations of the century in which he lived.

A few of Lully's works were published by Zetzner in 1598 and frequently reprinted; but the first systematic edition was begun by Salzinger in 1721, and after Salzinger's death completed in 1742. This edition is nominally in 10 vols., but vols. vii. and viii. were never published. In addition to older works, such as Perroquet (1667) and Nic. de Hauteville (1666) and the *Acta Sanctorum* (vol. xxiv.), the best account of Lully's life is to be found in an article by Delecluze in the *Revue d. d. Mondes* for 1840, and the fullest account of his method in Prantl, *Geschichte d. Logik*, iii. 145–177, and Erdmann, *Grundriss d. Gesch. d. Philosophie*, i. § 206. The philological importance of Lully's writings is brought out by A. Helfferich, *Raymond Lull und die Anfänge d. Catalonischen Literatur*, Berlin, 1858. (E. W.)

LUMBAGO, a term in medicine applied to a painful ailment affecting the muscles of the lower part of the back, generally regarded as of rheumatic origin. An attack of lumbago may occur alone, or be associated with rheumatism in other parts of the body at the time. It usually comes on by a seizure, often sudden, of pain in one or both sides of the small of the back, of a severe cutting or stabbing character, greatly aggravated on movement of the body, especially in attempting to rise from the recumbent posture, and also in the acts of drawing a deep breath, coughing, or sneezing. So intense is the suffering that it is apt to suggest the existence of inflammation in some of the neighbouring internal organs, such as the kidneys, bowels, &c., but the absence of the symptoms specially characteristic of these latter complaints, or of any great constitutional disturbance beyond the pain, renders the diagnosis a matter of no great difficulty. Lumbago seems to be brought on by exposure to cold and damp, and by the other exciting causes of rheumatism. Sometimes it follows a strain of the muscles of the loins. The attack is in general of short duration, but occasionally it continues for a long time, not in such an acute form as at first, but rather as a feeling of soreness and stiffness on movement. The treatment includes that for rheumatic affections in general (see RHEUMATISM) and the application of local remedies to allay the severe pain. Of these the best are hot fomentations with turpentine or laudanum applied by means of flannel or spongio-piline to the part; or the rubbing in, if this can be borne, of stimulating liniments, such as those of opium, belladonna, chloroform, aconite, &c. The old and homely plan of counter-irritation by applying a heated iron to the part with a sheet of brown paper interposed is often beneficial in chronic cases, as is also, on similar principles, Corrigan's button cautery. The subcutaneous injection of morphia or atropia is called for when the attack is very severe and prevents sleep.

LUMP-SUCKER, or LUMP-FISH (*Cyclopterus lumpus*), a marine fish, which with another genus (*Liparis*) forms a small family (*Discoboli*) closely allied to the Gobies (see GOBY). Like many fishes of the latter family, the lump-suckers have the ventral fins united into a circular concave disk, which, acting as a sucker, enables them to attach themselves firmly to rocks or stones. The body of the lump-sucker (properly so called) is short and thick, with a thick and scaleless skin, covered with rough tubercles, the larger of which are arranged in four series along each side of the body. The first dorsal fin is almost entirely concealed by the skin, appearing merely as a lump on the back. The lump-sucker inhabits the coasts of both sides of the North Atlantic; it is not rare on the British coasts, but becomes more common farther north. It is so sluggish in its habits that individuals have been caught with sea-weed growing on their backs. In the spring the fish approaches the shores to spawn, clearing out a hollow on a stony bottom in which it deposits an immense quantity of pink-coloured ova. Fishermen assert that the male watches the spawn until the young are hatched, a statement which receives confirmation from the fact that the allied gobies, or at least some of them, take similar care of their progeny. The vernacular name, "cock and hen paddle," given to the lump-fish on some parts of the coast, is probably expressive of the difference between the two sexes in their outward appearance, the male being only half or one-third the size of the female, and assuming during the spawning season a bright blue coloration, with red on the lower parts. This fish is generally not esteemed as food, but Faber (*Fisch. Islands*, p. 53) states that the Icelanders consider the flesh of the male as a delicacy.[1] Very peculiar is the structure of the bones, which are so soft, and contain so little inorganic matter, that the old ichthyologists placed the lump-sucker among the cartilaginous fishes.

[1] The "cock-padle" was formerly esteemed also in Scotland, and figures in the *Antiquary*, chap. xi.

LUND, a town of Sweden, in the län of Malmöhus, lies at a distance of 10 miles by rail north-east from Malmö. It is chiefly remarkable for its university, the second in Sweden, founded by Charles XI. in 1666, with faculties of philosophy, law, medicine, and theology; the number of students ranges from 500 to 600. The library contains about 100,000 volumes and 2000 MSS., and there are valuable collections in archæology and natural history. Among the more distinguished of its professors may be mentioned the names of Puffendorf and the poet Tegner. Linnæus was one of its alumni. The cathedral, a Byzantine structure, dedicated to St Lawrence, and said to be on the whole the finest church in Scandinavia, was founded about the middle of the 11th century, and consecrated in 1145. The crypt under the transept and choir is one of the largest in the world. The town has little else of interest to show. The statue of Tegner stands in the Tegner's Plats, and the house in which he lived from 1813 to 1826 is indicated by a stone slab with an inscription. The manufactures of Lund (woollen cloth, leather, tobacco, sugar, &c.) are unimportant. The population in December 1878 was 13,611.

Lund (*Londinum Gothorum*), the "Lunda at Eyrarsundi" of the *Egil's Saga*, was in Egil's time (about 920 A.D.) a place of considerable importance; one gathers that, if not actually a seaport, it was at least nearer the Sound then than at present. In the middle of the 11th century it was made a bishopric, and in 1103 it was advanced to the dignity of an archiepiscopal see, the archbishop receiving primatial rank over all Scandinavia in 1163. The archbishop of Upsala is now primate of Sweden, Lund since 1536 having been reduced to the rank of an ordinary bishopric, and lost its quondam title of "Metropolis Daniæ."

LÜNEBURG, the chief town of a district in the Prussian province of Hanover, is situated near the foot of a small hill named the Kalkberg, and on the river Ilmenau, 14 miles above its confluence with the Elbe, and 30 miles to the south-east of Hamburg. Numerous handsome mediæval buildings testify to its former prosperity, and part of the old town-wall also still survives. Of its four churches three—those of St John, St Nicholas, and St Michael—are large and fine Gothic edifices of the 14th and 15th centuries. The principal secular buildings are the town-house, a huge pile dating from the 13th to the 18th century, the old palace, and the convent of St Michael, now converted into a school. Lüneburg owes its importance chiefly to the gypsum and lime quarries of the Kalkberg, which afford the materials for its cement works, and to the productive salt-spring at its base. Hence the ancient saying, which, grouping with these the commercial facilities afforded by the bridge over the Ilmenau, ascribes the prosperity of Lüneburg to its *mons*, *fons*, *pons*. The industries of the town also include the making of iron-ware, soda, and haircloth. Population in 1880, 19,045.

Lüneburg existed as early as the days of Charlemagne, but did not become of any importance till after the erection of a convent and a castle on the Kalkberg in the 10th century. The decisive event, however, in fixing its future development was the destruction, in 1189, of Bardewieck, situated on the Ilmenau below Lüneburg, and then the chief commercial town in North Germany. Lüneburg inherited its trade, and subsequently appears as one of the leading towns in the Hanseatic League. From 1267 to 1369 it was the capital of an independent principality of its own name, and it was afterwards frequently involved in the quarrels of the Guelphic princes. It reached the height of its prosperity in the 15th century, and even in the 17th was the depôt for all the merchandise exported from Saxony and Bohemia to the mouth of the Elbe. The German war of liberation in 1813 was begun by an engagement with the French under General Morand near Lüneburg. Lüneburg gives its name to the Lüneburger Haide or Lüneburg Heath, an immense tract of moorland occupying the greater part of eastern Hanover.

Compare Volger, *Führer durch die Stadt Lüneburg* and *Urkundenbuch der Stadt Lüneburg*; also the *Alterthümer der Stadt Lüneburg*, 1852-72

LUNÉVILLE, the chief place of an arrondissement in the department of Meurthe and Moselle, France, 240 miles east of Paris by rail on the line to Strasburg, stands in the midst of meadows between the Meurthe and the Vezouze a little above their confluence. It is a handsome town regularly built. The chateau, designed early in the 18th century by the royal architect Boffrand, was the favourite residence of Duke Leopold of Lorraine, where he gathered round him the academy composed of eminent men of the district. It is now a cavalry barrack. Lunéville has always been an important cavalry station, and has a riding school where two hundred horsemen can exercise at the same time. The church of St Jacques, with its two towers, dates from the same period as the chateau. The church of St Maur, in the Byzantine style, is but thirty years old. The district round Lunéville is mainly agricultural, and the town has a fine corn exchange. The manufactures include pottery, embroideries, gloves, cotton cloth, and cooking stoves. There are starch works and gypsum kilns, and a considerable trade in grain, flour, hops, and other agricultural produce. The population in 1876 was 16,041.

The name of Lunéville is derived from an ancient cult of Diana. A sacred fountain and medals with the effigy of this goddess have been found at Leormont, some 2 miles east of the town. Lunéville formed part of Austrasia, and after various changes fell to the crown of Lorraine. A walled town in the Middle Ages, it suffered in the Thirty Years' War and in the campaigns of Louis XIV. from war and its consequences—plague and famine. The town flourished again under Dukes Leopold and Stanislas, on the death of the latter of whom, which took place at Lunéville, Lorraine was united to France (1766). The treaty of Lunéville between France and Austria (1801) confirmed the former power in the possession of the left bank of the Rhine. The town was the birthplace of the emperor Francis, husband of Maria Theresa, and of the painter Jean Girardet.

LUPERCALIA, one of the most remarkable and interesting Roman festivals. Its origin is attributed to Evander, or to Romulus before he founded the city, and its ceremonial is in many respects unique in Roman ritual. In front of the Porta Romana, on the western side of the Palatine hill, close to the *Ficus Ruminalis* and the *Casa Romuli*, was the cave of Lupercus; in it, according to the legend, the she-wolf had suckled the twins, and the bronze wolf which is still preserved in the Capitol was placed in it in 296 B.C. But the festival itself, which was held on February 15th under the direction of the *flamen dialis*, contains no reference to the Romulus legend, which is probably later in origin (see Mommsen in *Hermes*, 1881). The celebrants, who were called Luperci, offered in sacrifice goats and a dog; the *flamen dialis* himself was forbidden to touch either kind of animal, and it can hardly be doubted that the Lupercal sacrifice is older than the prohibition. After the sacrifice two of the Luperci were led to the altar, their foreheads were touched with a bloody sword, and the blood wiped off with wool dipped in milk; then the ritual required that the two young men should laugh. The sacrificial feast followed, after which the Luperci cut thongs from the skins of the victims and ran in two bands round the walls of the old Palatine city, striking the people who crowded near. A blow from the thong prevented sterility in women. These thongs were called *Februa*, the festival *Februatio*, and the day *Dies Februetus*; hence arose the name of the month February, the last of the old Roman year. The nearest analogy in the Roman religion to the Lupercalia is the occasional Amburbium, in which the victims were led round the walls of Rome and then sacrificed. The Lupercalia was associated with the circuit of the Palatine city, which had been a city long before the seven-hilled Rome, and the line of the old Palatine walls was marked with stones for the Luperci to run round. Unger has proved that the festival was originally a rite peculiar to the tribe of the Ramnes, the old dwellers on the Palatine, and that it was in the 3d century B.C. widened to a festival of the whole city. It is probable that then the whole ceremonial was modified; the Luperci, who were originally chosen from the Ramnes alone, were chosen from the whole body of the Equites, the people assembled round the hill, and the ceremony of scourging to avert sterility was added. Originally therefore the Luperci simply encompassed the walls as the victims did at the Amburbium, and the ceremonial connected with the two young men has generally been taken as a proof that they were at one time actually sacrificed after being led round the walls, and that a vicarious sacrifice was afterwards substituted for the ancient human offering. The Lupercalia was therefore a ceremony of purification performed for the walls and for the whole of the old Palatine city, from which it follows that it was dedicated to the peculiar god of that city. In early time the name of the god was kept strictly secret, as it was unsafe that an enemy should know it and be able to invoke him. Hence arise many conflicting statements as to the name. In later times, when the bonds of early religion were relaxed, the name became known. The god was, as Livy relates, Inuus, an old Italian deity known chiefly in southern Etruria, where there existed two towns named Castrum Inui. He was a form of the supreme heaven-god, very like Mars in character, and the rites with which his anger was averted may be compared with those of Zeus on Mount Pelion or with the Maimacteria in Athens. The Luperci were divided into two *collegia* called Quintiliani or Quinctiales (the form is doubtful, see Mommsen, *Röm. Forsch.*, i. 17) and Fabiani; at the head of each was a *magister*. In 44 B.C. a third *collegium*, *Juliani*, was instituted in honour of Julius Cæsar, the first *magister* of which was M. Antony.

This account follows in almost every particular that of Unger (*Rhein. Mus.*, 1881). He derives Lupercus from *lua* and *parco* in the old sense of restrain, and Inuus from a root seen in *avis inubra* or *inebra*, ἀναίνομαι, &c., meaning to avert or prohibit, and sees in the festival a national ceremony of the Palatine city, not with Marquardt (*Röm. Staatsverw.*, iii. 421) a widened gentile cultus of the Fabri and Quinctii or Quintilii.

LUPINE, *Lupinus*, L., a genus, of over eighty species, of the tribe *Genisteæ* of the order *Leguminosæ*. Species with digitate leaves range along the west side of America from British Columbia to Bolivia, while a few occur in the Mediterranean regions. A few others with entire leaves are found in South Carolina, the Cape, and Cochin-China (DC., *Prod.*, ii. p. 406; Benth. and Hook., *Gen. Pl.*, i. 480). The leaves are remarkable for "sleeping" in three different ways. From being in the form of a horizontal star by day, the leaflets either fall and form a hollow cone with their bases upwards (*L. pilosus*), or rise and the cone is inverted (*L. luteus*), or else the shorter leaflets fall and the longer rise, and so together form a vertical star (many sp.); the object in every case being to protect the surfaces of the leaflets from radiation (Darwin, *Movements of Pl.*, p. 340). The flowers are of the usual "papilionaceous" or pea-like form, blue, white, purple, or yellow, in long terminal spikes. The stamens are monadelphous and bear dimorphic anthers. The species of which earliest mention is made is probably *L. Termis*, Forsk., of Egypt. This is possibly the ἐρέβινθος of Homer (*Il.*, xiii. 589). It is no longer found in Greece, but is extensively cultivated in Egypt. Its seeds are eaten by the poor after being steeped in water to remove their bitterness; the stems furnish fuel and the best charcoal for gunpowder (Pick., *Chron. Hist. of Pl.*, 183). Two other species appear to have been cultivated by the ancients, *L. sativus* (*albus*, L.) allied to *L. Termis*, and *L. hirsutus*, L., this latter only about Sparta (Pick., *l.c.*, p. 202); *L. angustifolius*, L., was a corn-field weed, the θέρμος ἄγριος of Dioscorides. The θέρμος ἥμερος was used to counteract the effects of drink (Athen., 55, C.). The seeds were used as money on the stage (Plaut., *Pœn.*, 3, 2, 20; Hor., *Ep.*, i. 7, 23). *L. albus*, L., was also cultivated as a field lupine, the *L. sativus* of the Romans, referred to by Cato, *R. R.*, 34, 2; Virgil, *Georg.*, i. 75; Pliny, xviii. 36; &c. In 1597 Gerard (*Herball*, p. 1042) writes:—"There be diuers sortes of the flat Beane called Lupine, some of the garden, and others wild"; and he figures three species, *L. sativus* (now *L. albus*, L.), *L. luteus*, L., and *L. varius*, L. Few species are in cultivation now, but the varieties are very numerous (see Paxton's *Bot. Dict.*, p. 345; Hemsley's *Hand. of Hardy Trees*, &c., p. 115). Of species now grown, *L. albus*, L., is still extensively cultivated in Italy, Sicily, and other Mediterranean countries for forage, for ploughing in to enrich the land, and for its round flat seeds, which form an article of food. This, as well as the other two mentioned by Gerard, have been superseded as garden flowers by the American species, *e.g.*, *L. arboreus*, Sims, and *L. polyphyllus*, from California; *L. versicolor* and *L. tomentosus*, from Peru.

LURAY CAVERN, in Page county, Virginia, United States, 39° 35′ N. lat. and 78° 17′ W. long., is 1 mile west of the village of Luray, on the Shenandoah Valley Railroad. The valley, here 10 miles wide, extends from the Blue Ridge to the Massanutton mountain, and displays remarkably fine scenery. These ridges lie in vast folds and wrinkles; and elevations in the valley are often found to be pierced by erosion. Cave Hill, 300 feet above the water-level, had long been an object of local interest on account of its pits and oval hollows, or sink-holes, through one of which, August 13, 1878, Mr Andrew J. Campbell and others entered, thus discovering the extensive and beautiful cavern now described.

Geologically considered, the Luray cavern does not date beyond the Tertiary period, though carved from the Silurian limestone. At some period long subsequent to its original excavation, and after many large stalactites had grown, it was completely filled with glacial mud charged with acid, whereby the dripstone was eroded into singularly grotesque shapes. After the mud had been mostly removed by flowing water, these eroded forms remained amid the new growths. To this contrast may be ascribed some of the most striking scenes in the cave. The many and extraordinary monuments of aqueous energy include massive columns wrenched from their place in the ceiling and prostrate on the floor; the hollow column 40 feet high and 30 feet in diameter, standing erect, but pierced by a tubular passage from top to bottom; the leaning column, nearly as large, undermined and tilting like the campanile of Pisa; the organ, a cluster of stalactites dropped points downward and standing thus in the room known as the cathedral; besides a vast bed of disintegrated carbonates left by the whirling flood in its retreat through the great space called the Elfin Ramble.

The stalactitic display exceeds that of any other cavern known, and there is hardly a square yard on the walls or ceiling that is not thus ornamented. The old material is yellow, brown, or red; and its wavy surface often shows layers like the gnarled grain of costly woods. The new stalactites growing from the old, and made of hard carbonates that had already once been used, are usually white as snow, though often pink, blue, or amber-coloured. The size attained by single specimens is surprising. The Empress Column is a stalagmite 35 feet high, rose-coloured, and elaborately draped. The double column, named from Professors Henry and Baird, is made of two fluted pillars side by side, the one 25 and the other 60 feet high, a mass of snowy alabaster. Several stalactites in the Giant Hall exceed 50 feet in length. The smaller pendents are innumerable; in the canopy above the Imperial Spring it is estimated that 40,000 are visible at once.

The "cascades" pointed out are wonderful formations like foaming cataracts caught in mid-air and transformed into milk-white or amber alabaster. The Chalcedony Cascade displays a variety of colours. Brand's Cascade, which is the finest of all, being 40 feet high and 30 feet wide, is unsullied and wax-like white, each ripple and braided rill seeming to have been polished.

The Swords of the Titans are monstrous blades, eight in number, 50 feet long, 3 to 8 feet wide, hollow, 1 to 2 feet thick, but drawn down to an extremely thin edge, and filling the cavern with tones like tolling bells when struck heavily by the hand. Their origin and also that of certain so-called scarfs and blankets exhibited is from carbonates deposited by water trickling down a sloping and corrugated

surface. Sixteen of these alabaster scarfs hang side by side in Hovey's Balcony, three white and fine as crape shawls, thirteen striated like agate with every shade of brown, and all perfectly translucent. Down the edge of each a tiny rill glistens like silver, and this is the ever-plying shuttle that weaves the fairy fabric.

Streams and true springs are absent, but there are hundreds of basins, varying from 1 to 50 feet in diameter, and from 6 inches to 15 feet in depth. The water in them is exquisitely pure, except as it is impregnated by the carbonate of lime, which often forms concretions, called, according to their size, pearls, eggs, and snowballs. A large one is known as the cannon ball. On fracture these spherical growths are found to be radiated in structure.

Calcite crystals, drusy, feathery, or fern-like, line the sides and bottom of every water-filled cavity, and indeed constitute the substance of which they are made. Variations of level at different periods are marked by rings, ridges, and ruffled margins. These are strongly marked about Broaddus Lake, and the curved ramparts of the Castles on the Rhine. Here also are polished stalagmites, a rich buff slashed with white, and others, like huge mushrooms, with a velvety coat of red, purple, or olive-tinted crystals. In some of the smaller basins it sometimes happens that when the excess of carbonic acid escapes rapidly there is formed, besides the crystal bed below, a film above, shot like a sheet of ice across the surface. One pool 12 feet wide is thus covered so as to show but a third of its surface. The quantity of water in the cavern varies greatly at different seasons. Hence some stalactites have their tips under water long enough to allow tassels of crystals to grow on them, which, in a drier season, are again coated over with stalactitic matter; and thus singular distortions are occasioned. Contiguous stalactites are often inwrapped thus till they assume an almost globular form, through which, by making a section, the primary tubes appear. Twig-like projections, lateral outgrowths, to which the term helictite has been applied, are met with in certain portions of the cave, and are interesting by their strange and uncouth contortions. Their presence is partly due to the existence of a diminutive fungus peculiar to the locality, and designated from its habitat *Mucor stalactitis*. The Toy-Shop is an amusing collection of these freaks of nature.

The dimensions of the various chambers included in Luray Cavern cannot easily be stated, on account of the great irregularity of their outlines. Their size may be seen from the diagram on p. 67. But it should be understood that there are several tiers of galleries, and the vertical depth from the highest to the lowest is 260 feet. The tract of 100 acres owned by the Luray Cave Company covers all possible modes of entrance; and the explored area is much less than that.

The waters of this cavern appear to be entirely destitute of life; and the existing fauna is quite meagre, comprising only a few bats, rats, mice, spiders, flies, and small centipedes. When the cave was first entered, the floor was covered with thousands of tracks of raccoons, wolves, and bears,—most of them probably made long ago, as impressions made in the tenacious clay that composes most of the cavern floor would remain unchanged for centuries. Layers of excrementitious matter appear, and also many small bones, along with a few large ones, all of existing species. The traces of human occupation as yet discovered are pieces of charcoal, flints, moccasin tracks, and a single skeleton imbedded in stalagmite in one of the chasms, estimated to have lain where found for not more than five hundred years, judging from the present rate of stalagmitic growth.

The temperature is uniformly 54° Fahr., coinciding with that of the Mammoth Cave, Kentucky. The air is very pure, and the avenues are not uncomfortably damp.

The portions open to the public are now lighted by electric lamps. The registered number of visiters in 1881 was 12,000. (H. C. H.)

LURGAN, a market-town in the county of Armagh and province of Ulster, Ireland, is situated a few miles south of Lough Neagh, and 20 miles south-west of Belfast by rail. It consists principally of one spacious and well-built street. The parish church of Shankill has a finely proportioned tower. The other principal public buildings are the town-hall, the mechanics' institute, the model school, and the linen-hall. Contiguous to the town is Brownlow House, a fine Elizabethan structure, the seat of Lord Lurgan. Of late years the linen trade of the town has much increased, and there are also tobacco factories and coach factories. From 7774 in 1861 the population increased in 1871 to 10,632, but in 1881 it was only 10,184.

Lurgan was built by William Brownlow, to whom a grant of the town was made by James I. In 1619 it consisted of forty-two houses, all inhabited by English settlers. It was burned by the insurgents in 1641, and again by the troops of James II. After its restoration in 1690 a patent for a market and fair was obtained.

LURISTAN, or LÚRISTÁN, a province of western Persia, with ill-defined limits, but lying mainly between 31° and 33° N. lat. and between 47° and 52° E. long., and bounded N. and E. by Irak-Adjemi, S. by Farsistan, W. by Khuzistan and the Turkish vilayet of Baghdad. It thus stretches north-west and south-east some 260 miles, with a mean breadth of 70 miles and an area of rather less than 20,000 square miles. The surface is mostly mountainous, being occupied in the west by the Pusht-i-koh range, which forms the frontier line towards Turkey, in the east by the Bakhtiari (Zagros) range, which runs north-west and south-east, thus connecting the Kurdistan with the Kuh-Dinar or Farsistan highland systems. Between the parallel Pusht-i-koh and Bakhtiari chains there stretch some naturally fertile plains and low hilly districts, which, however, are little cultivated, although well-watered by the Karun, Dizful, and Kerkhah, the three chief rivers of the province. There are two main divisions—Luri Buzurg, or "Great Luristan," comprising the Bakhtiari highlands westwards to river Dizful, and Luri Kuchak, or "Little Luristan," stretching thence to Khuzistan and Turkey. The latter is again divided into the Pesh-koh and Pusht-i-koh districts ("before" and "behind" the mountains), and notwithstanding its name is by far the most populous and productive of the two. From the 12th to the 17th century it formed an independent principality under hereditary rulers with the title of "atabeg," the last of whom was deposed by Shah Abbas, and the government transferred to Husen Khan, chief of the Faili tribe, with the title of "vali." His descendants are still at the head of the administration; but the power of the valis has been much reduced since the transfer of the Pesh-koh district to Kirmanshah.

Lúristán takes its name from the Luri,[1] a semi-nomad people of Iranian stock and speech, who still form the vast majority of the population. Great uncertainty has hitherto prevailed regarding the nomenclature, the main divisions and the true affinity of the Luri to the other branches of the Iranian family. Thus, from the name of the present ruling clan all the tribes of Luri Kuchak are commonly spoken of as "Faili," a term which is now rejected by the Pesh-koh tribes, and which, if used at all as a general ethnical expression, ought to be restricted to those of Pusht-i-koh, still under the rule of the vali. The classifications of Layard, Rawlinson, and A. H. Schindler differ materially, while contradictory statements are made by well-informed writers regarding the physical and linguistic relations of the Luri to the neighbouring Kurds and Persians. From a careful consideration of the available evidence it would appear that the Luri are the true aborigines of their present domain, where they occupy an intermediate position between the Kurds and Persians, but resembling the former much more than the latter in speech, temperament, social habits, and physical appearance. Although they themselves reject the name of Kurd, the two languages are essentially one, so that the natives of Kirmanshah and Dizful have little difficulty in conversing together. Like the Kurds, they are also of a restless and unruly disposition, averse from a settled life, still dwellers in tents, mostly owners of flocks and herds, holding agriculture in contempt, and of predatory habits. "In appearance the Bakhtiari look rather fierce, owing probably to the mode of life they lead; the features of their face are cast in a rough mould, but although coarse they are in general regular. Their black eyes look wild and expressive, and the two black tufts of hair behind their ears give them, if possible, a still darker appearance. They are muscular built, and are chiefly of a middle stature" (E. Balfour). In a word, the Luri must be classed anthropologically in the same group as the Kurds. They are excellent stock breeders, and their horses and mules are regarded as the very best in Persia. Of the mules, about a thousand are annually exported to the surrounding provinces. Most of the hard work is left to the women, who tend the flocks, till the little land under cultivation, tread out the corn, and weave the carpets, black goat-hair tents, and horse cloths for which Luristan is famous. The men put their hands to no useful work, go about armed, and are always ready for a foray. Their constant intertribal feuds render the country unsafe for trade and travel, while their revolts against the central government often cause a total interruption of communi-

[1] Not to be confounded with the *Luri* or *Lori* of Baluchistan and Sind, tinkers, bards, strolling minstrels, &c., betraying a "marked affinity to the Gipsies of Europe" (Pottinger).

cation between the several districts. This evil, however, has somewhat abated since the tribal chiefs have been compelled to give hostages as security for their good behaviour.

Outwardly Mohammedans of the Shiah sect, the Lúri show little veneration either for the Prophet or the Koran. Their religion seems to be a curious mixture of Ali-Ilahism, involving a belief in successive incarnations and the worship of the national saint, Baba Buzurg, combined with many mysterious rites, sacrifices, and secret meetings certainly anterior to Islam, and possibly traceable to the ancient rites of Mithras and Anaitis.

The chiefs enjoy almost unlimited authority over their subjects, and the tribal organization is strongly marked by the feudal spirit.

The total population of Luristan is about 320,000, and the average revenue nearly £40,000 sterling.

LUSATIA (German, *Lausitz*) is a common name applied to two neighbouring districts in Germany, Lusatia Superior and Lusatia Inferior (Oberlausitz and Niederlausitz), belonging in part to Prussia and in part to Saxony. The country now known as Upper Lusatia was occupied in the 7th century by the Milcieni, a Slavonic tribe. In the 10th century it was annexed to the German kingdom by the margraves of Meissen, and from this time for several centuries it was called Budissin (Bautzen), from the name of the principal fortress. In the 11th and 12th centuries Budissin changed hands several times, being connected at different periods with Meissen, Poland, and Bohemia. The emperor Frederick I. granted it in 1158 to King Ladislaus of Bohemia, and under him and his immediate successors it was largely colonized by German immigrants. Between 1253 and 1319 it belonged to Brandenburg, to the margrave of which it was given in pledge by King Ottocar II. of Bohemia; and in 1268 it was divided into an eastern and a western part—Budissin proper and Görlitz. In 1319 Budissin proper was restored to Bohemia, which also recovered Görlitz in 1346. It was during this period that the fortunes of Budissin were associated with those of the country afterwards called Lower Lusatia, but originally Lusatia. It was inhabited by a Slavonic tribe, the Lusici, and reached in the earliest times from the Black Elster to the Spree. The Lusici were conquered by Margrave Gero in 963, and their land was soon formed into a separate march, sometimes attached to, sometimes independent of, the march of Meissen. In 1303 it passed, as Budissin had done, to Brandenburg, and in 1373, after several changes, it fell into the hands of the emperor Charles IV. as king of Bohemia. During the Hussite wars the people of Lusatia and Budissin remained loyal to the Roman Catholic Church, and in 1467 they recognized as their sovereign King Matthias of Hungary. Twenty-three years later they were again united to Bohemia, but in the meantime they had received from the Hungarian Government the names which they have since retained. In the 16th century the Reformation made way rapidly in Upper Lusatia, and the majority of the people became Protestants. The two countries were conquered in 1620, with the sanction of Ferdinand II., by the Saxon elector, John George I., to whom they were ceded in 1635, the emperor as king of Bohemia retaining a certain supremacy for the purpose of guarding the rights and privileges of the Roman Catholic Church. In 1815 the whole of Lower Lusatia and the half of Upper Lusatia were transferred from Saxony to Prussia. Lower Lusatia has 395,800 inhabitants, of whom 50,000 are Wends; the portion of Upper Lusatia belonging to Prussia has 243,500 inhabitants, of whom 32,000 are Wends. There are 300,000 inhabitants, including 50,000 Wends, in Saxon Upper Lusatia. Laws relating to Upper Lusatia, which are passed by the Saxon Parliament, must still be submitted to the Lusatian diet at Bautzen.

LUSHAI OR KUKI HILLS, a wild and imperfectly known tract of country on the north-eastern frontier of India, extending along the southern border of the Assam district of Cáchár and the eastern border of the Bengal district of Chittagong. On the east, the Lushái Hills stretch away into the unexplored mountains of Independent Burmah. This extensive region is occupied by a numerous family of tribes known to us indifferently as Lusháis or Kukis. All these tribes are nomadic in their habits, and subject to successive waves of migration. It is said that at the present time the entire race of the Lusháis is being forced southwards into British territory under pressure from the Soktis, a tribe advancing upon them from Independent Burmah. The principal characteristic common to all the Lusháis, and in which they markedly differ from the other tribes on the Assam frontier, is their feudal organization under hereditary chiefs. Each village is under the military command of a chief, who must come of a certain royal stock. The chief exercises absolute power in the village; and his dignity and wealth are maintained by a large number of slaves and by fixed contributions of labour from his free subjects. Cultivation is carried on according to the nomadic system of tillage on temporary clearings in the jungle; but the main occupation of the people is hunting and warfare

From the earliest times the Lusháis have been notorious for their sanguinary raids into British territory, which are said to be instigated by their desire to obtain human heads for use at their funeral ceremonies. The first of which we have record was in 1777. In 1849 a colony of Lusháis settled within Cáchár, was attacked by their independent kinsmen, and forced to migrate northwards across the Barák river, where they now live as peaceable British subjects, and are known as "Old Kukis." In 1860 a raid was made upon Tipperah district, in which 186 Bengálí villagers were massacred and 100 carried away into captivity. Retributive expeditions, consisting of small forces of sepoys, were repeatedly sent to punish these raids, but, owing to the difficult nature of the country and the fugitive tactics of the enemy, no permanent advantage was gained. At last the disturbed state of the frontier attracted the attention of the supreme government. A military demonstration in 1869 had entirely failed in its object. Relying upon their belief in the impracticable character of their native country, the Lusháis made a series of simultaneous attacks in January 1871 upon British villages in Cáchár, Sylhet, and Tipperah, as well as on the independent state of Manipur. The outpost of Monierkhál repelled a number of attacks, lasting through two days, made by a second body of Lusháis from the eastern tribes, who finally retired with a large amount of plunder, including many coolies and guns. Lord Mayo, the viceroy, resolved to make a vigorous effort to stop those inroads, once and for all. A punitive expedition was organized, composed of two Gúrkha battalions, two Punjab and two Bengal native infantry regiments, two companies of sappers and miners, and a detachment of the Pesháwar mountain battery. This little army was divided into two columns, one advancing from Cáchár and the other from the Chittagong side. Both columns were completely successful. The resistance of the Lusháis, though obstinate in parts, was completely overcome, and the chiefs made their personal submission and accepted the terms offered them. Upwards of one hundred British subjects were liberated from captivity. The actual British loss in fighting was very small, but a large number of soldiers and camp-followers died from cholera. Since this expedition, the Lusháis have remained quiet along the entire frontier, and active measures have been taken to open commercial intercourse between them and the people of the plains. Many *bázárs* have been established for this purpose, and trade by barter is now freely carried on.

LUSTRATION is a term that includes all the methods of purification and expiation among the Greeks and Romans. Among the Greeks there are two ideas clearly distinguishable—that human nature must purify itself from guilt before it is fit to enter into communion with God or even to associate with men (καθαίρω, κάθαρσις), and that guilt must be expiated voluntarily by certain processes which God has revealed in order to avoid the punishment that must otherwise overtake it (ἱλασμός). It is not possible to make such a distinction among the Latin terms *lustratio*, *piacula*, *piamenta*, *cærimoniæ*, and even among the Greeks it is not consistently observed. The conception of sin never reached a high moral standard, and the methods of lustration are purely ritualistic. Guilt and impurity arose in various ways; among the Greeks, besides the general idea that man is always in need of purification, the species of guilt most insisted on by religion are incurred by murder, by touching a dead body, by sexual intercourse, and by seeing a prodigy or sign of the divine will. The last three of these spring from the idea that man had been without preparation and in an improper manner brought into communication with God, and was therefore guilty. The first, which involves a really moral idea of guilt, is far more important than the others in Hellenic religion. Among the Romans we hear more of the last species of impurity; in general the idea takes the form that after some great disaster the people become convinced that some guilt has been incurred somewhere and must be expiated. The methods of purification consist in ceremonies performed with water, fire, air, or earth, or with a branch of a sacred tree, especially of the laurel, and also in sacrifice and other ceremonial. Before entering a temple the worshipper dipped his hand in the vase of holy water (*περιρραντήριον*, *aqua lustralis*) which stood at the door; before a sacrifice bathing was a common kind of purification; salt-water was more efficacious than fresh, and the celebrants of the Eleusinian mysteries bathed in the sea (*ἅλαδε μύσται*); the water was more efficacious if a firebrand from the altar were plunged in it. The torch, fire, and sulphur (*τὸ θεῖον*) were also powerful purifying agents. Purification by air was most frequent in the Dionysiac mysteries; puppets suspended and swinging in the air (*oscilla*) formed one way of using the lustrative power of the air. Rubbing with sand and salt was another excellent method. The sacrifice chiefly used for purification by the Greeks was a pig; among the Romans it was always, except in the Lupercalia, a pig, a sheep, and a bull (*suovetaurilia*). In Athens a purificatory sacrifice and prayer was held before every public meeting; the Maimacteria in honour of Zeus Meilichios was an annual festival of purification, and several other feasts had the same character. On extraordinary occasions lustrations were performed for a whole city. So Athens was purified by Epimenides after the Cylonian massacre, and Delos in the Peloponnesian War. In Rome, besides such annual ceremonies as the *Ambarvalia*, *Lupercalia*, *Cerealia*, *Paganalia*, &c., there was a lustration of the fleet before it sailed, and of the army before it marched. Part of the ceremonial always consisted in leading or carrying the victims round the impure persons or things. After any disaster the *lustratio classium* or *exercitus* was often again performed, so as to make certain that the gods got all their due. The *Amburbium* was a similar ceremonial performed for the whole city on occasions of great danger or calamity. *Ambilustrium* was the purificatory ceremony, consisting in sacrifice and prayer, performed after the regular quinquennial census of the Roman people.

LUTE. The European lute is derived in form and name from the Arabic "el 'ûd," "the wood," the consonant of the article "el" having been retained in the European languages for the initial of the name (French, *luth*; Ital., *liuto*; Span., *laud*; German, *Laute*; Dutch, *luit*). The Arab instrument, with convex sound-body, pointing to the resonance board or membrane having been originally placed upon a gourd, was strung with silk and played with a plectrum of shell or quill. It was adopted by the Arabs from Persia, the typical instrument being the two-stringed "tanbur," and ultimately found its way to the West at the time of the crusades. The modern Egyptian "'ûd" is the direct descendant of the Arabic lute, and, according to Lane, is strung with seven pairs of catgut strings played by a plectrum. A specimen at South Kensington, given by the Khedive, has four pairs only, which appears to have been the old stringing of the instrument. When frets are employed they are of catgut disposed according to the Arabic scale of seventeen intervals in the octave, consisting of twelve limmas, an interval rather less than our equal semitone, and five commas, which are very small but quite recognizable differences of pitch.

The lute family is separated from the guitars, also of Eastern origin, by the formation of the sound body, which is in all lutes pear-shaped, without the sides or ribs necessary to the structure of the flat-backed guitar and cither. Observing this distinction, we include with the lute the little Neapolitan mandoline of 2 feet long, and the large double-necked Roman chitarrone, which not unfrequently attains to a length of 6 feet. Mandolines are partly strung with wire, and are played with a plectrum, indispensable for metal or short strings. Perhaps the earliest lutes were so played, but the large lutes and theorbos strung with catgut have been invariably touched by the fingers only, the length permitting this more sympathetic means of producing the tone.

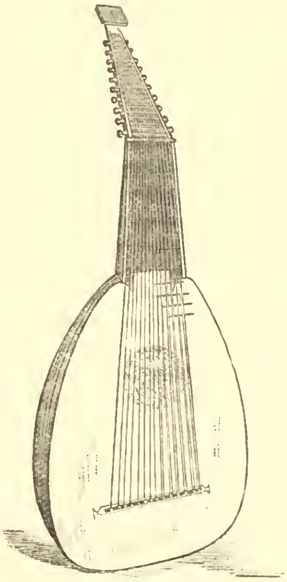
The Neapolitan is the best known mandoline; it was indicated by Mozart in the score of *Don Giovanni*, to accompany the famous serenade. The four pairs of strings are tuned like the violin, in fifths :—

The Milanese is larger, and has five and six pairs :—

or, as in a specimen at South Kensington,

The mandola or mandore is larger than either, with eight pairs of strings. This name has been derived from the Italian word, similarly spelled but differently accented, signifying almond, which the mandola is supposed to resemble in shape, but *ban*, *man*, *pan*, and *tan* are first syllables of lute and guitar instruments met with all over the world, the oldest form of which is the borrowed Greek "*πανδοῦρα*," an Asiatic word, which the Arabs changed to "tanbur." Prætorius (*Organographia*, Wolfenbüttel, 1619, a scarce work, of which the only copy in Great Britain is in the Advocates' Library, Edinburgh), writing when the lute was in universal favour, mentions seven varieties distinguished by size and tuning. The smallest would be larger than a mandoline, and the melody string, the "chanterelle," often a single string, lower in pitch. Prætorius calls this an octave lute, with the chanterelle C or D. The two discant lutes have respectively B and A, the alto G, the tenor E, the bass D, and the great octave bass G, an octave below the alto lute which may be taken as the model lute cultivated by the amateurs of the time. The bass lutes were most likely theorbos, that is, double-necked lutes, as described below. The accordance of an alto lute was

founded upon that of the original eight-stringed European lute, to which the highest and lowest notes had, in course of time, been added. A later addition was the  also on the finger-board, and bass strings, double or single, known as diapasons, which, descending to the deep C of the violoncello, were not stopped with the fingers. The diapasons were tuned as the key of the piece of music required. The illustration represents an Italian instrument made by one of the most celebrated lute makers, Venere of Padua, in 1600; it is 3 feet 6 inches high, and has six pairs of unisons and eight single diapasons. The finger-board, divided into approximately equal half tones by the frets, as a rule eight in number, was often further divided on the higher notes, for ten, eleven, or, as in the woodcut, even twelve, semitones. The head, bearing the tuning pegs, was placed at an obtuse or a right angle to the neck, to increase the bearing of the strings upon the nut, and be convenient for sudden requirements of tuning during performance, the trouble of keeping a lute in tune being proverbial.



Lute, by Venere of Padua.

The lute was in general use during the 16th and 17th centuries. In the 18th it declined; still the great J. S. Bach wrote a "partita" for it, which remains in manuscript. The latest date we have met with of an engraved publication for the lute is 1760.

The large double-necked lute, with two sets of tuning pegs, the lower for the finger-board, the higher for the diapason strings, was known as the theorbo; also, and especially in England, as the archlute; and, in a special form, the neck being then very long, as the chitarrone. Theorbo and chitarrone appear together at the close of the 16th century, and their introduction was synchronous with the rise of accompanied monody in music, that is, of the oratorio and the opera. Peri, Caccini, and Monteverde used theorbos to accompany their newly-devised recitative, the invention of which in Florence, from the impulse of the Renaissance, is well known. The height of a theorbo varied from 3 feet 6 inches to 5 feet, the Paduan being always the largest, excepting the Roman 6-feet long chitarrone. These large lutes had very deep notes, and doubtless great liberties were allowed in tuning, but the strings on the finger-board followed the lute accordance already given, or another quoted by Baron (*Untersuchung des Instruments der Lauten*, Nuremberg, 1727) as the old theorbo or "violway" (see Mace, *Musick's Monument*, London, 1676):—

We find again both these accordances varied and transposed a tone higher, perhaps with thinner strings, or to accommodate local differences of pitch; Prætorius recommends the chanterelles of theorbos being tuned an octave lower on account of the great strain. By such a change, another authority, the Englishman Thomas Mace, says, the life and spruceness of airy lessons were quite lost. The theorbo or archlute had at last to give way to the violoncello and double bass, which are still used to accompany the "recitativo secco" in oratorios and operas. Handel wrote a part for a theorbo in *Esther* (1720); after that date it appears no more in orchestral scores, but remained in private use until nearly the end of the century.

We cannot refrain from admiring the beauty of decoration of ivory, mother of pearl, and tortoiseshell, the characteristic patterning of the "knots" or "roses" in the sound-boards, all of which was so well allied with the extremely artistic forms of the different lutes, rendering them, now their musical use is past, objects of research for collections and museums. The present direction of musical taste and composition is adverse to the cultivation of such tenderly sensitive timbre as the lute possessed. The lute and the organ share the distinction of being the first instruments for which the oldest instrumental compositions we possess were written. It was not for the lute, however, in our present notation, but in tablature, "lyrawise," a system by which as many lines were drawn horizontally as there were pairs of strings on the finger-board, the frets being distinguished by the letters of the alphabet, repeated from A for each line. This was the English manner; the Italian was by numbers instead of letters. The signs of time were placed over the stave, and were not repeated unless the mensural values changed.

LUTHER (1483–1546). *First Period* (1483–1517).—Martin Luther (Lyder, Lüder, Ludher—from Lothar, some say) was born at Eisleben in the county of Mansfeld, in Thuringia, on the 10th of November 1483. His father Hans Luther, a slate-cutter by trade, belonged to a family of free peasants. His mother was Margaret Lindeburn. Hans Luther had left Möhra, his native village, and had come to Eisleben to work as a miner. When Martin was six months old he went to Mansfeld and set up a forge, the small profits of which enabled him to send his son to the Latin school of the place. There the boy so distinguished himself that his father determined to make him a lawyer, and sent him for a year to a Franciscan school at Magdeburg, and then to Eisenach near Möhra. There Luther, with other poor scholars, sang for alms in the streets, and his fine tenor voice and gentle manners attracted the attention and gained for him the motherly care of Ursula Cotta, the wife of the burgomaster of Eisenach. From Eisenach he went in his eighteenth year to the high school of Erfurt, where his favourite master was the humanist Trutwetter, who taught him classics and philosophy. He took his bachelor's degree in 1502, and his master's in 1505. At Erfurt the preaching of the town's pastor Weisemann made a deep impression on his mind, as did the preacher's frequent exhortations to study the Scripture. Luther tells us that he sought in vain for a whole Bible, and that he could only get portions to read. A dangerous illness, the death of a near friend, together with other circumstances, so wrought on his pious, sensitive nature that in spite of father and family he resolved to give up all his prospects and become a monk. He entered the Augustinian convent at Erfurt in June 1505, taking with him Plautus and Virgil, the solitary mementos of the life he had abandoned. His first years of monastic life were spent in fierce mental struggle. He had found a whole Bible and read it diligently, but it did not bring him peace. The feeling of universal human sinfulness, and of his own, was burnt into him both by his dogmatic studies and by his reading of the Scripture. He lived a life of the severest mortification, and invented continually new forms of penance, and all the while heart and head alike told him that outward acts could never banish sin. "I tormented myself to death," he said, "to make my peace with God, but I was in darkness and found it not." The vicar-general of his order, Staupitz, who had passed through somewhat similar experiences, helped him greatly. "There is no true repentance," he said, "but that which begins with the love of righteousness and of God. Love Him then who has first loved thee." Staupitz had been taught heart religion by the mystics, and he sent Luther to the sermons of Tauler and to the *Theologia Germanica*.

When Luther regained his mental health, he took courage to be ordained priest in May 1507, and next year, on the recommendation of Staupitz, the elector of Saxony appointed him professor in the university of Wittenberg, which had been founded in 1502. While in the monastery Luther had assiduously pursued his studies, and his severe mortifications and penances had never interrupted his theological work. He read all the great scholastic theologians, but Augustine was his master in theology, while Erfurt studies under Trutwetter doubtless made him pore over Occam ("mein lieber Meister," as he afterwards fondly called him) till he got his bulky folios by heart. He began by lecturing on Aristotle; and in 1509 he gave Biblical lectures, which from the very first were a power in the university. His class-room was thronged; his fellow-professors were students. Staupitz forced him also to preach; and his marvellous eloquence, felt to be from the heart, attracted great crowds of hearers. The year 1511 brought an apparent interruption, but in fact only a new development, of Luther's character and knowledge of the world. He went to Rome, probably in fulfilment of an old vow, and the journey was a marked event in his life. He went up in true pilgrim spirit, a mediæval Christian, and he came back a Protestant. The pious German was horrified with what he saw in Rome, and he afterwards made telling use of what he had seen in various tracts, and notably in his address to the German nobles. He tells us that at Wittenberg he had pondered over the text, "The just shall live by faith," that while in Rome the words came back to him, and that on his return journey to Germany the evangelical meaning of the phrase rushed into his mind. On his return to the university he was promoted to the degree of doctor of divinity, in October 1512. The oath he had to take on the occasion "to devote his whole life to study, and faithfully to expound and defend the holy Scripture," was to him the seal of his mission. He began his work with lectures on the Psalms, and then proceeded to comment on the epistles of Paul to the Romans and Galatians, enforcing especially his peculiar views of the relations between law and gospel. His lectures and his sermons were attended by great audiences, and disciples gathered round him. As early as 1516 his special principles were publicly defended at academical disputations. Staupitz made him district-vicar of his order for Meissen and Thuringia. He made short preaching tours, and his influence was felt far beyond Wittenberg. When the plague came to that university town he remained at his post when others fled. Then came 1517, the year of the Reformation. The new pope, Leo X., had sent agents through Germany to sell indulgences, and had chosen John Tetzel, a Dominican monk, for Saxony. Luther, who had passed through deep soul-struggles ere he won pardon, knew that God's forgiveness could not be purchased for money, and thundered against Tetzel and his indulgences from Wittenberg pulpit. He wrote anxiously to the princes and bishops to refuse the pardon-seller a passage through their lands. When Tetzel got to Jüterbogk near Wittenberg, Luther could stand it no longer. He wrote out ninety-five propositions or theses denouncing indulgences, and on the eve of All Saints, October 31, nailed the paper to the door of the Castle church. In a short time all Germany was ablaze.

The Wittenberg theses

These ninety-five theses are one continuous harangue against the doctrine and practice of pardon-selling, but they do not openly denounce indulgence in every form. They make plain these three things:—(1) there may be some good in indulgence if it be reckoned one of the many ways in which God's forgiveness of sin can be proclaimed; (2) the external signs of sorrow are not the real inward repentance, nor are they as important as that is, and no permission to neglect the outward expression can permit the neglect of true repentance; (3) every Christian who feels true sorrow for sin is there and then pardoned by God for Christ's sake without any indulgence ticket or other human contrivance. And in his sermons on indulgence Luther declared that repentance consisted in contrition, confession, and absolution, and that contrition was the most important, and in fact the occasion of the other two. If the sorrow be true and heartfelt, confession and pardon will follow. The inward and spiritual fact of sorrow for sin, he thought, was the great matter; the outward signs of sorrow were good also, but God, who alone can pardon, looks to the inward state. These theses, with the sermons explaining them, brought Germany face to face with the reality of blasphemy in the indulgences. Luther's public life had opened; the Reformation had begun.

Luther preaching.

Second Period (1517–1524).—Pilgrims who had come to Wittenberg to buy indulgences returned with the theses of Luther in their hands, and with the impression of his powerful evangelical teaching in their hearts. The national mind of Germany took up the matter with a moral earnestness which made an impression, not only upon the princes, but even upon bishops and monks. At first it seemed as if all Germany was going to support Luther. The traffic in indulgences had been so shameless that all good people and all patriotic Germans had been scandalized. But Luther had struck a blow at more than indulgences, although he scarcely knew it at the time. In his theses and explanatory sermons he had declared that the inward spiritual facts of man's religious experience were of infinitely more value than their expression in stereotyped forms recognized by the church, and he had made it plain too that in such a solemn thing as forgiveness of sin man could go to God directly without human mediation. Pious Christians since the day of Pentecost had thought and felt the same, and all through the Middle Ages men and women had humbly gone to God for pardon trusting in Christ. They had found the pardon they sought, and their simple Christian experience had been sung in the hymns of the mediæval church, had found expression in its prayers, had formed the heart of the evangelical preaching of the church, and had stirred the masses of people in the many revivals of the Middle Ages. But those pious people, hymn-writers, and preachers had not seen that this inward experience of theirs was really opposed to a great part of the ecclesiastical system of their day. The church had set such small store by that inward religious experience that the common speech of the times had changed the plain meanings of the words "spiritual," "sacred," "holy." A man was "spiritual" if he had been ordained to office in the church; money was "spiritual" if it had been given to the church; an estate, with its roads, woodlands, fields, was "spiritual" or "holy" if it belonged to a bishopric or abbey. And the church that had so degraded the meaning of "spiritual" had thrust itself and its external machinery in between God and the worshipper, and had proclaimed that no man could draw near to God save through its appointed ways of approach. Confession was to be made to God through the priest; God spoke pardon only in the priest's absolution. When Luther attacked indulgences in the way he did he struck at this whole system.

Compelled to examine the ancient history of the church, he soon discovered the whole tissue of fraud and imposture by which the canon law had from the 9th century downwards been foisted upon the Christian world. There is scarcely any essential point in ancient ecclesiastical history bearing upon the question of the invocation of saints, of clerical priesthood, of episcopal and metropolitan pretensions, which his genius did not discern in its true light. Whatever Luther denounced as fraud or abuse, from its contradiction to spiritual worship, may be said to have been openly or tacitly admitted to be such. But what produced the greatest effect at the time were his short popular treatises, exegetical and practical—his *Interpretation of the Magnificat or the Canticle of the Virgin Mary*, his *Exposition of the Ten Commandments, and of the Lord's Prayer.* The latter soon found its way into Italy, although without Luther's name, and has never been surpassed either in genuine Christian thought or in style. He resolved also to preach throughout Germany, and in 1518 appeared at a general meeting of his order at Heidelberg. There he held a public disputation on certain theses called by him paradoxes, in which he strove to make apparent the contrast between the external view of religion taught by the schoolmen and the spiritual view of gospel truth based upon justifying faith. He made many disciples on this occasion, of whom perhaps the most notable was Martin Bucer. On his return to Wittenberg in May 1518, Luther wrote and published an able and moderate exposition of the theses, and sent it to some of the German bishops. He proclaimed the need for a thorough reformation of the church, which he thought could only be effected, with the aid of God, by an earnest co-operation of the whole of Christendom. This energy awakened opponents. Conrad Wimpina at Frankfort, Hoogstraten at Cologne, Sylvester Trierias at Rome, and above all John Eck, an old fellow student, at Ingolstadt, attacked his theses, and discovered heresy in them. The result was that Luther was summoned to appear before the pope at Rome, but the elector of Saxony intervened, and got the matter so arranged that Luther was cited to appear before the pope's legate at Augsburg.

t Augsburg before the legate.

The pope was unwilling to quarrel with Germany, where the whole people seemed to be supporting Luther, and the cardinal legate James de Vio of Gaeta, commonly called Cajetan, was told to be conciliatory. Luther went to Augsburg on foot, and presented himself before the legate, but the interview was not a successful one. The cardinal began by brow-beating the monk, and ended by being somewhat afraid of him. "I can dispute no longer with this beast," he said; "it has two wicked eyes and marvellous thoughts in its head." Luther could not respect either the learning or the judgment of Cajetan. He left Augsburg by stealth, afraid of capture, condemned, but appealing "from the pope ill-informed to the pope to-be-better-informed." On his return to Wittenberg he found the elector in great anxiety of mind, in consequence of an imperious letter from the cardinal, and offered to leave Saxony for France. The elector, however, allowed him to remain, and the pope sent another legate to settle the affairs of Germany. This was Carl von Miltitz, a native of Saxony, a man of the world, and no great theologian. He resolved to meet Luther privately, and did so in the house of Spalatin, court preacher to the elector of Saxony. In his interview with Cajetan Luther had refused to retract two propositions—that the treasury of indulgences is not filled with the merits of Christ, and that he who receives the sacrament must have faith in the grace offered to him. Miltitz made no such demands. He apparently gave up Tetzel and the indulgences, agreed with much of Luther's theology, but insisted that he had not been respectful to the pope, and that such conduct weakened the authority which rightly belonged to the church. He wished Luther to write to the pope and apologize. Luther consented. It was further arranged that both parties were to cease from writing or preaching on the controverted matters, and that the pope was to commission a body of learned theologians to investigate. Luther accordingly wrote to the pope, telling him that he "freely confessed that the authority of the church was superior to everything, and that nothing in heaven or on earth can be preferred before it save only Jesus Christ, who is Lord over all." This was in March 1519. Meanwhile Luther had appealed from the pope to a general council to be held in Germany. In the end of 1518 a papal bull concerning indulgences had appeared, confirming the old doctrine, without any reference to the late dispute.

The years 1519, 1520, 1521 were a time of fierce but triumphant struggle with the hitherto irresistible Church of Rome, soon openly supported by the empire. The first of these years passed in public conferences and disputations. Luther had promised Miltitz to refrain from controversy, on the understanding that his adversaries did not attack him, and he kept his word. But his old antagonist John Eck published thirteen theses attacking Luther, and challenged Andrew Bodenstein of Carlstadt, a friend and colleague of Luther, to a public disputation. Luther instantly replied to Eck's theses, and the disputation between Carlstadt and Eck was immediately followed by one between Eck and Luther. In this famous Leipsic disputation the controversy took a new shape. It was no longer a theological dispute; it became a conflict between two opposing sets of principles affecting the whole round of church life. Luther and Eck began about indulgences and penance, but the debate soon turned on the authority of the Roman Church and of the pope. Eck maintained the superiority of the Roman Church and of the pope as successor of St Peter and vicar-general of Christ. His argument was "no pope no church." Luther denied the superiority of the Roman Church, and supported his denial by the testimony of eleven centuries, by the decrees of Nicæa, by the Holy Scriptures. He maintained that the Greek Church was part of the church of Christ, else Athanasius, Basil, and the Gregories were outside Christianity. The pope has more need of the church, he said, than the church has of the pope. Eck retorted that these had been the arguments of Wickliffe and of Huss, and that they had been condemned at the council of Constance. Luther refused to admit that the condemnation was right; Eck refused to debate with an opponent who would not abide by the decision of œcumenical councils; and so the disputation ended. But Luther immediately afterwards completed his argument and published it. He asserted that he did not mean to deny the bishop of Rome's primacy, provided the pope kept his own place as servant of the church, but that he did mean to deny that there could be no church apart from the pope. The church, he said, is the communion of the faithful, and consists of the elect, and so never can lack the presence of the Holy Spirit, who is not always with popes and councils. This church, he declared, is invisible, but real, and every layman who is in it and has Holy Scripture and holds by it is more to be believed than popes or councils, who do not. This Leipsic disputation had very important consequences. On the one hand, Eck and his associates felt that Luther must now be put down by force, and pressed for a papal bull to condemn him; and Luther himself, on the other hand, felt for the first time what great consequences lay in his opposition to the indulgences. He saw that his Augustinian theology, with its recognition of the heinousness of sin, and of the need of the sovereign grace of God, was incompatible with the whole round of mediæval ceremonial life, proved it to be impossible for men to live perfectly holy lives, and so made saints and saint worship and relics and pilgrimages

Leipsic disputation.

impossible things. He saw the uselessness of the monastic life, with its vigils and fasts and scourgings. These things were not helps, he saw, but hindrances to the true religious life. The Leipsic disputation made Luther feel that he had finally broken with Rome, and it made all Germany see it too, and raised the popular enthusiasm to a white heat. The people of the towns declared their sympathy with the bold monk. Ulrich von Hutten and the German humanists saw that this was more than a monkish quarrel, and recognized Luther as their leader. Franz von Sickingen and the free knights hailed him as a useful ally. Even the poor down-trodden peasants hoped that he might be a luckier leader than Joss Fritz, and that he might help them to free themselves from the unbearable miseries of their lot. Luther became the leader of the German nation after the Leipsic disputation.

During 1520 the first great political crisis occurred, on the occasion of the death of Maximilian, and ended fatally, in consequence of the want of patriotic and political wisdom among the German princes. Ranke has pointed out the political elements which then existed for creating a Germany as free and independent as France or England; and Justus Möser of Osnabruck had long before truly declared, "If the emperor at that time had destroyed the feudal system, the deed would have been, according to the spirit in which it was done, the grandest or the blackest in the history of the world." Möser means that if the emperor had embraced the Reformed faith, and placed himself at the head of the lower nobility and cities, united in one body as the lower house of a German parliament, this act would have saved Germany. Probably some such idea was in the mind of the archbishop of Treves when he proposed that Frederick, the elector of Saxony, should be chosen emperor. Frederick might have carried out this policy, just because, if elected, he had nothing to rely upon except the German nation, then more numerous and powerful than it has been since; but he had not the courage to accept a dignity which he supposed to require for its support a more powerful house than his own. Charles, the son of Maximilian, was elected emperor, and that election meant the continuation of a mediæval policy in Germany.

Meanwhile Luther was at Wittenberg continuing his course of preaching, lecturing, and writing. The number of matriculated students had increased from 232 in 1517 to 458 in 1519, and to 579 in 1520; but large numbers besides these came to hear Luther. The study of Greek and Hebrew was diligently carried on, and the university was in a most flourishing state. Some of the finest productions of Luther's pen belong to this period,—his *Sermons* on the sacraments, on excommunication, on the priesthood, on good works, his *Address to the Christian Nobility of the German Nation on the Reformation of Christendom*, and *The Babylonian Captivity of the Church*. The address to the German nobles, published on June 26, 1520, created a great deal of excitement not only in Germany but beyond it. It was this appeal which first made Zwingli feel in sympathy with Luther, who showed in this little book that the Romish doctrine of two estates, one secular and the other spiritual, was simply a wall raised round the church to prevent reform. *All* Christians are spiritual, he said, and there is no difference among them. The secular power is of God as well as the spiritual, and has rule over all Christians without exception,—pope, bishops, monks, and nuns. He also appealed to the people to prevent so much money going out of the kingdom to Italy. "Why," he said, "should 300,000 florins be sent every year from Germany to Rome?" His address raised the cry of Germany for the Germans, civil government uncontrolled by ecclesiastics, a married clergy, while he called for a national system of education as the foundation of a better order of things. The most important work of the time, however, was the *Babylonian Captivity of the Church of God* (October 1520), in which he boldy attacked the papacy in its principles. The main thought in the book is expressed in the title. The catholic church had been taken into bondage by the papacy, as the Jewish people were taken to Babylon, and ought to be brought back into freedom. Luther described the sacraments, real and pretended, and showed how each had been carried into captivity and ought to be delivered. He concluded in a very characteristic fashion. "I hear that bulls and other papistical things have been prepared, in which I am urged to recant or be proclaimed a heretic. If that be true, I wish this little book to be part of my future recantation." The printing press sent thousands of these books through Germany, and the people awaited the bull, armed beforehand against its arguments. The bull was published at Rome on July 15, 1520. It accused Luther of holding the opinions of Huss, and condemned him. Eck brought it to Leipsic, and published it there in October. It was posted up in various German towns, and usually the citizens and the students tore it down. At last it reached Luther. He answered it in a pamphlet, in which he called it the execrable bull of Antichrist, and at last he proclaimed at Wittenberg that he would publicly burn it. On December 10, 1520, at the head of a procession of professors and students, Luther passed out of the university gates to the market-place, where a bonfire had been laid. One of the professors lighted the fuel, and Luther threw the bull on the flames; a companion flung after it a copy of the canon law. Germany was henceforth to be ruled by the law of the land, and not by the law of Rome. The news flashed over all Germany, kindling stern joy. Rome had shot its last bolt; if Luther was to be crushed, only the emperor could do it. On December 17th Luther drew up before a notary and five witnesses a solemn protest, in which he appealed from the pope to a general council. This protest, especially when we take it along with other future acts of Luther, meant a great deal more than many historians have discerned. It was the declaration that the Christian community is wider than the Roman Church, and was an appeal from later mediæval to earlier mediæval ideas of catholicity. In the times immediately preceding the Reformation, the common description of Christian society was social life in communion with the bishop of Rome, but in the earlier Middle Ages Christian society had also been defined to be social life within the holy Roman empire. For the Roman empire had imposed on all its subjects a creed, and to that extent had made itself a Christian community. The œcumenical council was the ecclesiastical assembly and final court of appeal for this society, whose limits were determined by the boundaries of the mediæval empire, and Luther by this appeal not only declared that he could be a catholic Christian without being in communion with Rome, but secured an ecclesiastical standing ground for himself and his followers which the law could not help recognizing. It was an appeal from the catholic church defined ecclesiastically to the catholic church defined politically, and foreshadowed the future political relations of the Lutheran Church.

Luther excommunicated.

He burns the pope's bull.

The pope had appealed to the emperor to crush heresy in Germany, and Charles V., with his Spanish training and his dreams of a restored mediæval empire, where he might reign as vicar of God *circa civilia*, had promised his aid. He had declared, however, that he must pay some regard to the views of Frederick of Saxony, from whom he had received the imperial crown, and had in the end resolved to summon Luther before the diet to be held at Worms. The diet was opened by Charles in January 1521, and the ɩefore he mperor t Vorms.

papal nuncio Hieronymus Alexander (afterwards archbishop of Brindisi and cardinal) urged first privately and then publicly in the diet that Luther should be condemned unheard, as one already tried and convicted by the papal bull. He threatened the Germans with extermination, it is said, in case of their refusal to accede to his requests,—"We shall excite the one to fight against the other, that all may perish in their own blood,"—a threat to which the whole subsequent history of Germany offers the commentary. But the princes had their own quarrel with Rome, and urged besides that it would be unfair to condemn a man unheard and untried. A committee appointed by the diet presented a list of one hundred grievances of the German nation against Rome. This startled the emperor, who, instead of ordering Luther's books to be burned, issued only a provisional order that they should be delivered to the magistrate. He then sent to summon Luther before him, and granted him a safe conduct to and from the diet. In April Luther set out for Worms. Before leaving Wittenberg he had devised with his friend Lucas Cranach the artist what he called "a good book for the laity," a series of woodcuts depicting contrasts between Christ and the pope, with explanations in pithy German:—Christ washing the disciples' feet on one page, the pope holding out his toe to be kissed, on the other; Christ bearing his cross, the pope carried in state through Rome on men's shoulders; Christ driving money-changers out of the temple, the pope selling indulgences, with piles of money before him; and so on. Luther went to Worms, believing that he was going to his death. Everywhere on the road he saw the imperial edict against his books posted up, yet his journey was in some sort a triumphal progress; the people came out in crowds to meet him, and at Erfurt the herald gave way to the universal request, and, against his instructions, permitted Luther to preach. On the 16th Luther entered the imperial city amidst an immense concourse of people. Next day he was brought before the diet. When the hour approached he fell on his knees, and uttered in great agony a prayer such as can only be pronounced by a man filled with the spirit of Him who prayed in Gethsemane. When he appeared before the diet he was asked by John Eck, an official of the archbishop of Treves (to be distinguished from Eck the theologian), whether the books piled on a table were his, and whether he would retract what was written in them. Luther acknowledged his writings, and requested that as the matter written concerned the highest of all subjects, the word of God and the welfare of souls, he might have time for consideration before he answered the second question. His request was granted, and he retired. Luther's resolution had been taken before he appeared at the diet; he only desired to convince friends as well as foes that he did not act with precipitation at so decisive a moment. The next day he employed in prayer and meditation, making a solemn vow upon a volume of Scripture to remain faithful to the gospel, should he have to seal his confession with his blood. When he was again brought before the diet, he answered at great length, dividing his writings into three kinds:—(1) those in which he had written about faith and morals in such fashion that even his opponents admitted that what he had said was worth reading: he could not retract these; (2) those in which he had condemned the papacy and popish doings, which had ruined Christendom body and soul: to retract these would be mean and wicked, and he would not; (3) those in which he had attacked private persons with perhaps more vehemence than was right: he would not retract, but would readily listen to any one who pointed out errors. He spoke in German with earnestness and force, but the emperor and his followers scarcely understood him, and he was asked to repeat his answer in Latin. He did so, and the papal party were irritated; the official declared that they were not there to make distinctions or to discuss things which had been long ago settled by councils; let the accused say whether he recanted or not. Luther answered, "Well then, if your imperial majesty and your graces require a plain answer, I will give you one of that kind without horns and teeth. It is this. I must be convinced either by the witness of Scripture or by clear arguments, for I do not trust either pope or councils by themselves, since it is manifest that they have often erred and contradicted themselves—for I am bound by the Holy Scriptures which I have quoted, and my conscience is held by the word of God. I cannot and will not retract anything, for to act against conscience is unsafe and unholy. So help me God. Amen." Eck asked him whether he actually meant to say that general councils had erred. He answered that he declared, and that openly, that councils had erred several times, that the council of Constance had erred. Eck replied that he surely did not mean to say that general councils had erred. Luther persisted that he could prove that they had erred in many places. The emperor made a sign to end the matter, and Luther said, "I can do nought else. Here stand I. God help me. Amen." He went back to his lodgings in deep depression of spirit, but was comforted on learning that the elector had told Spalatin, "Doctor Martin has spoken well in Latin and in German before the emperor and all the princes and estates of the empire; only he is too keen for me." Luther's answer created very various feelings among those who heard him. The Italians and Spaniards wished the safe conduct revoked, and Luther burnt at once. Most of the Germans resolved to protect him at all hazards. The emperor deliberated for a day, and then declared that he meant to permit Luther to return safely from the council, but that his opinions were to be condemned, and all who clung to them punished for the future. But the proposal to cancel the safe conduct had roused the people. There were threatenings of insurrections of the peasants, and of Sickingen and the knights; and the emperor, to allay the feeling, resolved that three days should be given to Luther to reconsider what he had said. Theologians came to argue with him, and to induce him to make some recantation, but in vain. At last the edict of the diet was pronounced, in which Luther was condemned in the severest terms, and placed under the ban of the empire. This meant that when his safe conduct expired he was an outlaw, and that all people were forbidden to give him food or fire or shelter. His books were to be burnt, his goods confiscated, and his adherents punished. Whoever disobeyed the edict incurred the ban of the empire.

At the Wartburg.

Frederick the elector of Saxony thought that Luther's life was no longer safe, as in twenty-one days his safe conduct would expire. Luther was hurried away from Worms, and as he travelled back to Wittenberg he was stopped near Eisenach by a band of armed knights, and carried to the fortified castle of the Wartburg above Eisenach by Frederick's orders. The elector's fears, as matters turned out, were exaggerated. Germany was in no mood to give Luther up, and there were threatenings of risings when he disappeared, only appeased when it was whispered about that he was in friendly keeping. Luther remained at the Wartburg, dressed as a knight, ordered to let his beard grow, and bearing the name Junker George, for ten months, and made use of his enforced leisure to begin what was perhaps his greatest literary work, his translation of the Scriptures from the original texts. The New Testament was almost entirely his own work. He used for the text Erasmus's fourth edition, and took incredible pains with his work. Some of his MS. still survives, and shows that he corrected and recorrected with great pains. Some passages were altered at least fifteen times. He often felt at a loss for want of technical knowledge, and laid all his friends under contribution. Thus, when in difficulty about the translation of Rev. xxi. he wrote to Spalatin to ask for names and descriptions of all the precious stones mentioned. When engaged in the translation of the descriptions of the slaughter of beasts for sacrifice, he got a butcher to kill some sheep for him, that he might learn what every part of a sheep was called. His aim was to reproduce the tone and spirit of the original as far as he possibly could. No fine courtly words, he said to Spalatin; this book can only be explained in a simple popular style. It must be understood by the mother in the house, by the children in the streets, and by the "common man in the market." The translation of the New Testament was first published on September 21, 1522, and a second edition appeared in October. By choosing the Franconian dialect in use in the imperial chancery, Luther made himself intelligible to those whose vernacular dialect was High German or Low German, and his Bible is still the standard of the German tongue, and has preserved unity of language, literature, and thought to the German nation during its political disintegration. The translation of the Old Testament, begun in the same year, was a much more tedious task, and Luther was assisted in it by what Matthesius calls a private Sanhedrim. The friends met once a week, several hours before supper, in the old Augustinian monastery at Wittenberg, which had become Luther's house. Bugenhagen, Justus Jonas, Melanchthon, Aurogallus, Roser, and several Jewish rabbis made the "Sanhedrim." Luther thus describes the work: "We are labouring hard to bring out the prophets in the mother-tongue. Ach Gott! what a great and difficult work it is to make the Hebrew writers speak German! They resist it so, and are unwilling to give up their Hebrew existence and become like Germans." At the Wartburg Luther was ill in health and somewhat troubled in mind. He had been ill before he was summoned to Worms, and his long journey in the waggon with its cloth tent, the excitement at Worms, and the solitude at the Wartburg had enfeebled him; but his literary activity was untiring. He wrote short commentaries on the 68th Psalm and on other portions of Scripture, and a set of homilies intended to guide evangelical preachers, the *Kirchen-postille*. He also wrote one or two short treatises on worship, on the mass, on confession, and on monkish vows, intended to guide the reformed churches in the rejection of superstitious usages. Up to this time there had been no change in the church services. The true doctrine of the gospel had been preached in Germany, and Romish rites and ceremonies had been exhibited as abuses, but not a single word or portion of these ceremonies had been changed, and Luther felt that the time had come to bring the preaching and the usages into harmony with each other. In the midst of these labours news came to him that Germany was threatened with a new sale of indulgences. The cardinal archbishop of Mainz, Albert of Brandenburg, unable to pay the 26,000 ducats due to Rome for his pallium, had resolved to raise the money by indulgences. Luther wrote a fierce tractate *Against the New Idol at Halle*. The archbishop getting word of this, sent to Frederick asking him to restrain Luther from attacking a brother-elector, and Frederick wished Luther to desist. He was indignant, but at the request of Melanchthon he agreed to lay the treatise aside until he had written to the archbishop. "Put down the idol within a fortnight, or I shall attack you publicly," he wrote; and the archbishop in reply thanked Luther for his Christian brotherly reproof, and promised, "with the help of God, to live henceforth as a pious bishop and Christian prince."

Back to Wittenberg.

Luther's absence from his congregation, his students, and his friends and books at Wittenberg weighed heavily upon him, and he began to hear disquieting rumours. Carlstadt and other friends at Wittenberg were urging on the Reformation at too rapid a rate. Their idea was that everything in worship not expressly enjoined in the Bible should at once be abolished. The churches were to be stripped of crucifixes, images of saints, and the ritual of the mass; the festivals of the Christian year were to be neglected, the monastic life put down by force; and some even wished it ordained that all clergymen should be married. To Luther all this seemed dangerous, and sure to provoke a reaction; the changes insisted upon were to him matters of indifference, which might be left to the individual to do or leave undone as he pleased. Auricular confession, the reception of the Lord's Supper under both forms, pictures in churches, the observance of festivals and fasts, and the monastic life were *adiaphora*. He wrote earnestly warning his friends against rashness and violence, and he was anxious and distressed. Still he held out patiently till events occurred which called for his presence. Certain men claiming to be prophets, Nicolaus Storch, a weaver, and his disciple Thomas Münzer, belonging to the village of Zwickau, near the Erzgebirge on the borders of Bohemia, preached wildly a thorough-going reformation in the church and the banishment of priests and Bibles. All believers were priests, they said, and all the faithful had the Holy Spirit within them, and did not need any such external rule as Holy Scripture. They were banished from Zwickau, and came to Wittenberg, where Carlstadt joined them. Fired by their preaching, the people tore down the images in the churches and indulged in various kinds of rioting. Luther felt he could remain no longer in hiding. He wrote to the elector telling him that he must quit the Wartburg, and at the same time declaring that he left at his own peril. "You wish to know what to do in the present troublesome circumstances," he said. "Do nothing. As for myself, let the command of the emperor be executed in town or country. Do not resist if they come to seize and kill me; only let the doors remain open for the preaching of the word of God." He was warned that Duke George of Saxony, a violent enemy of the Reformation, was waiting to execute the sentence of the ban. "If things were at Leipsic as they are at Wittenberg," he said, "I would go there, if it rained Duke Georges for nine days running, and every one of them nine times as fierce as he." He left the Wartburg, suddenly appearing in Wittenberg on March 3, 1522, and plunged at once into the midst of struggles very different from those which he had hitherto so victoriously overcome. He found things in a worse state than he had feared; even Melanchthon had been carried away. Luther preached almost daily for eight consecutive days against Carlstadt and the fanatics from Zwickau, and in the end he prevailed and the danger was averted. His theme was that violence does no good to God's word; there are in religion matters of indifference. "The Word created heaven and earth and all things; the same Word must also now create, and not we poor sinners. *Summa summarum*, I will preach it, I will talk of it, I will write about it, but I will not use force or compulsion with any one." "In this life every one must not do what he has a right to do, but must forego his rights, and consider what is useful to his brother. Do not make a 'must be' out of a 'may be,' as you have now been doing, that you may not have to answer for those whom you have misled by your uncharitable liberty." Storch and Münzer, sincere though misguided men, sought an interview with him. They laid their claims for support before him; they said that they were inspired and could prove it, for they would tell him what then passed through his mind. Luther challenged them to the proof. "You think in your own heart that my doctrine is true," said one of them impressively. "Get thee behind me, Satan," exclaimed Luther, and dismissed them. "They were quite right," he said to his friends afterwards; "that thought crossed my mind about some of their assertions. A spirit evidently was in them; but what could it be but the evil one?"

ither d the et at urem- rg.

When Charles V. had laid Luther under the ban of the empire, he had undoubtedly been greatly influenced by political considerations. Francis I. of France and Charles of Spain were rivals, and the whole of the European policy of the time turns on this rivalry. The opponents schemed to attract to themselves and to divert from their neighbour the two outside powers of England and the papacy, and in 1521 it was the policy of Charles to win alliance with the pope. The Germans saw that they were being sacrificed in this game of statecraft, and there was no great willingness even among Roman Catholics to put the edict of Worms in force. Luther at the Wartburg and at Wittenberg was protected by the national feeling of Germany from attack. The diet of the empire met in 1522 at Nuremberg, and the new imperial council, which ruled in the emperor's absence, and very fairly represented the popular feeling in Germany, was in no mood to yield to the papacy. Leo X. had died, and his successor Adrian VI., an orthodox Dominican and an advocate for reformation in the cloisters and in the lives of the clergy, proposed to begin reformation by crushing the German heresy. He instructed his nuncio to the diet to demand the execution of the edict of Worms. The imperial council refused until the grievances of Germany were heard and redressed. They spoke of concordats broken and papal pledges unfulfilled, and finally they demanded a free œcumenical council to be held in Germany within a year, which should settle abuses, and until it met they wished the creed to be an open question. The nuncio found that the pulpits of the free imperial city were filled with preachers, mostly monks, who were making the city resound with gospel preaching. He asked the diet at least to arrest the preachers; the diet pleaded incompetence. He proposed to seize them himself in the pope's name; the magistrates threatened to release them by force, and the nuncio had to desist. The diet then presented a hundred gravamina or subjects of complaint which the German nation had against the papacy, including in the list indulgences, dispensations bought for money, absentee bishops and other ecclesiastics, the use of bans and interdicts, pilgrimages, excessive demands for money, and the decisions of matrimonial cases in ecclesiastical courts. The complaint was an expansion of Luther's address to the German nobles. The nuncio could do nothing, and was forced to accept by way of compromise a decision from the diet that only the *verum, purum, sincerum, et sanctum evangelium* was to be preached in Germany. Nuremberg reversed the edict of Worms. Next year the diet met again at Nuremberg, and the new pope, Clement VII., sent the celebrated cardinal-legate Lorenzo Campeggio to demand the execution of the edict of Worms. The diet asked in return what had become of the hundred grievances of the German nation, to which Rome had never deigned to return an answer. Campeggio declared that at Rome the document had been considered merely as a private pamphlet; on which the diet, in great indignation, insisted on the necessity of an œcumenical council, and proceeded to annul the edict of Worms,—declaring, however, in their communication to the pope, that it should be conformed to as much as possible, which with respect to many cities and princes meant not at all. Finally it was resolved that a diet to be held at Spires was to decide upon the religious differences. But between Nuremberg and Spires an event occurred, the revolt of Sickingen and the knights, which was destined to work harm to the Reformation. The diet of Spires met, and, many of the members being inclined to connect Sickingen and Luther, there was a strong feeling against the Reformation, but the feeling was not strong enough to induce the diet to comply with the demands of the legate Campeggio and revoke the decisions of Nuremberg, and it refused to execute the edict of Worms. Campeggio, however, was able to separate Germany into two parties, and this separation became apparent at the convention of Ratisbon, where Bavaria, Austria, and other South-German states resolved to come to separate terms with the papacy. The curia promised to stop a number of ecclesiastical extortions and indulgences, to make better appointments to benefices, and to hand over some of the ecclesiastical estates to the Austrian and Bavarian princes; while the states promised to set aside the gravamina, and to permit no toleration of the new doctrines. On the other hand, many states which had kept aloof from the Reformation now joined it, and declared against the seven sacraments, the abuses of the mass, the worship of saints, and the supremacy of the pope. The emperor's brother and successor Ferdinand was a bitter foe to the Reformation, and urged persecution. Four Augustinian monks at Antwerp were the first martyrs; they were burnt on 1st July 1523. Ferdinand began the bloody work of persecution in the hereditary states of Austria immediately after the convention of Ratisbon. At Passau in Bavaria, and at Buda in Hungary, the faggots were lighted. The dukes of Bavaria followed the same impulse.

Luther's writings during this period.

Luther's literary activity during these years was unparalleled. In 1522 he published, it is said, one hundred and thirty treatises, and eighty-three in the following year, among them the famous *Contra Henricum regem Angliæ*, in which, after having dealt mercilessly with the royal controversialist, he exclaims, "I cry 'Gospel! Gospel! Christ! Christ!' and they cease not to answer 'Usages! Usages! Ordinances! Ordinances! Fathers! Fathers!' The apostle St Paul annihilates with a thunderstorm from heaven all these fooleries of Henry." His principal work, however, during these years was the publication of certain short tracts upon worship and its reform, followed by various directories for public worship, which afterwards served as a model for the numerous Lutheran Church ordinances. In 1522, while Luther was still in the Wartburg, Carlstadt had published for the church at Wittenberg an ordinance for directing the government and worship of the church. It was very brief, but very revolutionary (*cf.* Richter's *Evangel, Kirchenordnungen*, vol. ii. p. 484). This was withdrawn after Luther's return; but the Reformer felt that the time had come for a definite reform of public worship and for publishing his views upon the subject. Accordingly, after a series of tracts in 1522 upon religious and monastic vows, the abolition of private masses, the Lord's Supper under both forms, saint worship, the so-called spiritual estate, and the married life, he published in 1523 *The Order of the Worship of God*. He was, as usual, conservative, and made as few changes as possible in the form of service, caring only to give full place to prayer and the reading and preaching of the word. The order of worship was followed by the *Formula Missæ*, published in Latin, but at once translated into German by Paul Speratus, in which the ancient form was as much preserved as is consistent with evangelical doctrine. Luther was of opinion that the more difficult introits should be removed from the order of the Eucharist, and simpler hymns put in their place, and he also was strongly in favour of the singing of hymns in the common worship. This led to the publication in 1524 of a small collection of church hymns, which was Luther's first *German Church Hymn-book*, and which was the beginning of the wonderfully rich German Protestant hymnology. In the same year Luther translated the order of baptism, and published it under the title of *Das Tauf-Büchlein*. He also drew up a directory for public worship for Leisnig (*cf.* Richter, *op. cit.*, vol. i.). The hymn-book was followed by a prayer-book, and by the publication of a short summary of the heads of Christian truth fitted for the instruction of the "rude common man." Luther's catechism for children completed this series of works, intended to aid worship, public and private. Notwithstanding this immense amount of literary work, Luther found time to make preaching tours, and visited in this way Altenburg, Zwickau, Eilenburg, Erfurt, Weimar, and many other places, and was cheered by the progress of the Reformation throughout North Germany. About this time also he sent a powerful address to the municipal councils of the German towns, exhorting them to establish everywhere Christian schools, both elementary and secondary. "Oh my dear Germans," he exclaimed, "the divine word is now in abundance offered to you. God knocks at your door; open it to Him! Forget not the poor youth. . . . The strength of a town does not consist in its towers and buildings, but in counting a great number of learned, serious, honest, and well-educated citizens." He tried to impress upon them the necessity for the highest education, the knowledge of Greek and Hebrew, by showing how serviceable such learning had been to him in his attack upon the abuses of Rome. He also appealed to the princes and cities to help the gospel and the Reformed churches; but church rule and church maintenance could not be fixed on a legal basis until much later.

Here we conclude this first glorious period of Luther's life. The problem to be solved was not to be solved by Luther and by Germany; the progressive vital element of reformation passed from Germany to Switzerland, and through Switzerland to France, Holland, England, and Scotland. Before he descended into the grave, and Germany into thraldom, Luther saved, as much as was in him, his country and the world, by maintaining the fundamental principles of the Reformation against Melanchthon's pusillanimity; but three Protestant princes and the free cities were the leaders. The confession was the work of Melanchthon; but the deed was done by the laity of the nation. The German Reformation was made by a scholastically trained monk, seconded by professors; the Swiss Reformation was the work of a free citizen, an honest Christian, trained by the classics of antiquity, and nursed in true hard-won civil liberty. Luther's work was continued, preserved, and advanced by the work of the Swiss and French Reformers. The monk began; the citizen finished. If the one destroyed Judaism, the other converted paganism, then most powerful, both as idolatry and as irreligious learning. But as long as Luther lived he did not lose his supremacy, and he deserved to keep it. His mind was universal, and therefore catholic in the proper sense of the word.

Third Period (1525–1546). In this third period the epic of Luther's life was changed into tragedy; the revolt of the knights under Sickingen, the Anabaptist tumults, and the peasants' war in the Black Forest alienated the sympathies of many from the Reformation, and resulted in a divided Germany (see vol. x. p. 498, vol. i. p. 786). From Sickingen's rising Luther sedulously kept himself aloof, but the insurgent had more than once proclaimed himself on Luther's side, and that was enough to make many of the princes resolve to have nothing to do with reform. The convention of Ratisbon was the result of Sickingen's abortive revolt. The Anabaptists have to do with Luther's history mainly in so far as his contact with them modified and gave final shape to his doctrine of baptism. In his tract on the *Sacrament of Baptism*, 1519, Luther distinguishes carefully between the sign and the thing signified. The ordinance is just the sign, the thing signified is the death to sin, the new birth, and a new life in Christ. This new life goes on here on earth, so does the death to sin. Believers die daily to sin, not once for all in baptism, and their life in Christ is not a full life whilst earth's life lasts; and so baptism is merely a sign of what is never really accomplished till after death. In the *Babylonian Captivity of the Church of God*, 1520, Luther adopted a view not unlike Calvin's. He said that God's word was always more than a statement, it was also a promise. Baptism was therefore a seal or pledge, a promise that what was signified by the ordinance would be bestowed. Only unbelief can rob the baptized of the benefits of their baptism and make the ordinance of none effect. But after Luther came in contact with the Anabaptists he departed from this simple theory, for he thought that he could not justify infant baptism upon it, and so in his *Sermon on Baptism*, 1535, he introduced a third theory, which approached much nearer to mediæval views. He explained that in the ordinance of baptism God through His word so works on the water in the sacrament that it is no longer mere water, but has the power of the blood of Christ in some mysterious fashion. Luther then asked if faith was required for the worthy partaking of the sacrament, and he felt obliged to confess that the faith of the recipient was not needed. This sermon marks Luther's reaction towards ideas he had abandoned in 1519–20.

Revolt under Sickingen.

Anabaptist tumults.

Peasants' war.

More important was the connexion between the Lutheran movement and the peasant revolt. The first coalitions of the peasants against the intolerable rapacity and cruelty of the feudal aristocracy had begun before the close of the 15th century. But all the oppressed inclined towards Luther, and the oppressors, most of whom were sovereigns, bishops, and abbots, towards the pope. The struggle in the peasants' war was really between the reforming and the papist party, and it could easily be foreseen that Luther would be dragged into it. As early as January 1525 the revolutionary movement had extended from the Black Forest into Thuringia and Saxony, and the peasants were eagerly looking to Luther for help. The more moderate party published their programme in twelve articles, with a very remarkable preface, in which they stated that they did not wish for war, and asked nothing that was not in accordance with the gospel. These articles were the following:—(1) the whole congregation to have power to elect their minister, and if he was found unworthy to dismiss him; (2) the great tithe, *i.e.*, the legal tithe of corn, to be still payable for the maintenance of the pastor, and what is over to go to support the poor; the small tithes to be no longer payable; (3) serfdom abolished, since Christ has redeemed us all by His precious blood; (4) game, fish, and fowl to be free as God created them; (5) the rich have appropriated the forests, this to be rearranged; (6) compulsory service to be abolished—wages for work; (7) peasant service to be limited by contract, and work done above contract to be paid for; (8) fair rents; (9) arbitrary punishments abolished; (10) the commons restored; (11) the right of heriot, *i.e.*, the right of the lord to take the vassal's best chattel, to be abolished; (12) all these propositions to be tested by Scripture, and what cannot stand the test to be rejected. Most impartial historians have declared that their demands were on the whole just, and most of them have become law in Germany. The words of Scripture brought forward by the peasants prove clearly that Luther's preaching of the gospel had acted, not as an incentive, but as a corrective. The peasants declared their desire to uphold the injunctions of the gospel, peace, patience, and union. Like the Puritans in the following century, the peasants say that they raise their voice to God who saved the people of Israel; and they believe that God can save them from their powerful oppressors, as he did the Israelites from the hand of Pharaoh. Luther evidently felt himself appealed to. The crisis was difficult, and, in spite of what has been said in his defence, he failed, as he failed afterwards in the conference with the Swiss deputies at Marburg. Had Luther thrown the weight of his influence into the peasants' scale, and brought the middle classes, who would certainly have followed him, to the side of the peasants, a peaceful solution would in all probability have been arrived at, and the horrors of massacre averted. But Luther, bold enough against the pope or the emperor, never had courage to withstand that authority to which he was constantly accustomed, the German prince. He began by speaking for the peasants in his address to the lords, and had courage enough to tell them some plain truths, as when he said that some of the twelve articles of the peasants are so equitable as to dishonour the lords before God and the world, when he told them that they must not refuse the peasants' demands to choose pastors who would preach the gospel, and when he said that the social demands of the peasants were just, and that good government was not established for its own interest nor to make the people subservient to caprice and evil passion, but for the interest of the people. "Your exactions are intolerable," he said, "you take away from the peasant the fruit of his labour in order to spend his labour upon your finery and luxury." He was courageous enough also in asking the peasants to refrain from violence, and in telling them that they would put themselves in the wrong by rebellion. But what Luther did not see was that the time for good advice had gone by, and that he had to take his stand on one side or the other. He trusted too much in fine language. His advice that arbiters should be chosen, some from the nobility and some from towns, that both parties should give up something, and that the matter should be amicably settled by human law, came ten months too late. The bloody struggle came; the stream of rebellion and destruction rolled on to Thuringia and Saxony, and Luther apparently lost his head, and actually encouraged the nobles in their sanguinary suppression of the revolt, in his pamphlet entitled *Against the Murdering, Robbing Rats of Peasants*, where he hounds on the authorities to "stab, kill, and strangle." The princes leagued together, and the peasants were routed everywhere. One army, with neither military arms nor leaders, was utterly routed at Frankenhausen, another in Würtemberg. Fifty thousand were slain or butchered by wholesale executions. Among this number many of the quietest and most moderate people were made victims in the general slaughter, because they were known or suspected to be friends of the Reformation and of Luther, which indeed all the citizens and peasants of Germany were at that time. None felt more deeply, when it was too late, this misery, and what it involved in its effects on the cause of the gospel in Germany, than Luther; and he never recovered the shock. He thus unburdens his soul at the close of this fatal year, which crushed for centuries the rights and hopes of the peasants and labourers, and weakened the towns and cities, the seats of all that was best in the national life,—"The spirit of these tyrants is powerless, cowardly, estranged from every honest thought. They deserve to be the slaves of the people;" and in the next year—"I fear Germany is lost; it cannot be otherwise, for they will employ nothing but the sword."

The prospect was dark enough for the Reformer. Ferdinand of Austria and the duke of Bavaria were imprisoning and slaying Christians on account of the gospel. The emperor, fresh from his victory at Pavia, and the pope were combining to crush the Reformation, and it was rumoured that the kings of France and England were to lend their aid. The convention of Ratisbon had resulted in a Roman Catholic league in which Duke George of Saxony, Albert elector-archbishop of Mainz, and the duke of Brunswick were the leaders. Luther also found that the war had demoralized the Protestant congregations, and that they were becoming ignorant and savage. And in May 1525 the elector Frederick died.

Luther's marriage.

It was under such auspices that Luther decided at last to take a wife, as he had long advised his friends among the priests and monks to do. He married Catherine von Bora, a lady twenty-four years of age, of a noble Saxon family, who had left her convent together with eight other sisters in order to worship Christ without the oppression of endless ceremonies, which gave neither light to the mind nor peace to the soul. The sisters had lived together in retirement, protected by pious citizens of Torgau. Luther married her on June 11, 1525, in the presence of Lucas Cranach and of another friend as witnesses. Catherine von Bora had no dowry, and Luther lived on his appointment as professor; he would never take any money for his books. His marriage was a happy one, and was blessed with six children. He was a tender husband, and the most loving of fathers. In the close of the year 1525 Luther was engaged in controversy with Erasmus on the freedom of the will.

Progress of the Reformation.

The princes who were friendly to the Reformation gradually gained more courage. The elector John of Saxony established the principle in his state that all rites should be abrogated which were contrary to the Scriptures, and that the masses for the dead be abolished at once. The young landgrave Philip of Hesse gained over the son of the furious Duke George to the cause of the Reformation. Albert, duke of Prussia, had established it at Königsberg, as hereditary duke, abolishing the vows of the order whose master he had been, saying:—"There is only one order, and that is Christendom." At the request of the pope, Charles placed Albert under interdict as an apostate monk. The evangelical princes found in all these circumstances a still stronger motive to act at Augsburg as allies in the cause of the evangelical party; and when the diet opened in December 1525 they spoke out boldly:—"It is violence which brought on the war of the peasants. If you will by violence tear the truth of God out of the hearts of those who believe, you will draw greater dangers and evils upon you." The Romanist party was startled. "The cause of the holy faith" was adjourned to the next diet at Spires. The landgrave and the elector made a formal alliance in February 1526 at Torgau.

Luther, being consulted as to his opinion, felt helpless. "You have no faith; you put not your trust in God; leave all to Him." The landgrave, the real head of the evangelical alliance, perceived that Luther's advice was not practical—that Luther forsook the duty of self-defence and the obligation to do one's duty according to the dictates of reason, in religious matters as well as in other political questions. But the alliance found no new friends. Germany showed all her misery by the meanness of her princes and the absence of any great national body to oppose the league formed by the pope, the emperor, and the Romanists throughout Europe. The archbishop of Treves preferred a pension from Charles to the defence of the national cause. The evangelically-disposed elector of the palatinate desired to avoid getting into trouble. The imperial city of Frankfort, surrounded by open enemies and timid friends, declined to accede to the alliance. There was more national feeling and courage in the Anglo-Saxon north of Germany. The princes of Brunswick, Luxemburg, Mecklenburg, Anhalt, and Mansfeld assembled at Magdeburg, and made a solemn and heroic declaration of their resolution "to pledge their estates, lives, states, and subjects for the maintenance of the holy word of God, relying on Almighty God, as whose instruments they would act." The town of Magdeburg (which then had about three times as many inhabitants as now) and Duke Albert of Prussia adhered to the alliance. The league doubled its efforts. Charles, strong and rendered safe by the peace of Madrid concluded with Francis, sent word from Seville in March 1526, through the Romish Duke Henry of Brunswick, that he would soon come himself to crush the heresy. Luther saw the dangers crowding around him; his advice was,—"We are threatened with war; let us force our enemies to keep the peace, conquered by the Spirit of God, before whose throne we must now combat with the arms of prayer; that is the first work to be done."

Diet of Spires, 1526.

The emperor commissioned his brother Ferdinand to preside at the diet of Spires and carry out his wishes. But before the diet met Francis and the pope had formed a league against him, and Charles had commissioned Count Frundsberg to levy an army of Germans to fight against the pope, while Ferdinand was called to Hungary to maintain against the Turks and others the kingdoms of Hungary and Bohemia, bequeathed to him by King Louis after the battle of Mohacz. When the diet at Spires met (June 1526), after some deliberation a proposition presented by the free cities was accepted that until a general council met "every state shall live, rule, and bear itself as it shall be ready to answer for to God and his imperial majesty,"—a decision which foreshadowed the famous Augsburg formula *cujus regio ejus religio*, the principle on which the German Protestant church was afterwards legally based. The Reformation had thus the three years, 1526–1529, to organize and consolidate itself. The man of Germany at that time among the princes was Philip, landgrave of Hesse, and he was taught what to do by a citizen James Sturm, the deputy of Strasburg at Spires. Sturm had convinced Philip that the basis of the true evangelical church was the acknowledgment of the self-government of the church by synods composed of the representatives of the whole Christian people; and this was embodied in the first Protestant constitution, the *Reformatio ecclesiarum Hassiæ juxta certissimam sermonum Dei regulam ordinata*.[1] The constitution acknowledged the episcopal element, but not episcopal rule; the *jus episcopale* was invested in the Christian community, and the flock of Christ were to hear only the voice of their shepherd Christ. Bishops and deacons were to be elected by the Christian people; bishops were to be consecrated by imposition of the hands of three bishops, and deacons instituted by the imposition of the hands of elders; while elders were associated with the pastors in the pastoral care of the congregation. A general or land synod was to be held annually, consisting of the pastor of each parish and of pious men elected from the various congregations, and there were provisions made for provincial and congregational synods. Three men were to be elected annually to exercise the right of visitation. This was afterwards found to be inconvenient, and six and then thirteen superintendents for life were substituted. This board of superintendents became afterwards an oligarchy, and at last a mere instrument of state, overriding the original democratic constitutions of the church, a consequence of the disruption of Germany and of the paralysis of all national institutions. Luther had in 1523 and 1524 professed principles almost identical with those established in 1526 in Hesse. His action ceased there; after the peasants' war he abandoned his more liberal ideas, and insisted on leaving everything to the princes, and what could a people do cut up into four hundred sovereignties? Luther never acknowledged Cæsaropapism or Erastianism as a principle and as a right. He considered the rights of the Christian people as a sacred trust provisionally deposited in the hands of the princes their representatives. "Where," he asked, "are the people to form the synods? I cannot find them." It was Melanchthon's influence that facilitated the despotic system and hampered the thorough reform of the forms of worship. Luther withdrew from a sphere which he felt was not his. He busied himself during these years with plans to improve and simplify the church services at Wittenberg. Some portions of the music in the communion service were too difficult for the people. Luther induced the elector to provide music teachers, and also to permit a simpler service. This led to the *German Mass and Order of Worship for Wittenberg*. The churches too throughout electoral Saxony were becoming better attended, and Luther had to consider and devise plans for church extension and supervision. His letters to Philip of Hesse, disapproving of the new constitution of the church there, show how jealous he had become of the entrance of democratic ideas. He asked the elector of Saxony to take charge of the church within his dominions, and Melanchthon's articles for the visitation of the churches in Saxony, which foreshadowed the Lutheran consistorial organization, show that Luther distinctly contemplates the transfer of the *jus episcopale* to the princes and magistrates. It is true that he called these magistrates *Nothebischöfe*, but he could not see any other solution of the difficulty, and undoubtedly from the legal point of view it was easy to transfer the right of supervision from one external authority to another, and difficult to hand it over from the bishops to the congregation. The new ecclesiastical organization adopted in Hesse and electoral Saxony had the effect of making the archbishop of Mainz renounce in 1528 the spiritual jurisdiction he had hitherto exercised over these two districts.

Diet of Spires, 1529.

Meanwhile the emperor had been again successful in his political schemes. His German army under the Constable Bourbon and General Frundsberg had seized upon Italy and had sacked Rome, and again he had brought the pope and Francis to terms. It only remained to subdue the Reformation, and the mediæval empire might be restored. He first sent a dispatch saying that the edict of Worms was to be held as in force. When the diet met at Spires in 1529, the imperial commissioners forbade the celebration of worship according to the reformed usage in churches, and afterwards in the houses of the elector and of the landgrave. The Act of Toleration of 1526 was to be abrogated. The diet appeared to be hopelessly divided, a majority with the emperor and a minority with the elector and the landgrave, and the majority passed an edict which amounted to this that where the edict of Worms could not be executed without fear of revolution no further reforms were to be allowed. The minority prepared a protest. "The diet has overstepped its authority," they said; "our acquired right is that the decree of 1526, unanimously adopted, remains in force until a council can be convened. Up to this time the decree has maintained the peace, and we protest against its abrogation." Ferdinand, who represented his brother, assured the princes that nothing remained for them but to submit; he threatened the free cities with the loss of their privileges

The protest and Protestantism.

[1] See Richter, *Evang. Kirchenordnungen*, i. p. 56; and Lechler, *Gesch. d. Presb. u. Synod. Verfassung*, p. 14.

and with an interdict, and he left the diet while the evangelical members were deliberating. In spite of these threats the protest was signed by John of Saxony, George of Brandenburg, Ernest of Lüneburg, Philip of Hesse, and Wolfgang of Anhalt among the princes, and by the representatives of the free cities of Strasburg, Nuremberg, Ulm, Costnitz (Constance), Lindau, Memmingen, Kempten, Nördlingen, Heilbronn, Reutlingen, Isny, St Gall, Weissenburg, and Windsheim. This celebrated protest of April 15, 1529, from which comes the name Protestant, is one of the noblest documents of Christian history. The protesting princes and cities claimed as their right as Germans the sacred duty freely to preach the word of God and the message of salvation, that all who would hear it might join the community of believers. It was also an earnest of true evangelical union; for it was well known that most of the cities were more inclined towards Zwingli's than towards Luther's view of the sacrament.

If this great act be considered impartially, it is impossible not to see that neither Luther nor Melanchthon was the real leader of the time. Luther had no real comprehension of what had to be done in Germany to preserve the gospel from destruction. He had shown little sympathy with the first attempt made in Hesse at the self-government of the church; still less did he see the importance of the protest at Spires, and of the unity it gave to the evangelical cause. It was evident that nothing but the inroad of the Turks had saved the Protestant princes after the diet, and that Charles was so far master of Germany as to make it impossible for Germany to become a Protestant nation. The Protestants were lost unless they strengthened the alliance which they had just founded at Spires. But Luther disliked such alliances; he dissuaded the elector from sending deputies to the meeting agreed to be held at Smalkald, and when the Saxon deputies prevented any business being done he was proud of the result. This apparent blindness and perversion of mind requires explanation. Luther lived under the shadow of the Middle Ages, and had been trained in scholastic law as well as in scholastic theology. To the mediæval jurist the emperor was the impersonation of all social order and moral law; he was the vicar of God. In the later Middle Ages the jurists had exaggerated this sacredness of the emperor, and had done so quite naturally in order to protect civil law from canon law, and to uphold the state against the church. Luther could throw off scholastic theology, but he could not throw off that scholastic jurisprudence that all his mediæval heroes, Occam, Wickliffe, and Huss had found so useful in their attacks on the papacy, and that Luther himself had found so serviceable when he appealed from the church defined by the pope to the church defined by the empire. He could not bear to think of an alliance against the holy Roman empire. Luther too had been trained in the school of Tauler and the *Theologia Germanica*, and partook greatly of their quietism. "Suffer God to do His work in you and about you" was their motto. There was a theological scruple also at the bottom of Luther's opposition to a vigorous Protestant alliance and a national attitude. This betrayed itself, first, in an uneasiness about Zwingli's rising influence in Germany, and, secondly, as a doctrinal idiosyncrasy respecting the sacrament of the Eucharist. Philip of Hesse saw through this instantly, and said, "I see they are against the alliance on account of these Zwinglians; well, let us see whether we cannot make these theological differences disappear."

uther nd wingli n the u- iarist.

When Luther was raised above himself by the great problem before him in that glorious period of action from 1518 to 1524, he had considered the sacrament as a part of the services of the church, and a secondary matter compared with the right view of faith or the inward Christianity which implies necessarily an unselfish believing and thankful mind. He was convinced that there was no virtue inherent in the elements apart from the communion, and it was a matter indifferent how the spirituality of the action and the real presence, even the transubstantiation, might be reconciled with faith. But the peasants' war and Carlstadt's mystical enthusiasm alarmed him. Where was this to lead to, he asked, and he seems to have settled down into a great resolve to abide by the tradition of the church, and alter as little as possible provided room was found for the exercise of living faith. So when he felt called upon to form a theory of the doctrine of the sacrament of the Eucharist he went back to his scholasticism to find there some theory which should be traditional and yet afford room for the spiritual priesthood of all believers, and for the exercise of faith on the promises of God. He found it in the writings of that schoolman whom he more than once calls "his dear master," the daring Englishman William of Occam. Transubstantiation, the Romish doctrine, offended Luther in his two essential requirements: it demanded a miracle which could be performed by a priest only, and this miraculous power so separated clergy from laity that it denied the spiritual priesthood of all believers; and, when the elements had been made by the priest's creating word the body and blood of the Lord, their supernatural efficacy, apart from the faith of the communicant, imparted grace. Occam had championed a theory which in some form or other had been in the church since the 10th century at least, and which openly rejected one of these stumbling blocks, and, as Luther saw, really did away with the other also. According to Occam's scholastic distinctions, matter can be present in two ways—(1) when it occupies a distinct place by itself, excluding every other body, *e.g.*, two stones mutually exclude each other, and (2) when it occupies the same space as another body at the same time. Everything which is omnipresent or ubiquitous must be able to occupy the same space as other things, else it could not be ubiquitous. Christ's resurrection body, said Occam, had this power when our Lord appeared among His disciples while they were in a room with the doors shut; at a certain moment of time it and a portion of door or wall must have been in the same place at the same time; and besides Christ's body is ubiquitous. It is therefore in the elements bread and wine, in, with, and under them. Luther took over this doctrine from Occam without alteration. The very illustrations he uses in his *Bekenntniss vom Abendmahl* are taken almost verbatim from Occam, *De Altaris Sacramento*. From this it followed that consubstantiation involved no miracle. Christ's body was not brought into the elements by the priest; it was there naturally. But its presence in these elements on sacramental occasions brought with it a blessing, and imparted grace, not because of the presence, but because God had promised that this particular presence of the everywhere present body of Christ would bring blessings to the faithful partaker. Occam's theory of consubstantiation fulfilled all Luther's wants, and above all it involved no explaining away of the plain meaning of the sentence, "This is my body," such as had offended him in Carlstadt. It is easy to see therefore how Luther was alarmed at Zwingli. The Swiss Reformer seemed to attack everything that Luther prized. He did not care for tradition or church usage; he seemed engaged in a rationalistic attack on the presence of Christ in the church, and on the word of God, and so he was guilty, in Luther's estimation, both of self-confidence and of a rationalism. On the other hand, Zwingli could not understand what Luther meant; and yet he was anxious to unite with him, and was willing to leave this one difficulty an open question. It was in these circumstances—suspicion on the part of Luther, blank amazement on the part of

Marburg conference.

Zwingli—that Philip of Hesse induced the Swiss and the German theologians to meet at Marburg. Luther was gloomy and suspicious, "as he had never been seen before," a friend said. The frank declarations of the Swiss Reformers soon cleared away all shadows of difference and dissent on all points but one, and fourteen articles defining the chief heads of Christian doctrine were adopted by both parties. Then came the discussion on the fifteenth, the doctrine of the Eucharist. Luther took a piece of chalk and wrote upon the table *Hoc est corpus meum*, and when worsted in argument, as he usually was, appealed to the sentence. The discussion, which lasted four days, however, resulted in the parties recognizing exactly where the point of difference lay, and in reducing it to its smallest dimensions. Both declared that they agreed in recognizing the Eucharist to be a sacrament of the true body and blood of Christ, and that a spiritual partaking of this body was a means of grace. They differed whether the true body and blood of Christ were *corporeally* in the sacrament. It was hoped that time would bring about alliance if not agreement, but Luther was obstinate. "Submit yourselves, believe as we do, or you cannot be acknowledged as Christians." He refused Zwingli's hand; "You have another spirit from us," he said, meaning that there was no objective basis of faith between them owing to what he thought to be Zwingli's rationalism. The result was a sad one, but Zwingli was to some extent a gainer; his view became naturalized in Germany, where Swabia adopted it, as did many of the imperial cities, and Philip of Hesse indicated that he preferred it.

Diet of Augsburg and the Augsburg confession.

The Marburg conference was a sad prelude to the decisive diet to be held at Augsburg in 1530. The new diet was anxiously awaited. Charles had made known his intention to be present, and that he intended to enforce obedience to the edict of Worms. He entered Augsburg with great magnificence, and was in fact at the zenith of his power. He had broken the might of France, humbled the papacy, been crowned at Bologna, reorganized Italy, and driven back the Turk. His only remaining task, and it seemed easy, was to crush the Reformation. He first summoned before him the protesting princes and asked them to withdraw the protest. This they refused to do; they had a clear constitutional right, founding on the decision of Spires, to resist the emperor, and they resolved to exercise it. Divine service after Lutheran fashion was held at their quarters, and they refused to join in the procession of the host at the festival of Corpus Christi. Meanwhile Luther, Melanchthon with him, was at Coburg, near enough at hand for consultation and yet beyond the emperor's reach. Melanchthon was preparing a confession with a defence, the so-called *Apology*, in case the emperor should require a statement of their doctrines. Luther was writing commentaries on the Psalms and the prophets, and was also preparing a popular edition of *Æsop's Fables.* He also wrote comforting letters to the elector, and addressed one of his most powerful writings to the Roman Catholic clergy assembled in the diet at Augsburg. Melanchthon was sent for to consult about the confession which the emperor had asked for, and Luther remained alone at Coburg full of anxiety, for he knew his friend's helplessness in the actual bustle of life. When Melanchthon got to Augsburg he really became a source of weakness. He induced the elector for the sake of peace to give up the services in the Franciscan church, and the Protestant preachers left the town in despair. Luther all the while had been quiet, waiting in patience; but this was too much for him, and he wrote to encourage the elector to resist. At length the Protestants were asked to present their confession. The emperor ordered it to be read in Latin. "No," said the elector, "we are Germans and on German ground. I hope therefore your majesty will allow us to speak German." When the vice-chancellor of the elector, Dr Christian Baier, had read the first part of the confession, which expounds the principles of the Reformation, and in particular the doctrine of justification by faith, "that faith which is not the mere knowledge of an historical fact, but that which believes, not only the history, but also the effect of that history upon the mind," it is said that an indescribable effect was produced upon the assembly. The opponents felt that there was a reality before them which they had never imagined; and others said that such a profession of faith by such princes was a more effectual preaching than that which had been stopped. "Christ," said Jonas, "is in the diet, and he does not keep silence; the word of God is indeed not to be bound." The Roman Catholic theologians present answered the confession, and then the emperor engaged Protestant and Roman Catholic theologians in negotiations in which Melanchthon soon showed his yielding character, even granting that the Protestants might acknowledge the jurisdiction of the bishops and the supremacy of the pope. At this critical moment Luther's indignation found vent. "I understand," he wrote to Melanchthon, "that you have begun a marvellous work, to make Luther and the pope agree together, but the pope will say that he will not, and Luther begs to be excused. Should you, however, after all succeed in your affair, I will follow your example and make an agreement between Christ and Belial. Take care that you give not up justification by faith; that is the heel of the seed of the woman to crush the serpent's head. Take care not to acknowledge the jurisdiction of the bishops; they will soon take all. In short, your negotiations have no chance of success unless the pope will renounce papacy." The Romanists fortunately demanded too much. Not even Melanchthon could yield the acknowledgment of private masses, of auricular confession, and of the meritorious character of good works; and the negotiations ceased. While they were in progress the emperor tried to intimidate the princes by calling the imperial troops into the free city of Augsburg and closing the gates. The landgrave escaped, and this frightened the Catholics. Unfortunately the Protestants had confessed their want of union by presenting three confessions of faith:—the Lutherans had presented the Augsburg confession; Strasburg, Constance, Memmingen, and Lindau, which sympathized to some extent with Zwingli, presented the Confessio Tetrapolitana; and Zwingli had sent a confession which was not, however, laid before the diet. The diet broke up with the final decision that the Protestants should have till next spring to consider whether they would voluntarily return to the church, and that, if they proved obstinate, then measures would be taken for their extermination.

To the student of Luther's life the diet of Augsburg is noteworthy chiefly because it was the occasion of the composition of the Augsburg confession, or *Augustana*, which afterwards became the symbol or confession of faith for the Lutheran Church. It was prepared by Melanchthon, founding on the fifteen articles of the Marburg conference, on the seventeen articles of Schwabach, and on the articles of Torgau. These various sets of articles had been written by Luther, and therefore the Augsburg confession was strictly Luther's own. It consists of two parts—one dogmatic, in twenty-one articles, which states the principal doctrines of the evangelical church, beginning with the Trinity and ending with the worship of saints; and the other in seven articles, rejecting the celibacy of the clergy, the sacrifice of the mass, auricular confession, ceremonial feasts and fasts, monastic vows, and the secular jurisdiction of bishops. It was signed at Augsburg by John of

Saxony, George of Brandenburg, Ernest of Lüneburg, Philip of Hesse, and Wolfgang of Anhalt, and by the representatives of the towns of Nuremberg and Reutlingen, and during the sitting of the diet by the representatives of Kempten, Heilbronn, Windsheim, and Weissenburg.

Smalkald league.

The edict of the diet was published on November 19, and the Protestant princes, after having overcome the resistance of Luther, met for conference at Smalkald on Christmas 1530, and formed an armed league for mutual defence. It had been declared that the edict would be put into execution in the spring of 1531, but when the time came the emperor had other work on hand: France had become troublesome, and the Turks were again moving. He found also that he could not count on the support of the Roman Catholic princes in the suppression of the Protestants. In presence of danger the Zwinglians and Lutherans showed a united front, and the Smalkald league grew to be a formidable power. The emperor resolved to come to terms with his Protestant subjects, and the result was the religious peace or rather truce of Nuremberg, which left things as they were until a general council should settle matters. The years following this peace of Nuremberg were comparatively prosperous to the Reformation. The Smalkald league was the only organized power in Germany, and very effectually prevented the oppression of Protestants by Roman Catholics. Year by year their numbers increased, and Luther saw the evangelical cause prospering. First Würtemberg was won back for young Duke Christopher, who had become a Protestant, and found on his entry to his dukedom that his people were already secret Protestants. In northern and central Germany whole districts embraced the evangelical doctrines. Electoral Brandenburg and ducal Saxony had received Protestant rulers, who found their people more than willing to accept the creed of their new sovereigns. At last the only large states that were able to maintain a firm front against the Lutheran doctrines were Austria, Bavaria, the Palatinate, and the great ecclesiastical provinces on the Rhine, and even in these regions visitations of the churches had shown that the people were forsaking the old faith. It appeared that a more serious defection than any might at any moment be made. The elector-archbishop of Cologne showed signs of abandoning the Roman Catholic faith and secularizing his vast episcopal territories, and this threatened defection made Charles bestir himself. If the elector became a Protestant the Lutherans would be in a majority in the electoral college, and a Protestant emperor might be elected.

Work of Luther's later years.

During all these years Luther was quietly at work at Wittenberg, lecturing, preaching, and writing. At first he felt anxious lest civil war should break out, and he had scruples about many of the doings, and even about the very existence, of that league which was really giving the land peace. Under Philip of Hesse the Reformation was assuming a national and political shape which alarmed Luther, who was more than ever content to keep out of public life and keep himself to his books. He began publishing his lectures on various portions of Scripture, on the Epistle to the Galatians and on the Psalms of Degrees. He wrote one or two controversial tracts, mainly to show how the Reformed could not accept the conditions offered by the Roman Catholics at Augsburg. In 1534, to his great joy, the first complete translation of the whole Bible was published, and next year appeared a new edition of the Wittenberg hymn-book, containing several new hymns. Philip of Hesse, notwithstanding the failure of the conference at Marburg, still thought that something might be done to remove the theological differences between Switzerland and Saxony, or at least between Swabia, Strasburg, and Wittenberg. The divines of Switzerland and of South Germany had by their publications made this somewhat easier. The confession of Basel, drafted by Œcolampadius (1531), revised by Myconius, and published by the magistracy of Basel, had declared that in the Lord's Supper Christ is the food of the soul to everlasting life, and Bucer and the other South-German divines were anxious for a union. Philip of Hesse, Bucer, and Melanchthon met in conference at Cassel to arrange preliminaries, not without suspicion on Luther's part, for he could not trust Melanchthon at a conference, and, as he remarked to Justus Jonas, he hated trimmers above all men on the earth's round. The result, however, was better than he had hoped for. Bucer drew up a short confession which was to be submitted to the Wittenberg theologians, and was favourably received by them, and the South German theologians were invited to a further conference at Wittenberg. The meeting very fairly represented all the German states, and the result was the document known as the *Wittenberg Concordia.* This document, mainly drawn up by Bucer and Melanchthon, contains a statement of the doctrine of the sacrament of the supper expressed according to the Lutheran formula, with the declaration that unworthy or faithless partakers really do not participate in the sacrament. Melanchthon and Bucer had used too much diplomatic skill in drawing up the formula, for the essential differences between the Wittenberg and the Strasburg school were not really faced and explained; they were covered over with ambiguous language. Nor could the document be accepted by the Swiss; but for a time it seemed as if a satisfactory basis of peace had been established. The general satisfaction was increased by the publication of the First Helvetic Confession, which, while stating the doctrine of the sacrament of the supper in a manner essentially Zwinglian, laid special emphasis on the real spiritual presence of Christ in the elements. Luther in a letter to Meyer, burgomaster of Basel, and also in his answer to the Reformed cantons, acknowledged the earnest Christianity of the confession, and promised to do his best to promote union with the Swiss. It is sad to think that only three years later his old animosity to Zwingli and his countrymen broke out again in his book against the Turks, and that he renewed the sacramental controversy with even more than the old fury in his *Short Confession of the Holy Sacrament*, published in 1544. This first Helvetic confession was drawn up, however, for another purpose than to appease the Wittenberg theologians. Charles V. was urging the pope to call a general council to end the disputes within the Christian church, and it seemed so probable that a council would meet that the Protestants were everywhere preparing themselves by doctrinal statements for taking their share in its work. The German princes and their theologians were also greatly exercised about this council, and the thought of it and how Protestants should bear themselves in its presence was filling Luther's mind. He wrote several short papers on the subject in the years 1534–39, beginning with the *Convocatio Concilii liberi* and ending with *Von den Conciliis und Kirchen.* The pope, Paul III., yielding to the pressure of the emperor and of such liberal Roman Catholics as Vergerius, his legate in Germany, called a council to meet in May 1537 at Mantua, and invited the Lutherans to be present. The Lutheran princes and theologians felt compelled to face the question whether they could or could not accept the invitation, and Luther, at the request of the elector of Saxony, prepared a creed to be used as a basis of negotiations. This was submitted to the princes and theologians assembled at Smalkald, and was in substance adopted by them. It is called the Smalkald Articles, and is important because in its statement of the doctrine of the sacrament of the supper it repudiates the Wittenberg Concord. The princes decided that they would have nothing to do with a council which did not meet on German soil. The emperor, alarmed at the progress of Protestantism, and at the united front shown by German Protestants, and troubled by the refusal of the pope to consent to a council to be held out of Italy, strove to bring Protestants and Roman Catholics together by means of religious conferences. The first of these, held at Hagenau, came to nothing. Next year (1541) the conference was renewed at Worms, when the Roman Catholic party promised reforms on condition that the Protestants first submitted to the pope. This condition could not be accepted. Representatives met the same year at Ratisbon, and here the conference was wrecked on the doctrine of transubstantiation, but the diet renewed the terms of the edict of Nuremberg of 1532—the Ratisbon Interim. It was felt by all parties that this provisional state of matters must come to an end some time, and that the Protestants must either be allowed to have their own way or win it by fighting. The emperor was not ready for war, and at the diet at Spires in 1544 it was agreed that the Protestants were to maintain their rights until a general council met. Whatever hopes they might have from such a council were soon dissipated. The council of Trent was opened that year, and its earliest acts were to refuse to pass the conciliatory measures proposed by some of the liberal Roman Catholics. The emperor still temporized and promised reforms, if not by a council then by a national assembly, and many of the Protestants, Luther among them, still hoped that matters might settle themselves without civil war. This hope inspired what was called the *Wittenberg Reformation*, a document setting forth how near the evangelical church might approach the Roman Catholic and still retain the truths it had upheld. The year 1546 began, however, with unmistakable indications that Charles was now ready to strike a decisive blow.

Luther had been suffering much during the last few years, and he felt his end to be near. In the month of January 1546 he undertook a journey to Eisleben in very inclement weather, in order to restore peace in the family of the counts of Mansfeld; he caught a violent cold, but preached four times, and took all the time an active part in the work of conciliation. On the 17th of February he felt that his release was at hand; and at Eisleben, where he was born, he died, in faith and prayer, on the following day. Nothing can be more edifying than the scene presented by the last days of Luther, of which we have the most authentic and detailed accounts. When dying, he collected his last strength and offered up the following prayer:—"Heavenly Father, eternal, merciful God, thou hast revealed to me Thy dear Son, our Lord Jesus Christ. Him I have taught, Him I have confessed, Him I love as my Saviour and Redeemer, whom the wicked persecute, dishonour, and reprove. Take my poor soul up to Thee!" Then two of his friends put to him the solemn question,—"Reverend Father, do you die in Christ and in the doctrine you have constantly preached?" He answered by an audible and joyful "Yes"; and, repeating the verse, "Father, into thy hands I commend my spirit," he expired peacefully, without a struggle, on the 18th of February 1546, at four o'clock in the afternoon.

The books on the life and work of Luther are so very numerous that it is impossible to do more than mention one or two. The best editions of Luther's works are (1) the Wittenberg, 1539-58, 19 vols. folio (7 in Latin and 12 in German; Melanchthon wrote the prefaces, and inserted a life of Luther in the beginning of the 2d vol.); (2) Walch's edition, 24 vols. 4to, 1740-53; (3) the Erlangen edition, 65 vols. and 2 vols. of indices, in all 67 vols., in German, and 33 vols. in Latin, and not yet complete, 1826-73; (4) the last edition is from Frankfort-on-the-Main, publishing at the expense of the Prussian Government.

Luther's letters have been collected and edited by (1) De Wette and Seidemann, *L. Briefe*, 6 vols., 1825-56; (2) this emendated by Burkhardt, *Luther's Briefwechsel*, 1866; (3) Seidemann, *Lutherbriefe*, 1859.

The *Table Talk* was translated (1) by William Hazlitt, 1848, and (2) by Bindseil, *Colloquia*, &c., 3 vols., last published 1866.

Lives of Luther.—(1) J. Mathesius, *Historie von D. M. Luther's*, &c., Nuremberg, 1566; (2) Cochlæus, *Acta et Scripta Lutheri*, Paris, 1565 (Roman Catholic and abusive); (3) Merle d'Aubigné, *Hist. of the Ref.*, vols. i.-iii., 1838, &c.; (4) Michelet, *Life of Luther* (his statements about himself collected), translated by Hazlitt, 1846 and 1862; (5) Croly, *Life of Luther*, 1857; (6) Julius Köstlin, *Martin Luther, sein Leben, &c.*, 2 vols., 1875. The last is the best; it has been summarized for popular reading in one volume, with interesting illustrations, 1882.

The Times of Luther.—(1) Ranke, *Deutsche Geschichte im Zeitalter d. Ref.*, 6 vols., 1st ed. 1839-47, reached a 6th ed., Eng. transl. by Sarah Austin, 1845-47; (2) Löscher, *Reformations Akta*, Leipsic, 1720; (3) Häusser, *The Period of the Reformation*, 2 vols., 1873; (4) Seebohm, *Era of the Protestant Revolution*, 1877 (a very short but good and clear summary of events). (T. M. L.)

LUTHERANS are that body of Christians who adopted the principles of Martin Luther in his opposition to the Roman Church, to the Swiss theologians, and to the sectaries of Reformation times. They called themselves "Evangelical" in distinction from the "Reformed" or followers of Calvin, and formed one of the two great divisions of the Reformation Church. In the early days of controversy the stricter Lutherans held it to be their peculiar function to preserve the *status religionis in Germania per Lutherum instauratus* and to watch over the *depositum Jesu Christi* which Luther had left in their charge. Luther himself was much more fitted to be a reformer and preacher than an exponent of a scheme of theology or the organizer of an ecclesiastical system. His wonderfully sympathetic nature was easily moved, and his own liking and disliking ruled him too strongly to make him able to expound in calm fashion the whole round of theology, giving to each doctrine its proper place in the system. His nominalist training, his quietism got from the mystics of the 14th and 15th centuries, his occasional fits of morbid melancholy, all kept him from looking at the whole system of Christian doctrine, and made him intensify the value and importance of special aspects of truth. The early Lutheran theology reflected the character of its founder. It lacked systematic completeness, more especially in its failure to construct a comprehensive doctrine of the work of the Holy Spirit, and it swayed from side to side in violent controversies, until at length out of the conflicts emerged the Form of Concord, which, it was hoped, would succeed in pacifying the church. The dogmatic symbols of the Lutheran Church are usually said to include nine separate creeds, three of which are taken from the early Christian Church while six are the production of the 16th century. They are the Apostles' Creed, the Nicæo Constantinopolitan Creed in its Western form (*i.e.*, with the *filioque*), the so-called Athanasian Creed, the Augsburg Confession or Confessio Augustana, the Apology for the Augsburg Confession, the Smalkald Articles, Luther's two Catechisms, and the Form of Concord. These nine confessions together make up the *Liber Concordiæ* of the Lutheran Church; but only the three pre-Reformation creeds and the Augsburg confession are recognized by all Lutherans. Luther's catechisms, especially the shorter of the two, have been almost universally accepted, but the Form of Concord was expressly rejected by many Lutheran churches. The Augsburg Confession and Luther's Shorter Catechism may be said to contain the distinctive principles of Lutheranism which all Lutherans unite to maintain, but, as the principal controversies of the Lutheran Church all arose after the publication of the Augsburg Confession, and were fought out between men who united in accepting that symbol, it does not contain all that is distinctively Lutheran. The Augsburg Confession itself perhaps owed its universal recognition to the fact that it existed in two forms which vary slightly in the way in which they state the doctrine of the sacrament of the supper, the *variata* and the *invariata*; and this also bears witness to the lack of dogmatic coherence which is a characteristic of Lutheranism. Melanchthon's *Hypotyposes* or *Theological Commonplaces* (first published in 1521) may also rank along with these creeds as an authoritative exposition of Lutheran theology; and the changes it underwent in its successive editions show the incompleteness of the system.

The earliest controversy which divided the Lutheran Church arose in Luther's lifetime and lasted till 1560 (1537–60). It sprang out of differences of opinion about the precise meaning to be attached to the term law in Luther's famous distinction between law and gospel. According to Luther, and the distinction runs through all Lutheranism, law and gospel are the two factors which bring home to the individual experience the knowledge of salvation. Law is the rule of life given by God and accompanied by threatening and promise, which counts on fulfilment from selfish motives, threatens, terrifies, and so produces contrition; while the gospel, which is the message of salvation, comes after the law has done its work, and soothes. In this description the term law has a distinct and definite meaning; it signifies legal injunction or command; and Luther and his followers were accustomed to say, using law in this definite way, that Christ was not under the dominion of the law, and that Christ's people are also free from its restraints. They said that believers ascend to the Christian life only when they have transcended a rule of life which counts on selfish motives for obedience. The word law manifestly means more than Luther put into this definition, and certain Lutherans who accepted Luther's distinction between law and gospel did not understand his limitation of the term law, and taught that believers were not bound by the moral law. These antinomians, of whom Agricola was chief, took Luther's statements about law in the sense of legal injunction, and applied them to law in the sense of ethical rule. The confusion perplexed the Lutheran Church for more than twenty years.

The debates which harassed the Reformed Church in the Arminian controversy, and the Roman Catholic Church in the Jansenist controversy, appeared in the Lutheran Church in three separate disputes lasting from about 1550 to 1580. In these discussions the stricter Lutherans were on the one side and Melanchthon with his followers on the other. The first dispute was about the relation of good works to conversion. George Major, founding on an expression in Melanchthon's *Commonplaces* (ed. 1543), said that good works were both necessary and useful to holiness. He was attacked by Mat. Flacius and Nic. Amsdorf, and after a long and tedious discussion, in the course of which it was made plain that both sides were sadly in want of general principles to guide them, and that important words were used ambiguously, George Major's proposition was condemned because it savoured of Pelagianism. The problem took a new form in the Synergist controversy, which discussed the nature of the first impulse in conversion, and in the controversy about original sin which followed. Pfeffinger taught that the first impulse in conversion came from grace and was due to the Holy Spirit, but he said that this impulse and its effect might be compared with the reviving of a man apparently dead. According to the strict Lutherans the sinner was not apparently but actually dead, and grace was not merely the occasion, it was also the actual cause, of the new life. Flacius, who had made this last assertion, which seemed to be generally approved of, started a fresh controversy by his assertion that sin was part of the substance of man in his present natural condition, and that man was no more able to co-operate with grace in conversion than was a stick or a stone. This was contradicted by Striegel, a follower of Melanchthon, who asserted that sin had not totally destroyed man's ethical nature, but that grace by its action changed what was morally insensible into what was morally living and sensible, so that there could be an actual synergy or co-operation between God's grace and man's will.

The controversy raised by Andrew Osiander was much more important, and revealed the lack in Lutheranism of a systematic doctrine of the work of the Holy Spirit. Osiander felt that Lutheran dogmatic had omitted to make adequate answer to a most important practical question in theology, how Christ's death on the cross could be so brought into connexion with each individual believer as to be the ground of his actual justification. The mediæval church had spanned the centuries by their doctrine of the prolongation of Christ's death throughout time in the sacrifice of the mass, but he could not see any such real connexion of time in Luther's theology. He proposed to get rid of the difficulty by saying that justification is a real work in the believer done by that same Christ who had died so many centuries before. He distinguished between redemption, which he said was the result of the historical work of Christ upon the cross, and justification, which was another work of the same Redeemer within the individual, and was the influence renewed daily of the Saviour upon each believer. The controversy which followed was full of ambiguities and misunderstandings, but out of it rose two distinct theories, one of which was generally adopted by the Lutherans, while the other has become a characteristic of Reformed or Calvinist theology. Striegel declared that the principal effect of the work of Christ upon the cross was to change the attitude of God towards the whole human race, and that in consequence whenever men come into being and have faith they can take advantage of that change of attitude, the ground of their assurance being that because of what Christ did God regards all men benevolently. Calvinist divines, on the other hand, found in Osiander's criticism the starting point of that close connexion between Christ's work and His redeemed which is expressed in the doctrine of the limited reference in the atonement.

These controversies all implied more or less vagueness in the earlier dogmatic teaching of Luther. Others, however, arose from what may be called the distinctive teaching of Luther upon the sacrament of the Lord's Supper and what was implied therein. In the article LUTHER it is stated that Luther, at least after the peasants' war, held strongly a theory of the connexion between the elements (the bread and wine) and the body and blood of Christ in the sacrament of the supper which has been called *consubstantiation*, and that this theory depended not merely on certain scholastic definitions of bodily presence but also on the supposition that the attribute of ubiquity belonged to the glorified body of Christ. A large number of Lutherans, followers of Melanchthon, were inclined to depart from these views and approach the more reasonable opinions of Calvin, and this occasioned controversies about Crypto-Calvinism and about Christology. The university of Jena was the theological headquarters of the stricter Lutherans, while Wittenberg was the centre of the Philippists or Crypto-Calvinists, as the followers of Melanchthon were called. At first the controversy mainly gathered round the questions of the corporeal presence, the oral manducation, and the literal eating of Christ's body by unbelievers as well as by the truly faithful, but it soon included discussions on the person of Christ, and into these discussions Reformed theologians were brought. The result was various conferences at Maulbronn (1564), which only confirmed both parties in their peculiar opinions; at Dresden (1571), where the Lutheran theologians of Wittenberg and Leipsic renounced the doctrine of the ubiquity of Christ's body and agreed with the Calvinists; and elsewhere. It seemed as if the Lutheran Church was about to fall in pieces.

Out of these disputes came the Form of Concord, due principally to Jacob Andreæ of Tübingen, to Martin Chemnitz of Brunswick, and to Nicolas Selnecker of Leipsic. Various theological conferences were held, and various articles of agreement more or less successful were framed, of which the most notable was the *Torgau Book* of 1576; and at last in 1577 the Form of Concord was published, and after much discussion and negotiation was adopted by most of the Lutherans in Germany. Its recognition was mainly due to the exertions of Augustus, elector of Saxony It was also adopted by the Lutheran churches of Sweden in 1593, and of Hungary in 1597. It was rejected by the Lutheran Church of Denmark and by the churches of Hesse, of Anhalt, of Pomerania, and of several imperial cities. It was at first adopted and afterwards rejected by Brunswick, by the Palatinate, and by Brandenburg. The German churches which refused to adopt it became for the most part Reformed or Calvinist; and the Form of Concord, which ended the more violent theological controversies among the Lutherans, greatly decreased their numbers and territorial extent.

The divided state of Germany in the 16th century, aided by the maxim of the peace of Augsburg which gave Protestantism a legal standing, and by the consistorial system of ecclesiastical rule which followed in consequence, divided the Lutherans in Germany into a number of separate churches as numerous as the principalities. At the peace of Augsburg the adherents to the Augsburg Confession were recognized legally as having a right to exist within the German empire, and the power of determining whether the Roman Catholic or Lutheran confessions should be the recognized creed of the state was left, with some reservation, in the hands of the supreme civil authority in each separate principality (*cujus regio ejus religio*). This virtually gave the direction of the church of each German state into the hands of the supreme civil power therein; it belonged to the princes in the various principalities and to the municipal councils in the free imperial cities. This legal recognition of the supreme authority of the civil power in ecclesiastical affairs was intensified by the adoption in the Lutheran Church of the consistorial system of church government, which was the distinctive mark of the Lutheran as opposed to the Reformed Church. The consistorial system took a great variety of forms, but it had one common characteristic: it simply transferred the *jus episcopale* from the bishops to the civil authorities, and, as the bishops ruled their dioceses in ecclesiastical and other matters by means of councils or consistories appointed by themselves, so in the

Lutheran Church these old episcopal consistories were transformed into councils whose members were appointed by the civil rulers. Thus each petty German state had its own church with its special organization and peculiar regulations. Richter in his *Evangelische Kirchenordnungen des 16ten Jahrhunderts* (2 vols., 1846) has collected more than one hundred and eighty separate constitutions of churches adhering to the Augsburg Confession. This minute subdivision makes it almost impossible to recognize any unity in the Lutheran Church save what comes from the profession of a common creed.

The publication of the Form of Concord drew the strict Lutherans more together, and set over against them in Germany a Calvinist Church, and the divided state of Protestantism greatly weakened its strength in the religious wars of the 17th century. As the smaller German states came together in larger principalities the awkwardness of the separate Protestant churches was more keenly felt. Many attempts were made by conferences, as at Leipsic (1631), Thorn (1645), Cassel (1661), to unite Lutherans and Reformed, though without success. At length the union of the two churches was effected mainly by the force of the civil authority in Nassau (1817), in Prussia (1817), in Hesse (1823), in Anhalt Dessau (1827). These unions for the most part aimed, not at incorporating the two churches in doctrine and worship, but at bringing under one government the two confessions, and permitting every congregation to use at pleasure either the Lutheran or the Heidelberg Catechism. They were sometimes accompanied, as in Prussia, by a separation of the stricter Lutherans, who formed themselves into dissenting churches. The separation in Prussia was caused mainly by a new liturgy which Frederick William III. forced on the church, and which the dissenters or Old Lutherans refused to use. The divisions caused in this way were at first repressed but were afterwards tolerated, and have reproduced themselves in the flourishing Lutheran Church of the United States.

LUTON, a market-town and municipal borough of Bedfordshire, England, is situated in a fine valley near the source of the Lea, 31 miles north-west of London. The parish church of St Mary, dating from the 14th century, a very fine building in the Decorated Norman and Later English styles, contains a large number of old monuments and brasses. Its entire length is 182 feet, the width of nave and aisles 57 feet, and the width of the transepts from north to south 101 feet. On the process of restoration, begun in 1865, £6000 has been expended. The other principal public buildings are the town-hall, the corn exchange, the court-house, and the plait hall. Luton is the principal seat of the straw-plait manufacture in England. The industry originated in the colony of straw-plaiters transplanted by James I. from Scotland, whither they had been brought from Lorraine by Queen Mary. Though the town is very ancient, it was first incorporated in February 1876. The population, which in 1871 was 17,317, was 23,959 in 1881.

LUTZK, a district town of Russia, in the government of Volhynia, on the Styr, 162 miles west-north-west of Szitomir, and 5 miles from the Kivertzy station of the railway between Kieff and Brest-Litovsky. It is a very old town, supposed to have been founded in the 7th century; in the 11th century it was known under the name of Luchesk, and was the chief town of an independent principality. In the 15th century it was the seat of a bishop, and became a wealthy town, but during the wars between Russia and Poland in the second half of the 16th century, and especially after the extermination of its 40,000 inhabitants, it lost its importance. In 1791 it was taken by Russia. It is now a rather poor town, situated in an unfertile district, and its 11,500 inhabitants, many of them Jews, live mainly by shipping goods on the Styr.

LUXEMBOURG, FRANÇOIS HENRI DE MONTMORENCY-BOUTTEVILLE, DUC DE (1628–1695), marshal of France, the comrade and successor of the great Condé, was born at Paris on January 8, 1628. His father, the Comte de Montmorency-Boutteville, had been executed six months before his birth for killing the Marquis de Beuvron in a duel, but his aunt, the Princesse de Condé, recognizing in him the last male heir of her great family De Montmorency, took charge of him, and educated him with her son, the Duc d'Enghien. The young Montmorency attached himself enthusiastically to his cousin, and shared his successes and reverses throughout the troubles of the Fronde. He returned to France in 1659 and was pardoned, and Condé, who was then much attached to the Duchesse de Châtillon, Montmorency's sister, contrived the marriage of his adherent and cousin to the greatest heiress in France, the Princesse de Tingry, after which he was created Duc de Luxembourg and peer of France. At the opening of the war of the devolution, 1667–68, Condé, and consequently Luxembourg, had no command, but in the second campaign he served as one of Condé's lieutenants in the conquest of Franche Comté. During the four years of peace which followed the peace of Aix-la-Chapelle, Luxembourg diligently cultivated the favour of Louvois, and in 1672 received orders to commence hostilities with the Dutch. He defeated the prince of Orange, whom he was to beat again and again, at Woerden, and ravaged Holland, and in 1673 made his famous retreat from Utrecht with only 20,000 men in face of 70,000, an exploit which placed him in the first rank of generals. In 1674 he was made captain of the gardes du corps, and in 1675 was made marshal of France. In 1676 he was placed at the head of the army of the Rhine, but failed to keep the duke of Lorraine out of Philipsburg; in 1677 he stormed Valenciennes; and in 1678 he defeated the prince of Orange, who attacked him at St Denis after the signature of the peace of Nimeguen. His reputation was now at a great height, and it is commonly reputed that he quarrelled with Louvois, who managed to mix him up in the confessions of the poisoners, and get him sent to the Bastille. Rousset in his *Histoire de Louvois* has, however, shown that this quarrel is probably apocryphal. There is no doubt that Luxembourg spent some months of 1680 in the Bastille, but on his release took up his post at court as *capitaine des gardes*, and was in no way disgraced. When the war of 1690 broke out, the king and Louvois also recognized that Luxembourg was the only general they had fit to cope with the prince of Orange, and accordingly he was put in command of the army of Flanders. On July 1, 1690, he defeated the prince of Waldeck at Fleurus with the loss of 14,000 men and 49 pieces of cannon. In the following year he commanded the army which covered the king, who was besieging Mons, and defeated William III. of England at Leuze on September 18, 1691. Again in the next campaign he covered the king's siege of Namur, and utterly defeated William at Steenkerk on June 5, 1692; and on July 29, 1693, he won his greatest victory over his old adversary at Neerwinden, in which he took 76 pieces of cannon and 80 flags. No wonder he was received with enthusiasm at Paris by all but the king, who looked coldly on a relative and adherent of the Condés. He conceived himself strong enough to undertake an enterprise which St Simon describes at length in the first volume of his *Memoirs*: instead of ranking as eighteenth peer of France according to his patent of 1661, he claimed through his wife to be Duc de Piney of an old creation of 1571, which would place him second on the roll. The whole affair is described with St Simon's usual keen interest in all that concerned the peerage, and was chiefly checked through his assiduity. In the campaign of 1694, possibly owing to this check, Luxembourg did but little in Flanders, except his well-known march from Vignamont to Tournay in face of the enemy. On his return to Versailles for the winter he fell ill, and died on January 4, 1695. In his last moments he was attended by the famous Jesuit priest Bourdaloue, who said on his death, "I have not lived his life, but I would wish to die his death." The holy father certainly had not lived like Luxembourg, whose morals were conspicuously bad even in those times, and whose life had shown very slight signs of religious conviction. But as a general he was Condé's grandest pupil. Utterly slothful, like Condé, in the management of a campaign, and therein differing from Turenne, at the moment of battle he seemed seized with happy inspirations, against which no ardour of William's and no steadiness of Dutch or English soldiers could stand. His death and Catinat's disgrace close the second period of the military history of the reign of Louis XIV., and Catinat and Luxembourg, though inferior to Condé and Turenne, were very far superior to Tallard and Villeroi. He was distinguished for a pungent wit. One of his best retorts referred to his deformity. "I never can beat that cursed hump-back," William was reputed to have said of him. "How does he know I have a hump?" retorted Luxembourg, "he has never seen my back." He left four sons, the youngest of whom was a marshal of France as Maréchal de Montmorency.

See the various memoirs and histories of the time. There are some interesting facts in Desormeaux's *Histoire de la Maison de Montmorency*. Camille Rousset's *Louvois* should also be studied.

LUXEMBURG, a grand-duchy of Europe, governed under a special constitution by the king of the Netherlands, is bounded on the N. and E. by Rhenish Prussia, S. by Lorraine and the French department Meurthe-et-Moselle, and W. by Belgian Luxemburg. It measures 32 miles from Hartelingen to Rosport, both on the Sure, and 50 miles from Rumelange in the south to Weiler in the north. The surface contains 639,000 acres (998 square miles), of which 293,554 acres are arable, 61,033 meadow-land, 143,812 woodland, 54,135 coppice, and 540 vineyards. The hills in the south of the duchy are a continuation of the Lorraine plateau; and the northern districts are crossed in all directions by outrunners from the Ardennes. With the exception of the Chiers, which flows into the Meuse near Sedan after a course of 50 miles, the streams all drain into the Moselle, which forms the boundary between Luxemburg and the Rhine province for about 20 miles. The Sure or Sauer, the most important stream in the duchy, rises at Vaux-les-Rosières in Belgian Luxemburg, crosses the duchy, and forms the eastern boundary from the confluence of the Our till it joins the Moselle after a course of 50 miles, during which it receives the Wiltz, the Woltz, the Alzet, &c. At Mondorf there are mineral wells and a bathing establishment. The soil of Luxemburg is generally good; the southern districts are on the whole the most fertile as well as the most populous. Building materials of all sorts are obtained throughout the duchy, and in the south there is iron-ore of fair quality—the mining area at present occupying from 8000 to 10,000 acres. Galena is worked on the frontier between Oberwampach and Longville, and antimony at Gösdorf near Wiltz. Since 1842 Luxemburg has been included in the Zollverein, and its principal dealings are, consequently, with Germany. Besides the iron furnaces,—situated all of them in the south near the Lorraine plateau,—the industrial establishments of the country comprise a large number of tanneries, a dozen weaving factories, an important glove-making factory, a pottery, paper-mills for all sorts of paper, breweries and distilleries, and two sugar refineries. A German patois mixed with French words is spoken throughout the country; but French, which is universally employed by the commercial community, is also the common speech of all classes on the French and Belgian frontiers. Though perfect liberty of worship prevails, Roman Catholicism is almost the sole form of religion in the duchy, the only dissenters worthy of note being the Protestant Prussian employés and about three hundred Jewish families. The government is in the hands of the grand-duke, who sanctions and promulgates the laws. Between 1850 and 1879 the king of the Netherlands was represented in his grand-ducal functions by his brother Prince Henry; but since the prince's death he has resumed the personal direction of affairs. The grand-duchy is a neutral and independent state, and its crown hereditary in the Nassau family (Treaty of London, March 11, 1867). A house of representatives and a council of state, named by the grand-duke, compose the administrative body. The representatives, to the number of forty-four, are chosen by the people in the proportion of one for from 4000 to 5500 inhabitants. No law can be passed without the consent of the house of representatives. Bills are introduced by the grand-duke, but the house has also the right of initiative. A single battalion (150) of Luxemburg chasseurs composes the grand-ducal army,—all voluntary recruits. The gendarmerie also consists of about 150 men. There are two courts of first instance in the duchy,—one at Luxemburg, the other at Diekirch,—and a high court and a court of appeal, both at Luxemburg. Criminals appear before the court of assize at Luxemburg. By grand-ducal decree the order of the Crown of Oak was instituted for the duchy, December 29, 1841, and that of the Golden Lion, February 5, 1858. The communal councils are under the supervision of the district commissioners, who are subject in turn to the minister of the interior. The administration of the town of Luxemburg depends immediately on the Government. Education is in a flourishing state: there are 642 primary schools attended by 31,000 pupils; Luxemburg has a normal school and an athenæum; Diekirch and Echternach have each a gymnasium. The bishopric of Luxemburg, containing 13 diaconates, subdivided into 253 parishes, holds its authority directly from the Holy See. From 6,000,000 to 7,000,000 francs is the annual amount of the state budget, and the public debt was 12,000,000 francs in 1863. Since 1854 there has been a grand-ducal bronze coinage.

The following table shows the administrative divisions and the population (total, 205,158) according to the census of 1875.

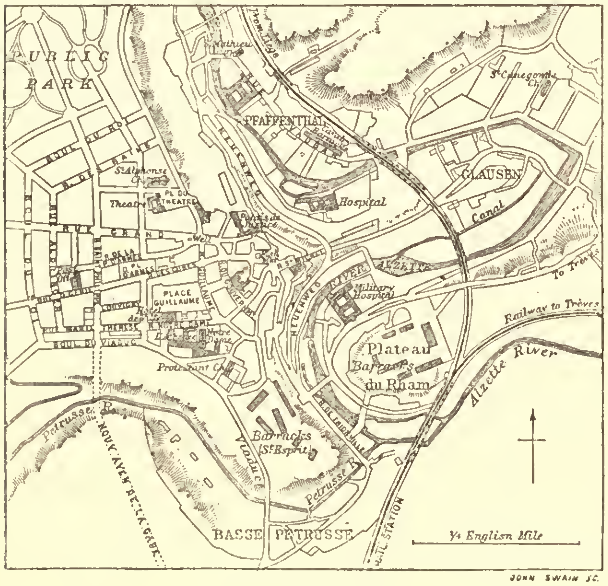
Districts.	Cantons.	Communes.	Population.
Luxemburg	Luxemburg	13	42,066
	Capellen	11	16,363
	Esch	13	24,158
	Mersch	11	14,264
Grevenmacher	Echternach	8	13,136
	Grevenmacher	9	14,918
	Remich	10	13,796
Diekirch	Clerf	10	13,899
	Diekirch	13	18,254
	Redingen	13	15,042
	Vianden	3	3,350
	Wiltz	13	15,972

Next to the capital come Echternach with 3920, and Diekirch with 3130 inhabitants,—both worthy of note for their blast furnaces. At Echternach an annual procession is held in honour of St Willibrord, dating from 1374. Grevenmacher is the centre of a great wine district.

The Luxemburg territory as well as the country of Ardenne was included in Belgica Prima at the first division of Gaul by Augustus in 27 B.C.; during the Frankish period it formed part first of Austrasia, then of Lorraine, and then of Lower Lorraine. On the dismemberment of ancient Austrasia the countship of Ardenne fell to Ricuin; and, when after Ricuin's death his children divided his possessions, Ardenne proper was obtained by Count Sigfried (Sigefroi). The county of Luxemburg, as Ardenne came to be called after the chief town, was raised to be a duchy in 1354, and existed as an independent state till 1451, when it was seized by Philip, duke of Burgundy. The dynasty which he displaced had been ambitious and active, and had, in the person of Henry VII., attained the imperial dignity, and in that of John ascended the throne of Bohemia. As a Burgundian possession Luxemburg came to the house of Austria, and, after forming part of the archduchy governed by Albert and Isabella, 1598–1632, followed the fate of the Spanish Netherlands till it was ceded by the treaty of Utrecht to the house of Hapsburg. It was deprived of Thionville, Montmedy, Damvilliers, Ivoix, and Marville by the treaty of the Pyrenees (1659) in favour of France; and Louis XIV. occupied the town and great part of the province from 1684 till the treaty of Ryswick (1697). Seized by the French in 1793, it went in the main to form the department of Forêts. On the 16th March 1815 William I. declared himself king of the Netherlands and duke of Luxemburg, and his claims were sanctioned by the treaty of Vienna,—Luxemburg being considered compensation for the loss of the small principalities of Hadamar, Siegen, Dietz, and Nassau-Dillemburg, the surrender of which to Prussia had deprived William of his place in the Germanic confederation. The fortress was assigned to the confederation itself, and was garrisoned by six thousand men, of whom one-fourth belonged to the grand-duke and three-fourths to the confederation. From the recognition of Belgian independence in 1830 to the treaty of London in 1839, matters were still more complicated; there were two governments in Luxemburg—one at Luxemburg, acting for the grand-duke, and the other at Arlon, acting for Belgium. By the treaty of London about 1218 square miles of the duchy with 149,571 inhabitants were transferred to Belgium, the German confederation and King William being compensated with parts of Limburg. On the dissolution of the confederation the duchy became free from its connexion with Germany, but the fortress remained in the hands of Prussia. A diplomatic contest for possession of the duchy took place between France and Prussia; and the matter became the object of a special conference of the plenipotentiaries of the great powers, Holland, Belgium, and Italy, in 1867. The result was that the neutrality of Luxemburg was guaranteed and the military importance of the town destroyed. The actual demolition of the fortifications evacuated by the Prussians in September 1867 did not take place till 1872.

See Bertholet, *Hist. du duché de Luxembourg*, Luxemburg, 1741–43; Vandermaelen, *Dict. géogr. du Luxembourg*, Brussels, 1838; Schötter, *Krit. Erörterungen über die früh. Gesch. der Grafschaft Luxemburg*, Luxemburg, 1859; Grövig, *Luxemburg, Land und Volk*, Luxemburg, 1867.

LUXEMBURG, the capital of the grand-duchy, lies 34 miles north of Metz and 25 south-west of Treves, in a position as remarkable for natural beauty as for military strength. The main part of the town is built on a rocky table-land terminating precipitously towards the north-east and south;



Plan of Luxemburg.

the modern portions, known as Pfaffenthal, Clausen, and Grund, lie 200 feet below, in the valley of the Alzette. Till their demolition in terms of the treaty of 1867 the fortifications, on which the engineers of three centuries had expended their skill, were the great feature of the place; in point of strength they ranked, according to Carnot, second only to those of Gibraltar, and like them they were to a great extent hewn out of the solid rock. The site is now occupied partly by a fine public park, partly by new districts of handsome houses, which give the city more of the outward appearance of a capital. Among the buildings of historical interest are the cathedral of Notre Dame, erected by the Jesuits in 1613; the church of St Michel, dating from 1320; the Government-house, built in 1443, and still regularly occupied by the legislative assemblies; the town-house, built in 1830; the law courts, dating from 1565, but serving till 1795 as the residence of the governor of Luxemburg; and the athenæum, built in 1594, and now (1882) attended by 500 to 600 pupils. The population of the city and suburbs, which was 15,930 in 1875, is now estimated at 19,000.

Luxemburg (formerly called Lützelburg) appears in 738 as a castle presented to the abbey at Treves by Charles Martel. The town grew up in the course of the 10th century, and soon began to surround itself with walls; but it was not till 1503 that a regular system of fortifications was commenced, and the principal features of the modern fortress were due to Vauban, who accompanied Créqui in his capture of the place in 1664. Extensive additions were made to the works in 1728–34.

See Coster, *Gesch. der Festung Luxemburg*, Luxemburg, 1869.

LUXEMBURG, a province of the kingdom of Belgium, lying at the south-eastern extremity of the country, and bounded N. and W. by the provinces of Liége and Namur, S. by France, and E. by Prussia and by the grand-duchy of Luxemburg, from which it was separated in 1839. It is the largest and most thinly populated of the Belgian provinces,—75 miles in length, 30 in breadth; the population is 204,000. The ground is high, averaging 1200 feet above sea-level, and rising in parts over 2000. The soil is dry and slaty, with occasional sand and limestone. The aspect of the country is a succession of broad tracts of table-land or plateaus covered with wood or heather, and intersected by wide and deep valleys; these contain streams, half-dry during the summer, but quickly changed to sweeping torrents by rain or melting snow. Peat is found on the hills, and occasional morasses, known by the name of "hautes fanges," are to be met with on the tops of the highest mountains. The whole district is comprised within the region of Ardennes. The agricultural produce is poor; the various breeds of horses, cattle, sheep, &c., are remarkably small, though they all possess individual qualities of endurance or their flesh of flavour; the hams are renowned. The forests abound in game of all kinds; red deer are plentiful, and wild boars have of late become so abundant as to be a serious nuisance. The mineral productions are worthy of note. Iron is found in the valley of the Ourthe, and also farther south near Arlon; lead is extracted at Longwilly, manganese at Biham, zinc at Longwilly and Bleid. Building stone is to be had throughout the province, and is generally employed, brick houses being the exception. There are quarries of grey and rose-coloured marble at Wellin, and extensive slate quarries on the banks of the Semois, the Sure, and the Salm. The trade in wood and bark is considerable, and there are some important tanneries, as well as iron works, paper-mills, and limekilns. The principal rivers are the Semois, the Lesse, and the Ourthe, affluents of the Meuse, and the Sure, which flows into the Rhine; of these the Ourthe alone is navigable for a few miles down from Barvaux. There are no canals in the province, so that Luxemburg is entirely dependent on railways for its traffic. The Brussels and Basel line runs through the whole province, with a station at Arlon, the capital; and branch lines have been established to connect the principal markets, Marche, Durbuy, Bastogne, Virton, &c., with the main artery. The language spoken by the inhabitants is French, with an admixture of Walloon dialect and an inferior kind of German on the borders of the grand-duchy. The king of the Belgians and his brother the count of Flanders possess summer residences, with extensive forest lands, in the province of Luxemburg.

LUXOR, more properly El-Aksur, "The Castles" (*plur. pauc.* of kaṣr), a village on the Nile, 450 miles above Cairo, occupies part of the site of the ancient Thebes, and has its name from the ruins described in vol. vii. p. 777. The village is also called Abu'l Ḥajjáj from the patron saint whose tomb is mentioned by Ibn Baṭuṭa, i. 107, ii. 253. See also Yáḳút, i. 338. Luxor is the centre for visitors to the ruins of and about Thebes, and is increasingly frequented by travellers and invalids in the winter season, being the only place above Osyûṭ (Sayûṭ) provided with hotel accommodation suitable for Europeans. The district is the seat of an extensive manufacture of forged antiques, often very skilfully made.

LUZON, or LUÇON. See PHILIPPINE ISLANDS.

LYCANTHROPY is a term used comprehensively to indicate a belief, firmly rooted among all savages, and lingering in the form of traditional superstition among peoples comparatively civilized, that men are in certain circumstances transformed temporarily or permanently into wolves and other inferior animals. In the European history of this singular belief, wolf transformations appear as by far the most prominent and most frequently recurring instances of alleged metamorphosis, and consequently in most European languages the terms expressive of the general doctrine have a special reference to the wolf. Examples of this are found in the Greek λυκάνθρωπος, Russian *volkodlák*, English *were-wolf*, German *währwolf*, French *loup-garou*. And yet general terms (*e.g.*, Latin, *versipellis*; Russian, *ôboroten*; Scandinavian, *hamrammr*; English, *turnskin*, *turncoat*) are sufficiently numerous to furnish some evidence that the class of animals into which metamorphosis was possible was not viewed as a restricted one. It is simply because the old English general terms have been long diverted from their original signification that the word "lycanthropy" has recently been adopted in our language in the enlarged sense in which it has been defined above.

There are two unfailing characteristics of lycanthropous belief:—(1) there can nowhere be a living belief in contemporary metamorphosis into any animal which has ceased to exist in the particular locality; (2) belief in metamorphosis into the animal most prominent in any locality itself acquires a special prominence. These characteristics apart, the phenomena of lycanthropy exhibit a very considerable diversity in their nature.

Throughout the greater part of Europe the were-wolf is preferred on the principles just noted. There are old traditions of his existence in England, in Wales, and in Ireland. In southern France, the Netherlands, Germany, Lithuania, Bulgaria, Servia, Bohemia, Poland, and Russia he can hardly be pronounced extinct now. In Denmark, Sweden, Norway, and Iceland the bear competes with the wolf for pre-eminence. In Persia the bear is supreme, in Japan the fox; in India the serpent vies with the tiger, in Abyssinia and Bornou the hyæna with the lion, in eastern Africa the lion with the alligator; in western Africa the leopard is perhaps most frequently the form assumed by man, among the Abipones the tiger, among the Arawaks the jaguar, and so on. In none of these cases, however, is the power of transformation limited exclusively to the prominent and dominant animal.

The most familiar phase of the superstition is also the latest and most sophisticated. It was no belief in mere transformation; the transformation here was accomplished by Satanic agency voluntarily submitted to, and that for the most loathsome ends, in particular for the gratification of a craving for human flesh. "The were-wolves," writes Richard Verstegan (*Restitution of Decayed Intelligence*, 1628), "are certayne sorcerers, who having annoynted their bodies with an oyntment which they make by the instinct of the devill, and putting on a certayne inchaunted girdle, doe not onely unto the view of others seeme as wolves, but to their owne thinking have both the shape and nature of wolves, so long as they weare the said girdle. And they do dispose themselves as very wolves, in wourrying and killing, and most of humane creatures." Such were the views about lycanthropy current throughout the continent of Europe when Verstegan wrote. France in particular seems to have been infested with were-wolves during the 16th century, and the consequent trials were very numerous. In some of the cases,—*e.g.*, those of the Gandillon family in the Jura, the tailor of Châlons, and Roulet in Angers, all occurring in the year 1598,—there was clear evidence against the accused of murder and cannibalism, but none of association with wolves; in other cases, as that of Gilles Garnier in Dôle in 1573, there was clear evidence against some wolf, but none against the accused; in all the cases, with hardly an exception, there was that extraordinary readiness in the accused to confess and even to give circumstantial details of the metamorphosis, which is one of the most inexplicable concomitants of mediæval witchcraft. Yet, while this lycanthropy fever, both of suspectors and of suspected, was at its height, it was decided in the case of Jean Grenier at Bordeaux, in 1603, that lycanthropy was nothing more than an insane delusion. From this time the *loup-garou* gradually ceased to be regarded as a dangerous heretic, and fell back into his pre-Christianic position of being simply a "man-wolf-fiend," as which he still survives among the French peasantry. In Prussia, Livonia, and Lithuania, according to the bishops Olaus Magnus and Majolus, the were-wolves were in the 16th century far more destructive than "true and natural wolves," and their heterodoxy appears from the assertion that they formed "an accursed college" of those "desirous of innovations contrary to the divine law." In England, however, where at the beginning of the 17th century the punishment of witchcraft was still zealously prosecuted by James I., the wolf had been so long extinct that that pious monarch was himself able (*Demonologie*, lib. iii.) to regard "warwoolfes" as victims of delusion induced by "a naturall superabundance of melancholie." Only small creatures, such as the cat, the hare, and the weasel, remained for the malignant sorcerer to transform himself into; but he was firmly believed to avail himself of these agencies. Belief in witch-animals still survives among the uneducated classes in parts of the United Kingdom.

The were-wolves of the Christian dispensation were not, however, all heretics, all viciously disposed towards mankind. "According to Baronius, in the year 617, a number of wolves presented themselves at a monastery, and tore in pieces several friars who entertained heretical opinions. The wolves sent by God tore the sacrilegious thieves of the army of Francesco Maria, duke of Urbino, who had come to sack the treasure of the holy house of Loreto. A wolf guarded and defended from the wild beasts the head of St Edmund the martyr, king of England. St Oddo, abbot of Cluny, assailed in a pilgrimage by foxes, was delivered and escorted by a wolf."[1] Many of the were-wolves were most innocent and God-fearing persons, who suffered through the witchcraft of others, or simply from an unhappy fate, and who as wolves behaved in a truly touching fashion, fawning upon and protecting their benefactors. Of this sort were the "Bisclaveret" in Marie de France's poem (*c.* 1200), the hero of "William and the Were-wolf" (translated from French into English about 1350), and the numerous princes and princesses, knights and ladies, who appear temporarily in beast form in the *Mährchen* of the Aryan nations generally. Nay the power of transforming others into wild beasts was attributed not only to malignant sorcerers, but also to Christian saints. "Omnes angeli, boni et mali, ex virtute naturali habent

[1] A. de Gubernatis, *Zoological Mythology*, 1872, vol. ii. p. 145.

potestatem transmutandi corpora nostra," was the dictum of St Thomas Aquinas. A Russian story tells how the apostles Peter and Paul turned an impious husband and wife into bears; St Patrick transformed Vereticus, king of Wales, into a wolf; and St Natalis cursed an illustrious Irish family, with the result that each member of it was doomed to be a wolf for seven years. In other tales the divine agency is still more direct, while in Russia, again, men are supposed to become were-wolves through incurring the wrath of the devil.

There is thus an orthodox as well as a heterodox were-wolf; and, if a survey be taken of the lycanthropous beliefs of non-Christian peoples, this distinction among shape-changers will be equally obvious. The gods of ancient mythology, Hindu, Persian, Greek, and Teutonic, had an apparently unlimited power of assuming animal forms. These gods, moreover, constantly employed themselves in changing men and women into beasts, sometimes in punishment of crime, sometimes out of compassion, and sometimes from pure voluptuousness. Thus Kabandha was changed by Indra into a monster, Trisanku by the sons of Vasishtha into a bear, Lycaon by Zeus into a wolf, Callisto into a bear, Io into a heifer; the enemies of Odin became boars, and so on. It is admittedly difficult to trace the original meaning of these legends, but the alleged metamorphosis of a god is at times clearly associated with his worship under the form of the animal he turned into in the region where the metamorphosis was said to have occurred. Indra in the form of a bull encountered the monster Vritra, and released the cows he had stolen; Indra was invoked as a bull, and to him the bull and the cow were sacred among the Hindus. Derketo became a fish near Ascalon; a fish-goddess identified with her was worshipped in Syria, and the fish sacred to her were not eaten. Poseidon, the inventor of horses, was, as a horse, the father of the steeds Arion and Pegasus, and the horse was sacred to him. Jupiter Ammon appeared as a ram in the deserts of Libya; in Libya he had an oracle where the ram was sacred to him, and his image wore ram's horns. So too metamorphosis by gods is in some cases connected with local traditions. The Arcadians, or bear-tribe, sprang from the were-bear Callisto; the Lycians, or wolf-tribe, were wolves when they conducted to the river Xanthus the were-wolf Leto, mother of the Lycian Apollo. Turning from the gods to the heroes of classical romance, we find traditions more interesting and more instructive, because they must have some real historical foundation. Yet they also abound in episodes of beast mothers and beast fathers, and also of lycanthropy proper. Cyrus was suckled by a bitch, the Servian hero Milosh Kobilitch by a mare, the Norse Sigurd by a hind, the German Dieterich and the Latin Romulus by wolves; the progenitor of the Merovingian kings was a bull, of the Danish royal race a bear; Sigmund and Sinfiotli in the *Volsunga Saga* become wolves, Nagli in the *Eyrbyggia Saga* a boar. The Berserkir of Iceland asserted their ability to become bears and wolves, and dressed themselves in the skins of these animals; their existence, their garb, and their pretensions are historical facts. In the Sanskrit epic, the *Mahabharata*, the hero Puloman becomes a wild boar to carry off the wife of Bhrigu; the house of Brabant traced its origin to a transformed swan. Beast-form is, however, in mythology proper far oftener assumed for malignant than for benignant ends; indeed the heroes and anthropomorphic gods of the great religious systems are principally distinguished for their victories over the semi-human semi-bestial demons. The bull Indra fights the demon serpent Vritra, and so forth; the Theban Cadmus, the Russian Ivan, the Norse Sigurd, all encounter dragons or serpents, which possess human characteristics. In most of such cases indeed the human as well as the beast form is distinctly attributed to the demon.

It is because they may after all be properly associated with the undoubted phenomena of modern savage life that these facts of ancient mythology are here alluded to. Among savages there is the most confident belief in metamorphosis,—metamorphosis effected for the most salutary and for the most baneful ends. In the neighbourhood of Tette on the Zambesi every chief is credited with the power of assuming lion shape; every lion is respected as being a transformed chief or the spirit of a chief departed. Moreover, there is a special class of "doctors" or medicine-men, known as "pondoros," scattered through the villages, who pretend to powers of metamorphosis, and thus are regarded with both respect and dread; their kindly disposition they display by hunting for the community in lion shape, and then bringing home the game. Among the Arawaks of Guiana, the Kandhs of Orissa, and the Jakuns of the Malay peninsula, beast form is said to be assumed by those desiring to avenge themselves justly on enemies. Beast-parents and cases of women alleged to have borne beast children are also familiar to savages. But this is only one side of the picture. The "kanaima-tiger" (*i.e.*, man-jaguar) of Arawak may be possessed by the spirit of a man devoted to bloodshed and cannibalism; "there is," writes the Rev. Mr Brett, "no superstition more prevalent among the Indians than this, and none which causes more terror." In Ashango-land, where there are distinct traces of animal worship, a were-leopard was at the time of Du Chaillu's visit charged with murder and metamorphosis, and, confessing both, was slowly burnt to death, quite in the style of mediæval Europe. Similar occurrences have been known among the Kols (of Chútiá-Nágpúr) and among the Arabs.

The expedients supposed to be adopted for effecting change of shape may here be noticed. One of the simplest apparently was the removal of clothing, and in particular of a girdle of human skin, or the putting on of such a girdle,—more commonly the putting on of a girdle of the skin of the animal whose form was to be assumed. This last device is doubtless a substitute for the assumption of an entire animal skin, which also is frequently found. In other cases the body is rubbed with a magic salve. To drink water out of the footprint of the animal in question, to partake of its brains, to drink of certain enchanted streams, were also considered effectual modes of accomplishing metamorphosis. Olaus Magnus says that the Livonian were-wolves were initiated by draining a cup of beer specially prepared, and repeating a set formula. Mr Ralston in his *Songs of the Russian People* gives the form of incantation still familiar in Russia. Various expedients also existed for removing the beast-shape. The simplest was the act of the enchanter (operating either on himself or on a victim); another was the removal of the animal girdle. To kneel in one spot for a hundred years, to be reproached with being a were-wolf, to be saluted with the sign of the cross, or addressed thrice by baptismal name, to be struck three blows on the forehead with a knife, or to have at least three drops of blood drawn were also effectual cures. The last-mentioned was quite essential to the subsistence of the superstition. Its absurdity would have much sooner appeared, but for the theory that, directly the were-wolf was wounded, he resumed his human shape; in every case where one accused of being a were-wolf was taken, he was certain to be wounded, and thus the difficulty of his not being found in beast form was satisfactorily disposed of.

The foregoing types of lycanthropy, in which the divine or diabolical agency is always emphasized, are presumably less primitive than those cases in which superhuman agency is not so prominent. The following cases, therefore, seem to be more intimately connected with the origin of the belief. (1) The Kandhs believe "natural tigers to kill game only to benefit men, who generally find it but partially devoured and share it; while the tigers which kill men are either Tari (a goddess), who has assumed the form of a tiger for purposes of wrath, or men who, by the aid of a god, have assumed the form of tigers, and are called 'mleepa tigers.'" A distinction was previously drawn between friendly and hostile lycanthropists; here a distinction is drawn between friendly and hostile tigers, and lycanthropy is introduced to explain the cases of hostility. Again (2) in the native literature of modern savages there constantly occur stories of the "Beauty and the Beast" type, so distinctly resembling those of the Aryan *Mährchen* as to indicate identity of origin; but, while in the Aryan story the beast-form of the hero or heroine is generally at last removed, in the savage story the incongruity of the beast-form is scarcely realized, and the Indian lover lives happily with his beaver bride, the Zulu maiden with her frog husband. And (3) in many instances the power or necessity of transformation is ascribed, not to individuals, but to clans or nations. Thus the aboriginal Naga tribes of India seemed to the Aryans to take the form of serpents; the Neuri seemed to the Scythians, and the Hirpini to the Romans, to become wolves, as also did the native Irish of Ossory to the early Christian priests; the Abyssinians credit the Buda caste (blacksmiths and potters of alien stock) with ability to become hyænas at pleasure; the Berserkr-rage of Iceland is perpetuated in the modern Scandinavian belief that Lapps and Finns can take the form of bears. In mediæval times Blois had a special celebrity for were-wolves, and persons named Garnier or Grenier were generally assumed to be lycanthropists.

When we find that these three distinct classes of primitive facts regarding lycanthropy are all referable to a common origin, there seems good reason for regarding that as being in truth the origin of lycanthropous belief. And thus we are led to refer lycanthropy to the more general facts of primitive TOTEMISM (*q.v.*), for the facts recited are as undoubtedly characteristic of the latter as of the former. Where the totem is an animal, it is regarded as the ancestor of the tribe; all animals of its species are revered, and are never willingly killed; however dangerous to life, they are feigned by the tribe to be friendly to them, and hostile only to their enemies. Applying these facts to the foregoing lycanthropous phenomena in order, we observe (1) that the tiger is a totem god among the Kandhs; consequently he reserves his wrath for their enemies.[1] Individual enemies would, however, be created whenever an individual Kandh had the blood-feud against another, for then his totem was bound to aid him. Such we saw was in fact the Kandh explanation of the wrath of the totem. The development of sorcery would naturally lead to the utilization of the totem as assistant in it also. The Arawak "kanaima" is both lawful avenger and cruel sorcerer; and from a similar reason probably did the wolf or were-wolf in Europe become a synonym for outlaw. The outlaw was at first simply the peaceless man—the man who preferred vendetta to money composition for injuries,—as he was originally *bound* to do, subsequently *entitled* to do, and finally *prohibited* from doing. (2) The beast-hero of savage story ceases to be strange when we learn that "a beaver," "a dog," "a grizzly bear," mean respectively a person of a tribe having the animal in question for totem. And so too (3) with the third class of phenomena which contemplates tribes turned into beasts. The Nagas had the serpent for totem; apparently the Hirpini, and the native Irish in many districts, had the wolf; they certainly venerated and worshipped that animal. The Lapps are known to worship the bear. Blois means the "city of wolves." Doubtless all cases of this sort admit of similar explanation.

The doctrine of lycanthropy or metamorphosis of living men must be distinguished from the doctrine of metempsychosis or transmigration of souls. It no doubt was usual to conclude that the souls of cataleptic and epileptic patients sojourned temporarily in animals, while the patients were unconscious; but this phase of lycanthropy is too rare and too abnormal to be associated with the origin of the superstition. Transmigration after death, involving the belief in a future state, raises questions as puzzling as does lycanthropy itself, and questions quite of a different kind, because in normal lycanthropy the change effected is an actual corporeal one. Mr Tylor therefore throws little light on the origin of lycanthropy when he connects it with metempsychosis. In the form familiar to us it doubtless involves the doctrine of "animism"—the doctrine that animals, plants, and things are prompted to action by spirits similar to those possessed by men; but, whether lycanthropy is simply a special application of a general doctrine of animism, and is not rather one of the earliest advances from a blind totemism to a general animistic theory, may fairly be questioned. This at least seems plain: animism, apart from totemism, is not itself sufficient to explain lycanthropy, for even animistic beliefs are not developed abnormally, but along lines predetermined by circumstances. Mr Tylor's views are, however, so cautiously and so suggestively expressed as to deserve close study. Hardly so satisfactory are the other theories on the subject, which, passing over variations in detail, fall into two classes—the mythological and the rationalistic. On the former view, now upheld by a large school of inquirers, the ancient Aryan myths, and their modern representatives the *Mährchen*, are regarded as imaginative descriptions (principally due to the use of metaphorical language) of the great elemental powers and changes of nature. On such a view the occurrence of shape-changing gods and heroes is simple and natural, so long as the persons are purely mythical, because thus far nothing need be deemed strange or unnatural. But the theory breaks down when it ventures on elucidation of historical facts. It seems vain to contend,—although it is contended,—that "the terrible delusion of lycanthropy arose from the mere use of an equivocal word" (λύκος, "wolf," for λευκός, "shining"). Attempt to substantiate in detail this explanation of history is absolutely fatal. "Whence," it is asked, "came the notions that men were changed into wolves, bears, and birds, and not into lions, fishes, or reptiles?" and the triumphant reply is that the first-named animals were selected for glossiness or luminosity of coat.[2] Consequently, if transformation into the other animals was also believed in, the theory stands self-refuted. Now Hippomenes and Atalanta were for impiety turned into lion and lioness, Cadmus and Harmonia into serpents; and these cases of transformation have almost as intimate an association with the historical belief in men-lions and men-serpents as the case of Lycaon (mythologically = the shiner, the sun) has with lycanthropy. Cognate to the mythological doctrine is the doctrine of the personification as demons of all obstacles which men have encountered in the long struggle for existence,—among these the wilder and more savage animals. This is just a one-sided animism; it is inadequate to explain how the savage beasts so often became mild and gentle men. The rationalistic theories are open to the same objections: to account for divine and benignant lycanthropists they have to be supplemented by the mythological theories; they themselves deal exclusively with the more repulsive characteristics. The most recent exponent of the rationalistic theory is Mr Baring Gould, who rests his case on a proof of the facts that there is "an innate craving for blood implanted in certain natures, restrained under ordinary circumstances, but breaking forth occasionally, *accompanied with hallucination*, leading in most cases to cannibalism." That cannibalism and craving for blood had a natural (though not a necessary) connexion with lycanthropy, if it originated among savages, need not be disputed; but Mr Baring Gould's instances, drawn from mediæval European history, are undoubtedly exceptional. Hallucination, however, has been accepted as sufficient explanation of lycanthropy by many eminent authorities, besides Mr Gould, and raises a graver question. Belief in transformation into beasts has been acknowledged as a distinct type of monomania by medical men since the days of Paulus Ægineta (7th century) at least; but even in madness there is method, and insane delusions must reflect the usages and beliefs of contemporaneous society. Here the weakness of the case appears. Mr Gould, for instance, merely states that the victims were rustics, and wolves the chief terror of their homesteads, an explanation valid only on the assumption that the idea of metamorphosis was already familiar,—an assumption, that is, of the whole matter at issue. Besides, it is the popular, not the individual, belief in transformation that is strange; to trace its origin to insane delusion makes it stranger still, for sane men are particularly sceptical regarding the reality of the impressions of the insane. Sane men, moreover, believed in transformation, not only into malignant wolves, but also into harmless cats and hares, which in consequence became malignant and dangerous. How can the rationalistic theory account for a phenomenon like this? On the whole, there seems little doubt that, whether the origin of lycanthropy rests in totemism or not, Mr

[1] The Watusi of East Africa distinctly describe all wild beasts save their own totem-animals as enemy-scouts.

[2] Sir G. W. Cox, *The Mythology of the Aryan Nations*, London, 1870, vol. i. pp. 63 note, 231, 363, 459; vol. ii. p. 78 note.

Tylor is right in referring lycanthropous insane delusions to an antecedent belief in lycanthropy, instead of ascribing lycanthropy to insane delusions.

Literature.—In the numerous mediæval works directed to the study of sorcery and witchcraft, the contemporaneous phases of lycanthropy occupy a prominent place. In addition to the authors who have been already mentioned, the following may be named as giving special attention to this subject:—Wier, *De Præstigiis Dæmonum*, Amsterdam, 1563; Bodin, *Démonomanie des Sorciers*, Paris, 1580; Boguet, *Discours des Sorciers*, Lyons, 2d ed. 1608; Lancre, *Tableau de l'Inconstance de Mauvais Anges*, Paris, 1613; Psellus, *De Operatione Dæmonum*, Paris, 1615; see also Glanvil, *Saddücismus Triumphatus*, for the English equivalents of lycanthropy. Treatises solely confined to lycanthropy are rare both in mediæval and in modern times; but a few are well known, as, for instance, those of Bourquelot and Nynauld, *De la Lycanthropie*, Paris, 1615; Hartz, *De Werwolf*, Stuttgart, 1862; Baring Gould, *The Book of Were-wolves*, London, 1865. Incidentally, however, lycanthropy has engaged the attention of a large number of writers, most of whom theorize regarding its origin. An exhaustive enumeration of these cannot be here attempted; but the following works will be found particularly instructive:—Grimm, *Deutsche Mythologie*, vols. ii. and iii., 4th ed., Berlin, 1878; Welcker, *Kleine Schriften*, vol. iii., Bonn, 1850; Waitz, *Anthropologie*, vol. ii., Leipsic, 1860; Dasent, *Popular Tales from the Norse* (Introduction), Edinburgh, 1859; Afanasief, *Poeticheskiya Vozzryeniya Slavyan na Prirodu*, vol. iii., Moscow, 1869; Tylor, *Primitive Culture*, vol. i., London, 1871, and *Anthropology*, chap. xiv. and xv., London, 1881; Gubernatis, *Zoological Mythology* (especially chaps. xi. and xii.), London, 1872; Ralston, *Songs of the Russian People*, London, 1872; Laisnel de la Salle, *Croyances et Legendes du Centre de la France*, Paris, 1875; Conway, *Demonology and Devil Lore*, vol. i., London, 1879. For the medical aspects of lycanthropy, consult the *Asylum Journal of Mental Science*, vol iii. p. 100 (Dr D. H. Tuke), and authorities there cited. (J. F. M'L.)

LYCAON, son of Pelasgus or of Aizeus, was the mythical first king of Arcadia, who founded the first city Lycosoura and the worship of Zeus on Mount Lycæus. He, or his fifty impious sons, entertained Zeus and set before him a dish of human flesh; the god pushed away the dish in disgust and overturned the table at a place called Trapezus. In punishment either lightning slew the king and his sons, or they were turned into wolves. Pausanias (viii. 2) says that Lycaon sacrificed a child to Zeus, and was during the sacrifice turned into a wolf. Henceforth the story ran—a man was turned into a wolf at each annual sacrifice to Zeus Lycæus, recovering his human form after ten years if he had not during that time eaten human flesh. Lycaon is evidently the Lycæan form of a very common conception, viz., the divine first man, whose life is the heavenly fire, who comes to earth and returns to heaven as the lightning. The oldest city, the oldest cultus, and the first civilization of Arcadia are attributed to him. The mysterious cultus and the human sacrifices, which continued apparently through the historical period (Paus., viii. 38), of Zeus Lycæus have moulded the legends of the Lycæan first man and first king. Moreover his name, which is connected with that of the mountain, suggested a derivation from λύκος, wolf; and legends analogous to those of the Teutonic were-wolf (see LYCANTHROPY) naturally grew round him.

Plate II. LYCAONIA, in ancient geography, was the name given to a province in the interior of Asia Minor, north of Mount Taurus. It was bounded on the E. by Cappadocia, on the N. by Galatia, on the W. by Phrygia and Pisidia, while to the S. it extended to the chain of Mount Taurus, from which it was, however, in part separated by Isauria, though some writers included that district in Lycaonia. Its boundaries appear indeed to have varied at different times, as was the case with all the nations of Asia Minor. The name is not found in Herodotus, but Lycaonia is mentioned by Xenophon as traversed by Cyrus the younger on his march through Asia. That author, however, describes Iconium, one of the principal cities of Lycaonia, as included in Phrygia. But in Strabo's time the limits of the province were more clearly recognized, though Isauria was by some authors considered as a part of Lycaonia, by others as a distinct province. Ptolemy, on the other hand, includes Lycaonia as a part of Cappadocia, with which it may have been associated by the Romans for administrative purposes; but the two countries are clearly distinguished both by Strabo and Xenophon.

Lycaonia is well described by Strabo as a cold region of elevated plains, affording pasture to wild asses and to sheep. It in fact forms a part of the great table-land which constitutes the whole interior of Asia Minor, and has throughout its whole extent an elevation of more than 3000 feet above the sea. It suffers, moreover, severely from the want of water, aggravated by the abundance of salt in the soil, so that the whole northern portion of the province, extending from near Iconium to the salt lake of Tatta, and the frontiers of Galatia, was almost wholly barren. Other portions of the country, however, notwithstanding the deficiency of water, were well adapted for feeding sheep, so that Amyntas, king of Galatia, to whom the district was for a time subject, maintained there not less than three hundred flocks, which brought him in a large revenue.

Though the greater part of Lycaonia is a broad open plain, extending as far as the underfalls of the Taurus, its monotonous character is interrupted by some minor ranges, or rather groups of mountains, of volcanic character, of which the Kara Dagh in the southern portion of the district, a few miles north of Karaman, rises to a height of above 8000 feet, while the Karadja Dagh, to the north-east of the preceding, though of very inferior elevation, presents a striking range of volcanic cones. The mountains in the north-west of the province, near Iconium and Laodicea, on the other hand, are the termination of the great range of the Sultan Dagh, which traverses a large part of Phrygia.

The Lycaonians appear to have been in early times to a great extent independent of the Persian empire, and were like their neighbours the Isaurians a wild and lawless race of freebooters; but their country was traversed by one of the great natural lines of high road through Asia Minor, from Sardis and Ephesus to the Cilician gates, and a few considerable towns would naturally grow up along this line of route. The most important of these was Iconium, in the most fertile spot in the province, of which it has always continued to be the capital. It is still called Konieh. A little farther north, immediately on the frontier of Phrygia, stood Laodicea (Ladik), called Combusta, to distinguish it from the Phrygian city of that name; and in the south, near the foot of Mount Taurus, was Laranda, now called Karaman, which has given name to the province of Karamania. Derbe and Lystra, which appear from the Acts of the Apostles to have been considerable towns, were apparently situated in the same part of the district, but their sites have not been identified. The other towns mentioned by ancient writers were insignificant places.

The Lycaonians appear to have still retained a distinct nationality in the time of Strabo, but we are wholly in the dark as to their ethnical affinities, or relations to the tribes by which they were surrounded. The mention of the Lycaonian language in the Acts of the Apostles (xiv. 11) is evidently only intended to designate the vernacular tongue, as opposed to Greek, and cannot be regarded as any proof that they spoke a different language from their neighbours the Phrygians or Cappadocians.

LYCIA, in ancient geography, was the name given to a Plate II.
district in the south-west of Asia Minor, occupying the portion of the coast between Caria and Pamphylia, and extending inland as far as the ridge of Mount Taurus. The region thus designated is one strongly marked by nature, as constituting a kind of peninsula or promontory projecting towards the south from the great mountain masses of the interior. It was also inhabited from a very early period by a distinct people, known to the Greeks as Lycians, but whose native name, according to Herodotus, was Termilæ, or (as it is written by Hecatæus) Tremilæ, and this is confirmed by native inscriptions, in which the name is written Tramilæ. Herodotus tells us also that they were not the original inhabitants of the country, which was previously occupied by the Milyans, and this is rendered probable by the fact that a people of that name was still found in the rugged mountainous district in the north-east, who appear to have always continued distinct from the Lycians. But

LYCAONIA, LYCIA, LYDIA, &c.

the statement of the same historian that they originally came from Crete is in the highest degree improbable; and the attempts to connect them with the Greek legendary history through Sarpedon and Lycus, a son of Pandion, may be safely rejected as mere fictions.

The Lycians alone among the nations in the west of Asia Minor preserved their independence against the kings of Lydia; but after the fall of the Lydian monarchy (in 546 B.C.) they were subdued by Harpagus, the general of Cyrus, though not till after an obstinate resistance in which Xanthus, their chief city, was utterly destroyed. But, though they were from this time nominally subject to Persia, they appear to have enjoyed a considerable amount of independence, which they afterwards maintained by joining the Athenian maritime league. They were conquered almost without resistance by Alexander, and thus passed under the Macedonian dominion, sometimes of the Ptolemies, sometimes of the Seleucidans. But through all these vicissitudes, as well as after their ultimate submission to the Roman power, they continued to preserve their federal institutions, which remained unimpaired, in form at least, as late as the time of Augustus. Strabo, who has preserved to us an account of their constitution, which he regards as the wisest form of federal government with which he was acquainted (a judgment confirmed by the high authority of Montesquieu), tells us that the league consisted of twenty-three cities in all, of which the six principal were Xanthus, Patara, Pinara, Olympus, Myra, and Tlos. These six had each three votes in the general assembly; of the remaining cities the more considerable had each two votes, and the rest only one. The payment of taxes and other public burthens were apportioned in the same manner, and the choice of the supreme magistrate, who was styled Lyciarch, and the other magistrates of the league rested with the federal assembly. At the same time the internal affairs of each city were managed by a senate or council (Boule), and a general assembly of the people (Demos), in the same manner as was usual with Greek cities. This system of government continued to subsist under the Roman empire, though of course subject to the control as well as protection of the sovereign power; but in the time of Claudius dissensions among the separate cities afforded a pretext for the intervention of Rome, and Lycia became formally annexed to the Roman empire. It was at first united in the same province with Pamphylia; but in the reign of Theodosius it was constituted a separate province.

Almost the whole of Lycia is a rugged mountainous country, traversed by offshoots and branches of the great range of Mount Taurus, which occupies the whole interior or northern part of the district, and sends down to the sea great arms or branches, constituting lofty promontories. The consequence is that the coast, though less broken and irregular than that of Caria, is indented by a succession of bays,—the most marked of which is that called in ancient times the Glaucus Sinus, now the Gulf of Macri, in the extreme west of the province, and separating Lycia from Caria. A number of smaller bays, and broken rocky headlands, with a few small islets lying off them, constitute the coast-line from thence to the south-eastern promontory of Lycia, formed by a long narrow tongue of rocky hill, known in ancient times as the Sacred Promontory, with three small adjacent islets, called the Chelidonian islands, which was regarded by some ancient geographers as the commencement of Mount Taurus—an opinion justly controverted by Strabo. But it really forms an important point in the geography of Asia Minor, where the coast trends abruptly to the north till it reaches the confines of Pamphylia. It was believed by Strabo to be directly opposite to Canopus in Egypt, and to be the point where the interval between the two continents was the shortest.

Though the mountain ranges of Lycia may all be considered as in reality offshoots of Mount Taurus, several of them in ancient times were distinguished by separate names. Such were Mount Dædala in the west, adjoining the Gulf of Macri, Mount Cragus on the sea-coast, west of the valley of the Xanthus, and Mount Massicytus nearly in the centre of the region, rising to a height of 10,000 feet, while Mount Solyma in the extreme east, above Phaselis, rises abruptly from the sea to an elevation of 7800 feet. The steep and rugged pass between this mountain and the sea, called the Climax, or Ladder, was the only direct communication between Lycia and Pamphylia.

The only two considerable rivers in Lycia are (1) the Xanthus, which descends from the central mass of Mount Taurus, and flows through a narrow valley till it reaches the city of the same name, below which it forms a plain of some extent before reaching the sea, and (2) the Limyrus, which enters the sea near Limyra. The Arycandus and the Andriacus, which are intermediate between the two, are much less considerable streams, and do not flow from the central chain. The small alluvial plains at the mouths of these rivers are the only level ground in Lycia; but the slopes of the hills that rise from thence towards the mountains are covered with a rich arborescent vegetation of the most beautiful character. (See the description of it by Forbes, quoted in Asia Minor, vol. ii. p. 709.) The upper valleys and mountain sides afford good pasture for sheep, and the main range of Mount Taurus encloses several extensive *yailahs* or upland basin-shaped valleys of the peculiar kind so characteristic of that range throughout its extent (see Asia Minor, p. 704).

It is very difficult to determine the limits of Lycia towards the interior; and the boundary seems to have varied repeatedly at different times. The high and cold upland tract to the north-east, called Milyas (which was supposed to retain some remains of the aboriginal population of Lycia), was by some writers included in that province, though it is naturally more connected with Pisidia. A similar tract to the west of this, and also situated to the north of the watershed of Mount Taurus, was termed Cabalia; but this had no natural connexion with Lycia, nor was in early times ever politically united with it, the four cities that were situated in this region—Cibyra, with its dependent towns of Œnoanda, Balbura, and Bubon—having always formed a separate league or Tetrapolis, which had no connexion with the Lycian league. It was not till after their annexation to Rome that Cibyra, with the district adjoining it, termed the Cibyratis, was united to Phrygia, while the three other towns above enumerated were annexed to Lycia.

According to Artemidorus (whose authority is followed by Strabo), the towns that formed the Lycian league in the days of its integrity were twenty-three in number; but Pliny tells us that Lycia once possessed seventy towns, of which only twenty-six remained in his day. Recent researches have fully confirmed the fact that, notwithstanding its rugged character, the sea-coast and the valleys that ran up into the interior were thickly studded with towns, which in many cases are proved by existing remains to have been places of considerable importance. The names have been for the most part identified by means of inscriptions, and we are thus enabled to fix the position of the greater part of the cities that are mentioned in ancient authors. On the Gulf of Glaucus, near the frontiers of Caria, stood Telmessus, an important place, while a short distance from it in the interior were the small towns of Dædala and Cadyanda. At the entrance of the valley of the Xanthus were Patara, Xanthus itself, and, a little higher up, Pinara on the west and Tlos on the east side of the valley, while Araxa stood at the head of the valley, just at the foot of the pass leading into the interior. Sidyma, on the slope of Mount Cragus, seems also to have borne the name of the mountain, as was also the case with Massicytus, if there was really a city of the name at all. Myra, one of the most important cities of Lycia, occupied the entrance of the valley of the Andriacus; on the coast between this and the mouth of the Xanthus stood Antiphellus, while in the interior, at a short distance, were found Phellus, Cyaneæ, and Candyba. In the alluvial plain formed by the outlets of the rivers Arycandus and Limyrus stood Limyra, and encircling the same bay the three small towns of Rhodiapolis, Corydalla, and Gagæ. Arycanda commanded the upper valley of the river of the same name. On the east coast stood Olympus, one of the cities of the league, though it could never have been more than a small town, while Phaselis, a little farther north, which was a much more important place, never belonged to the Lycian league, and appears to have always maintained an independent position. We have thus in all twenty-one towns of which the sites have been ascertained, but the occurrence of other considerable ruins, to which no names can be attached with any certainty, confirms the statement of Pliny as to the great number of the Lycian towns.

The cold upland district of the Milyas appears never to have contained any town of importance. Podalia seems to have been its chief place. Between the Milyas and the Pamphylian Gulf was the lofty mountain range of Solyma, which was supposed to derive its name from the Solymi, a people mentioned by Homer in connexion with the Lycians and the story of Bellerophon. No such name was known in historical times as an ethnic appellation, but they were supposed by some writers to be the same people with the Milyans, while others regard them as a distinct people of Semitic origin. It was in the flank of this mountain, near a place called Deliktash, that the celebrated fiery source called the Chimæra, which gave rise in ancient times to so many fables, was found. It has been visited in modern times by Captain Beaufort, Messrs Spratt and Forbes, and other travellers, but is merely a stream of inflammable gas issuing from crevices in the rocks, such as are found in several places in the Apennines. No traces of recent volcanic action exist in Lycia.

Few parts of Asia Minor were less known in modern times than Lycia until a very recent period. Captain Beaufort was the first to visit several places on the sea-coast, and the remarkable rock-hewn tombs of Telmessus had been already described by Dr Clarke, but it was Sir Charles Fellows who first discovered and drew attention to the extraordinary richness of the district in ancient remains, especially of a sepulchral character. His two visits to the country, in 1838 and 1840, were followed by a more regular expedition sent out by the British Government in 1842 for the purpose of transporting to England the valuable monuments now in the British Museum, while Lieutenant (now Admiral) Spratt and Professor Edward Forbes explored the interior of the district, and laid down its physical features on an excellent map. The monuments thus brought to light are certainly among the most interesting of any that have been discovered in Asia Minor, and, while showing the strong influence of Greek art, both in their architecture and sculpture, prove also the existence of a native architecture of wholly distinct origin, especially in the rock-cut tombs, some of which present a strange resemblance to our English Elizabethan style, while others distinctly evince their derivation from the simple construction of the mud and timber built cottages of the natives. But the theatres that are found in almost every town, some of them of very large size, are alone sufficient to attest the pervading influence of Greek civilization; and this is confirmed by the sculptures, which are for the most part wholly Greek. None of them, indeed, can be ascribed to a very early period, and hardly any trace can be found of the influence of Assyrian or other Oriental art.

One of the most interesting results of these recent researches has been the discovery of numerous inscriptions in the native language of the country, and written in a character, or at least an alphabet, before unknown, and which appears to have been peculiar to Lycia. A few of these inscriptions are fortunately bilingual, in Greek and Lycian, which has afforded a clue to their partial interpretation, and the investigations of Mr Daniel Sharpe in the first instance, followed by the more mature essays of Moritz Schmidt and Savelsberg, have established the fact that the Lycian language belonged to the great Aryan family, and had close affinities with the Zend. The alphabet in which the inscriptions are written is obviously derived from the Greek, no less than twenty-four of the letters being identical, while most of the additional letters appear to have been invented in order to express vowel sounds which were not distinguished in Greek. None of the Lycian inscriptions, however, any more than the sculptures, can lay claim to a high antiquity. It is remarkable that the Greek alphabet upon which it was founded appears not to have been the Ionic alphabet which was in general use in Asia Minor, but was more akin to the Doric alphabet in use in the Peloponnese.

For these modern researches see *A Journal written during an Excursion in Asia Minor*, London, 1839, by Sir Charles Fellows; *An Account of Discoveries in Lycia*, by the same author, London, 1841; *Travels in Lycia, Milyas, and the Cibyratis*, by Lieutenant Spratt and Professor Edward Forbes, 2 vols., London, 1847; Moritz Schmidt, *Neue Lykische Studien*, Jena, 1869; Savelsberg, *Beiträge zur Entzifferung der Lykischen Sprachdenkmäler*, Bonn, 1874. (E. H. B.)

LYCOPHRON was a Greek poet who flourished at Alexandria in the time of Ptolemy Philadelphus (285–47 B.C.). He was born at Chalcis in Eubœa, and was the son of Lycus. He wrote a number of tragedies, forty-six or sixty-four, and Suidas gives the title of twenty of them. Only a few lines are preserved of these works, which gained him a place in the Pleiad of Alexandrian tragedians. He was entrusted by Ptolemy with the task of arranging the comedies in the Alexandrian library, and out of this work grew his treatise περὶ κωμῳδίας, in at least eleven books. It seems to have treated of the history of comedy, of the lives of the comic poets, and of various topics subsidiary to the proper understanding of their poems, but nothing has been preserved of the work. One of his poems called *Cassandra*, containing 1474 lines of iambic, has been preserved entire. It is in the form of a prophecy uttered by Cassandra, and relates the later fortunes of Troy and of the Greek and Trojan heroes. References to various events of mythic and of later time are introduced, and the poem ends with a reference to Alexander the Great, who was to unite Asia and Europe in his world-wide empire. The style, as befits a prophecy, is so enigmatical as to have procured for Lycophron, even among the ancients, the title of the "obscure" (ὁ σκοτεινός). The poem is evidently intended to display the writer's knowledge of obscure names and uncommon myths; it is full of unusual words of doubtful meaning gathered from the older poets, along with many long-winded compounds coined by the author. It has none of the qualities of poetry, and was probably written not for the enjoyment of the public but as a show-piece for the Alexandrian school. It was very popular in the Byzantine period, and was read and commented on very frequently; the collection of scholia by I. and J. Tzetzes is very valuable, and the MSS. of the *Cassandra* are numerous. A few neat and well-turned lines which have been preserved from Lycophron's tragedies show a much better style; they are said to have been much admired by Menedemus of Eretria, although the poet had ridiculed him in a satyric drama. Lycophron is also said to have been a skilful writer of anagrams, a reputation which does not speak highly for his poetical character.

Two passages of the *Cassandra*, 1446–50 and 1226–82, in which the career of the Roman people and their universal empire are spoken of, could evidently not have been written by an Alexandrian poet of 250 B.C. Hence it has been maintained by Niebuhr and others that the poem was written by a later poet mentioned by Tzetzes, but the opinion of Welcker is generally counted more probable, that these paragraphs are a later interpolation: a prophetic poem is peculiarly liable to have additions inserted, and the Roman rule was the most natural subject to add.

See Welcker, *Griech. Trag.*; Konze, *De Lycophronis Dictione*; and Bernhardy's and other histories of Greek literature.

LYCOPODIUM. This and *Selaginella* are the two chief genera of the order *Lycopodiaceæ* or club mosses. They are flowerless herbs, and mostly creeping; but during the period of the development of coal plants members of this order attained to the dimensions of lofty trees. A remarkable bed of Scotch coal called the "better bed" was found on microscopical examination to be almost entirely composed of the spores and sporanges of some "lycopod." There are one hundred species, which occur in all climates, five being British. The leaves of lycopodium are for the most part small, and thickly cover the stem and branches. The "fertile" leaves are arranged in cones, and bear sporanges in their axils, containing spores of one kind only (of two kinds in *Selaginella*). The prothallium developed from the spore is a subterranean mass of tissue of considerable size, and bears the male and female structures (*antheridia* and *archegonia*). See *Micrographic Dict.*; Le Maout and Decaisne's *Desc. and Anal. Bot.*, Eng. ed., p. 911; and Sach's *Text-book of Bot.*, Eng. ed., p. 400 *sq.* Gerard, in 1597, described two kinds of lycopodium (*Herball*, p. 1373) under the names *Muscus denticulatus* and *Muscus clavatus* (*L. clavatum*, L.) as "Club Mosse or Woolfes Clawe Mosse," the names being in Low Dutch, "Wolfs Clauwen," from the resemblance of the club-like or claw-shaped shoots to the toes of a wolf, "whereupon we first named it *Lycopodion*." Gerard also speaks of its emetic and many other supposed virtues. *L. Selago*, L., and *L. catharticum*, Hook., of South America, have been said to be, at least when fresh, cathartic; but, with the exception of the spores ("lycopodium powder"), lycopodium as a drug has fallen into disuse. The powder is used for rolling pills in, as a dusting powder for infants' sores, &c. It is highly inflammable, and is used in pyrotechny and for artificial lightning on the stage. If the hand be covered with the powder it cannot be wetted on being plunged into water. Another use of lycopodium is for dyeing; woollen cloth boiled with species of lycopodium, as *L. clavatum*, becomes blue when dipped in a bath of Brazil wood.

LYCURGUS, a famous Spartan lawgiver. As even the ancients themselves differed so widely in their accounts of Lycurgus that Plutarch could begin his life by saying that he could assert absolutely nothing about him which was not controverted, it is not surprising that modern historical criticism has been disposed to relegate him wholly into the region of pure myth. One tradition would put him as far back as the age of Troy; another would connect him with Homer; while Herodotus implies that he lived in the 10th century B.C. It is now usual, on the strength of a passage in Thucydides (bk. i. chap. 18), which represents Sparta as having enjoyed a well-established political constitution for as much as four hundred years before the Peloponnesian war, to assign him to the 9th century B.C., and to accept him as a real historical person. But as to the character and result of his legislative work there still remain very conflicting opinions, due to the circumstance that such data as we possess are susceptible of exceedingly diverse inferences and interpretations. Plutarch's life, which is the fullest and most detailed account we have of him, is not merely the compilation at second hand of a late age (2d century), but also abounds in statements which any one with any knowledge of the early growth of political societies feels to be inherently improbable. Grote prefers on the whole to be guided by what may be fairly inferred from the allusions to his legislation in Aristotle, as being one of our earliest sources of information and certainly the most philosophical estimate of his work. With Thirlwall he takes him to have been a real person, and assumes that he was the instrument of establishing good order among the Spartans, hitherto, according to Herodotus, the most lawless of mankind, and of thus laying the foundations of Spartan strength and greatness.

The traditional story was that when acting as guardian to his nephew, Labotas, king of the Spartans, he imported his new institutions from Crete, in which a branch of the Dorian race had for a considerable period settled themselves. It was said that he had travelled widely, and gathered political wisdom and experience in Egypt and even in India. With the support of the Delphic oracle, which was specially reverenced by Dorians, he was able to accomplish his work and to regulate, down to the smallest details, the entire life of Sparta. He lived to see the fruit of his labour, and, having bound his fellow countrymen to change nothing in his laws till his return, he left then for Delphi, and was never seen by them again. The oracle declared that Sparta would prosper as long as she held fast by his legislation, and upon this a temple was built to his honour, and he was worshipped as a god.

It was the fashion with writers like Plutarch, from whom our notions of Lycurgus have been mainly derived, to represent the Spartan lawgiver as the author of a wholly new set of laws and institutions. It need hardly be said that any such view has long been abandoned, and that Lycurgus's work, great as it no doubt was, did not go beyond formulating what already existed in germ, and was in fact the peculiar heritage of the Spartans as members of the Dorian race. It has been contended that the laws of Sparta were the typical Dorian laws, and that Sparta herself was the special representative, politically and socially, of the Dorian race. It appears, however, to have been the general view of the Greeks themselves that many of her most important institutions, more especially the severity of her military training and of her home-discipline, were peculiar to Sparta, and were by no means shared by such states as Corinth, Argos, Megara, all of Dorian origin. Grote lays great stress on this point (*History of Greece*, chap. vi.), and maintains that it was the singularity of the Spartan laws which made such a deep impression on the Greek mind. The truth indeed seems to be that Sparta's political organization in its main lines was of the Dorian type, and resembles the pictures given us in the Homeric poems, but that much in her social life and military arrangements was absolutely unique. It is here that in all probability may be traced the genius and foresight of Lycurgus, and he may thus well deserve the credit of having started Sparta on a new career.

The council of elders (*gerousia*, or senate), a distinctive feature of the Hellenic states generally, must have existed at Sparta long before Lycurgus, nor is it at all certain that he fixed its number at twenty-eight, the two kings who sat and voted in it making it up to thirty members. It was elected from the people from candidates who had reached the age of sixty, and a senator once elected was a senator for life. It united the functions of a deliberative assembly and of a court of justice, and it prepared measures which were from time to time submitted to periodical assemblies of the people, which, however, had simply to accept or reject, without any power of amendment or criticism. So far the constitution of Sparta was distinctly oligarchical. The two kings, whose office was hereditary, and whose descent was from the famous family of the Heraclids, had but very limited political powers, and, with some few exceptions, even little more than ordinary senators. They owed their position and prerogatives to the religious sentiment of the people, which reverenced their noble and quasi-divine origin, and accepted them as legitimately the high priests of the nation, and as specially qualified in great emergencies to consult the Delphic oracle and receive its answers. An ample royal domain was assigned to them, and some rather delicate legal matters, such as the bestowment of the hand of an orphan heiress, were entrusted to their discretion. By far the most important of their duties was the command of the army on a foreign expedition, with, however, the assistance of a council of war. In fact they closely resembled at all points the kings of the heroic age, and the honour and reverence in which they were held was far greater than their actual power, which really was curtailed within such narrow limits that it was not possible for them to establish anything like a tyranny or despotism.

One great check on the kings was a board of magistrates, annually elected by the people, termed ephors, a name not confined to Sparta, whence we may fairly infer that this institution also by no means owed its origin to Lycurgus. A comparison has been suggested between the Spartan ephors and the tribunes at Rome. Both were certainly popular magistrates, and as it was at Rome, so too at Sparta, at any rate in her later days, these magistrates made themselves the great power in the state. There was a form of ancient oaths between the king and the ephors, the king swearing that he would respect the established laws, and the ephors swearing that on that condition he should retain his authority and prerogatives. The unanimous view of antiquity was that it was the special business of the ephors "to protect the people and restrain the kings." We gather from passages in Thucydides that they had in his time great political influence, and in the time of Aristotle they had attained such a position that he says they did not choose to conform themselves to the strict discipline prescribed to Spartan citizens. Although the king took the command in war, it was for the ephors to say when war should be made, and on what terms peace should be concluded. Any public magistrate, the kings not excepted, was liable to be called to account by them, while they themselves seem to have been irresponsible. Of course the fact that they were annually elected necessitated a general conformity in their policy to the popular will. But so great and arbitrary were their powers that Plato hints that the Spartan constitution might be almost described as a tyranny. Indeed they were to Sparta what the House of Commons is to England, "the moving spring," as Arnold says (*Thucy.*, App. II.), of the whole Spartan government.

Of the institutions we have described, not one, as we have seen, was peculiar to Sparta, or, it may be inferred, due to Lycurgus. They were indeed all connected by tradition with his name, and we may believe that he did his best to put them on a sound basis, though, as to the ephors, there is reason to think that they formed no part of the original Spartan constitution. One thing is certain that there was a permanence about Lycurgus's work, whatever it may have been, to which Sparta's long freedom from revolution was unanimously attributed. She owed this no doubt mainly to her peculiar social customs and usages, and it is here that in the opinion of both Grote and Thirlwall we must specially look for the reforming hand of Lycurgus.

It was of the first importance that the Spartan should be an efficient soldier. He was a conqueror in the midst of a subject population, to which he stood in the same relation in which the Norman for a time at least stood to the Saxon. This subject population was made up of two classes, the Periœci (dwellers round the city) and the Helots, the first being freemen and proprietors scattered throughout the townships and villages of Laconia, with some powers of local self-government, but with no voice in the affairs of the state, while the latter were simply serfs, attached to the soil which they cultivated, like the villein of the feudal period, for Spartan proprietors, to whom they paid a rent equivalent, it is said, to half of the entire produce. Their condition, though a humble and in some respects a degraded one, was at least free from the worst incidents of slavery, as they lived with their wives and families, and could not be sold out of the country. Thus they must have felt themselves an integral part of the state, which employed them in military service, and rewarded them from time to time with the gift of freedom. Still, as an oppressed class, they often gave uneasiness to Sparta, and on one memorable occasion, recorded by Thucydides (iv. 80), as many as two thousand of them were treacherously and secretly massacred for reasons of state expediency. There was even a regular and legalized system of thinning their numbers by stealthy assassination, known as the "crypteia," and carried into effect by young Spartans who were annually commissioned to range the country with daggers for this horrible purpose. If under ordinary circumstances the frugal and industrious Helot might exist in tolerable comfort and even hope for freedom, he must have been made to feel that it was exceedingly dangerous to be too aspiring, and the inferiority of his condition was clearly marked by a distinctive dress which he dared not lay aside, any more than he might presume to sing any of the national songs of Sparta.

It was by the toil of the Helots that the Spartan was enabled to live, as we should say, the life of a gentleman, devoting himself to hunting and military exercises along with some slight admixture of mental culture, based mainly on music and poetry. It was not, however, a life of ease and enjoyment. His physical training was proverbially severe. From the age of seven he was put under a rigorous state discipline which inured him to the patient endurance of the most extreme hardships. The ideal at which he was specially taught to aim was a calm passive fortitude, which implied that he lived solely for the state. Spartan youths would compete with each other in submitting themselves to the lash before the altar of the goddess Artemis, and would, it is said, sometimes suffer even to death without any visible emotion. The story that they were habitually trained to theft means that they had licence to roam the country and forage for food, which they were expected to carry off without detection. In every way they were trained to feel themselves at home amid peril and hardship.

The Spartan woman, whose business it was to be the mother of brave and robust children, was naturally held in great honour, and according to Aristotle had at least in his time great influence on public affairs. The maiden was trained in much the same fashion as the youth, and was exercised in running, wrestling, and boxing, and thus at Sparta there was a much freer intermingling of the sexes than in any other Greek state. In this respect Spartan fashions of life seem to have been altogether peculiar to Spartans. The effect of such a training on the women would as a matter of course be to give them masculine sentiments and aspirations, and we can well understand what regard would be paid to their praise or censure. The position of women in Sparta takes us back to the old heroic ages, and reminds us of many passages in the poems of Homer.

One of the features of Spartan life, in thorough harmony with its general purpose and tenor, was the public mess, the "syssitia," according to the Greek phrase. Every citizen was bound to be a member of the mess, which was arranged in a number of joint tables, each providing from his allotment of land a prescribed quota of provisions, with wine and game from the public forests, and the guests being distributed into parties of fifteen persons, and chosen by ballot. Attendance at the mess was strictly enforced, and even the kings were not permitted to excuse themselves. The claims of the state on her citizens, and the duty of obedience to state discipline, were thus kept perpetually present to the Spartan's mind.

With trade and industrial occupations, even agriculture, the Spartan had nothing to do, all this being left to the Periœci and Helots. We might have anticipated that such would be the case with a military aristocracy. The story that Lycurgus restricted Sparta to an iron coinage cannot well be reconciled with the fact that silver money was not in use among the Greeks till a century after his time.

The organization of the Spartan army was always greatly admired by the ancients. Xenophon praises its system of tactics for "an admirable simplicity in the midst of seeming intricacy," and in Thucydides (v. 66) we have it described as based on an elaborate graduation of authority, by means of which the general's orders were transmitted to the rank and file with the utmost promptitude and accuracy. The strength of the army consisted mainly in infantry, every Spartan being a heavy-armed soldier, and the light troops being made up out of the Periœci and Helots. The Spartan cavalry never had much repute, and it was always regarded as a decidedly inferior branch of the service. Nor did they seriously apply themselves to sieges or to sea warfare. Though a brave, they were a very cautious and wary people, and all their military operations were conducted with extreme secrecy. It was a fixed principle with them not to engage the same enemy with needless frequency, and not to carry a pursuit further than victory really required. Anything like cowardice was a disgrace which reduced a citizen to the condition of an outcast. "With it or on it" were the words with which the Spartan mother would bid her son return when he left home with his shield to fight for Sparta.

Lycurgus is fairly described by Grote (*Hist. of Greece*, chap. 6) as "the founder of a warlike brotherhood rather than the lawgiver of a political community." The Spartan was to be almost wholly estranged from home ties, and to live only for the state. His training, though admired both by Plato and Aristotle as directed towards a noble ideal, was felt by them to be very imperfect, inasmuch as it cultivated only one side of human virtue and contemplated the circumstances of a camp or a garrison rather than of a state organized on a really perfect basis.

With the reforms of Lycurgus Plutarch connects a sweeping readjustment of the entire system of landed property, whereby Laconia was parcelled out into 39,000 equal lots, 9000 being assigned to Spartan citizens, and the remainder to their free subjects, the Periœci. It was the fashion with certain ancient writers to assume some such measure in the case of every early legislator or reformer. But it is to be noted that we have no hint of any such repartition of land by Lycurgus till we come to Plutarch, and this fact so much impressed Grote that he utterly rejects the story. All historical evidence, he maintains, points to great inequalities of property among the Spartans from the earliest times, and is therefore irreconcilable with any such belief. Here indeed he seems to be on sure ground, but it may be quite possible that even with equal lots of land there were decided inequalities in wealth. There may have been citizens rich in flocks and herds pastured on common ground, of which, we have reason to believe, there was considerable extent. Plutarch's account is favoured by the fact that equal distributions of land were often made in early days by conquering peoples. The question is one on which it seems impossible to arrive at a certain and definite conclusion. Possibly, as has been suggested by M. Laveleye, some old tradition of an equality of landed property may have been the origin of the belief that a redivision into equal portions was a part of the system of Lycurgus.

There was, however, an equality which he certainly did attempt to establish. Every Spartan, rich or poor, had to submit to the same hard discipline and to aim at the same ideal. The attempt was not altogether unsuccessful, though the subsequent history of Sparta shows that several of her citizens fell so far short of it as to disgrace themselves by actual dishonesty in the public service. But we may fairly credit Lycurgus with a work which laid deep the foundations of a very remarkable and at times a truly noble patriotism both in the men and women of Sparta.

The best accounts of Lycurgus and his legislation will be found in Grote's and Thirlwall's histories, and in Müller's *Dorians*. The chief original sources from which our knowledge of the subject is derived are the writings of Plutarch and Xenophon, and Aristotle's *Politics*. (W. J. B.)

LYCURGUS, one of the ten great Attic orators, was born about 396–93 B.C. His father was named Lycophron, and he belonged to the old Attic family of the Eteobutadæ. He is said to have been a pupil both of Plato and of Isocrates. His early career is quite unknown, but after the real character of the great struggle with Philip of Macedon was becoming manifest he was recognized along with Demosthenes and Hyperides as one of the chiefs of the national party. He left the care of external relations to his colleagues, and devoted himself to the internal organization and the financial administration of the state. He managed the finances of Athens for twelve successive years, being chosen ταμίας τῆς κοινῆς προσόδου, probably in 341 B.C., for a term of four years, and in the two succeeding terms, when the actual office was forbidden him by law, directing it through a nominal official chosen from his party. Part of one of the deeds in which he rendered account of his term of office is still preserved in an inscription (*Corp. Inscr. Gr.*, i. No. 247; *Corp. Inscr. Att.*, ii. pt. 2, No. 289). During this time 18,900 talents passed through his hands, and he raised the public income to 1200 talents yearly. His integrity and his skilful management were highly appreciated by the people, who refused to deliver him up when Alexander the Great demanded his surrender; many private persons deposited money under his charge. He was also appointed to various other offices connected with the preservation and improvement of the city. He was very strict in his superintendence of the public morals, and passed a sumptuary law to restrain extravagance. On the other hand he showed a noble and liberal spirit in all that concerned public expenditure; he did much to beautify and improve the city by fine buildings; and he passed a famous law ordering that statues of the three great tragedians should be erected, and that a careful edition of their tragedies should be made and preserved among the state archives.

Lycurgus was a man of action and not of words: his orations, of which fifteen were published, are criticized by the ancients for their awkward arrangement of matter, harshness of style, and the tendency to digressions about mythology and past history, while the noble spirit and the lofty morality that breathe through them are highly praised. Only one of the orations, that against Leocrates, has been preserved, and fully bears out the criticism of the ancients. He was evidently one of the last examples of the finest Athenian type—full of religious feeling, as became one of the Eteobutadæ, the family in which the priesthood of Athene Polias was hereditary, proud of the history and the religion of his country, and resolved to act worthily of it and to make others do the same, severe and stern in his treatment of offenders and frequently prosecuting them in the public courts, but generous and liberal in all that concerned the glory of Athens.

LYDGATE, JOHN, a monk of Bury St Edmunds, was the most famous English poet of the 15th century. He is a standing refutation of a popular notion that the extraordinary collapse of English poetry after Chaucer disappeared from the stage was due to the unsettled state of public affairs. The exact dates of his birth and death are not ascertained, but he began his occupation as a versemaker before Chaucer's death, and probably ended it several years before the Wars of the Roses broke out. Public affairs were not more unsettled during his lifetime than during the lifetime of Chaucer. Like Chaucer, Lydgate enjoyed the patronage of the royal family. He was the "poet laureate" of his generation. He translated Benoît de St Maure's *History of Troy* "at the commandment" of Henry V.; he wrote a poem on the battle of Agincourt; the coronation of Henry VII. furnished him with another theme; the "Good Duke Humphrey" of Gloucester "commanded" his translation of *Bochas upon the Fall of Princes.* The monk of Bury was in short a professional poet. According to Warton he opened a school in his monastery for teaching the sons of the nobility the arts of versification and the elegancies of composition, and it would seem from the character and the variety of the pieces attributed to him—"disguisings," "mummings," lives of saints, translations of standard works, devotional pieces in metre, metrical paraphrases of proverbs—that he was ready to write to order on any theme submitted to him. Lydgate attracted a good deal of attention from our early printers and antiquaries, his *Fall of Princes* being reprinted four times before the accession of Elizabeth. The fact that it was the largest poem in English of a tragic cast may have had something to do with the popularity of this work. The *Story of Thebes*, based on Statius and Boccaccio, is generally supposed to have been one of his first essays. It is told as one of the Canterbury tales,—the poet in his prologue feigning himself to have joined Chaucer's pilgrims at Canterbury, and recited this tale at the host's command as they rode back. Possibly more than one of two hundred and fifty-one separate poems, most of them short, ascribed to Lydgate by Ritson, have been ascribed to him on very slender authority. But the works undoubtedly his are so commonplace in thought and sentiment, and so clumsy in execution,—with all allowance for transcribers' errors and imperfect editing,—that no injustice can have been done to his reputation by attributing any doggerel to his facile pen. He was evidently a great reader of poetry, a scholar accomplished in amount, had probably a large indiscriminate enjoyment of poetry, and probably also a boisterous enjoyment of his own facility in building up stanzas. His own mental life was probably the reverse of dull. But, like many another self-satisfied versifier, he is the cause of dulness in others. In reading him with his own contented spirit, one catches some faint reflexion of the gleeful happiness with which he seems to have poured out his abundant store of thrice-repeated phrases and images. Of artistic sensibility he was entirely destitute. He claims our sympathy by his warm admiration for Chaucer, but admiration gave him no share of Chaucer's economy of touch, rapid vivacious movement, and subtle wit. His lines are eked out by tautologous and feeble epithets, and garrulous repetitions—"as clerkes can you tell," "in bookes as I rede," "the story saith certain," "the story can devise," "the story can reherse," "the story specifies," "the story maketh mind." Something is expressed in learned terms, and then the same thing is repeated "in plain English." Lydgate is seen at his best in his illustrations of proverbs and maxims of homely morality, and by far his most successful metre is a stave of eight four-beat lines with a rhyme from the first half recurring in the second. *A Satirical Balad on the Times*, with the refrain "So as the crab gothe forwarde"; *A Satirical Description of his Lady*, with the refrain "When she hath on hire hood of green"; *A Lover's Complaint*; *Thonke God of Alle*; and *Make Amendes*—all in this metre—are among the most favourable specimens of his powers. A line of five accents seems always to have driven him into prolixity. *The London Lackpenny*, to the refrain of "But for lack of money I might not speed," the best known of his humorous poems, is also in four-beat lines, though there are seven lines in the stanza. Lydgate's copiousness of detail in describing customs, dresses, architecture, as well as in making literary comparisons, render his verses useful as materials for the historian; but in artistic skill he is a sad falling off from Chaucer. Personally he seems to have been a lively monk enough. In his *Testament* he makes confession to having been a terrible boy, "disposed to many unbridled passions." He fought with his schoolfellows, and scoffed and made mouths at them "like a wanton ape"; he played truant, and "forged leesings" in excuse; neither hedge nor wall could keep him out of orchards; he "told cherry-stones" when he ought to have been at church, and threw his paternoster and his creed at the cock. Highly decorous respectable old men often take a pleasure in looking back, as Justice Shallow did, to the follies of their youth, and perhaps exaggerating them, but there is nothing in Lydgate's confession inconsistent with his poetry. A dull writer is generally a person of high animal spirits; only that could sustain him through platitudes which other people find so dreary. (W. M.)

LYDIA. It is difficult to fix the boundaries of Lydia very exactly, partly because they varied at different times, partly because we are still but imperfectly acquainted with the geography of western Asia Minor. The name is first found, under the form of Luddi, in the inscriptions of the Assyrian king Assur-bani-pal, who received tribute from Gyges about 660 B.C. In Homer we read only of Mæonians (*Il.*, ii. 865, v. 43, x. 431), and the place of the Lydian capital Sardes is taken by Hyde (*Il.*, xx. 385), unless this was the name of the district in which Sardes stood (see Strabo, xiii. p. 626).[1] The earliest Greek writer who mentions the name is Mimnermus of Colophon, in the 37th Olympiad. According to Herodotus (i. 7), the Meiones (called Mæones by other writers) were named Lydians after Lydus, the son of Attys, in the mythical epoch which preceded the rise of the Heraclid dynasty. In historical times, however, the Mæones were a tribe inhabiting the district of the Upper Hermus, where a town called Mæonia (now *Mennen*) existed (Pliny, *N. H.*, v. 30; Hierocles, p. 670). The Lydians must originally have been an allied tribe which bordered upon them to the north-west, and occupied the plain of Sardes or Magnesia at the foot of Tmolus and Sipylus. They were cut off from the sea by the Greeks, who were in possession, not only of the Bay of Smyrna, but also of the country north of Sipylus as far as Temnus, in the Boghaz, or pass, through which the Hermus forces its way from the plain of Magnesia into its lower valley.[2] In an Homeric epigram the ridge north of the Hermus, on which the ruins of Temnus lie, is called Sardene. Northward the Lydians extended at least as far as the Gygæan Lake (Lake Coloe, now *Mermereh*), and the Sardene range (now *Dumanly Dagh*). The plateau of the Bin Bir Tepé, on the southern shore of the Gygæan Lake, was the chief burial-place of the inhabitants of Sardes, and is still thickly studded with tumuli, among which the "tomb of Alyattes" towers to a height of 260 feet. Next to Sardes, Magnesia ad Sipylum was the chief city of the country, having taken the place of the ancient Sipylus, now probably represented by an almost inaccessible acropolis discovered by Mr Humann not far from Magnesia on the northern cliff of Mount Sipylus. In its neighbourhood is the famous seated figure of "Niobe" (*Il.*, xxiv. 614–17), cut out of the rock, and probably intended to represent the goddess Cybele, to which the Greeks attached their legend of Niobe. According to Pliny (v. 31), Tantalis, afterwards swallowed up by earthquake in the pool Sale or Saloe, was the ancient name of Sipylus and "the capital of Mæonia" (Paus., vii. 24; Strabo, xii. p. 579).

Plate I

[1] Pliny (v. 30) makes it the Mæonian name.
[2] See W. M. Ramsay in the *Journal of Hellenic Studies*, ii. 2.

Under the Heraclid dynasty the limits of Lydia must have been already extended, since according to Strabo (xiii. p. 590), the authority of Gyges reached as far as the Troad, and we learn from the Assyrian inscriptions that the same king sent tribute to Assur-bani-pal, whose dominions were bounded on the west by the Halys. But under the Mermnads Lydia became a maritime as well as an inland power. The Greek cities were conquered, and the coast of Ionia included within the Lydian kingdom. The successes of Crœsus finally changed the Lydian kingdom into a Lydian empire, and all Asia Minor westward of the Halys, with the exception of Lycia, owned the supremacy of Sardes. Lydia never again shrank back into its original dimensions. After the Persian conquest the Mæander was regarded as its southern boundary, and in the Roman period it comprised the country between Mysia and Caria on the one side and Phrygia and the Ægean on the other.

Lydia proper was exceedingly fertile. The hill-sides were clothed with vine and fir, and the rich broad plain of Hermus produced large quantities of corn and saffron. The climate of the plain was soft but healthy, though the country was subject to frequent earthquakes. The Pactolus, which flowed from the fountain of Tarne in the Tmolus mountains, through the centre of Sardes, into the Hermus, was believed to be full of golden sand; and gold mines were worked in Tmolus itself, though by the time of Strabo the proceeds had become so small as hardly to pay for the expense of working them (Strabo, xiii. 591). Mæonia on the east contained the curious barren plateau known to the Greeks as the Catacecaumene or Burnt country, once a centre of volcanic disturbance. The Gygæan lake (where remains of pile dwellings have been found) still abounds with carp, which frequently grow to a very large size.

Herodotus (i. 171) tells us that Lydus was a brother of Mysus and Car. The statement is on the whole borne out by the few Lydian, Mysian, and Carian words that have been preserved, as well as by the general character of the civilization prevailing among the three nations. The language, so far as can be judged from its scanty remains, was Indo-European, and more closely related to the western than to the eastern branch of the family. The race was probably a mixed one, consisting of aborigines and Aryan immigrants. It was characterized by industry and a commercial spirit, and, before the Persian conquest, by bravery as well.

The religion of the Lydians resembled that of the other civilized nations of Asia Minor. It was a nature-worship, which at times became wild and sensuous. By the side of the supreme god Medeus stood the sun-god Attys, as in Phrygia the chief object of the popular cult. He was at once the son and bridegroom of Cybele or Cybebe, the mother of the gods, whose image carved by Broteas, son of Tantalus, was adored on the cliffs of Sipylus (Paus., iii. 22). Like the Semitic Tammuz or Adonis, he was the beautiful youth who had mutilated himself in a moment of frenzy or despair, and whose temples were served by eunuch priests. Or again he was the dying sun-god, slain by the winter, and mourned by Cybele, as Adonis was by Aphrodite in the old myth which the Greeks had borrowed from Phœnicia. This worship of Attys was in great measure due to foreign influence. Doubtless there had been an ancient native god of the name, but the associated myths and rites came almost wholly from abroad. The Hittites in their stronghold of Carchemish on the Euphrates had adopted the Babylonian cult of Istar (Ashtoreth) and Tammuz-Adonis, and had handed it on to the tribes of Asia Minor. The close resemblance between the story of Attys and that of Adonis was the result of a common origin. The old legends of the Semitic East had come to the West through two channels. The Phœnicians brought them by sea and the Hittites by land. But though the worship of Makar or Melkarth on Lesbos (*Il.*, xxiv. 544) shows that the Phœnician faith had found a home on this part of the coast of Asia Minor, it could have had no influence upon Lydia, which, as we have seen, was cut off from the sea before the rise of the Mermnads. It was rather to the Hittites that Lydia, like Phrygia and Cappadocia, owed its faith in Attys and Cybele. The latter became "the mother of Asia," and at Ephesus, where she was adored under the form of a meteoric stone, was identified with the Greek Artemis. Her mural crown is first seen in the Hittite sculptures of Boghaz Keui on the Halys, and the bee was sacred to her. A gem found near Aleppo represents her Hittite counterpart standing on this insect. The priestesses by whom she was served are depicted in early art as armed with the double-headed axe, and the dances they performed in her honour with shield and bow gave rise to the myths which saw in them the Amazons, a nation of woman-warriors. The præ-Hellenic cities of the coast—Smyrna, Samorna (Ephesus), Myrina, Cyme, Priene, and Pitane—were all of Amazonian origin, and the first three of them have the same name as the Amazon Myrina, whose tomb was pointed out in the Troad. The prostitution whereby the Lydian girls gained their dowries (Herod., i. 93) was a religious exercise, as among the Semites, which marked their devotion to the goddess Cybele. In the legend of Hercules, Omphale takes the place of Cybele, and was perhaps her Lydian title. Hercules is here the sun-god Attys in a new form; his Lydian name is unknown, since E. Meyer has shown (*Z. D. M. G.*, xxxi. 4) that Sandon belongs not to Lydia but to Cilicia. By the side of Attys stood the moon-god Manes or Men.

According to the native historian Xanthus (460 B.C.) three dynasties ruled in succession over Lydia. The first, that of the Attyads, is wholly mythical. It was headed by a god, and included geographical personages like Lydus, Asies, and Meles, or such heroes of folk-lore as Cambletes, who devoured his wife. To this mythical age belongs the colony which, according to Herodotus (i. 94), Tyrsenus, the son of Attys, led to Etruria. Xanthus, however, puts Torrhebus in the place of Tyrsenus, and makes him the eponym of a district in Lydia. There was no connexion between the Etrurians and Lydians in either language or race, and the story in Herodotus rests solely on the supposed resemblance of Tyrrhenus and Torrhebus. It is doubtful whether Xanthus recognized the Greek legends which brought Pelops from Lydia, or rather Mæonia, and made him the son of Tantalus. The legends must have grown up after the Greek colonization of Æolis and Ionia, though Dr Schliemann's discoveries at Mycenæ have shown a certain likeness between the art of early Greece and that of Asia Minor, while the gold found there in such abundance may have been derived from the mines of Tmolus. The second dynasty was also of divine origin, but the names which head it prove its connexion with the distant East. Its founder, a descendant of Hercules and Omphale, was, Herodotus tells us (i. 7), a son of Ninus and grandson of Belus. The Assyrian inscriptions have shown that the Assyrians had never crossed the Halys, much less known the name of Lydia, before the age of Assur-bani-pal, and consequently the old theory which brought the Heraclids from Nineveh must be given up. But we now know that the case was otherwise with another Oriental people, which was deeply imbued with the elements of Babylonian culture. The Hittites had overrun Asia Minor and established themselves on the shores of the Ægean before the reign of the Egyptian king Ramses II.

The subject allies who then fight under their banners include the Masu or Mysians and the Dardani of the Troad from Iluna or Ilion and Pidasa (Pedasus); and, if we follow Brugsch, Iluna should be read Mauna and identified with Mæonia. At the same time the Hittites left memorials of themselves in Lydia. Mr G. Dennis has discovered an inscription in Hittite hieroglyphics attached to the figure of "Niobe" on Sipylus, and a similar inscription accompanies the figure (in which Herodotus [ii. 106] wished to see Sesostris or Ramses II.) carved on the cliff of Kārabel, the pass which leads from the plain of Sardes to that of Ephesus. We learn from Eusebius that Sardes was first captured by the Cimmerians 1078 B.C.; and, since it was four centuries later before the real Cimmerians appeared on the horizon of history, we may perhaps find in the statement a tradition of the Hittite conquest. Possibly the Ninus of Herodotus points to the fact that Carchemish was called "the old Ninus" (Amm. Marc., xiv. 8), while the mention of Belus may indicate that Hittite civilization came from the land of Bel (see Sayce, *Trans. Soc. Biblical Arch.*, vii. 2). At all events it was when the authority of the Hittite satraps at Sardes began to decay that the Heraclid dynasty arose. According to Xanthus, Sadyattes and Lixus were the successors of Tylon the son of Omphale. After lasting five hundred and five years, the dynasty came to an end in the person of Sadyattes, as he is called by Nicolas of Damascus, whose account is doubtless derived from Xanthus. The name Candaules given him by Herodotus meant "dog-strangler," and was a title of the Lydian Hermes. Gyges, termed Gugu in the Assyrian inscriptions, Gog in the Old Testament, put him to death and established the dynasty of the Mermnads 690 B.C. (Euseb., 698 B.C.). Gyges initiated a new policy, that of making Lydia a maritime power; but his attempt to capture Old Smyrna was unsuccessful. Towards the middle of his reign the kingdom was overrun by the Cimmerians, called Gimirræ in the Assyrian texts, Gomer in the Old Testament, who had been driven from their old seats on the Sea of Azoff by an invasion of Scythians, and thrown upon Asia Minor by the defeat they had suffered at the hands of Esar-haddon. The lower town of Sardes was taken by them, and Gyges turned to Assyria for aid, consenting to become the tributary of Assur-bani-pal or Sardanapalus, and sending him among other presents two Cimmerian chieftains he had himself captured in battle (about 660 B.C.). At first no one could be found in Nineveh who understood the language of the ambassadors. A few years later, Gyges joined in the revolt against Assyria, which was headed by the viceroy of Babylonia, Assur-bani-pal's own brother. The Ionic and Carian mercenaries he despatched to Egypt enabled Psammetichus to make himself independent. Assyria, however, was soon avenged. The Cimmerian hordes returned, Gyges was slain in battle after a reign of thirty-eight years, and Ardys his son and successor returned to his allegiance to Nineveh. The second capture of Sardes on this occasion was alluded to by Callisthenes (Strabo, xiii. p. 627). Alyattes the grandson of Ardys finally succeeded in extirpating the Cimmerians, as well as in taking Smyrna, and thus providing his kingdom with a port. The trade and wealth of Lydia rapidly increased, and the Greek towns fell one after the other before the attacks of the Lydian kings. Alyattes's long reign of fifty-seven years saw the foundation of the Lydian empire. All Asia Minor west of the Halys owned his sway, and the six years' contest he carried on with the Medes was closed by the marriage of his daughter Aryenis to Astyages, and an intimate alliance between the two empires. The Greek cities were allowed to retain their own institutions and government on condition of paying taxes and dues to the Lydian monarch, and the proceeds of their commerce thus flowed into the imperial exchequer. The result was that the king of Lydia became the richest prince of his age. Alyattes was succeeded by Crœsus, who had probably already for some years shared the royal power with his father, or perhaps grandfather, as Floigl thinks (*Geschichte des semitischen Alterthums*, p. 20). He reigned alone only fifteen years, Cyrus the Persian, after an indecisive battle on the banks of the Halys, marching upon Sardes, and capturing both acropolis and monarch before his allies could come to his help (Euseb., 546 B.C.). The place where the acropolis was entered was believed to have been overlooked by the mythical Meles when he carried the lion round his fortress which made it invulnerable; it was really a path opened by one of the landslips which have reduced the sandstone cliff of the Acropolis to a mere shell, and threaten in a few years to carry it altogether into the plain below. The overthrow of Crœsus gave rise to many legends among both Lydians and Greeks, and he was held to have escaped death at the conqueror's hands through the intervention of the gods. The revolt of the Lydians under Pactyas, whom Cyrus had appointed to collect the taxes, caused the Persian king to disarm them, though we can hardly credit the statement that by this measure their former warlike spirit was crushed. Sardes now became the western capital of the Persian empire, and its burning by the Athenians was the indirect cause of the Persian War. After Alexander's death, Lydia passed to Antigonus; then Achæus made himself king at Sardes, but was defeated and put to death by Antiochus. The country was presented by the Romans to Eumenes, and subsequently formed part of the proconsular province of Asia. By the time of Strabo (xiii. p. 631) its old language was entirely supplanted by Greek.

The Lydian empire may be described as the industrial power of the ancient world. The Lydians were credited with being the inventors, not only of games such as dice, huckle-bones, and ball (Herod., i. 94), but also of coined money. The oldest known coins are the electrum coins of the earlier Mermnads (Madden, *Coins of the Jews*, pp. 19-21), stamped on one side with a lion's head or the figure of a king with bow and quiver; these were replaced by Crœsus with a coinage of pure gold and silver. To the latter monarch were probably due the earliest gold coins of Ephesus (Head, *Coinage of Ephesus*, p. 16). Mr Head has shown that the electrum coins of Lydia were of two kinds, one weighing 168·4 grains for the inland trade, and another of 224 grains for the trade with Ionia. The standard was the silver "mina of Carchemish," as the Assyrians called it, which contained 8656 grains. Originally derived by the Hittites from Babylonia, but modified by themselves, this standard was passed on to the nations of Asia Minor during the period of Hittite conquest, but was eventually superseded by the Phœnician mina of 11,225 grains, and continued to survive only in Cyprus and Cilicia. The inns, which the Lydians were said to have been the first to establish (Herod., i. 94), were connected with their attention to commercial pursuits. Their literature has wholly perished, and the only specimen of their writing we possess is on a marble base found by Mr Wood at Ephesus (Schliemann, *Ilios*, p. 698). They were celebrated for their music and gymnastic exercises, and their art formed a link between that of Asia Minor and that of Greece. A marble lion at Achmetly represents in a modified form the Assyrian type, and the engraved gems found in the neighbourhood of Sardes and Old Smyrna resemble the rude imitations of Assyrian workmanship met with in Cyprus and on the coasts of Asia Minor. For a description of a pectoral of white gold, ornamented with the heads of animals, human faces, and the figure of a goddess, discovered in a tomb on Tmolus, see *Academy*, January 15, 1881, p. 45. Lydian sculpture was probably similar to that of the Phrygians as displayed at Doghanly, Kumbet, and Ayazin, a necropolis lately discovered by Mr Ramsay. Phallic emblems, for averting evil, were plentiful; even the summit of the tomb of Alyattes is crowned with an enormous one of stone, about 9 feet in diameter. The tumulus itself is 281 yards in diameter and about half a mile in circumference. It has been partially excavated by Spiegelthal and Dennis, and a sepulchral chamber discovered in the middle, composed of large well-cut and highly polished blocks of marble, the chamber being 11 feet long, nearly 8 feet broad, and 7 feet high. Nothing was found in it except a few ashes and a broken vase of Egyptian alabaster. The stone basement which, according to Herodotus, formerly surrounded the mound has now disappeared. (A. H. S.)

LYELL, Sir Charles (1797–1875), one of the greatest of geological thinkers, was the eldest son of Charles Lyell of Kinnordy, Forfarshire, and was born November 14, 1797, on the family estate in Scotland. His father was a man of literary and scientific tastes, known both as a botanist and as the translator of the *Vita Nuova* and the *Convito* of Dante. From his boyhood Lyell had a strong inclination for natural history, especially entomology, a taste which he was able to cultivate in the New Forest, to which his family had removed soon after his birth. He was educated chiefly at Midhurst, and then at Exeter College, Oxford, where the lectures of Dr Buckland first opened out to him that field of geological study which became the passion of his life. After taking his degree in 1821, he entered Lincoln's Inn, and in 1825, after a delay caused by chronic weakness of the eyes, he was called to the bar, and went on the western circuit for two years. During the whole of this time, though not neglecting his profession, he was slowly gravitating towards the life of a student of science. In 1819 he had been elected a member of the Linnean and Geological Societies, communicating his first paper, "On the Marls of Forfarshire," to the latter society in 1822, and acting as one of the honorary secretaries in 1823. In that year he went to France, with introductions to Cuvier, Humboldt, and other men of science, and in 1824 made a geological tour in Scotland in company with Dr Buckland. In 1826 he was elected a fellow of the Royal Society, from which in later years he received both the Copley and Royal medals; and in 1827 he finally abandoned the legal profession, and devoted himself to geology.

Long prior to this, however, he had already begun the sketch of his principal work, *The Principles of Geology*. The subsidiary title, "An Attempt to Explain the Former Changes of the Earth's Surface by Reference to Causes now in Operation," gives the keynote of the task to which Lyell devoted his life, and in pursuance of which he made geological tours over large portions of the Continent, and in later years to Madeira and to the United States and Canada. The journey undertaken with Murchison in 1828 was especially fruitful in results, for not only did it give rise to two joint papers on the volcanic district of Auvergne and the Tertiary formations of Aix-en-Provence, but it was apparently while examining Signor Bonelli's collection of Tertiary shells at Turin, and subsequently when (after parting with Murchison) he studied the marine remains of the Tertiary rocks of Ischia and Sicily, that Lyell conceived the idea of dividing the Tertiaries into three or four principal groups, characterized by the proportion of recent to extinct species of shells. To these groups, after consulting Dr Whewell as to the best nomenclature, he gave the names now universally adopted—Eocene (*dawn of recent*), Miocene (*less of recent*), and Pliocene (*more of recent*) Upper and Lower; and with the assistance of M. Deshayes, who had arrived by independent researches at very similar views, he drew up a table of shells in illustration of this classification. The first volume of the *Principles of Geology* appeared in 1830, and the second in January 1832. Received at first with considerable opposition, at least so far as its leading theory was concerned, the work had ultimately a great success, and it had already reached a second edition in 1833 when the third volume, dealing with the successive formations of the earth's crust, was added.[1]

In August 1838 Lyell published the *Elements of Geology*, which, from being originally an expansion of the fourth book of the *Principles*, became a standard work of reference in stratigraphical and palæontological geology. This book went through six editions in Lyell's lifetime (some intermediate ones being styled *Manual of Elementary Geology*), and in 1871 a smaller work, the *Student's Elements of Geology*, was based upon it. His third great work, *The Antiquity of Man*, appeared in 1863, and ran through three editions in one year. In this he laid before the world a general survey of the arguments for man's early appearance on the earth, derived from the discoveries of worked flint implements in Post-Pliocene strata in the Somme valley and elsewhere, and in it also he first gave in his adhesion to Darwin's theory of the origin of species. A fourth edition appeared in 1873.

While thus occupied with his writings, Lyell lost no opportunity of carrying out original investigations, and whenever absent from his literary work in London was always to be heard of in the field either in England or on the Continent. In 1831 he held for a short time the post of professor of geology at King's College, London, and delivered while there a highly appreciated course of lectures, which became the foundation of the *Elements of Geology*. In 1832 he married Mary, eldest daughter of Leonard Horner, who became thenceforward associated with him in all his literary and scientific labours, aiding him substantially with her ready intellect, and by her pre-eminent social qualities making his home a centre of attraction to all men of talent. In 1834 he made an excursion to Denmark and Sweden, the result of which was his celebrated paper to the Royal Society, "On the Proofs of the Gradual Rising of Land in Certain Parts of Sweden," and another to the Geological Society, "On the Cretaceous and Tertiary Strata of Seeland and Möen." In 1837 he was again in Norway and Denmark, and in 1841 he spent a year in travelling through the United States, Canada, and Nova Scotia. This last journey, together with a second one to America in 1845, when he visited Boston, Philadelphia, New Orleans, and the alluvial plain of the Mississippi, gave rise, not only to numerous original papers, but also to the publication of two works not exclusively geological, *Travels in North America* (1845) and *A Second Visit to the United States* (1849). In the second work especially he did much to promote good feeling between England and America, by showing a just appreciation of American society and institutions. It was in the course of these journeys that he estimated the rate of recession of the falls of Niagara, and of the annual average accumulation of alluvial matter in the delta of the Mississippi, and studied those vegetable accumulations in the "Great Dismal Swamp" of Virginia, which he afterwards used in illustrating the formation of beds of coal. He also studied with great care the coal-formations in Nova Scotia, and discovered in company with Dr Dawson of Montreal the earliest known land shell, *Pupa vetusta*, in the hollow stem of a *Sigillaria*. But it was chiefly in bringing a thorough knowledge of European geology to bear upon the more widely extended and massive formations of the North American continent that Lyell rendered immense service to geologists on both sides of the Atlântic.

Besides these Transatlantic journeys Lyell undertook geological excursions at different times to all parts of the British Isles, to Belgium, Switzerland, Germany, Spain, Madeira, and Teneriffe, in which latter islands, which he visited in company with G. Hartung, he accumulated much valuable evidence on the age and deposition of lava-beds and the formation of volcanic cones. He also revisited Sicily in 1858, when he made such observations upon the structure of Etna as entirely refuted the theory of "craters of elevation" upheld by Von Buch and Élie de Beaumont (see *Roy. Soc. Proc.*, 1859).

[1] Between 1830 and 1872 eleven editions of this work were published, each so much enriched with new material and the results of riper thought as to form a complete history of the progress of geology during that interval. Only a few days before his death Sir Charles finished revising the 12th edition, which appeared in 1876.

Lyell received the honour of knighthood in 1848, and was created a baronet in 1864, in which year he was president of the British Association, meeting at Bath. His services to the science of geology were now universally recognized both at home and abroad, and he was a member of almost every Continental and American Society. He was elected corresponding member of the French Institute and of the Royal Academy of Sciences at Berlin, and was created a knight of the Prussian Order of Merit.

During the latter years of his life his sight, always weak, failed him altogether, and he became very feeble. He died on February 22, 1875, in his seventy-eighth year, and was buried in Westminster Abbey. His funeral was attended by an immense concourse of public men, all his personal friends; for by young and old the veteran master of geology was deeply loved and revered. His gentle nature, his intense love of truth, his anxiety to help and encourage those who cultivated his favourite science, endeared him to all who approached him; while the extreme freshness of his mind kept him free from that dogmatism which is so often the accompaniment of old age, and enabled him to accept and appreciate heartily the work of younger men.

In order to appreciate justly the influence of Lyell's works upon the geology of the 19th century, it is necessary to bear in mind what was the state of knowledge upon this subject at the time when he entered the field in 1822. The rival schools of Werner and Hutton were then at the height of their famous contest, and, while the vehement discussions between the Neptunists and Vulcanists gave an impetus to the study of rock-masses, the one true principle upon which Hutton himself had so strongly insisted had dropped into oblivion, namely, that "in examining things present we have data from which to reason with regard to what has been," and that therefore we have no need to imagine other causes than those now in action to account for the past. Meanwhile a reaction against the speculative discussions which had so long occupied the world inclined many of the leaders of geological study to confine themselves to the collection of facts, and the science became for a time a mere branch of mineralogy, which, though most valuable in laying a true foundation, was quite inadequate to deal with the earth's history, since it took little or no account of organic remains, and their real significance was not in the least understood. Both in England and France, however, materials were being accumulated which prepared the way for a wider basis. In 1799 William Smith, travelling over England, first grouped the formations according to the fossils contained in them, and in 1815 he published his geological map of England, thus making the first step in stratigraphical geology; and almost simultaneously, in 1812, Cuvier's restorations of the extinct mammalia of the Paris basin, and Lamarck's classification of recent and fossil shells, gave the first impulse to palæontology. But the older schools of geologists, hampered by preconceived theories, were not prepared to make full use of the new facts. Cuvier himself, while insisting on the value of fossils in the chronology of the earth, yet retained all the old notions of sudden and violent convulsions, attributing the destruction of the fauna of the Paris basin to the deluge, or to the bursting of lakes caused by a sudden revolution of the globe; and in like manner Buckland, Sedgwick, and their compeers still explained everything by the diluvial theory, attributing the erratic blocks strewn over the Continent to the universal deluge, and accepting as demonstrated Élie de Beaumont's theory of the sudden elevation of mountain chains. Sedgwick in his address to the Geological Society in 1834 even spoke confidently of the extinct forms in geological strata as "indications of change and of an adjusting power altogether different from what we commonly understand by the laws of nature."

To shake off the influence of preconceived opinions such as these there was needed a fresh impartial mind capable of appreciating the evidence which had been accumulating during the past thirty years, and especially alive to the discoveries of palæontology. These requisites were found in Lyell. His early study of natural history gave him advantages possessed by few of his contemporaries, while the clear insight and calm judgment for which he was thus early remarkable led him alone of the younger school of geologists to grasp the truth enunciated by Hutton of the power of gradual changes to produce great results if only time enough be allowed. This truth he illustrated with such a wealth of facts, derived from his own observation and that of others, that in the first edition of the *Principles* we find sketched in broad outline, and demonstrated by actual examples, nearly all those fundamental truths which, though often vehemently opposed at the time, have now become so much the accepted basis of geology that it is difficult to realize how novel they were in 1830.

Even the opening historical chapters cut boldly at the root of catastrophic geology by showing how the prejudices concerning the short duration of past time on the globe had led men to the mistaken conclusion that "centuries were implied where the characters imported thousands, and thousands where the language of nature signified millions"; and the arguments for the uniform action of nature followed with overwhelming force, as Lyell proceeded to lay under contribution all countries of the world to show how the face of the earth is now being altered by rivers, torrents, springs, currents and tides, volcanoes and earthquakes.

In the second volume the changes in the organic world were used to teach the same lesson. The proofs of extinction of specific forms in historical times were accumulated to explain that the presence of extinct forms in geological formations was the effect of gradual causes and not of sudden and violent catastrophes, while the tranquil imbedding of organic remains now in progress was used to strengthen the previous argument derived from inorganic causes for the slow and gradual accumulation of fossiliferous strata. It was in this volume that Lyell made in 1830 his celebrated attack upon Lamarck's theory of the transmutation of species, and, though this has often been held as a want of appreciation on his part of the arguments of the great naturalist, yet, as we shall see presently, it was really a curious illustration of the impartiality of Lyell's mind (though acting under what he himself would have called the influence of "inherited belief") that this theory, so eminently calculated to harmonize with his own views of the power of minute causes to work appreciable change, was rejected by him because it rested upon an assumption of a law of innate progressive development, which could not be shown to be in accordance with natural facts.

The third volume of the *Principles*, which did not appear till two years later, completed the task which Lyell had set himself, by interpreting the fragmentary record which remains to us of the successive geological formations of the earth's crust with their imbedded remains and the associated volcanic rocks, and thus restoring as far as possible the past history of the earth. Through all its successive editions this volume has remained the standard text-book of geological history, as its two predecessors have of the philosophical principles of the science.

So immediate was the effect of this remarkable work that from the time of its publication the earlier cosmogonies disappeared from the field, and even Cuvier's *Theory of the Earth* never reached another edition. Yet, although geologists began insensibly to follow the lines which Lyell had marked out, they were long in receiving the principles upon which these were founded. Sedgwick, in the address already quoted, while pronouncing a eulogy on the book as a whole, regretted that "from the very title-page of his work Mr Lyell seems to stand forward as the champion of a great leading doctrine of the Huttonian hypothesis," *i.e.*, the explanation of former changes by reference to causes now in operation; and Lyell's oldest friend and fellow-labourer Murchison remained to the last the exponent of the converse truth, that we have no evidence forbidding the possibility of a greater intensity of the forces in action during past periods. This form of catastrophic geology has indeed always prevailed upon the Continent, and still does so in a great degree. There is, however, nothing necessarily antagonistic in the two theories; and, if Lyell in his earlier years accentuated perhaps somewhat too strongly the necessity for making unlimited drafts upon the "bank of time," as he often called it, to the exclusion of intensified volcanic or aqueous action, it was because he had to combat the opposite and deeply rooted error.

Between the year 1853, when the 9th edition of the *Principles* was published, and 1863, when he "read his recantation," as he himself would sometimes express it, in the *Antiquity of Man*, the discovery of the flint implements associated with bones of extinct mammalia at Abbeville, and subsequently in the valley of the Thames and elsewhere, threw an entirely new light upon the data of human existence upon the earth, allowing far more time for the development of the numerous varieties of mankind than had hitherto been supposed possible. In conjunction with these discoveries came also the evidence adduced by Darwin and Wallace of the action of natural causes in producing modifications in living forms,—thus applying the very same principle to organic life which Hutton and Lyell had used to explain the gradual modification of the earth's surface. Then it was that Lyell, who had rejected Lamarck's theory because it rested on a purely imaginary law of innate progressive development, at once accepted "natural selection" as a *vera causa* helping to explain those evidences of the gradual change in organic forms presented in successive geological formations. By recognizing the value of the new principle, and incorporating its results in his *Principles*, Lyell completed in 1872 in a fuller sense than he had contemplated in 1850 the task of "explaining former changes of the earth's surface (including the history of its living inhabitants) by reference to causes now in action"; while at the same time he gave to his original conception that element of expansion and pliability which was alone needed to ensure its continued influence and the permanent celebrity of its author.

Besides his books, Lyell contributed seventy-six geological papers to various societies. The only authorities yet published for his life are *Life and Letters of Sir Charles Lyell*, 1881, edited by Mrs Lyell, and the obituary notices in 1875 at the Royal and other Societies. (A. B. B.)

LYLY, or LILLY, or LYLIE, JOHN (1553–1606), the famous author of *Euphues*, was born in Kent in 1553 or 1554. At the age of sixteen, according to Wood, he became a student of Magdalen College, Oxford, where in due time he proceeded to his bachelor's and master's degrees (1573 and 1575), and from whence we find him in 1574 applying to Lord Burghley "for the queen's letters to Magdalen College to admit him fellow." The fellowship, however, was not granted, and Lyly shortly after left the university. He complains of what seems to have been a sentence of rustication passed upon him at some period in his academical career, in his address to the gentlemen scholars of Oxford affixed to the second edition of the first part of *Euphues*, but in the absence of any further evidence it is impossible to fix either its date or its cause. If we are to believe Wood, he never took kindly to the proper studies of the university. "For so it was that his genius being naturally bent to the pleasant paths of poetry (as if Apollo had given to him a wreath of his own bays without snatching or struggling) did in a manner neglect academical studies, yet not so much but that he took the degrees in arts, that of master being compleated 1575." After he left Oxford, where he had already the reputation of "a noted wit," Lyly seems to have attached himself to Lord Burghley. "This noble man," he writes in the "Glasse for Europe," in the second part of *Euphues* (1580), "I found so ready being but a straunger to do me good, that neyther I ought to forget him, neyther cease to pray for him, that as he hath the wisdom of Nestor, so he may have the age, that having the policies of Ulysses he may have his honor, worthy to lyve long, by whom so many lyve in quiet, and not unworthy to be advaunced by whose care so many have been preferred." Two years later we possess a letter of Lyly to the treasurer, dated July 1582, in which the writer protests against some undefined accusation which had brought him into trouble with his patron, and demands a personal interview for the purpose of clearing his character. What the further relations between them were we have no means of knowing, but it is clear that neither from Burghley nor from the queen did Lyly ever receive any substantial patronage. In 1578 he began his literary career by the composition of *Euphues, or the Anatomy of Wit*, which was licensed to Gabriel Cawood on December 2, 1578, and published in the spring of 1579. In the same year the author was incorporated M.A. at Cambridge, and possibly saw his hopes of court advancement dashed by the appointment in July of Edmund Tylney to the office of master of the revels, a post at which, as he reminds the queen some years later, he had all along been encouraged to "aim his courses." *Euphues and his England* appeared in 1580, and, like the first part of the book, won immediate popularity. For a time Lyly was the most successful and fashionable of English writers. He was hailed as the author of "a new English," as a "raffineur de l'Anglois;" and, as Edmund Blount, the editor of his plays, tells us in 1632, "that beautie in court which could not parley Euphuism was as little regarded as she which nowe there speakes not French." After the publication of *Euphues*, however, Lyly seems to have entirely deserted the novel form himself, which passed into the hands of his imitators, and to have thrown himself almost exclusively into play-writing, probably with a view to the mastership of revels whenever a vacancy should occur. Eight plays by him were probably acted before the queen by the children of the Chapel Royal and the children of St Paul's between the years 1584 and 1589, one or two of them being repeated before a popular audience at the Blackfriars Theatre. Their brisk lively dialogue, classical colour, and frequent allusions to persons and events of the day maintained that popularity with the court which *Euphues* had won. In 1589 Lyly published a tract in the Martin Marprelate controversy, called *Pappe with an hatchet, alias a figge for my Godsonne; Or Crack me this nut; Or a Countrie Cuffe, &c.*[1] About the same time we may probably date his first petition to Queen Elizabeth. The two petitions, transcripts of which are extant among the Harleian MSS., are undated, but in the first of them he speaks of having been ten years hanging about the court in hope of preferment, and in the second he extends the period to thirteen years. It may be conjectured with great probability that the ten years date from 1579, when Edmund Tylney was appointed master of the revels with a tacit understanding that Lyly was to have the next reversion of the post. "I was entertained your Majestie's servaunt by your own gratious favor," he says, "strengthened with condicions that I should ayme all my courses at the Revells (I dare not say with a promise, but with a hopeful Item to the Reversion) for which these ten yeres I have attended with an unwearyed patience." But in 1589 or 1590 the mastership of the revels was as far off as ever,—Tylney in fact held the post for thirty-one years,—and that Lyly's petition brought him no compensation in other directions may be inferred from the second petition of 1593. "Thirteen yeres your highnes servant but yet nothing. Twenty freinds that though they saye they will be sure, I finde them sure to be slowe. A thousand hopes, but all nothing; a hundred promises but yet nothing. Thus casting up the inventory of my friends, hopes, promises, and tymes, the *summa totalis* amounteth to just nothing." What may have been Lyly's subsequent fortunes at court we do not know. Edmund Blount says vaguely that Elizabeth "graced and rewarded" him, but of this there is no other evidence. After 1590 his works steadily declined in influence and reputation; other stars were in possession of the horizon; and so far as we know he died poor and neglected in the early part of James I.'s reign. He was buried in London at St Bartholomew the Less on November 20, 1606. He was married, and we hear of two sons and a daughter.

Comedies.—In 1632 Edmund Blount published "Six Court Comedies," including *Endymion, Sappho and Phao, Alexander and Campaspe, Midas, Mother Bombie*, and *Gallathea*. To these should be added the *Woman in the Moone* (Lyly's earliest play, to judge from a passage in the prologue and therefore earlier than 1584, the date of *Alexander and Campaspe*), and *Love's Metamorphosis*, first printed in 1601. Of these, all but the last are in prose. *A Warning for Faire Women* (1599) and *The Maid's Metamorphosis* (1600) have been attributed to Lyly, but on altogether insufficient grounds. The first editions of all these plays were issued between 1584 and 1601, and the majority of them between 1584 and 1592, in what were Lyly's most successful and popular years. His importance as a dramatist has been very differently estimated. Prof. Minto denies him any appreciable influence upon our literature, while Professor A. Ward, on the other hand, rightly believes his work to have had a great effect upon the development of dramatic dialogue, and the prose drama in general. Lyly's dialogue is still a long way removed from the dialogue of Shakespeare. But at the same time it is a great advance in rapidity and resource upon anything which had gone before it; it represents an important step in English dramatic art. His nimbleness, and the wit which struggles with his pedantry, found their full development in the dialogue of *Twelfth Night* and *Much Ado about Nothing*, just as "Marlowe's mighty line" led up to and was eclipsed by the majesty and music of Shakespearian passion. One or two of the songs introduced into his plays are justly famous, and show a real lyrical gift. Nor in estimating his dramatic position and his effect upon his time must it be forgotten that his classical and mythological plots, flavourless

[1] The evidence for his authorship may be found in Gabriel Harvey's *Pierce's Supererogation* (written November 1589, published 1593), in Nash's *Have with you to Saffron Walden* (1596), and in various allusions in Lyly's own plays. See Fairholt's *Dramatic Works of John Lilly*, vol. i. p. 20.

and dull as they would be to a modern audience, were charged with interest to those courtly hearers who saw in Midas Philip II., Elizabeth in Cynthia, and perhaps Leicester's unwelcome marriage with Lady Sheffield in the love affair between Endymion and Tellus which brings the former under Cynthia's displeasure. As a matter of fact his reputation and popularity as a play-writer were considerable. Gabriel Harvey dreaded lest Lyly should make a play upon their quarrel; Meres, as is well known, places him among "the best for comedy;" and Ben Jonson names him among those foremost rivals who were "outshone" and outsung by Shakespeare.

Euphues.—It was not, however, as a dramatist, but as the author of *Euphues*, that Lyly made most mark upon the Elizabethan world. His plays amused the court circle, but the "new English" of his novel threatened to permanently change the course of English style. The plot of *Euphues* is extremely simple. The hero, whose name may very possibly have been suggested by a passage in Ascham's *Schoolmaster*, is introduced to us as still in bondage to the follies of youth, "preferring fancy before friends, and this present humour before honour to come." His travels bring him to Naples, where he falls in love with Lucilla, the governor's light-minded daughter. Lucilla is already pledged to Euphues's friend Philautus, but Euphues's passion betrays his friendship, and the old lover finds himself thrown over by both friend and mistress. Euphues himself, however, is very soon forsaken for a more attractive suitor. He and Philautus make up their quarrel, and Euphues writes his friend "a cooling card," to be "applied to all lovers," which is so severe upon the fair sex that Lyly feels it necessary to balance it by a sort of apology addressed "to the grave matrons and honest maidens of Italy." Euphues then leaves Naples for his native Athens, where he gives himself up to study, of which the first fruits are two long treatises—the first, "Euphues and his Ephœbus," a disquisition on the art of education addressed to parents, and the second, "Euphues and Atheos," a discussion of the first principles of religion. The remainder of the book is filled up with correspondence between Euphues and his friends. We have letters from Euphues to Philautus on the death of Lucilla, to another friend on the death of his daughter, to one Botonio "to take his exile patiently," and to the youth Alcius, remonstrating with him on his bad behaviour at the university. Finally a pair of letters, the first from Livia "at the emperour's court to Euphues at Athens," answered by "Euphues to Livia," wind up the first part, and announce to us Euphues's intention of visiting England. An address from Lyly to Lord Delawarr is affixed, to which was added in the second edition "An Address to the Gentlemen Scholars of England."

Euphues and his England is rather longer than the first part. Euphues and Philautus travel from Naples to England. They arrive at Dover, halt for the night at Fidus's house at Canterbury, and then proceed to London, where they make acquaintance with Surius, a young English gentleman of great birth and noble blood; Psellus, an Italian nobleman reputed "great in magick"; Martius, an elderly Englishman; Camilla, a beautiful English girl of insignificant family; Lady Flavia and her niece Fraunces. After endless correspondence and conversation on all kinds of topics, Euphues is recalled to Athens, and from there corresponds with his friends. "Euphues' Glasse for Europe" is a flattering description of England sent to Livia at Naples. It is the most interesting portion of the book, and throws light upon one or two points of Lyly's own biography. The author naturally seized the opportunity for paying his inevitable tribute to the queen, and pays it in his most exalted style. "O fortunate England that hath such a queene, ungratefull if thou praye not for hir, wicked if thou do not love hir, miserable if thou lose hir!"—and so on. The book ends with Philautus's announcement of his marriage to Fraunces, upon which Euphues sends characteristic congratulations and retires, "tormented in body and grieved in mind," to the Mount of Silexedra, "where I leave him to his musing or Muses."

Such is a brief outline of the book which for a time set the fashion for English prose. Two editions of each part appeared within the first year after publication, and thirteen editions of both are enumerated by Mr Arber up to 1636, after which, with the exception of a modernized version in 1718, *Euphues* was never reprinted until 1868, when Mr Arber took it in hand. The reasons for its popularity are not far to seek. As far as matter was concerned it fell in with all the prevailing literary fashions. Its long disquisitions on love, religion, exile, women, or education, on court life and country pleasures, handled all the most favourite topics in the secularized speculation of the time; its foreign background and travel talk pleased a society of which Lyly himself said "trafic and travel hath woven the nature of all nations into ours and made this land like arras full of device which was broadcloth full of workmanship;" and, although Lyly steered clear in it of the worst classical pedantries of the day, the book was more than sufficiently steeped in classical learning, and based upon classical material, to attract a literary circle which was nothing if not humanist. A large proportion of its matter indeed was drawn from classical sources. The general tone of sententious moralizing may be traced to Plutarch, from whom the treatise on education, "Euphues and his Ephœbus," and that on exile, "Letter to Botonio to take his exile patiently," are literally translated, as well as a number of other shorter passages either taken direct from the Latin versions or from some of the numerous English translations of Plutarch then current. The innumerable illustrations based upon a kind of pseudo natural history are largely taken from Pliny, while the mythology is that of Virgil and Ovid.

It was not the matter of *Euphues*, however, so much as the style which made it famous. The sources of Lyly's peculiar style have only recently been satisfactorily traced by a German scholar, Dr Landmann, whose interesting and well arranged pamphlet we need do little more than summarize (Landmann, *Der Euphuismus, sein Wesen, seine Quelle, seine Geschichte*, &c., Giessen, 1881). What, asks Dr Landmann, is Euphuism, properly so called? The term till now has been generally used as if it included all the affected modes of speaking and writing in vogue in England during the 16th century. It has even been made to cover all the corruption of English taste from Surrey to Dryden; and the common mode of explaining it has been to say that it was a mere "exaggeration of the Italianating taste which had begun with the revival of our poetical literature" under Henry VIII. In reality, however, *Euphues* has very little to do with the other affectations of the time. Its chief characteristics, to quote Dr Landmann, are "a peculiar combination of antithesis with alliteration, assonance, rhyme, and play upon words, a love for the conformity and correspondence of parallel sentences, and a tendency to accumulate rhetorical figures, such as climax, the rhetorical question, objections and refutations, the repetition of the same thought in other forms, &c." To this may be added constant references to antiquity and a great fondness for comparisons drawn from a sort of fabulous natural history. On the other hand the style is free from what Puttenham calls "mingle mangle," that is to say, from the pedantic and indiscriminate use of foreign or Latinized words, and also from the hyperbolical extravagances of the Petrarchians. Lyly's peculiarities are those of syntax and construction rather than of phraseology. Compared to that of the Surrey school, his diction is simple and direct, and he himself declares that he does not pretend to please those "Englishmen who desire to heare finer speech than the language will allowe," that is to say, the lovers of the Italianate circumlocutions which ruled English poetry from Surrey to Spenser. His work then is not simply to be regarded as the outcome of the classical and Italian influence at work in England since the beginning of the century. It has individual features which have to be accounted for, and which have now been traced with certainty by Dr Landmann to the influence of one foreign author—Don Antonio de GUEVARA (*q.v.*). Guevara's chief work was *El Libro Aureo de Marco Aurelio* (1529),—a sort of historical romance based upon Plutarch and upon Marcus Aurelius's *Meditations*, the object of which was to produce a "mirror for princes," of the kind so popular throughout the Renaissance. Within the year of its publication Guevara issued an enlarged edition of his book, calling it *Libro del Emperador Marco Aurelio con relox de Principes*; and a number of fresh editions and of translations into almost every European language followed. The book became almost immediately popular in England. The first edition, or rather a French version of it, was translated into English by Lord Berners in 1531, and published in 1534. Before 1560 twelve editions of Lord Berners's translation had been printed, and before 1578 six different translators of this and later works of Guevara had appeared. The translation, however, which had most influence upon English literature was that by North, the well-known translator of Plutarch, in 1568, called *The Dial for Princes, Compiled by the Reverend Father in God Don Antony of Guevara, Byshop of Guadix, &c., Englished out of the Frenche by Th. North.* It was from this book, and from certain other translations from Guevara, of which a full account will be found in Dr Landmann's pamphlet, that Lyly borrowed his peculiar style, and even a certain small proportion of his material. The sententious and antithetical style of the *Dial for Princes* is substantially that of *Euphues*, though Guevara on the whole handles it better than his imitator, and has many passages of real force and dignity. The general plan of the two books is also much the same. In both the biography is merely a peg on which to hang moral disquisitions and treatises. The use made of letters is the same in both. Even the names of some of the characters are similar. Thus Guevara's Lucilla is the flighty daughter of Marcus Aurelius. Lyly's Lucilla is the flighty daughter of Ferardo, governor of Naples; Guevara's Livia is a lady at the court of Marcus Aurelius, Lyly's Livia is a lady at the court "of the emperor," of whom no further description is given. The 9th, 10th, 11th, and 12th chapters of the *Dial for Princes* suggested the discussion between Euphues and Atheos. The letter from Euphues to Alcius is substantially the same in subject and treatment as that from Marcus Aurelius to his nephew Epesipo. Both Guevara and Lyly translated Plutarch's work *De Educatione Liberorum*, Lyly, however, keeping closer than the Spanish author to the original. The use made by Lyly of the university of Athens was an anachronism in a novel intended to describe his own time. He borrowed it, however, from Guevara, in whose book a university of Athens was of course entirely in place. The "cooling card for all fond lovers" and the address to the ladies and gentlemen of Italy have their counterparts among the miscellaneous letters by Guevara affixed by North to the *Dial for Princes*; and other instances of Lyly's use of these letters, and of two other treatises by Guevara on court and country life, could be pointed out.

Lyly was not the first to appropriate and develop the Guevaristic style. The earliest book in which it was fully adopted was *A petite Pallace of Pettie his Pleasure*, by George Pettie, which appeared in 1576, a production so closely akin to *Euphues* in tone and style that it is difficult to believe it was not by Lyly. Lyly, however, carried the style to its highest point, and made it the dominant literary fashion. His principal followers in it were Greene, Lodge, and Nash, his principal opponent Sir Philip Sidney; the *Arcadia* in fact supplanted *Euphues*, and the Euphuistic taste proper may be said to have died out about 1590 after a reign of some twelve years. According to Drayton it was Sidney's chief merit that—

> "He did first reduce
> Our tongue from Lillie's writing then in use,
> Talking of Stones, Stars, Plants, of Fishes, Flyes,
> Playing with words and idle similies,
> As th' English Apes and very Zanies be
> Of everything that they doe heare and see,
> So imitating his rediculous tricks
> They spake and writ all like meere lunatiques."

Shakespeare, Dr Landmann maintains, cannot strictly speaking be said to have ridiculed Euphuism. *Love's Labour Lost* is a caricature of the Italianate and pedantic fashions of the day, not of the peculiar style of *Euphues*. The only certain allusion in Shakespeare to the characteristics of Lyly's famous book is to be found in *Henry IV.*, where Falstaff, playing the part of the king, says to Prince Hal, "Harry, I do not only marvel where thou spendest thy time, but also how thou art accompanied; for, though the camomile the more it is trodden on the faster it grows, yet youth the more it is wasted the sooner it wears." Here the pompous antithesis is evidently meant to caricature the peculiar Euphuistic sentence of court parlance. That Shakespeare indeed was well acquainted with what was the court manual of his youth, and at times reproduces both ideas and phrases from it, has been amply proved by Mr Rushton, the German critic Hense, and others, but there is no evidence of antagonism between the two writers. It might have been otherwise had Lyly's Euphuism affected his plays. But these show little or no trace of Guevara's influence; their faults are the common faults of Elizabethan writing, from many of which Shakespeare himself was not free.

See *Euphues*, from early editions, by Edward Arber, 1868; Professor Ad. Ward's *English Dramatic Literature*, i. 151; Collier's *History of Dramatic Poetry*, iii. 172; *John Lilly and Shakespeare*, by C. C. Hense in the *Jahrbuch der deutschen Shakesp. Gesellschaft*, vols. vii. and viii. (1872, 1873); F. W. Fairholt's *Dramatic Works of John Lilly*, 2 vols., 1858; *Shakespeare's Euphuism*, by W. L. Rushton; "Euphuism" in the *Quarterly Review*, 1861. (M. A. W.)

LYMINGTON, a municipal and parliamentary borough and seaport town of Hampshire, England, is situated on the Lym at its entrance to the Solent opposite the Isle of Wight, 94 miles south-west of London and 15 south of Southampton. The parish church, dedicated to St Thomas à Becket, is an irregular structure, dating from the reign of Henry VI., but frequently restored. There are two grammar schools and several charities. The manufacture of salt and of Epsom salts has been declining for some years. A building yard here has turned out some of the most famous racing yachts. In summer the town is much frequented for sea-bathing. Lymington in Domesday is called *Lentune*, changed afterwards to *Limentum*. It was a borough by prescription, and received a grant of incorporation from James I. From the 27th of Elizabeth till 1867 it returned two members to parliament, and it still returns one. The population of the municipal borough (141 acres) was 2431 in 1881, and that of the parliamentary borough (4769 acres) 5462.

LYNCHBURG, a city in Campbell county, Virginia, U.S., is finely situated on the rising ground to the south of the James river 144 miles by rail, west by south of Richmond. Having excellent facilities of communication by the Richmond and Allegheny, the Norfolk and Western, and the Virginia Midland Railways, together with the James River canal, and possessing abundant water-power and immediate access to coal and iron, Lynchburg has become the seat of no small commercial and industrial activity. The tobacco trade, which formerly rendered it the wealthiest city of its size in the United States, except New Bedford, Mass., is still the staple; there are about eighty factories in the town, and the amount of tobacco sold in 1870-71 was 17,425,439 lb, while in 1880-81 it was 26,000,000 lb. Most of the operatives are negroes—men, women, and children all being employed. The local iron-works and flour-mills are of some importance, and large machine-shops are maintained at Lynchburg by the Norfolk and Western Railway. Two reservoirs, constructed in 1828 and 1878, supply the town with water. The population was 8067 in 1850, 6853 in 1860, 6825 (3353 coloured) in 1870, and 15,959 in 1880.

The town dates from 1786, and derives its name from a Mr Lynch who served in the war of independence and is erroneously credited by some with the origination of the term Lynch law. It was incorporated as a city in 1805. During the civil war it was a point of great importance to the Confederates as a base of supplies.

LYNCH LAW, a term used in the United States to characterize the action of private individuals, organized bodies of men, or disorderly mobs, who, without legal authority, proceed to punish by hanging or otherwise real or suspected criminals, without a trial according to the ordinary forms of law. The origin of the term is doubtful. American lexicographers generally refer it to the practice of a Virginia farmer of the 17th century, named Lynch, who, when he caught a wrongdoer, was wont to tie him to a tree and flog him, without waiting to summon the officers of the law. He is also said to have acted, by request of his neighbours, though without any legal authority, as a judge in the summary trial of persons accused of crime. Others trace the origin of the name to the act of James Fitzstephen Lynch, mayor and warden of Galway, Ireland, in 1493, who is said to have "hanged his own son out of the window for defrauding and killing strangers, without martial or common law, to show a good example to posterity." Others trace it still further to the old Anglo-Saxon verb *linch*, meaning to beat with a club, to chastise, &c., which they assert has survived in this cognate meaning in America, as have many other words and expressions long obsolete in Great Britain. While lynch law does not prevail in the old and well-settled States of the Union, and is almost universally deprecated, it is sometimes resorted to even in these States, in times of great popular excitement, or when the legal penalty seems disproportioned to the enormity of the offence. For example, the practice of lynching is said to have increased in Wisconsin since the abolition of the death penalty by law. Lynch law prevailed to a large extent in the early history of California, Oregon, Nevada, Kansas, Colorado, and other western States and Territories, and during the border troubles attending the outbreak of the civil war. Bodies of citizens, organized secretly or openly under the well-known names of "vigilance committees," "vigilantes," "regulators," "law-and-order-men," &c., punished with summary severity, and generally with wise discretion, horse thieves, highway robbers, burglars and swindlers, as well as murderers. Certain rude forms of trial were generally observed, but acquittals were rare, and the punishment was usually death by hanging. The practice, however barbarous under the conditions of well-settled government and society, has its justification in necessity in the newly-settled districts, frontier towns, and mining camps, where a rapid and extraordinary influx of population has preceded the establishment of civil government, or where the assembling of a large number of bold and hardened desperadoes has enabled them to defy the legally constituted authorities, and to commit crime at will, until suppressed by the voluntary and concerted action of the order-loving portion of the community.

LYNDHURST, John Singleton Copley, Baron (1772–1863), four times lord chancellor of England, was born at Boston, New England, in 1772. His father, son of an Englishman, but also a native of Boston, was a painter of very considerable note, who settled in London just before the commencement of the war of American independence. The son studied at Cambridge, where he was second wrangler and fellow of Trinity. Called to the bar in 1804, he gained a considerable practice; but it was not till 1817 that he began to come to the front. In that year he was one of the counsel for Dr Watson, tried for his share in the Spa Fields riot. On this occasion Copley so distinguished himself as to attract the attention of Castlereagh and other Tory leaders, under whose patronage he entered parliament, and was advanced to the highest legal positions, becoming solicitor-general in 1819, attorney-general in 1824, and lord chancellor in 1827, with the title of Lord Lyndhurst. Before being thus taken up by the Tories, Copley was a man of the most advanced views, a republican and Jacobin; and his accession to the Tories naturally excited a good deal of comment, which he bore with the greatest good humour. He gave a brilliant and eloquent but by no means rancorous support to all the reactionary measures of his chief. The same year that he became solicitor-general he married a fashionable wife, and began to take a conspicuous place in society, in which his noble figure, his ready wit, and his never-failing *bonhomie* made him a distinguished favourite.

As solicitor-general he took a prominent part in the trial of Queen Caroline. To the great Liberal measures which marked the end of the reign of George IV. and the beginning of that of William IV. he gave a vigorous opposition. During the Melbourne administration from 1835 to 1841 he figured conspicuously as an obstructionist from his seat in the House of Lords. In these years it was a frequent practice with him, before each prorogation of parliament, to entertain the House with a "review of the session," in which he mercilessly attacked the Whig Government. His former adversary Lord Brougham, now ineffably disgusted at his treatment by the Whig leaders, soon became his most powerful ally in opposition; and the two dominated the House of Lords. Throughout all the Tory Governments from 1827 Lyndhurst held the chancellorship; and in the Peel administration (1841–46) he resumed that office for the fourth and last time. As Peel never had much confidence in Lyndhurst, the latter did not exert so great an influence in the cabinet as his position and experience entitled him to do. But he continued a loyal member of the party. As in regard to Catholic emancipation, so in the agitation against the corn laws, he opposed reform till his chief gave the signal for concession, and then he cheerfully obeyed. After 1846 and the disintegration of the Tory party consequent on Peel's adoption of free trade, Lord Lyndhurst was not so assiduous in his attendance in parliament. Yet he continued to an extreme old age to take a lively interest in public affairs, and occasionally to astonish the country by the power and brilliancy of his speeches. That which he made in 1853, in denunciation of the aggressive policy of the Russian emperor Nicholas, made a sensation in Europe; throughout the Russian war he was a strong advocate of the energetic prosecution of hostilities. In 1859 he denounced with his old energy the restless ambition of Napoleon III. When he was released from the trammels of an official position, he came forward somewhat as the advocate of liberal measures. He strenuously supported the admission of Jews into parliament; his second wife was a Jewess. Under the influence of Mrs Norton he appeared also as the advocate of women's rights in questions of divorce. At the age of eighty-four he passed the autumn at Dieppe, "helping to fly paper kites, and amusing himself by turns with the writings of the Greek and Latin fathers on divorce and the amorous novels of Eugene Sue." His last speech, marked by "his wonted brilliancy and vigour," was delivered in the House of Lords at the age of eighty-nine. He died in 1863, in his ninety-second year. The impression we have of Lyndhurst from Lord Campbell's memoir is that of a man with rather an easy conscience in political life, not too scrupulous in his attention to judicial duties, but possessed of a fine and noble presence, a ready wit, an unfailing sweetness of temper, and a real kindness and charm of manner that won the hearts of men.

See *Lives of the Lord Chancellors of England*, vol. viii. (Lords Lyndhurst and Brougham), by Lord Campbell, 1869. Campbell was a personal friend, but a political opponent.

LYNDSAY, Sir David (*c.* 1490–1555), for about two centuries and a half perhaps the most popular poet of Scotland, was born about 1490, probably either at the family estate of The Mount, in the parish of Monimail, near Cupar in Fife, or at Garleton near Haddington in East Lothian, where the ruins of an old mansion house of the Lyndsays still remain. Little is known of his boyhood, but he is understood to have entered the university of St Andrews about 1505, and he became one of the *incorporati* of St Salvator's College in 1508 or 1509. After leaving college there is reason to think that he went abroad for a year or two, visiting, it is supposed, both France and Italy; but of this there is no certain information. In 1511 he must have been attached in some way to the court of James IV., as in the October of that year an entry appears in the royal treasurer's accounts for the sum of £3, 4s. for "blue and yellow taffities to be a play coat to David Lyndsay for the play playit in the king and queen's presence in the Abbey of Holyrood,"—so that even at that early period Lyndsay would seem to have developed his taste for masques and mummeries, play-acting and tale-telling. After this his name occurs in the treasurer's accounts for a regular salary of £40 a year; and on the birth of James V. in 1512 he was appointed to be the personal attendant of the young prince, in which situation he remained till James had attained his twelfth year in 1524—sometimes under the title of "keeper of the kingis grace," sometimes as the "kingis maister usher," and sometimes as "the kingis maister of houshald," but throughout with the yearly salary of £40. Lyndsay's close connexion with the court led to his being present at the remarkable scene just before Flodden, in the church of Linlithgow, when the so-called apparition came in "calling loudly for the king," and, after warning him against proceeding on his ill-judged expedition against England, vanishing away "as it had been a blink of the sun or ane whiss of the whirlwind." The incident is related both by Pitscottie and by Buchanan, expressly on the authority of Sir David; and Tytler shrewdly remarks that possibly Lyndsay knew more of the affair than he cared to confess, a conjecture which both Lyndsay's well-known prudence and sagacity in political affairs and his skill in arranging masques and stage plays renders exceedingly probable. In 1522 Sir David married Janet Douglas, of whom we know nothing except that she also was attached to the king's court, and was employed as sempstress to "his grace,"—various payments to her being entered in the accounts for her diligence in the humble office of "sewing the kingis sarkis." It is evident from many passages in Lyndsay's poems that his good sense and sweet temper, his varied accomplishments, and his skill in mingling amusement with instruction had greatly endeared him to the young king, and it would have been well for James if he had never listened to other and worse counsels than those of his wise and affectionate "maister usher."

It is to the credit of the king, however, and characteristic of the generous disposition of the earlier Stuarts, that he never forgot or forsook the friend of his infant and boyish years. For when he fell under the power of the Douglases in 1524, and when Lyndsay had to take his dismissal from court, James took care that his salary should continue to be paid him; and no sooner did he escape from their domination than Lyndsay was at once recalled, and the appointment of lyon-king conferred upon him. This was in 1529, and it is a remarkable proof of the reputation which Lyndsay had by this time acquired for prudence and sterling practical ability that he was at various times sent abroad in connexion with embassies from Scotland. In 1531 he went to the Netherlands to renew the commercial treaty with that country. On this occasion the embassy had a personal interview with the emperor Charles V., and the mission was perfectly successful. A few years afterwards (in 1536) he formed one of the envoys sent to France to conclude a treaty of marriage between the Scottish king and Marie de Bourbon, daughter of the Duc de Vendôme. It is evident therefore that Lyndsay's position and employments must have enabled him to gather much experience of life, and to obtain a somewhat varied knowledge both of men and things. His last sad office to his beloved sovereign was to attend at his bedside when the poor king was dying of a broken heart at Falkland, in December 1542. Lyndsay survived the king about thirteen years. At the time of Cardinal Beaton's assassination he held a seat in parliament as commissioner for the burgh of Cupar. In 1548 he was despatched to Denmark to negotiate a free trade, particularly in grain, for the Scottish merchants, which was readily granted. Mr Laing, on the authority of an entry in the Privy Seal Register, states that his death must have taken place early in 1555.

When Lyndsay was driven from the court by the advent of the Douglases to power, he no doubt felt it as a bitter misfortune and a disappointment of all his highest hopes. But we are greatly mistaken if he did not ere long come to regard it in a very different light. Like most men of genius, he had evidently two sides to his character. On the one side he had a taste for pleasure, sociality, pageantry, and frivolous amusements; and a few years more of these might have deadened his nature to everything else, and converted him into a mere dangler after royalty. But he had also elements of a better kind. He was well educated and accomplished; he had read somewhat extensively, and was master of most of the knowledge to be had in books at that time. He had seen not a little of the world, both in Scotland and in foreign countries; he was an acute discerner of character, and had both knowledge of and skill in affairs. Now then was just the time for a man like him, arrived at the full maturity of his intellect, to turn all these varied acquisitions to account. Lyndsay therefore, we may infer, retired to his country seat, either at The Mount, or as we fancy more likely to Garleton (that he might be more within call should a change take place in the political situation at Edinburgh), and there, after the first dull pang of disappointment was over, he doubtless found that there was no lack of subjects to engage his best thoughts. One of the great crises in the history of Europe and in the progress of human thought had just arisen. The trumpet of the Reformation had been sounded in Germany, and its reverberation had already been heard in Scotland, where both political and ecclesiastical disorder had nearly reached their worst, and were becoming the source of deep anxiety and desire for redress to all good men. For Lyndsay, therefore, there was something else to do than to brood moodily over his own private griefs. He had to make up his mind on a variety of great public questions, as well perhaps as to settle the great personal question of his own religious faith; and in his earliest work, *The Dreme*, which seems to have been composed at this time, we have a somewhat vivid picture of the turn his thoughts took.

He represents himself as having spent the long winter night without sleep, "through heavy thought, remembering of divers thingis gone." On getting up and walking out, he finds the dull winter season, with its bitter blasts and sharp sleety showers, but ill-fitted to console him, and only too much in harmony with his own melancholy. He goes down to the sea-shore, but things are no better there; for the "weltering of the waves" at once associates itself in his mind with "this false warld's instability." Thus far, then, his meditations seem to have had a merely personal reference. But by and by, on retiring into a cave near the shore, he falls into a trance, in which his thoughts take a wider range. The miserable state of his country, from misgovernment on the part of its rulers and the vices of both clergy and laity, fills his mind, and, reflecting on the ultimate fate of such men, he finds himself in the twinkling of an eye in hell, where he sees wicked popes, kings, conquerors, princes, and lords temporal, with no end of churchmen, "mansworn merchants," "unleil laboraris," craftsmen "out of number," "hurdaris of gold and common occararis," all "tormentit with pains intolerable." Then, leaving this "dolorous dongeon," he has a passing sight of purgatory, though apparently with some misgiving as to its reality, his significant remark being—

> "Sic things to be great clerkis does conclude,
> Howbeit my hope stands most in Chris'is blood."

Proceeding then to the realms of bliss, he sees something of the rewards of good and just rulers and righteous men; and by and by returning to the earth, and at length looking down upon Scotland, he sees a region both good and fair, its seas abounding in fish, its mountains covered with pasture, the valleys fit for corn, the forests full of game, mines with gold and silver, the people fair, intelligent, strong, and noble-minded,—and yet with all this, the country poor and the inhabitants miserable. What could be the cause? and the answer given is that the realm wants good government, impartial administration of justice, and freedom from war and discord. Viewing the country all over—on the borders

> "Betwixt the Merse and Lochmaben,
> He could not knaw a leil man from a thief.
> To show their reif, theft, murther and mischief,
> And vicious works, it would infest the air."

In the Highlands it was no better:—

> "Unthrift, sweirness, falset, poverty, and strife
> Put policy in danger of her life."

And even in the Lowlands, where better things might be expected, it was impossible for a poor man to live by his industry. If he settled in the towns, "singular profet" (by which we understand him to mean the system of monopolies and of close trade corporations, which everywhere prevailed) "gart him soon dislodge." And if he attempted to get redress to his wrongs there was no help for him anywhere. The spiritual state, plunged in simony, covetousness, pride, ambition, sensuality, and the love of pomp and pleasure, "held him at disdain"; and among the nobility and gentry "liberality and lawté both are lost," knightly courage is "turnit in brag and boast," and disorder and civil war have produced a state of things in which "there is nocht else bot ilk man for himself." The moral of the whole is—"Woe to the land that has ouer young ane king!"—"there sall na Scot have comforting till that I see the country guided by wisdom of ane gude auld prudent king." The poet is then awakened by the sound of cannon from a ship of war approaching the coast,—the suggestion, as we imagine, being that the existing state of things can only end in violence and uproar, in tumult and rebellion, most probably in foreign invasion and revolution.

On the whole *The Dreme* appears the most finished and artistic of Lyndsay's works. It has a tone of greater seriousness, bears the marks of more care and elaboration in the composition; and, though it has a good deal of the crudeness of a first attempt, we think we can discover an effort at least at a finer proportion and harmony of parts than in any of his subsequent poems. In its subject-matter it strikes the keynote of almost all that he afterwards wrote. The evils, the wrongs, the misgovernment of his country evidently filled his whole soul with grief, indignation, and the desire for reform; and we almost doubt if there is to be found anywhere except in the old Hebrew prophets a purer or more earnest breathing of the patriotic spirit. Indeed if we may judge from the motto prefixed to his *Dreme* we should almost fancy that he had made them his model:—*Prophetias nolite spernere. Omnia autem probate: quod bonum est tenete.* Lyndsay accordingly is to be judged of less as a poet than as a great political and ecclesiastical reformer. That his works are written in verse is merely incidental. Though not destitute of poetical genius, this was scarcely the special characteristic of his mind. His greatest work, and the only one to which it is necessary here to make further allusion, was his *Satire of the Three Estates*. It is a drama, and may be said to be in some respects one of the most remarkable that ever was written. The *dramatis personæ* are chiefly allegorical, and under the names of Rex Humanitas, Wantonness, the Vices (Flattery, Falset, and Deceit) in the habit of friars, King Correction, Good Counsel, Temporality, Sensuality, Chastity, Verity, John the Commonweal, &c., the most bitter and unsparing exposure is made of the wickedness and corruption of all classes of the community. King, clergy, lords, merchants, craftsmen —no one escapes the severest censure and the most unmitigated ridicule. And yet this extraordinary production was acted on the borough muir of Edinburgh before the king himself, many of the highest nobility and clergy, and an immense crowd of all classes of the people. How the author escaped being torn in pieces by the mob or burnt at the stake by the ruling powers it is difficult to understand. Perhaps the explanation is that each class saw every other brought under the lash equally with itself, and felt consoled for its own shame by enjoying the infliction visited on its neighbours. Very likely too the grotesque wit and the fun with which the serious matter of the play was so largely spiced charmed the audience into good humour, and left them unable to think of vengeance. It may be somewhat confidently inferred too that the dramatist so exactly expressed the public feeling of the time as to the evils and corruption under which the state was rapidly going to destruction that, even when his stinging reproaches most nearly touched themselves, their consciences were smitten and they were compelled to assent to the perfect truth and justness of his rebukes. But be this as it may, there can hardly be a doubt that this most singular drama formed one of the chief means by which the way was paved for the Reformation afterwards carried out by Knox and his coadjutors.[1] One thing is especially remarkable in Lyndsay's politics both civil and ecclesiastical, that, hopeless and depressing as the condition of the country must have been to a man like him, his opinions never end in mere negations, but are throughout constructive in their character. And yet more thoroughgoing radicalism it would be difficult elsewhere to find. He does not for example scruple to declare that kings who govern ill should be deposed. This, however, was merely a speculative opinion, and it is of more interest to ascertain what his practical suggestions were. Among them we find the following:—that the king should on no account attempt to do anything without the advice of his council and parliament; that John the Commonweal should have a greater voice in parliament, *i.e.*, in our modern phrase, that there should be a considerable extension of the franchise; that (as already mentioned) all close corporations and monopolies should be abolished; that temporal lands should be set in feu to the tenants on condition of their duly rendering the prescribed services to the state, a measure not very dissimilar in principle (if we understand it aright) to that lately introduced into Ireland; that lords should be responsible for thieves who find refuge on their lands, and make restitution to the poor who have been plundered by them; that courts of justice should be established in the remoter parts of the country, such as Elgin and Inverness, in order to avoid the expense attendant on the transference of pleas to the metropolis, and, to provide for their maintenance, the nunneries in that quarter to be abolished and their revenues sequestrated, the reason given being—

> "Thir wanton nuns are na way necessair
> Till common-weill, nor yet to the glorie
> Of Christis kirk, thocht they be fat and fair,
> And als that fragile order feminine
> Will nocht be missit in Christ's religion."

No less stringent and sweeping are his proposals for the reform of the church. The religion of Christ must be purged of all deceit and hypocrisy. The consistorial courts are to have no jurisdiction in matters temporal. No clergyman is to be admitted to office unless duly qualified in learning and piety. Celibacy is to be abolished. Bishops and priests must be compelled to preach regularly and "take better tent to souls under their dominion." Benefices are not to be purchased either from prince or pope, nor is money to be permitted to go to Rome for bulls and pleas. Pluralities and patronage are to be abolished, residence is to be enforced, and the people are to have a voice in the choice of their spiritual guides. In fact many of Lyndsay's proposals of reform have quite a modern look, and this perhaps explains in some degree the long-continued popularity of his works among his countrymen, which otherwise it is rather difficult to account for. They have none of the chivalric spirit-stirring power of many of our ancient songs and ballads, none of the tender love and melancholy which form the charm of Burns's lyrics, none of the joyous abandon of convivial or amorous ditties, and none of the fascination which springs from well-constructed tales or narrative poems, like those of Chaucer or Scott. It is difficult to suppose that even the humour which pervades them, seldom of the most refined kind and often very much the reverse, can have been in any great degree pleasing to readers of a later age than the author's own. The only explanation, we suspect, is that Lyndsay's intense and uncompromising love of liberty, his strong sympathy with the poor, his love of justice, his keen hatred of tyranny, wrong, and oppression, and his shrewd common sense easily found a responsive chord in Scottish bosoms. Nor was the interest which his works so long retained among the Scottish peasantry merely of a sentimental kind. For many of the evils against which he directed his severest invectives continued long afterwards to afflict his country, and even when somewhat changed in their aspect still reappeared in analogous forms or character. Prelatic usurpation and cruelty were as rife as ever in the century which succeeded that in which Lyndsay wrote; aristocratic venality and heartlessness have perhaps even yet hardly ceased out of the land; church patronage, always hateful to religious-minded Scotsmen, was hardly abolished before it was reimposed. And then such incidents as the massacre of Glencoe, the union with England, a measure intensely disliked by the great mass of the Scottish people, the infamous treatment of the Darien colonization scheme, the barbarities which followed the two Jacobite rebellions, the deprivation up to 1832 of any true parliamentary representation, and the continuance of close municipal and trade corporations, all tended to keep up a bitter sense of wrong to which Lyndsay's satires gave point and expression.

The best accessible editions of Lyndsay's works are those of George Chalmers, in 3 vols., London, 1806, and of David Laing, also in 3 vols., Edinburgh, 1879. These, with the Early English Text Society's edition, leave little to be desired for the establishment of a correct text, and for purely antiquarian illustration. In Warton's *History of English Poetry*, and in Irving's *History of Scottish Poetry*, good critical estimates will be found of Lyndsay's place as a poet. It is possible, however, that something yet remains to be done in order to determine his exact position as a great political and religious reformer, and to illustrate the effect which his works have had in directing popular feeling and opinion in Scotland. (J. T. BR.)

LYNN, a city in Essex county, Massachusetts, U.S., situated near the north end of Massachusetts Bay, on a harbour formed by the peninsula of Nahant, 10 miles north-east of Boston, with which it is connected by different lines of railway. The bulk of Lynn is built on the low grounds near the sea; but in the north-east the elevation is greater, and behind the city proper there is a range of porphyritic hills dotted with villas. Most of the houses are of wood, those of the main thoroughfare—Market Street—of brick. The city hall, a substantial erection of brick and brown stone, is considered one of the finest buildings of its class in New England. It contains the free public library, founded in 1862, and numbering 29,126 volumes in 1880. It was at Lynn that the first smelting-works in this part of the country were established, in 1643; but the place has long been famous rather for the making of boots and shoes, a department, indeed, in which it has hardly a rival in the world. This trade was introduced in 1750 by a Welshman, John Adam Dagyr; in 1767 the output was 80,000 pairs; in 1810, 1,000,000 pairs; in 1865, 5,360,000; in 1868 upwards of 10,000,000; and in 1880, 16,276,380,—the greater proportion being cheap shoes for women and children. About twelve thousand hands are employed, though labour-saving machinery is freely introduced. Another industry of great local importance is the tanning and dressing of sheep and goat skins, and the making of morocco leather. The population was 6138 in 1830, 14,257 in 1850, 28,233 in 1870, and 38,284 in 1880.

The foundation of the town belongs to 1629; and the name was given in memory of Lynn Regis in England, the home of its first pastor. It obtained incorporation as a city in 1850; Swampscott and Nahant, which it then included, were rendered independent in 1852 and 1853 respectively.

LYNN REGIS, KING'S LYNN, or LYNN, a parliamentary and municipal borough and seaport of Norfolk, England, is situated on the Great Ouse, about 2 miles from the Wash, and on several railway lines, 100 miles north of London and 48 west-north-west of Norwich. On the land side the town was formerly defended by a fosse, and there are still considerable remains of the old wall, including a handsome Gothic structure, known as the "South Gates." The streets are generally narrow and winding; some of the dwelling-houses are very ancient. The public walks form a fine promenade, and in the centre of them stands a quaint octagonal chapel called the Red Mount, at one time much frequented by pilgrims. The church of St Margaret's, formerly the priory church, is a fine Gothic building with two towers at the west end, one of which was formerly surmounted by a spire blown down in 1741. St Nicholas chapel, at the north end of the town, is also of mediæval date, and contains many interesting memorials of the past. All Saints church is a beautiful and ancient cruciform structure. At the grammar school, founded in the reign of Henry VIII., Eugene Aram was at one time usher. There are also national schools, a British school, and several charities. Among the other public buildings are the guildhall, with Renaissance porch, the corn exchange, the custom-house, and the athenæum. The shipping trade is steadily progressing, and there is now regular steam communication with Hamburg. The principal exports are corn, wool, and oilcake, and the principal imports, coal, timber, linseed, and manufactured goods. The total value of the exports in 1880 was £1,152,456, the average for the four years 1876–79 being £967,958, and for four years 1872–75 £519,479. The value of the exports in 1880 was £366,649, the average value for 1876-79 being £251,491, and for 1872-75 £140,974. The Alexandra dock, opened in 1869, has a water area of $6\frac{3}{4}$ acres, with an average depth of 31 feet. The fisheries of the town are important, and there are also breweries, corn-mills, iron and brass foundries, agricultural implement manufactories, shipbuilding yards, rope and sail works, and tobacco manufactories. The population of the borough in 1871 was 16,562, and in 1881 it was 18,475.

Lynn is supposed to have been a British town, and was known as a port before the Norman invasion, after which it became the possession of the bishops of Norwich, and was known as Lynn Episcopi. After the suppression of the monasteries it came into the hands of Henry VIII., and its name was changed to Lynn Regis or King's Lynn. The town was taken by the parliamentary forces in 1643. It received its first charter from King John, but its first governing charter from Henry VIII. Since the 23d of Edward I. it has returned two members to parliament.

LYNX, a name now appropriated to several animals forming a small section of the cats or genus *Felis*. It is not quite certain to which of these, if to any of them, the Greek name λύγξ was especially applied, though it was more probably the caracal than any of the northern species. The so-called lynxes of Bacchus were generally represented as resembling panthers rather than any of the species now known by the name. Various fabulous properties were attributed to the animal, whatever it was, by the ancients, that of extraordinary powers of vision, including ability to see through opaque substances, being one; whence the epithet "lynx-eyed," which has survived to the present day, although having no foundation in fact.

There are two forms of cats which are now called lynxes.

1. The caracal or Persian lynx, *Felis caracal*, an animal about the size of a fox, is of slender build, with a moderately long tail, reaching down to the heels. It is of a uniform vinous or bright fulvous brown colour above, and is paler, sometimes almost white, beneath. It is quite or almost entirely unspotted. The tail has a black tip, and the ears are black externally, long and upright, pointed, and surmounted by a pencil of fine black hairs. It inhabits Central and North-West India, Persia, Arabia, Syria, and the greater part of Africa.

2. The name lynx is given to various species or varieties of animals found in the northern and temperate regions of both the Old and New World, all of moderate size, that is, smaller than the lions, tigers, and leopards, and larger than the true cats, with long limbs, short stumpy tail, ears tufted at the tip, and pupil of the eye linear when contracted. Their fur is generally long and soft, varying, however, according to season and locality, and always longish upon the cheeks. Their colour is always light brown or grey, and generally more or less spotted with a darker shade. The naked pads of the feet are more or less covered by the hair that grows between them. The skull and skeleton does not differ markedly from those of the other cats, but the small anterior upper premolar tooth found in many other species is usually wanting. Their habits are exactly those of the other wild cats; they are excelled by none in the untameable savageness of their disposition. They capture their prey in the same manner, either lying in wait, or noiselessly stealing within reach, and then making a sudden rush or spring upon it. Their food consists of any mammals or birds which they can overpower. In inhabited countries they commit extensive ravages upon sheep, lambs, and poultry. They generally frequent rocky places and forests, being active climbers, and passing much of their time among the branches of the trees. Their skins are of considerable commercial value in the fur trade.

Zoologists are by no means agreed at present as to the specific distinctions, if any really exist, between the various modifications of this group. As many as eight species are sometimes recognized, four belonging to the Old and four to the New World. The former are *Felis lynx*, of Scandinavia, Russia, northern Asia, and till lately the forest regions of central Europe (it has not inhabited Britain during the historic period, but its remains have been found in cave deposits of Pleistocene age); *F. cervaria*, Siberia; *F. pardina*, Turkey, Greece, Sicily, Sardinia, and Spain; and *F. isabellina*, Tibet. The American varieties are *F. canadensis*, the most northern species, and *F. rufa*, the

European Lynx. From a Drawing by Wolf in Elliot's *Monograph of the Felidæ*.

American wild cat or bay lynx, extensively distributed from the Atlantic to the Pacific throughout nearly the whole latitude of the United States, but replaced in Texas and southern California by *F. maculata*, and in northern Oregon and Washington territory by *F. fasciata*.

In both cases, as might be supposed, specimens obtained from the more southern climates are shorter in their fur, more brightly coloured, and more distinctly spotted than those from colder regions. When only a few individuals of each most markedly different form are examined the distinctions are sufficiently evident. The occurrence, however, of transitional or intermediate forms makes it extremely difficult to draw the line between the different varieties or species, or to assign definite characters by which they can be separated. Wherefore it is best at present to accept the so-called species as only provisional, and wait until more abundant materials, with fuller knowledge of the localities from which they are derived, and of the variations due to age, sex, season, and climate, have been more carefully studied. We shall then probably come to the conclusion that all the existing forms of northern lynxes, whether American or Eurasian, belong to what may fairly be called a species, which is becoming by degrees differentiated into several more or less strongly marked local varieties. (W. H. F.)

LYONS (French, *Lyon*), in political, commercial, industrial, and military importance, as well as in point of size, the second city of France, formerly the capital of Lyonnais, and now the chief town of the department of Rhone, seat of a court of appeal and of a military government, and a fortified place, is situated at the confluence of the Rhone and the Saône, in 45° 46′ N. lat. and 4° 49′ 19″ E. long., at an altitude above the sea varying from 540 to rather more than 1000 feet. The population of the city and liberties in 1876 was 342,815. The rivers, both flowing south, are separated by the hill of Croix-Rousse. On the right the Saône is bordered by the scarped heights of Fourvières, St Irénée, and Ste Foy, leaving room only for the quays and one or two narrow streets; this is the oldest part of the city. Where it enters Lyons the Saône has on its right the faubourg of Vaise and on its left that of Serin, whence the ascent is made to the top of the hill of Croix-Rousse. The river next takes a semicircular sweep around the hill of Fourvières (410 feet above it), which is fully occupied by convents, hospitals, and seminaries, and has at its summit the famous church, the resort of 1,500,000 pilgrims annually. From this point the best view of the entire city is obtained. First the busy Saône is seen with its thirteen bridges and animated quays. Next, on the peninsula between the two rivers at the foot of the hill of Croix-Rousse, come the principal quarters of

the town: the Terreaux, containing the hôtel de ville, the prefecture, and the chief commercial establishments; Bellecour with its large open square, one of the finest in Europe; and the aristocratic Quartier de Perrache. The Rhone and Saône formerly met here, till, a hundred years ago, the sculptor Perrache reclaimed from the rivers the quarter which bears his name; on the peninsula thus formed stands the principal railway station. Here too are the docks of the Saône, factories, the arsenal, gas-works, prisons, and the slaughter-house.

The Rhone, less confined than the Saône, flows swiftly in a wide channel, broken when the water is low in spring by pebbly islets. On the right hand it skirts first St Clair, sloping upwards to Croix-Rousse, and then the districts of Terreaux, Bellecour, and Perrache; on the left it has a low-lying plain, subject to disastrous inundations, occupied by the Parc de la Tête d'Or and the quarters of Brotteaux and Guillotière. The park, defended by the Grand Camp embankment, comprises 282 acres, and contains a zoological collection, botanical and pharmaceutical gardens, and the finest greenhouses in France, with unique collections of orchids, palm-trees, and *Cycadaceæ*. Brotteaux is a modern town with boulevards and regular streets, and in this direction Lyons is extending every year. In the old districts there is no room for growth; they are crowded with old buildings of eight or ten stories, or even more, and it has been the task of the last thirty years to open them up by means of thoroughfares. Guillotière, to the south, is a workmen's quarter of wretched houses.

The Rhone is lined with broad quays, and crossed by ten fine bridges, two of them for railway traffic. On the right bank stand the lycée and the public library, the Hôtel Dieu, the military hospital, and the Hospice de la Charité; on the left bank is the long range occupied by the medical faculty. In the east of Guillotière the Geneva railway skirts the artillery barracks.

Northward from Fourvières appear the green slopes of Mont d'Or, descending towards the Saône by pleasant glades sprinkled with villas; to the east, beyond the somewhat monotonous plain, stretch the mountains of Savoy and Dauphiné; to the south, below the confluence of the Rhone and the Saône, the river traverses a rich landscape to pass out of sight at the foot of Mont Pilat; and to the west the horizon is bounded by the Forez hills.

Since 1852 the communes of Croix-Rousse and Guillotière have been united with Lyons. The Rhone and the old fortifications, which, on the right bank of the Saône, stretched in an unbroken line from the rock of Pierre Scize below Vaise to the bridge of Ainay, continued by those now replaced by the Croix-Rousse boulevard, marked the boundaries of the ancient city. The line of Croix-Rousse has now been thrown forward to the north, and further strengthened by Forts Caluire and Montessuy. On the left bank of the Rhone stand Forts Tête d'Or, Charpennes, Brotteaux and Part-Dieu, Villeurbanne, Lamotte, Colombier, and Vitriolerie. On the right bank of the Saône Forts Ste Foy, St Irénée, Loyasse, Vaise, and Duchère completed the defensive system of Lyons previous to 1870; but since that date the dominant points of the neighbourhood have begun to be crowned with batteries and redoubts; but only Forts Brou and Feyzin on the left bank of the Rhone, St Genis on the right bank, Mont Verdun on Mont d'Or, and Vencia are finished.

Of the ancient buildings in Lyons, Fourvières is the one which attracts most visitors. It derives its name from the ancient forum (*Forum vetus*), whose site it occupies. The first chapel, dedicated to the Virgin, was erected in the end of the 9th century. Consecrated afterwards to St Thomas of Canterbury, and then made a collegiate church, Notre Dame de Fourvières was created superior of twenty-five villages by Louis XI., on occasion of his visit in 1476. Laid waste by the Protestants, plundered at the Revolution, it began to be visited again in 1804, and in 1805 Pope Pius VII., returning from the coronation of Napoleon, ascended thither to give his benediction to the city—a ceremony renewed from year to year with great pomp. The church tower, 172 feet high, is surmounted by a statue of the Virgin in gilded bronze, 18 feet high, turned towards the town; on the pedestal are bronze plates with inscriptions assigning to the Virgin the credit of ending the plague of 1643, and of preserving the town during the cholera epidemics of 1832, 1835, and 1850. The first stone of a magnificent new church was laid in 1872. The crypt, 219 feet by 62, is as yet the only portion finished. At the foot of Fourvières, on the right bank of the Saône, lies the metropolitan church of St John (the archbishop of Lyons is primate of all Gaul). The choir belongs to the early years, the transept to the close of the 12th century; the building of the nave, carried on during the next three hundred years, was completed only in 1480. In one of the two towers there is a bell weighing nearly 10 tons. To the right and left of the altar stand two crosses preserved since the council of 1274 as a symbol of the union then agreed upon between the Greek and Latin Churches. St Martin d'Ainay, in the Perrache quarter, is the oldest church in Lyons, dating from the beginning of the 6th century; the chapels of the apse are adorned by paintings by Flandrin. St Nizier, in the heart of the city, was the first cathedral of Lyons; and the crypt in which St Pothinus officiated still exists. The present church is a Gothic edifice of the 15th century, with the exception of the porch, constructed by Philibert Delorme. In the crypt of the church of St Irenæus are the tomb of that saint and a vast quantity of bones, alleged to be those of 19,000 martyrs put to death in the persecution of Severus. The Place Bellecour is adorned west and east by two monumental façades originally erected after plans by Mansard, but destroyed in 1793, and rebuilt under the consulate in a somewhat modified style. In the middle stands an equestrian statue of Louis XIV. by Lemot. The Rue de l'Hôtel de Ville, connecting the Place Bellecour and the Place des Terreaux, and the Rue de la Republique running parallel with it are among the finest streets of the modern city. The east side of the Place des Terreaux (so called from the "terreaux" now occupying the place of the canal which formerly connected the Rhone and the Saône) is formed by the hôtel de ville, which, however, turns a better front in the opposite direction towards the theatre; the south is occupied by the Palais St Pierre (formerly a convent), which gives accommodation to the faculties of science and literature, and to the school of fine arts, the picture gallery, the museums of sculpture, archæology and natural history, and the art library. In the Rue de la Republique, between Place de la Bourse and Place des Cordeliers, each of which contains one of its highly ornamented fronts, stands the building occupied by the exchange and the commercial court. The former has its offices on the ground floor round the central glass-roofed hall; besides the court, the upper stories accommodate the council of prud'hommes, the chamber of commerce, and the industrial museum. The palais de justice, a fine building with a Corinthian colonnade, on the right bank of the Saône, occupies the site of the palace of the counts of Forez. A statue of Jacquart the inventor stands in Place Sathonay, and one of Marshal Suchet in Place Tholozan.

The Academy of Lyons has the five faculties of Catholic theology, science, literature, medicine and pharmacy, and law, with two lyceums, and a number of schools; and the Catholic institute has three faculties—law, science, and theology. The school of fine arts was founded in the 18th century to train competent designers for the textile manufactures, but has also done much for painting and sculpture. The veterinary school of Lyons, instituted in 1761, was the first of its kind in Europe; its laboratory for the study of comparative physiology is admirably equipped. L'École la Martinière (founded by the legacy of Claude Martin) furnishes gratuitous teaching of the sciences and industrial arts. The school of commerce and the Lyons central school complete the list of institutions for industrial education.

Besides the Académie des Sciences, Belles Lettres, et Arts (founded in 1700), Lyons possesses societies of agriculture, natural history, useful arts and sciences, geography, and horticulture.

The Hôtel Dieu, instituted in the beginning of the 6th century by King Childebert, is still one of the chief establishments of its kind in the city, and contains 929 beds. Its façade, fronting the Quai du Rhone for 1060 feet, was commenced according to the designs of Soufflot, architect of the Pantheon at Paris. The Hospice de la Charité and the military hospital are a little larger than the Hôtel Dieu. The Hospice de l'Antiquaille, at Fourvières (2000 beds), occupies the site of the ancient palace of the prætorian prefects, in which Germanicus, Claudius, and Caracalla were born. Lyons has many other benevolent institutions, and is also the centre of the operations of the Propagation de la Foi.

The museum is one of the best provincial collections in France, alike in its ancient, mediæval, and modern departments. Among the Gallo-Roman inscriptions, in which it is particularly rich, are the bronze tables discovered at Lyons in 1528, which contain the speech of the emperor Claudius in regard to the admission of the citizens of Gallia Comata into the Roman senate. The numismatic collection (30,000 pieces) includes a series of the coins struck at Lyons from 43 B.C. to 1857. There is a special gallery of works of Lyonese painters; and the Bernard collection of about 300 pictures is kept entire.

The museum of natural history (for which a new building is to be erected in the Parc de la Tête d'Or) contains a zoological department ranking next to that of Paris, and mineralogical, geological, and anthropological sections—the last enriched with specimens from the classic site of Solutré (Saône and Loire). The museum of art and industries, founded in 1864 by the chamber of commerce, is divided into three sections, the first intended to illustrate the various conceptions of the beautiful formed by different peoples, the second to show the whole method of the textile industry, and the third to give an historical conspectus of woven textures. The Guimet Museum, in a special building in the Tête d'Or, consists of objects brought from the extreme East (mainly by M. Émile Guimet) and designed to facilitate the comparative study of religions, especially those of the Eastern world. Since 1880 the institution has published its *Annales*, consisting of original essays or translations of foreign works.

The library of the school of arts contains 65,000 volumes and 22,000 engravings, and the town library 108,000 volumes and 1300 manuscripts,—about 600 of the printed works being incunabula, and 25 of the MSS. belonging to the Carlovingian period. In the latter institution is the great terrestrial globe made at Lyons in 1701, indicating the great African lakes, the rediscovery of which has been one of the events of the present century.

Under the Romans Lyons was admirably provided with water. Three ancient aqueducts on the Fourvières level, from Montroman, Mont d'Or, and Mont Pilat, can still be traced; and the last was no less than 52 miles long, and capable of supplying 11,000,000 gallons per day. Magnificent remains of this work may be seen at St Irénée and Chaponost. Traces also exist along the Rhone of a subterranean canal conveying the water of the river to a naumachia. At present the water supply of Lyons is obtained from the Rhone by powerful hydraulic engines situated above the town, which raise the water to the Montessuy and the Fourvières plateaus, 456 feet above the low level of the river. The reservoirs are capable of supplying 1,765,829 cubic feet of water per day.

Agrippa made Lyons the starting-point of the principal Roman roads throughout Gaul; and it still remains an important centre in the general system of communication. The Saône above the town and the Rhone below have large barge and steamboat traffic; and the latter river above the town may be used by steamboats during summer as far as Aix in Savoy. Navigation, however, is often interrupted, even below the town, by the lowness of the water, and a canal is projected to remedy this defect. The current of the Saône is less rapid than that of the Rhone, and is controlled by weirs.

The railway from Paris to Marseilles has two stations (Vaise and Perrache) in Lyons; and the line from Lyons to Geneva two (Brotteaux and St Clair). The Montbrison line starts from St Paul, on the right of the Saône. The terminus of Part-Dieu for the newly-opened East of Lyons line is between Perrache and Brotteaux. Within the town there are two rope railways,—the first mounting to Fourvières, and the second, popularly called the *ficelle*, from Rue Terme to Croix-Rousse.

In a city of such importance as Lyons the number of industries is naturally large, but by far the most extensive of them all is the silk manufacture. Derived from Italy, this industry rapidly developed under the patronage of Francis I., Henry II., and Henry IV.; and from time to time new kinds of fabrics were invented—silk stuffs woofed with wool or with gold and silver threads, shawls, watered silks, poplins, velvets, satinades, moires, &c. In the beginning of the present century Jacquart introduced his famous loom by which a single workman was enabled to produce elaborate fabrics as easily as the plainest web, and by changing the "cartoons" to make the most different textures on the same looms. In the 17th century the silk manufacture employed at Lyons 9000 to 12,000 looms. After the revocation of the edict of Nantes the number sank to 3000 or 4000; but after the Reign of Terror was past it rose again about 1801 to 12,000. At present there are about 70,000 in operation when no great commercial crisis comes to diminish production, giving employment to about 140,000 weavers. There are also a large number of persons engaged in the silk-worm hatcheries established in France. The workmen live for the most part in the Croix-Rousse quarter, but many of them inhabit the outskirts. The mean annual value of the silk goods manufactured is estimated at 375,000,000 francs (£15,000,000),—250,000,000 representing the value of the raw material and 125,000,000 the value of the labour. Including the purchase of raw materials and the sale of the manufactured goods, the silk trade gives a total turnover of 1000 million francs (£40,000,000). A special office (known as *La Condition des Soies*) determines the weight and nature of the silk. Extensive dye-works, chemical works, breweries, pork factories, engineering works, printing establishments, and hat factories represent the secondary industries of the place. A large trade is carried on in chestnuts brought from the neighbouring departments, and known as *marrons de Lyon*.

The earliest Gallic occupants of the territory at the confluence of the Rhone and the Saône were the Segusians. In 59 B.C., some Greek refugees from the banks of the Hérault, having obtained permission of the natives to establish themselves beside the Croix Rousse, called their new town by the Gallic name Lugdunum; and in 43 B.C. Munatius Plancus brought a Roman colony to Fourvières from Vienne. This settlement soon acquired importance, and was made by Agrippa the starting point of four great roads. Augustus, besides building aqueducts, temples, and a theatre, gave it a senate and made it the seat of an annual assembly of deputies from the sixty cities of Gallia Comata. Under the emperors the colony of Forum Vetus and the municipium of Lugdunum were united, receiving the *jus senatus*. The town was burnt by Nero in 59 A.D., and afterwards rebuilt by him in a much finer style; it was also adorned by Trajan, Adrian, and Antoninus. The martyrdom of Pothinus and Blandina occurred under Marcus Aurelius (177 A.D.), and in 197 a still more savage persecution of the Christians to k place under Septimius Severus, in which Irenæus, according to some authors, perished. After having been ravaged by the barbarians and abandoned by the empire, Lyons in 478 became capital of the kingdom of the Burgundians. It afterwards fell into the hands of the Franks, and suffered severely from the Saracens, but revived under Charlemagne, and after the death of Charles the Bald was made the capital of the kingdom of Provence. From 1024 it was a fief of the emperor of Germany. Subsequently the superiority over the town was a subject of dispute between the archbishops of Lyons and the counts of Forez; but the royal supremacy was finally established under Louis IX. and Philip the Handsome. The citizens were constituted into a commune ruled by freely elected consuls (1320). In the 13th century two ecclesiastical councils were held at Lyons—one in 1245, presided over by Innocent IV., at which the emperor Frederick II. was deposed; the second, the œcumenical, under the presidency of Gregory X., in 1274, at which five hundred bishops met. Pope Clement V. was crowned here in 1305, and his successor John XXII. elected in 1316. The Protestants obtained possession of the place in 1562; their acts of violence were fiercely avenged in 1572 after the St Bartholomew massacre. Under Henry III. Lyons sided with the League; but it pronounced in favour of Henry IV. In 1793 it rose against the Convention, but was compelled to yield to the army of the republic after enduring a siege of seven weeks (October 10). Terrible chastisement ensued: the name of Lyons was changed to that of Ville-affranchie; the demolition of its buildings was set about on a wholesale scale; and vast numbers of the proscribed, whom the scaffold had spared, were butchered with grape shot. The town resumed its old name after the fall of Robespierre, and the terrorists in their turn were drowned in large numbers in the Rhone. Napoleon rebuilt the Place Bellecour, reopened the churches, and made the bridge of Tilsitt over the Saône between Bellecour and the cathedral. In 1814-15 Lyons was occupied by the Austrians, under the government of Louis Philippe, and in 1870-71 there were several bloody émeutes; in 1856 a disastrous flood laid waste the Brotteaux and rendered 20,000 persons homeless. An international exhibition was held here in 1872. Among the many distinguished natives of Lyons may be mentioned Germanicus and the emperors Claudius, Marcus Aurelius, and Caracalla; Ampère the physicist; Richerand, Récamier, and Bonnet; De Jussieu the naturalist, J. B. Say the economist, Barême the mathematician, Suchet the marshal, Roland the Girondin, and Jacquard the inventor. (G. ME.)

LYONS, EDMUND LYONS, LORD (1790-1858), British admiral, was descended from a family connected with Antigua, and previously with Cork, and was born at Burton near Christchurch, Hampshire, 21st November 1790. He entered the navy at an early age, and served in the Mediterranean, and afterwards in the East Indies, where in 1810 he won promotion by distinguished bravery. He became post-captain in 1814, and in 1828 commanded the "Blonde" frigate at the blockade of Navarino. He took part with the French in the capture of the castle of Morea, receiving for his conduct the orders of St Louis of France and of the Redeemer of Greece. Shortly before his ship was paid off in 1835 he was knighted. From 1840 till the outbreak of hostilities with Russia Lyons was employed on the diplomatic service, being minister plenipotentiary to the court of Greece until 1849, then until 1851 ambassador to the Swiss cantons, whence he was transferred to a similar position at Stockholm. On the outbreak of the war with Russia he was appointed second in command of the British fleet in the Black Sea under Admiral Dundas, whom he succeeded in the chief command in 1854. As admiral of the inshore squadron he had the direction of the landing of the troops in the Crimea, which he conducted with marvellous energy and despatch. According to Kinglake, Lyons shared the "intimate counsels" of Lord Raglan in regard to the most momentous questions of the war, and throughout the Crimean campaign he toiled, with a "painful consuming passion," to guard against disaster, to clear away overpowering difficulties and obstacles, and to win the final purpose of the expedition. His actual achievements in battle were principally two—the support he rendered with his guns to the French at the Alma in attacking the left flank of the Russians, and the bold and brilliant part he took with his ship the "Agamemnon" in the first bombardment of the forts of Sebastopol; but his constant vigilance, his multifarious activity, and his suggestions and counsels were much more advantageous to the allied cause than his specific exploits. In 1855 he was created vice-admiral, and at the conclusion of the war he was, in June 1856, raised to the peerage with the title of Lord Lyons of Christchurch. He died November 23, 1858.

LYRA, NICOLAUS DE (c. 1270-1340), a well-known mediæval commentator, was a native of Lyre, near Evreux, Normandy, and was born most probably about 1270; at least he was still young when in 1291 he entered the Franciscan order at Verneuil. He afterwards studied at Paris, and became doctor of theology and a successful teacher there. In 1325 he became provincial of his order for Burgundy; and on October 23, 1340, he died at Paris.

Lyra (Lyranus) was the author of a controversial treatise against the Jews, entitled *De Messia, ejusque adventu præterito*, and of a *Tractatus de idoneo ministrante et suscipiente sancti altaris sacramentum*, but by far his most important work is the *Postillæ perpetuæ, sive brevia commentaria in universa Biblia*, first printed at Rome (5 vols. fol., 1471-72), and often subsequently. It may be said to mark the first beginnings of a school of natural exegesis; for, though recognizing the old doctrine of a fourfold sense—

"Litera gesta docet, quid credas allegoria,
Moralis quid agas, quo tendas anagogia"—

Lyra explicitly maintained and sought to give effect to the principle that the foundation of every mystical exposition must first be firmly laid by ascertaining the literal meaning. His qualities as an interpreter of Scripture included, besides comparative freedom from dogmatic prepossession, a good knowledge of Hebrew and a fair acquaintance with Greek. Luther was acquainted with his commentaries, and it is through the influence of Rashi upon Lyra that so many traces of the exegesis of that rabbi are found in Luther's writings; hence the oft-quoted saying, "Si Lyra non lyrasset, Lutherus non saltasset." See vol. xi. p. 601.

LYRE. Of all musical instruments the lyre has been the most associated with poetry, the recitations of Greeks having been accompanied by it. Yet the lyre was not of Greek origin; no root in the language has been discovered for λύρα, although the special names bestowed upon varieties of the instrument are Hellenic. We have to seek in Asia the birthplace of the genus, and to infer its introduction into Greece through Thrace or Lydia. The historic heroes and improvers of the lyre were of the Æolian or Ionian colonies, or the adjacent coast bordering on the Lydian empire, while the mythic masters, Orpheus, Musæus, and Thamyris, were Thracians. Notwithstanding the Hermes tradition of the invention of the lyre in Egypt, the Egyptians seem to have adopted it themselves from Assyria or Babylonia.

To define the lyre, it is necessary clearly to separate it from the allied harp and guitar, both, as far as we have record, instruments of as great antiquity. In its primal form the lyre differs from the harp, of which the earliest, simplest notion is found in the bow and bowstring; while the guitar (and lute) can be traced back to the typical "nefer" of the fourth Egyptian dynasty, the fretted finger-board of which, permitting the production of different notes by the shortening of the string, is as different in conception from the lyre and harp as the flute with holes to shorten the column of air is from the syrinx or Pandean pipes. The frame of a lyre consists of a hollow body or sound-chest (ἠχεῖον). From this sound-chest are raised two arms (πήχεις), which are sometimes hollow, and are bent both outward and forward. They are bound near the top by a crossbar or yoke (ζυγόν, ζύγωμα, or, from its having once been a reed, κάλαμος). Another crossbar (μάγας, ὑπολύριον), fixed on the sound-chest, forms the bridge which transmits the vibrations of the strings. The deepest note was the farthest from the player; but, as the strings did not differ much in length, more weight may have been gained for the deeper notes by thicker strings, as in the violin and similar modern instruments, or they were tuned with slacker tension. The strings were never of wire, the drawing of which was unknown to the nations of antiquity, but of gut (χορδή, whence chord). They were stretched between the yoke and bridge, or to a tailpiece below the bridge. There were two ways of tuning: one was to fasten the strings to pegs which might be turned (κόλλαβοι, κόλλοπες); the other was to change the place of the string upon the crossbar; probably both expedients were simultaneously employed. It is doubtful whether ἡ χορδοτόνος meant the tuning key or the part of the instrument where the pegs were inserted. The extensions of the arms above the yoke were known as κέρατα, horns.

The number of strings varied at different epochs, and possibly in different localities,—four, seven, and ten having been favourite numbers. They were, as already said, used without a finger-board, no Greek description or representation having ever been met with that can be construed as referring to one. Nor was a bow possible, the flat sound-board being an insuperable impediment. The plectrum, however (πλῆκτρον), was in constant use at all times. It was held in the right hand to set the upper strings in vibration (κρέκειν, κρούειν τῷ πλήκτρῳ); at other times it hung from the lyre by a ribbon. The fingers of the left hand touched the lower strings (ψάλλειν).

With Greek authors the lyre has several distinct names; but we are unable to connect these with anything like certainty to the varieties of the instrument. Chelys (χέλυς, "tortoise") may mean the smallest lyre, which, borne by one arm or supported by the knees, offered in the sound-chest a decided resemblance to that familiar animal. That there was a difference between lyre and cithara (κιθάρα) is certain, Plato and other writers separating them. Hermes and Apollo had an altar at Olympia in common because the former had invented the lyre and the latter the cithara. Perhaps the lyre and chelys on the one hand, and the cithara and phorminx on the other, were similar or nearly identical. Apollo is said to have carried a golden phorminx. But lyre has always been accepted as the generic name of the family, and understood to include all varieties. The large lyre was supported by a strong ribbon slung over the player's shoulder, passing through holes beneath the yoke in the arms of the instrument, and caught by the player's left hand, the ends hanging in a sash-like fashion. This cithara, or, it may be, phorminx (φόρμιγξ, "portable lyre"), is frequently, by the vase painters, delineated as so held,—the plectrum, attached by another ribbon, being represented, when not in use, as pendent, or as interlaced between the strings.

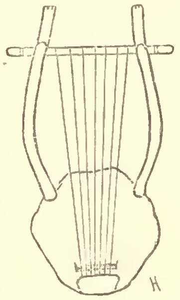

Fig. 1.—Chelys, from a vase in the British Museum, where also are fragments of such an instrument, the back of which is of shell.

Fig. 2.—Cithara or Phorminx, from a vase in the British Museum. Best period of Greek art.

Passing by the story of the discovery of the lyre from a vibrating tortoise-shell by Hermes, we will glance at the real lyres of Egypt and Semitic Asia. The Egyptian lyre is unmistakably Semitic. The oldest representation that has been discovered is in one of the tombs of Beni Hassan, the date of the painting being in the 12th dynasty, that is, shortly before the invasion of the shepherd kings. In this painting, which both Rosellini and Lepsius have reproduced, an undoubted Semite carries a seven or eight stringed lyre of fan-shaped form. The instrument has a four-cornered body and an irregular four-cornered frame above it, and the player carries it horizontally from his breast, just as a modern Nubian would his kissar. He plays as he walks, using both hands, a plectrum being in the right. This ancient lyre, dating 2000 B.C., exists to this day in a remarkable specimen preserved in the Berlin Museum (fig. 3), and is found again in form as well as in manner of holding in the Assyrian lyre of Khorsabad. During the rule of the shepherds the lyre became naturalized in Egypt, and in the 18th dynasty it is frequently depicted, and with finer grace of form. In the 19th and 20th dynasties the lyre is sometimes still more slender, or is quite unsymmetrical and very strong, the horns surmounted by heads of animals as in the Berlin one, which has horses' heads at those extremities. Prokesch copied one in the ruins of Wadi Halfa, splendid in blue and gold, with a serpent wound round it. The Egyptians always strung their lyres fan-shaped, like the modern Nubian kissar. Their paintings shew three to eight or nine strings, but the painters' accuracy may not be unimpeachable; the Berlin instrument had fifteen. The three-stringed lyre typified the three seasons of the Egyptian year—the water, the green, and the harvest; the seven, the planetary system from the moon to Saturn. The Greeks had the same notion of the harmony of the spheres.

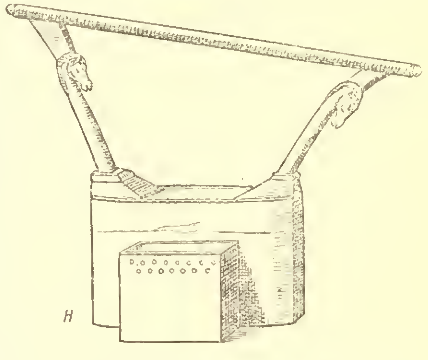

Fig. 3.—Egyptian Lyre now at Berlin. Drawn by permission of Director-General Schöne.

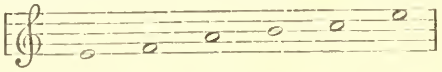
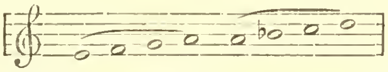
There is no evidence as to what the stringing of the Greek lyre was in the heroic age. Plutarch says that Olympus and Terpander used but three strings to accompany their recitation. As the four strings led to seven and eight by doubling the tetrachord, so the trichord is connected with the hexachord or six-stringed lyre depicted on so many archaic Greek vases. We cannot insist on the accuracy of this representation, the vase painters being so little mindful of the complete expression of details; yet we may suppose their tendency would be rather to imitate than to invent a number. It was their constant practice to represent the strings as being damped by the fingers of the left hand of the player, after having been struck by the plectrum which he held in the right hand. Before the Greek civilization had assumed its historic form, there was likely to be great freedom and independence of different localities in the matter of lyre stringing, which is corroborated by the antique use of the chromatic (half-tone) and enharmonic (quarter-tone) tunings, pointing to an early exuberance, as in language when nations are young and isolated, and perhaps also to an Asiatic bias towards refinements of intonation, from which came the χρόαι, the hues of tuning, old Greek modifications of tetrachords entirely disused in the classic period. The common scale of Olympus



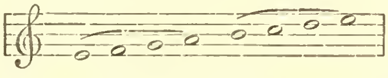
remained, a double trichord which had served as the scaffolding for the enharmonic varieties.

We may regard the Olympus scale, however, as consisting of two tetrachords, eliding one interval in each, for the tetrachord, or series of four notes, was very early adopted as the fundamental principle of Greek music, and its origin in the lyre itself appears sure. The basis of the tetrachord is the employment of the thumb and first three fingers of the left hand to twang as many strings, the little finger not being used on account of natural weakness. As a succession of three whole tones would form the disagreeable and untunable interval of a tritonus, two whole tones and a half-tone were tuned, fixing the tetrachord in the consonant interval of the perfect fourth. This succession of four notes being in the grasp of the hand was called συλλαβή, just as in language a group of letters incapable of further reduction is called syllable. In the combination of two syllables or tetrachords the modern diatonic scales resemble the Greek so-called disjunct scale, but the Greeks knew nothing of our categorical distinctions of major and minor. We might call the octave Greek scale minor, according to our descending minor form, were not the keynote in the middle the thumb note of the deeper tetrachord. The upper tetrachord, whether starting from the keynote (conjunct) or from the note above (disjunct), was of exactly the same form as the lower, the position of the semitones being identical. The semitone was a limma (λεῖμμα), rather less than the semitone of our modern equal temperament, the Greeks tuning both the whole tones in the tetrachord by the same ratio of 8 : 9, which made the major third a dissonance, or rather would have done so had they combined them in what we call harmony. In melodious sequence the Greek tetrachord is decidedly more agreeable to the ear than the corresponding series of our equal temperament. And although our scales are derived from combined tetrachords, in any system of tuning that we employ, be it just, mean-tone, or equal, they are less logical than the conjunct or disjunct systems accepted by the Greeks. But modern harmony is not compatible with them, and could not have arisen on the Greek melodic lines.

The conjunct scale of seven notes



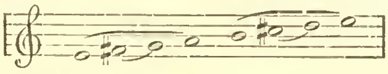
attributed to Terpander, was long the norm for stringing and tuning the lyre. When the disjunct scale



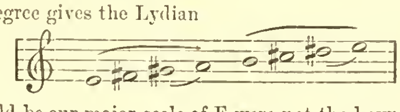
the octave scale attributed to Pythagoras, was admitted, to preserve the time-honoured seven strings one note had to be omitted; it was therefore customary to omit the C, which in Greek practice was a dissonance. The Greek names for the strings of seven and eight stringed lyres, the first note being highest in pitch and nearest the player, were as follows:—*Nete, Paranete, Paramese*; *Mese, Lichanos, Parhypate, Hypate*; or *Nete, Paranete, Trite, Paramese*; *Mese, Lichanos, Parhypate, Hypate*,—the last four from Mese to Hypate being the finger tetrachord, the others touched with the plectrum. The highest string in pitch was called the last, νεάτη; the lowest in pitch was called the highest, ὑπάτη, because it was, in theory at least, the longest string. The keynote and thumb string was μέση, middle; the next lower was λίχανος, the first finger or lick-finger string; τρίτη, the third, being in the plectrum division, was also known as ὀξεῖα, sharp, perhaps from the dissonant quality which we have referred to as the cause of its omission. The plectrum and finger tetrachords together were διαπασῶν, through all; in the disjunct scale, an octave.

In transcribing the Greek notes into our notation, the absolute pitch cannot be represented; the relative positions of the semitones are alone determined. We have already quoted the scale of Pythagoras, the Dorian or true Greek succession:—

Shifting the semitone one degree upwards in each tetrachord, we have the Phrygian



Another degree gives the Lydian



which would be our major scale of E were not the keynote A. The names imply an Asiatic origin. We will not pursue further the much debated question of Greek scales and their derivation; it will suffice here to remark that the outside notes of the tetrachords were fixed in their tuning as perfect fourths,—the inner strings being, as stated, in diatonic sequence, or when chromatic two half-tones were tuned, when enharmonic two quarter-tones, leaving respectively the wide intervals of a minor and major third, and both impure, to complete the tetrachord. (A. J. H.)

LYRE-BIRD, the name by which one of the most remarkable feathered inhabitants of Australia is commonly known, the *Menura superba* or *M. novæ-hollandiæ* of ornithologists. First discovered, January 24, 1798, on the other side of the river Nepean in New South Wales by an exploring party from Paramatta, under the leadership of one Wilson, a single example was brought into the settlement a few days after, and though called by its finders a "Pheasant"—from its long tail—the more learned of the colony seem to have regarded it as a Bird-of-Paradise.[1] A specimen having reached England in the following year, it was described by General Davies as forming a new genus of birds, in a paper read before the Linnean Society of London, November 4, 1800, and subsequently published in that Society's *Transactions* (vi. p. 207, pl. xxii.), no attempt, however, being made to fix its systematic place. Other examples were soon after received, but Latham, who considered it a Gallinaceous bird, in 1801 knew of only five having arrived. The temporary cessation of hostilities in 1802 permitted Vieillot to become acquainted with this form, though not apparently with any published notice of it, and he figured and described it in a supplement to his *Oiseaux Dorés* as a Bird of Paradise (ii. pp. 30 *sq.*, pls. 14–16), from drawings by Sydenham Edwards, sent him by Parkinson, the manager of the Leverian Museum.[2]

It would be needless here to enter at any length on the various positions which have been assigned to this singular form by different systematizers—who had to judge merely from its superficial characters. The first to describe any portion of its anatomy was Eyton, who in 1841 (*Ann. Nat. History*, vii. pp. 49–53) perceived that it was truly a member of the Order then called *Insessores*, and that it presented some points of affinity to the South American genus *Pteroptochus*;[3] but still there were many who could not take advantage of this step in the right direction. In 1867 Professor Huxley stated that he was disposed to divide his very natural assemblage the *Coracomorphæ* (essentially identical with Eyton's *Insessores*) into two groups, "one containing *Menura*, and the other all the other genera which have yet been examined" (*Proc. Zool. Soc.*, 1867, p. 472)—a still further step in advance.[4] In 1875 the present writer put forth the opinion in this work (BIRDS, vol. iii. p. 471) that *Menura* had an ally in another Australian form, *Atrichia* (see SCRUB-BIRD), which he had found to present peculiarities hitherto unsuspected, and accordingly regarded them as standing by themselves, though each constituting a distinct Family. This opinion was partially adopted in the following year by Garrod, who (*Proc. Zool. Society*, 1876, p. 518) formally placed these

[1] Collins, *Account of New South Wales*, ii. pp. 87–92 (London, 1802).

[2] Vieillot called the bird "Le Parkinson"! and hence Bechstein, who seems to have been equally ignorant of what had been published in England concerning it, in 1811 (*Kurze Uebersicht*, &c., p. 134), designated it *Parkinsonius mirabilis*!! Shaw also, prior to 1813, figured it (*Nat. Miscellany*, xiv. p. 577) under the name of *Paradisea parkinsoniana*. The name "*Menura lyra*, Shaw," was quoted by Lesson in 1831 (*Tr. d'Ornithologie*, p. 473), and has been repeated by many copyists of synonymy, but the present writer cannot find that such a name was ever applied by Shaw. Vieillot's principal figure (*ut supra*), which has a common origin with that given by Collins, has been extensively copied, in spite of its inartistic not to say inaccurate drawing. It is decidedly inferior to that of Davies (*ut supra*), the original describer and delineator.

[3] He subsequently (*Osteol. Avium*, pp. 97, 98, pl. 3, F and pl. 14) described and figured the skeleton.

[4] Owing to the imperfection of the specimen at his disposal, Professor Huxley's brief description of the bones of the head in *Menura* is not absolutely correct. A full description of them, with elaborate figures, is given by Professor Parker in the same Society's *Transactions* (ix. pp. 306–309, pl. lvi. figs. 1–5).

two genera together in his group of Abnormal Acromyodian *Oscines* under the name of *Menurinæ*; but the author sees no reason to change his mind, and herein he is corroborated by Mr Sclater, who has recently (*Ibis*, 1880, p. 345) recognized at once the alliance and distinctness of the Families *Menuridæ* and *Atrichiidæ*, forming of them a group which he calls *Pseudoscines.*

Since the appearance in 1865 of Gould's *Handbook to the Birds of Australia*, little if any fresh information has been published concerning the habits of this form, and the account therein given must be drawn upon for what here follows. Of all birds, says that author, the *Menura* is the most shy and hard to procure. He has been among the rocky and thick "brushes"—its usual haunts—hearing its loud and liquid call-notes for days together without getting sight of one. Those who wish to see it must advance only while it is occupied in singing or scratching up the earth and leaves; and to watch its actions they must keep perfectly still—though where roads have been made through the bush it may be more often observed and even approached on horseback. The best way of procuring an example seems to be by hunting it with dogs, when it will spring upon a branch to the height of 10 feet and afford an easy shot ere it has time to ascend further or escape as it does by leaps. Another method of stealing upon it is said to be practised by the natives, and is attained by the hunter fixing on his head the erected tail of a cock-bird, which alone is allowed to be seen above the brushwood. The greater part of its time is said to be passed upon the ground, and seldom are more than a pair to be found in company. One of the habits of the cock is to form small round hillocks, which he constantly visits during the day, mounting upon them and displaying his tail by erecting it over his head, drooping his wings, scratching and pecking at the soil, and uttering various cries—some his own natural notes, others an imitation of those of other animals. The wonderful tail, his most characteristic feature, only attains perfection in the bird's third or fourth year, and then not until the month of June, remaining until October, when the feathers are shed to be renewed the following season. The food consists of insects, especially beetles and myriapods, as well as snails. The nest is always placed near to or on the ground, at the base of a rock or foot of a tree, and is closely woven of fine but strong roots or other fibres, and lined with feathers, around all which is heaped a mass, in shape of an oven, of sticks, grass, moss, and leaves, so as to project over and shelter the interior structure, while an opening in the side affords entrance and exit. Only one egg is laid, and this of rather large size in proportion to the bird, of a purplish-grey colour, suffused and blotched with dark purplish-brown.[1]

Incubation is believed to begin in July or August, and the young is hatched about a month later. It is at first covered with white down, and appears to remain for some weeks in the nest. How much more is needed to be known for a biography of this peculiar and beautiful creature may be inferred by those who are aware of the diligence with which the habits of the much more easily observed birds of the northern hemisphere have been recorded, and of the many interesting points which they present. It is greatly to be hoped that so remarkable a form as the Lyre-bird, the nearly sole survivor apparently of a very ancient race of beings, will not be allowed to become extinct—its almost certain fate so far as can be judged—without many more observations of its manners being made and fuller details of them placed on record. The zoologists of Australia alone can do this, and the zoologists of other countries expect that they will.

Several examples of *Menura* have been brought alive to Europe, but none have long survived in captivity. Indeed a bird of such active habits, and requiring doubtless facilities for taking violent exercise, could not possibly be kept long in confinement until the method of menageries is vastly improved, as doubtless will be the case some day, and, we may hope, before the disappearance from the face of the earth of forms of vertebrate life most instructive to the zoologist.

Three species of *Menura* have been indicated—the old *M. superba*, the Lyre-bird proper, now known for more than eighty years, which inhabits New South Wales, the southern part of Queensland, and perhaps some parts of the colony of Victoria; *M. victoriæ*, separated from the former by Gould (*Proc. Zool. Soc.*, 1862, p. 23), and said to take its place near Melbourne; and *M. alberti*, first described by C. L. Bonaparte (*Consp. Avium*, i. p. 215) on Gould's authority, and, though discovered on the Richmond river in New South Wales, having apparently a more northern range than the other two. All those have the apparent bulk of a hen Pheasant, but are really much smaller, and their general plumage is of a sooty brown, relieved by rufous on the chin, throat, some of the wing-feathers, and the tail-coverts. The wings, consisting of twenty-one remiges, are rather short and rounded; the legs[2] and feet very strong, with long, nearly straight claws. In the immature and female the tail is somewhat long, though affording no very remarkable character, except the possession of sixteen rectrices; but in the fully-plumaged male of *M. superba* and *M. victoriæ* it is developed in the extraordinary fashion that gives the bird its common English name. The two exterior feathers (fig. 1, *a*, *b*) have the outer web very narrow, the inner very broad, and they curve at first outwards, then somewhat inwards, and near the tip outwards again, bending round forwards so as to present a lyre-like form. But this is not all; their broad inner web,

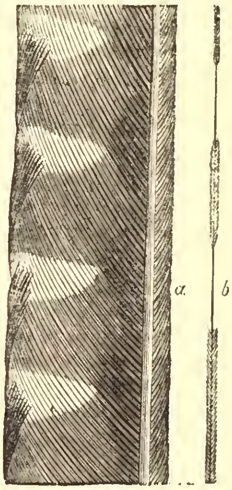


Fig. 1.

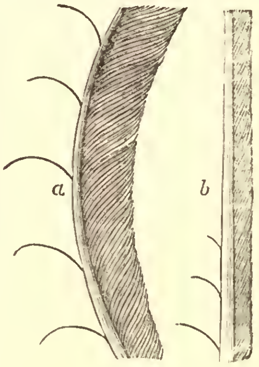

Fig. 2.

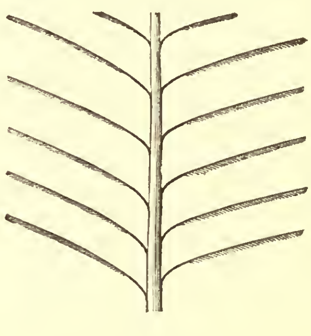

Fig. 3.

which is of a lively chestnut colour, is apparently notched at regular intervals by spaces that, according to the angle at which they are viewed, seem either black or transparent; and this effect is, on examination, found to be due to the barbs

[1] The nest and egg of *Menura alberti*, now in the British Museum, are figured in *Proc. Zool. Society*, 1853, *Aves*, pl. 53. The egg of *M. victoriæ* is represented in *Journ. für Ornithologie*, 1856, pl. ii. fig. 18, under the name of *M. superba*, but the real egg of that species does not seem to have been figured at all.

[2] The metatarsals are very remarkable in form, as already noticed by Eyton (*loc. cit.*), and their tendons strongly ossified.

at those spaces being destitute of barbules. The middle pair of feathers (fig. 2, *a*, *b*) is nearly as abnormal. These have no outer web, and the inner web very narrow; near their base they cross each other, and then diverge, bending round forwards near their tip. The remaining twelve feathers (fig. 3) except near the base are very thinly furnished with barbs, about a quarter of an inch apart, and those they possess, on their greater part, though long and flowing, bear no barbules, and hence have a hair-like appearance. The shafts of all are exceedingly strong. In the male of *M. alberti* the tail is not only not lyriform, but the exterior rectrices are shorter than the rest. (A. N.)

LYSANDER was the leading spirit of Lacedæmonian policy at the end of the Peloponnesian War. He is said by Ælian and Athenæus to have been of servile origin, and by Plutarch to have belonged to a Heraclid family. His father was named Aristoclitus or Aristocritus. He first appears in history when sent to command the fleet on the Ionian coast in 407 B.C. The story of his skilful diplomacy, of his influence with Cyrus the younger, of his naval victory at Notium, of his quarrel with his successor Callicratidas in 406, of his reappointment in 405, of the decisive victory at Ægospotami, and of the capitulation of Athens in 404, belongs to the history of Greece. After his return to Sparta his pride and vanity became boundless; he was celebrated by poets, and even worshipped in some places as a god. The restraint of life in Sparta, and the enemies whom he had there, were irksome to him, and he soon went to Asia Minor. He had established in all the Greek cities associations which maintained an oligarchical government, and his power over them was so great as to increase the jealousy felt for him at home. He was recalled to Sparta, and the machinations of the Persian satrap Pharnabazus brought him into danger. He had soon after the triumph of being sent with an army to support the oligarchy in Athens; but the king (Pausanias) was sent after him with a second army, and made terms with the restored Athenian democracy. When King Agis died in 398, Lysander worked to secure the succession for Agesilaus, but after two years he found that he had helped his most dangerous enemy. He began to concert revolutionary schemes, but had not proceeded to any overt act when he was sent with an army into Bœotia. He did not wait the arrival of Pausanias with an auxiliary army, but attacked Haliartus, and was slain in the battle, 395 B.C. He was buried on the road from Delphi to Chæronea, and a monument was erected on his tomb. It is to his credit that, after the power and opportunities he had enjoyed, he died a poor man.

LYSIAS, whose name follows those of Antiphon and Andocides on the list of the ten Attic orators, marks an important stage in the development of Greek literary prose, and is, in his own province, one of its most perfect masters. He never acquired the Athenian citizenship, but most of his years were passed at Athens; and his life has the interest of close personal association with the most critical period in the history of the Athenian democracy.

Date of birth.

His extant work belongs to the space from 403 to 380 B.C., but the date of his birth is uncertain. Dionysius of Halicarnassus, and the author of the life ascribed to Plutarch, give 459 B.C. This date was evidently obtained by reckoning back from the foundation of Thurii (444 B.C.), since there was a tradition that Lysias had gone thither at the age of fifteen. Modern critics would place his birth later,—between 444 and 436 B.C.,—because, in Plato's *Republic*, of which the scene is laid about 430 B.C., Cephalus, the father of Lysias, is among the *dramatis personæ*, and the emigration of Lysias to Thurii was said to have followed his father's death. The latter statement, however, rests only on the Plutarchic life; nor can Plato's dialogue be safely urged as a minutely accurate authority for a biographical detail. We must be content to say that, while the modern view avoids some difficulties, the higher date assigned by the ancient writers is not inconsistent with any ascertained fact, while it agrees better with the tradition that Lysias reached, or passed, the age of eighty. On the other view, all traces of his industry, previously unremitting, would cease abruptly at the age of sixty-six.

Life to 413 B.C.

Cephalus, the father of Lysias, was a native of Syracuse. On the invitation of Pericles he had settled at Athens as a "resident alien" (μέτοικος). The opening scene of Plato's *Republic* is laid at the house of his eldest son, Polemarchus, in the Peiræus. Cephalus complains that the visits of Socrates have been rare of late, and expresses the hope that he will come oftener, and without ceremony, as to intimate friends. The tone of the picture warrants the inference that the Sicilian family were well known to Plato, and that their houses must often have been hospitable to such gatherings as the *Republic* supposes. Thus we have an indirect, but very interesting, confirmation of the phrase used by Dionysius in regard to Lysias—"he grew up in the society of the most distinguished Athenians."

At the age of fifteen—when Cephalus, according to the Plutarchic life, was now dead—Lysias removed from Athens to Thurii, the Athenian colony newly planted on the Tarentine Gulf, near the site of the ancient Sybaris. There the boy may have seen the historian Herodotus,—another of Thurii's early residents,—now a man in middle life; and it pleases the imagination to think that, in their new Italian home, a friendship may have grown up between these two, neither of them an Athenian by birth, yet alike in a simple grace which Athens loved, and alike also in the love which they bore to Athens. At Thurii Lysias is said to have commenced his studies in rhetoric,—doubtless under a master of the Sicilian school,—possibly, as tradition said, under Tisias, the pupil of Corax, whose name is associated with the first attempt to formulate rhetoric as an art. In 413 B.C. the Athenian armament in Sicily suffered that crushing disaster which at the moment seemed to imperil the existence of Athens itself. The desire to link famous names is curiously illustrated by the ancient ascription to Lysias of a rhetorical exercise purporting to be a speech in which the captive general Nicias appealed for mercy to the Sicilians. The terrible blow to Athens quickened the energies of an anti-Athenian faction at Thurii. Lysias and his elder brother Polemarchus, with three hundred other persons, were "accused of Atticizing" (Ἀττικισμὸν ἐγκληθεῖσι),—a charge which, under the circumstances, implies an honourable loyalty. They were driven from Thurii.

412-404.

Lysias and Polemarchus now settled at Athens (412 B.C.). They were rich men, having inherited property from their father, Cephalus; and Lysias claims that, though merely resident aliens, they discharged public services with a liberality which shamed many of those who enjoyed the franchise (οὐχ ὁμοίως μετοικοῦντας ὥσπερ αὐτοὶ ἐπολιτεύοντο, *In Eratosth.*, § 20). The fact that they owned house property shows that they were classed as ἰσοτελεῖς, *i.e.*, foreigners who paid only the same tax as citizens, being exempt from the special tax (μετοίκιον) on resident aliens. Polemarchus occupied a house in Athens itself, Lysias another in the Peiræus, near which was their shield manufactory, employing a hundred and twenty skilled slaves. This life of comparative peace and prosperity was broken up by the defeat of Athens at Ægospotami (405 B.C.). In the next spring Athens surrendered to Lysander. The Thirty Tyrants were established at Athens under the protection of a Spartan garrison. One of their earliest measures was an attack upon the resident aliens, who were represented as disaffected to the new government. As foreign residents successful in commerce, the Attic *metoikoi* were exposed at such a time to perils like those of the Jews in a mediæval city, or in modern Russia. Lysias and Polemarchus were on a list of ten singled out to be the first victims. Polemarchus was arrested, and received "the usual message" (τὸ εἰθισμένον παράγγελμα, *In Eratosth.*, § 17) "to drink the hemlock." Lysias had a narrow escape, with the help of a large bribe and a lucky accident. He slipped by a back-door out of the house in which he was a prisoner, and took boat to Megara.

403-380. After the expulsion of the Thirty Tyrants, the democracy was formally restored in the autumn of 403 B.C. Lysias appears to have rendered valuable services to the exiles during the reign of the tyrants, both by his own liberality and by procuring aid from other quarters. Thrasybulus now proposed that these services should be recognized by the bestowal of the citizenship. The proposal happened to be informal in one particular. The senate of five hundred had not yet been reconstituted, and hence the measure could not be introduced to the ecclesia by the requisite "preliminary resolution" (προβούλευμα) of the senate. On this ground it was successfully opposed; and Lysias missed the reward which he had so well earned. That passage of his Ὀλυμπιακός (§ 3) in which he claims to give advice as a good citizen seems to breathe the feeling that, if he was still but an alien at Athens, he was at least a true πολίτης of Greece.

The last chapter of his life now opens. He is no longer the wealthy merchant, superintending his shield manufactory in the Peiræus. The pillage by the tyrants, and his own generosity to the Athenian exiles, had probably left him poor. He now appears as a hard-working member of a new profession,—that of writing speeches to be delivered in the law-courts. The thirty-four compositions extant under his name are but a small fraction of those which the ancient world possessed. From 403 to about 380 B.C. his industry must have been great and incessant. The notices of his personal life in these years are scanty. In 403 he came forward as the accuser of Eratosthenes, one of the Thirty Tyrants, and delivered the splendid oration which we possess. This was his only direct contact with Athenian politics. The story that Lysias wrote a defence for Socrates, which the latter declined to use, probably arose from a confusion. Several years after the death of Socrates the sophist Polycrates composed a declamation against him; and to this Lysias replied with a defence of the philosopher. A more authentic tradition represents Lysias as having spoken his own "Olympiacus" at the Olympic festival of 388 B.C. The occasion was one of peculiar interest. Dionysius I., tyrant of Syracuse, had sent to the festival a magnificent embassy. Tents embroidered with gold were pitched within the sacred enclosure; and the wealth of Dionysius was vividly brought before the minds of the Panhellenic concourse by the number of chariots which he had entered for the most costly and brilliant of the Olympic contests. This was the moment at which Lysias lifted up his voice to denounce Dionysius as, next to Artaxerxes, the worst enemy of Hellas, and to impress upon the assembled Greeks that one of their foremost duties was to deliver Sicily from a hateful oppression. The latest work of Lysias which we can date (a fragment of a speech "For Pherenicus") belongs to 381 or 380 B.C. He probably died in or soon after 380 B.C.

[Char]ar-[act]er of man [and] of [his] work. The qualities of the man are expressed in his work; indeed, it is through this, rather than through the recorded facts of his biography, that he becomes a living person to us. It is a kindly and genial nature which we see reflected there,—warm in friendship, loyal to country,—with a keen perception of character, and a fine, though strictly controlled, sense of humour. The literary tact which is so remarkable in the extant speeches is that of a singularly flexible intelligence, always obedient to an instinct of gracefulness. Among the earlier artists of Greek prose Lysias owes his distinctive place to the power of concealing his art. The clients of the professional "speech-writer," like those of the modern advocate, might be of all sorts and conditions. The modern advocate, however, speaks in his own person. The Athenian "logographer" merely wrote the speech which his client delivered. It was obviously desirable that such a speech should be suitable to the age, station, and circumstances of the person into whose mouth it was put. Lysias was the first disciple of Greek rhetoric who succeeded in making this adaptation really artistic. He aimed, not merely at impressive effect in eloquence, pathos, or argument, but at dramatic propriety. Hence it was absolutely essential for him to abandon the stiff and monotonous splendour of the earlier and cruder rhetoric. He could not achieve his purpose unless he brought his art into harmony with the ordinary idiom of everyday life. His client must appear to be speaking as the citizen, who was not a professed rhetorician, might conceivably speak. Lysias achieved this reconciliation with a skill which can be best appreciated if we turn from the easy flow of his graceful language to the majestic emphasis of his predecessor Antiphon, or to the self-revealing art of his successor Isæus. Translated into terms of ancient criticism, the achievement of Lysias is described by saying that he became the model of the "plain style" (ἰσχνὸς χαρακτήρ, ἰσχνή, λιτή, ἀφελὴς λέξις; *genus tenue* or *subtile*). From the latter part of the 4th century B.C. onwards, Greek, and then Roman, critics distinguished three styles of rhetorical composition—the "grand" (or "elaborate"), the "plain," and the "middle." These epithets were relative to the language of daily life,—the "plain" being nearest to this, and the "grand" furthest from it. Greek rhetoric began in the "grand" style; then Lysias set an exquisite pattern of the "plain"; and Demosthenes might be considered as having effected an almost ideal compromise. We moderns perhaps cannot fully seize that nameless and undefinable grace (χάρις) of Lysias which the Greek critic of the Augustan age indicates in such striking words:—

"When I am puzzled about one of the speeches ascribed to him," says Dionysius, "and when it is hard for me to find the truth by other marks, I have recourse to this excellence, as to the last piece on the board. Then, if the graces of speech seem to me to make the writing fair, I count it to be of the soul of Lysias; and I care not to probe the question further. But if the stamp of the language has no winningness, no loveliness, I am chagrined, and suspect that, after all, the speech is not by Lysias; and I do no more violence to my instinct (οὐκέτι βιάζομαι τὴν ἄλογον αἴσθησιν), even though in all else the speech seems to me clever and well finished,—believing that to write well, in special styles other than this, is given to many men, but that to write winningly, gracefully, with loveliness, is the gift of Lysias" (Dionys., *De Lys.*, ii.).

The more salient traits of the Lysian style can be Style. recognized by all. The vocabulary is pure and simple. Most of the rhetorical "figures" are sparingly used,—except such as consist in the parallelism or opposition of clauses. The taste of the day,—not yet emancipated from the influence of the Sicilian rhetoric,—probably demanded a large use of antithesis as an essential condition of impressive speaking. Lysias excels in vivid description; he has also a happy knack of marking the speaker's character by light touches. The structure of his sentences varies a good deal according to the dignity of the subject. He has equal command over the "periodic" style (κατεστραμμένη λέξις) and the non-periodic or "continuous" (εἰρομένη, διαλελυμένη)—using now one now the other, or blending them, according to circumstances. His disposition of his subject-matter is always simple. The speech has usually four parts,—introduction (προοίμιον), narrative of facts (διήγησις), proofs (πίστεις), which may be either external, as from witnesses, or internal, derived from argument on the facts, and, lastly, conclusion (ἐπίλογος). It is in the introduction and the narrative that Lysias is seen at his best. In his greatest extant speech—that "Against Eratosthenes"—and also in the fragmentary "Olympiacus," he has pathos and fire; but these were not characteristic qualities of his work. In Cicero's judgment, Demosthenes was peculiarly distinguished by force (*vis*), Æschines by resonance (*sonitus*), Hyperides by acuteness (*acumen*), Isocrates by sweetness (*suavitas*); the distinction which he assigns to Lysias is *subtilitas*, an Attic refinement,—which, as he elsewhere says, is often joined to an admirable vigour (*lacerti*), (Cic., *De Or.*, iii. 7, § 28; *Brutus*, § 64). The judgment is interesting as showing how a Roman critic of unquestionable competence recognized the peculiar place of Lysias in the development of Greek oratory. Nor was it oratory alone to which Lysias rendered service; his work had an important effect on all subsequent Greek prose, by showing how perfect elegance could be joined to plainness. Here, in his artistic use of familiar idiom, he might fairly be called the Euripides of Attic prose. And his style has an additional charm for modern readers, because it is employed in describing scenes from the everyday life of Athens.[1]

orks. Thirty-four speeches (of which three are fragmentary) have come down under the name of Lysias; no fewer than one hundred and twenty-seven more, now lost, are known from smaller fragments or from titles. In the Augustan age four hundred and twenty-five works bore his name, of which more than two hundred were allowed as genuine by the critics. The enormous number of ascriptions indicates that Lysias was reputed to have been a fertile writer. Our thirty-four works may be classified as follows:—

A. Epideictic.—1. Olympiacus, xxxiii., 388 B.C.; 2. Epitaphius, ii. (purporting to have been spoken during the Corinthian War; certainly spurious), perhaps composed about 380–340 B.C.

B. Deliberative.—Plea for the Constitution, xxxiv., 403 B.C.

C. Forensic, in Public Causes.—I. *Relating to Offences directly against the State* (γραφαὶ δημοσίων ἀδικημάτων); *such as treason, malversation in office, embezzlement of public moneys.* 1. For Polystratus, xx., 407 B.C.; 2. Defence on a Charge of Taking Bribes, xxi., 402 B.C.; 3. Against Ergocles, xxviii., 389 B.C.; 4. Against Epicrates, xxvii., 389 B.C.; 5. Against Nicomachus, xxx., 399 B.C.; 6. Against the Corndealers, xxii., 386 B.C. (?) II. *Cause relating to Unconstitutional Procedure* (γραφὴ παρανόμων). On the Property of the Brother of Nicias, xviii., 395 B.C. III. *Causes relating to Claims for Money withheld from the State* (ἀπογραφαί). 1. For the Soldier, ix. (probably not by Lysias, but by an imitator, writing for a real cause), 394 B.C. (?); 2. On the Property of Aristophanes, xix., 387 B.C.; 3. Against Philocrates, xxix., 389 B.C. IV. *Causes relating to a Scrutiny* (δοκιμασία); *especially the Scrutiny, by the Senate, of Officials Designate.* 1. Against Evandrus, xxvi., 382 B.C.; 2. For Mantitheus, xvi., 392 B.C.; 3. Against Philon, xxxi., between 404 and 395 B.C.; 4. Defence on a Charge of Seeking to Abolish the Democracy, xxv., 401 B.C.; 5. For the Invalid, xxiv., 402 B.C. (?) V. *Causes relating to Military Offences* (γραφαὶ λιποταξίου, ἀστρατείας). 1. Against Alcibiades, I. and II. (xiv., xv.), 395 B.C. VI. *Causes relating to Murder or Intent to Murder* (γραφαὶ φόνου, τραύματος ἐκ προνοίας). 1. Against Eratosthenes, xii., 403 B.C.; 2. Against Agoratus, xiii., 399 B.C.; 3. On the Murder of Eratosthenes, i. (date uncertain); 4. Against Simon, iii., 393 B.C.; 5. On Wounding with Intent, iv. (date uncertain). VI. *Causes relating to Impiety* (γραφαὶ ἀσεβείας). 1. Against Andocides, vi. (certainly spurious, but perhaps contemporary); 2. For Callias, v. (date uncertain); 3. On the Sacred Olive, vii., not before 395 B.C.

D. Forensic, in Private Causes.—I. *Action for Libel* (δίκη κακηγορίας). Against Theomnestus, x., 384–3 B.C. (the so-called second speech, xi., is merely an epitome of the first). II. *Action by a Ward against a Guardian* (δίκη ἐπιτροπῆς). Against Diogeiton, xxxii., 400 B.C. III. *Trial of a Claim to Property* (διαδικασία). On the Property of Eraton, xvii., 397 B.C. IV. *Answer to a Special Plea* (πρὸς παραγραφήν). Against Pancleon, xxiii. (date uncertain).

E. Miscellaneous.—1. To his Companions, a Complaint of Slanders, viii. (certainly spurious); 2. The ἐρωτικός in Plato's *Phædrus*, pp. 230 E–234. This has generally been regarded as Plato's own work; but the certainty of this conclusion will be doubted by those who observe (1) the elaborate preparations made in the dialogue for a recital of the ἐρωτικός which shall be *verbally exact*, and (2) the closeness of the criticism made upon it. If the satirist were merely analysing his own composition, such criticism would have little point. Lysias is the earliest writer who is known to have composed ἐρωτικοί; it is as representing both rhetoric and a false ἔρως that he is the object of attack in the *Phædrus*.

F. Fragments.—Three hundred and fifty-five of these are collected by Sauppe, *Oratores Attici*, ii. 170–216. Two hundred and fifty-two of them represent one hundred and twenty-seven speeches of known title; and of six the fragments are comparatively large. Of these, the fragmentary speech "For Pherenicus" belongs to 381 or 380 B.C., and is thus the latest known work of Lysias.

In literary and historical interest, the first place among the extant speeches of Lysias belongs to that "Against Eratosthenes" (403 B.C.), one of the Thirty Tyrants, whom Lysias arraigns as the murderer of his brother Polemarchus. The speech is an eloquent and vivid picture of the reign of terror which the thirty established at Athens; the concluding appeal, to both parties among the citizens, is especially powerful. Next in importance is the speech "Against Agoratus" (399 B.C.), one of our chief authorities for the internal history of Athens during the months which immediately followed the defeat at Ægospotami. The "Olympiacus" (388 B.C.) is a brilliant fragment, expressing the spirit of the festival at Olympia, and exhorting Greeks to unite against their common foes. The "Plea for the Constitution" (403 B.C.) is interesting for the manner in which it argues that the wellbeing of Athens—now stripped of empire—is bound up with the maintenance of democratic principles. The speech "For Mantitheus" (392 B.C.) is a graceful and animated portrait of a young Athenian ἱππεύς, making a spirited defence of his honour against the charge of disloyalty. The defence "For the Invalid" is a humorous character-sketch. The speech "Against Pancleon" illustrates the intimate relations between Athens and Platæa, while it gives us some picturesque glimpses of Athenian town life. The defence of the person who had been charged with destroying a *moria*, or sacred olive, places us amidst the country life of Attica. And the speech "Against Theomnestus" deserves attention for its curious evidence of the way in which the ordinary vocabulary of Athens had changed between 600 and 400 B.C.

All MSS. of Lysias yet collated have been derived, as H. Sauppe first showed, from the Codex Palatinus X (Heidelberg). The next most valuable MS. is the Laurentianus C (15th century), which I. Bekker chiefly followed. Speaking generally, we may say that these two MSS. are the only two which carry much weight where the text is seriously corrupt. In *Oratt.* i.–ix. Bekker occasionally consulted eleven other MSS., most of which contain only these nine speeches: viz., Marciani F, G, I, K (Venice); Laurentiani D, E (Florence); Vaticani M, N; Parisini U, V; Urbinas O. Bibliography.

Lysias in *Oratores Attici*, ed. I. Bekker, 1828; ed. G. S. Dobson, with variorum notes, 1828; ed. J. G. Baiter and Hermann Sauppe, 1850. In Teubner's series, ed. Carl Scheibe, 1st ed. 1852, 2d ed. (based on C. L. Kayser's collation of X), 1876. Text, ed. Cobet, 1863. Selections from Lysias and Æschines, ed. Bremi, 1826. Selections from Lysias, ed. Rauchenstein, 1864; ed. Frohberger, 1868; ed. Jebb, in *Selections from the Attic Orators*, 1880. German translation, with notes, by Baur (1869); and of selections, by Westermann (1869). (R. C. J.)

LYSIMACHUS, son of Agathocles, a Thessalian in the service of Philip of Macedon, was born about 361 B.C. During Alexander's campaigns he was one of his immediate bodyguard; he distinguished himself in India, and was appointed a trierarch when Alexander constructed his fleet on the Hydaspes. After the death of Alexander, Lysimachus was appointed to the government of Thrace and the district about the Chersonese. For a long time the Odrysians under their king Seuthes caused him so much trouble that he could take very little part in the struggles of the rival satraps; but in 316 he joined the alliance which Cassander, Ptolemy, and Seleucus made against Antigonus. In 309 he founded Lysimachia in a commanding situation on the neck connecting the Chersonese with the mainland. He followed the example of Antigonus in taking the title of king. When in 302 the second alliance between Cassander, Ptolemy, and Seleucus was made, Lysimachus, reinforced by troops from Cassander, entered Asia Minor, where he met with little resistance. On the approach of Antigonus he retired into winter quarters near Heraclea, marrying its widowed queen Amastris, a Persian princess. Seleucus joined him in 301, and the decisive battle was fought in the plain of Ipsus; Antigonus was slain, and his dominions divided among the victors, Lysimachus receiving the greater part of Asia Minor. Feeling that Seleucus was becoming dangerously great, he now allied himself with Ptolemy, marrying his

[1] For a detailed account of the life, the style, and the works of Lysias, the reader is referred to Jebb, *The Attic Orators from Antiphon to Isæus*, vol. i. pp. 142–316.

daughter Arsinoe. Amastris returned to Heraclea. During the absence of Antigonus's son Demetrius in Greece, Lysimachus seized his towns in Asia Minor and rebuilt Ephesus, calling it Arsinoe. He tried to carry his power beyond the Danube, but was defeated and taken prisoner by the Getæ, who, however, set him free on amicable terms. After Demetrius had entered Macedon to help Alexander against his brother Antipater, and by murdering the former had gained possession of the whole country, he invaded Thrace, but had to retire in consequence of a rising in Bœotia, and an attack from Pyrrhus of Epirus. In 287 Lysimachus and Pyrrhus invaded Macedon. Demetrius marched against Pyrrhus, thinking the Macedonians would not fight against Lysimachus, one of Alexander's companions in arms; but his army went over to Pyrrhus, and he was obliged to fly. Lysimachus claimed a share of the kingdom and received it. Demetrius, crossing into Asia Minor, seized Caria and Lydia, but Agathocles, the son of Lysimachus by an Odrysian princess, was sent against him, and forced him to retreat into the territory of Seleucus, who obliged him to surrender. Lysimachus attacked Pyrrhus and Demetrius's son Antigonus, now his ally, and forced Pyrrhus to give up part of Thessaly and the whole of Macedon. Amastris had been murdered by her two sons, and Lysimachus resolved to avenge her; he got them into his hands on pretence of friendship and put them to death. On his return Arsinoe asked the gift of Heraclea, and he granted her request, though he had promised to free the city. In 284 Arsinoe, desirous of gaining the succession for her sons in preference to Agathocles, intrigued against him with the help of her brother Ptolemy Ceraunus; they accused him of conspiring with Seleucus to seize the throne, and he was put to death. To remove the disquietude of the Egyptian court, Agathocles being the husband of Ptolemy's daughter Lysandra, Lysimachus married his daughter Arsinoe to the young Ptolemy Philadelphus. The widow of Agathocles fled to Seleucus, and war between the latter and Lysimachus soon followed. In 281 the decisive battle took place at the plain of Corus, the exact situation of which is doubtful; Lysimachus was killed; after some days his body was found on the field watched by a faithful dog.

Lysimachus was a man of distinguished bravery and great personal strength; on one occasion he had killed a lion single-handed, though at the cost of fearful wounds. He did not rise to political importance till after the battle of Ipsus. Tenacious and insatiate, he framed schemes of aggrandisement till his death, and in pursuit of the schemes his craft suggested he was ready to sacrifice even his own family.

LYSIPPUS, a Greek sculptor whose professional activity falls between the years 372 and 316 B.C. In addition to the sketch with accompanying illustrations of his style given under ARCHÆOLOGY (vol. ii. p. 361, figs. 9 and 11), it may here be stated that the head of Alexander the Great (fig. 11 just referred to) is now admitted to be the best existing representation of the style of Lysippus in portrait sculpture. When we read of successful portraits by him of Socrates and Æsop, as well as of Alexander, we are driven to believe that one of the forces of which he was conscious within himself was that of seizing the spiritual expression and making it illumine faces and forms which under other conditions would be more or less repulsive. This in fact is confirmed by the head of Alexander in the British Museum (fig. 11 *supra*). But with the possession of this force it is difficult to reconcile the tradition of his having taken as his model the Doryphorus of Polycletus, the style of which may be seen in the bronze statuette fig. 6 in the article ARCHÆOLOGY, and, to a less extent, in fig. 7 of the same article. There everything turns on the refinements of physical form. It is admitted that Lysippus introduced great changes in the accepted rules for the proportions of the human figure, and from a number of sculptures traceable to his time, or shortly after his time, it is not only obvious but strikingly in contrast with earlier works that the legs are made long and massive while the body is proportionately shortened, though still retaining a very powerful rendering of the forms. Among the best examples of this are two bronze statuettes of Neptune and Jupiter in the British Museum found at Paramythia in Epirus, or, less satisfactory, the larger bronze of Hercules from Byblus, also in the British Museum. In these cases the limbs and various parts of the figure are studied with extreme skill worthy of the best time. Yet the combined effect is such as to do away with the impassive beauty which is ascribed to Polycletus, and to replace it with a beauty of expression so far as was consistent with powerful physical form. One of his works famed in antiquity was a bronze statuette of Hercules, called Epitrapezius, because, as the story goes, Alexander the Great carried it with him to be placed always on his table. A copy of this, in stone, enlarged somewhat from the original, was obtained by the British Museum from Babylonia in 1881. It is signed with the name of an artist, Diogenes, apparently otherwise unknown, and it bears clearly the evidence of having been copied from a work in bronze. But except in the face, which is carefully executed ("argutiæ operum custoditæ in minimis quoque rebus" is said of Lysippus by Pliny, *Nat. Hist.*, xxxiv. 65), the sculpture is poor and could not be quoted as illustrating any particular style of art, though not inconsistent with the characteristics of Lysippus. With reference to the marble statue of Alexander the Great in Munich, standing with one foot raised on a helmet, it is clear that this affected attitude, which occurs in several other existing statues, such as the so-called Jason in Lansdowne House, cannot fairly be traced to the invention of Lysippus, since it is to be found twice on the frieze of the Parthenon. At the same time the merit may belong to him, as has recently been claimed, of having first applied this attitude in producing a new type of the god Neptune for his temple on the isthmus of Corinth. It was a bolder step to apply this attitude to a draped female figure as in the existing statues of the Muse Melpomene standing with one foot raised on a rock, and if this was really introduced into art by Lysippus it would confirm to some extent his reputation for novelties of representation. But at present we cannot do more than say that he is known to have made a group of the Muses for the town of Megara, and that several statues still exist representing a Muse in an attitude corresponding with that of the Alexander in Munich, which is reasonably inferred to be a copy from a work of Lysippus. If it could be proved that in these cases Lysippus had worked upon Athenian types, we should then understand how it happens that in some respects he was in ancient times classed with the Athenian Praxiteles (Quintilian, xii. 10, 9, "ad veritatem Lysippum ac Praxitelem accessisse optime affirmant"), and is still compared with him so far as the remaining works of both, or copies therefrom, enable a comparison to be made.

See Kekulé, *Ueber den Kopf des Praxitelischen Hermes*, Stuttgart, 1881; Lange, *Das Motiv des aufgestützten Fusses*, Leipsic, 1879.

LYTE, HENRY FRANCIS (1793–1847), a well-known hymn-writer, was born at Kelso, June 1, 1793, received his early education in Ireland, and entered Trinity College, Dublin, in 1812, becoming a scholar of that college in the following year. Having entered deacon's orders in 1815, he for some time held a curacy near Wexford. He did not long remain in Ireland, however, chiefly because of infirm health; and, coming to England, after several changes he finally, in 1823, settled in the parish of Brixham, where he laboured until fatal illness interrupted his work. In 1844 his health, never robust, gave way; and he died at Nice on the 20th November, 1847.

Lyte's first work was *Tales in Verse illustrative of several of the Petitions in the Lord's Prayer*, which was completed during a period of rest at Lymington, but was not published till the year 1826; it drew a word of warm commendation from a competent critic in the *Noctes Ambrosianæ*. He next published a volume of *Poems, chiefly Religious*, in 1833, and in the following year a little collection of psalms and hymns entitled *The Spirit of the Psalms*. These productions were drawn from various sources, but many were his own; and the idea of the book was to express, in language specially accordant with Christian experience, the leading thoughts contained in the Psalter. Probably one of the best productions of Lyte's pen was a finely appreciative memoir of Henry Vaughan, the "Silurist," which he prefixed to an edition of his works. After his death, a volume of *Remains* with a memoir was published, and the poems contained in this, with those in *Poems, chiefly Religious*, were afterwards issued in one volume. In the region of pure poetry Lyte cannot be said to have taken any special rank; refinement and pathos, rather than great imaginative power, were the chief marks of his work. As a divine he was evangelical in doctrine, but his ecclesiastical sympathies were with the Oxford school; as a preacher he was simple, earnest, and graceful in style; but his chief claim to remembrance lies in the beauty and spiritual elevation of his hymns, some of which may be said to have become classical. The best known are "Abide with me! fast falls the eventide"; "Jesus, I my cross have taken"; "Praise, my soul, the King of Heaven"; and "Pleasant are thy courts above."

LYTTELTON, George, Lord (1709–1773), statesman and man of letters, born at Hagley, Worcestershire, in 1709, was a descendant of the great Thomas de Littleton (*q.v.*), and the eldest son of Sir Thomas Lyttelton, Bart., who at the Revolution of 1688 and during the following reign was one of the ablest Whig debaters of the House of Commons. Lyttelton was educated at Eton and Oxford, and in 1728 set out on the grand tour, spending considerable periods at Paris and Rome. On his return to England he sat for Okehampton, Devonshire, beginning public life in the same year with Pitt; and from 1744 to 1754 he held the office of a lord commissioner of the treasury. In 1755 he succeeded Legge as chancellor of the exchequer, but in the following year he quitted office, on which occasion he was raised to the peerage as Lord Lyttelton, baron of Frankley, in the county of Worcester. In the political crisis of 1765, before the formation of the Rockingham administration, it was at one time suggested that he might be placed at the head of the treasury, but he firmly declined to take part in any such scheme. The closing years of his life were devoted chiefly to literary pursuits. He died on August 22, 1773.

Lyttelton's earliest publication (1735), *Letters from a Persian in England to his Friend at Ispahan*, appeared anonymously. Much greater celebrity was achieved by his *Observations on the Conversion and Apostleship of St Paul*, also anonymous, published in 1747. It takes the form of a letter to Gilbert West, and is designed to show that St Paul's conversion is of itself a sufficient demonstration of the divine character of Christianity. The drift of the argument is that it is equally inconceivable that the apostle could have been the victim or the originator of a cheat, and that therefore he must have been divinely inspired. It is interesting to know that Dr Johnson regarded the work as one "to which infidelity has never been able to fabricate a specious answer." Lord Lyttelton's *Dialogues of the Dead*, a creditable performance, though hardly rivalling either Lucian or Landor, appeared in 1760. His *History of Henry II.* (1764–67), the fruit of twenty years' labour, is not now cited as an authority, but is painstaking and fair. Lyttelton was also a writer of verse; his *Monody* on his wife's death has been praised by Gray for its elegiac tenderness, and his *Prologue* to the *Coriolanus* of his friend Thomson shows genuine feeling. He was also the author of the well-known stanza in the *Castle of Indolence*, in which the poet himself is described. A complete collection of the *Works* of Lord Lyttelton was published after his death by his nephew, G. E. Ayscough. See *Memoirs and Correspondence of Lord Lyttelton*, 1734–1773 (2 vols., 1845).

LYTTON, Edward George Earle Lytton Bulwer Lytton, Baron (1805–1873), novelist, dramatist, poet, politician, miscellaneous essayist, the most versatile writer and one of the most active and widely discursive theorizers of his generation, was born in May 1805, the youngest of the three sons of General Bulwer, of Heydon Hall and Wood Dalling, Norfolk. He was a few months younger than Benjamin Disraeli; the two lives acted not a little one on the other, and offer many curious points of likeness and contrast. Bulwer's father died when he was two years old; the care of the boy devolved on his mother, one of the Lyttons of Knebworth, Hertfordshire, whose name he afterwards assumed. To this devoted and accomplished mother he always expressed the warmest gratitude for his early training. He was not sent to a public school; he was educated privately.

In his novels and essays he often discusses the advantages and disadvantages of public schools. One thing is tolerably certain—that if he had been sent to a public school he would not have published at the age of fifteen a volume of poems (*Ismael, an Oriental Tale, with other Poems*, 1820). Generous sentiment and eager love of fame are more conspicuous in these juvenile productions than metrical faculty. One of the poems dwells warmly on the ancient glories of the house of Lytton; the volume as a whole is dedicated to "the British public—that generous public who have always been the fosterers of industry or genius, who have always looked forward from the imperfections of youth to the fruits of maturity." The youthful poet criticizes Byron from the point of view of a respectable household; but, though he seems to have been taught to make Pope, Gray, and Collins his models, the Byronic influence is very apparent both in phrase and in sentiment. In the local colouring of the "Oriental Tale" he gives promise, afterwards amply fulfilled, of painstaking study of his materials; and "Geraldine, or the Fatal Boon," gives a good foretaste of his fertility in the invention of romantic incident.

At Cambridge, in 1825, Bulwer won the chancellor's medal with a poem on "Sculpture." In 1826 he printed for private circulation *Weeds and Wild Flowers*. In 1827 he published *O'Neill, or the Rebel*, a romance, in heroic couplets, of patriotic struggle in Ireland, dedicated to Lady Blessington. These juvenilia, and also a metrical satire, *The Siamese Twins*, issued in 1831, he afterwards ignored, describing *The New Timon* as his first publication in verse, with the exception of his dramas and translations from Schiller.

Bulwer's first romance, *Falkland*, published anonymously in 1827, was in the vein of fantastic German romance popular at the beginning of the century, and did not bring him the fame that he coveted so ardently. It was otherwise with *Pelham*, published in the following year. In this he went with the native stream of fiction, and at once made himself felt as a power. For two or three years before he wrote *Pelham*, the books of the season had been novels of remarkable freshness and brilliancy dealing with fashionable life—Plumer Ward's now forgotten but then much-talked-of *Tremaine*, Theodore Hook's *Sayings and Doings*, Lister's *Granby*, Disraeli's *Vivian Grey*. With these brilliant celebrities Bulwer, always a chivalrous emulator of whatever was famous, entered into direct competition, and at once became at least their equal in popular favour. If we compare this his first novel with any of his last productions, he strikes us as having attained at a bound to the full measure of his powers. That he wrote *Pelham* at twenty-two is a much more remarkable fact than that he wrote ballads at five. The plot is not perhaps so closely woven together as in *The Parisians*, but the variety of character introduced from high life, low life, and middle life is quite as great. He had evidently been fascinated by *Wilhelm Meister*, and the central purpose of his story is to run the hero through an apprenticeship like Wilhelm's. All kinds of human beings and all their works are interesting to Pelham, the man of fashion, the bustling statesman, the selfish epicure, the retiring scholar, the reckless rogue and vagabond, the melodramatic Byronic man of mystery; and his adventures are so contrived as to bring him in contact with many different types. The novel might have been called *The Londoners*; most of the criticisms of life and books in *England and the English*, published in 1833, may be found in *Pelham*, delivered through the mouths of various characters. These characters are great talkers; no subject, from a rare dish or a nicety of costume to a painting or a philosophical treatise, is strange to them. And, curiously enough, the judgments of the youth of twenty-two are as mature, as large, catholic, generous, widely sympathetic, as those of the sage of sixty-six, and his knowledge of men and books hardly less extensive. *Pelham* displayed—in the literal sense of the word—extraordinary vivacity of intellect and range of interest. The author was yet to prove that with his wonderful powers of reading, observing, and reflecting was combined a faculty rarely found in union with such gifts, untiring rapidity of production. In the preface to his juvenile "Ismael," he speaks of a habit of his never to leave anything unfinished, and during his long life he began and finished many works in many different veins. *Pelham* was followed in quick succession by *The Disowned* (1828), *Devereux* (1829), *Paul Clifford* (1830), *Eugene Aram* and *Godolphin* (1833). Bulwer was deeply impressed with German theories of art; all these novels were novels with a purpose, moral purpose, psychological purpose, historical purpose. To embody the leading features of a period, of a phase of civilization, to trace the influence of circumstance on character, to show how the criminal may be reformed by the development of his better nature, and how men of fine nature may be led stage by stage into crime, to explain the secrets of success and failure in life—these, apart from the purely dramatic object of exhibiting inward struggles between the first conceptions of desires and their fulfilment, and between triumph and retribution, were his avowed aims as a novelist. He did not leave his purposes to the interpreter; he was a critic as well as a creator, and he criticized his own works frankly, and laboured to admit other critics to a fair point of view. It was perhaps a tribute to the intrinsic interest of his plots, characters, and descriptions that he was under the necessity of begging attention to these higher aims. In *The Pilgrims of the Rhine* (1834), a work of graceful fantasy, in which some of his most acute observations on human life are incorporated with the sayings and doings of elves and fairies, an ambitious author is made to complain that "the subtle aims that had inspired him were not perceived," and that he was often approved for what he condemned himself. The *Pilgrims*, charmingly written in many passages, was too German in its combination of serious thought and mundane personages with fairies to be heartily welcomed by the English public. Bulwer was more successful in another attempt to break new ground in *The Last Days of Pompeii* (1834) and *Rienzi* (1835). No historical romances dealing with times and scenes so remote were ever more widely popular in England, and in aiming at popularity the author laboured hard to secure historical accuracy. In *Athens, its Rise and Fall* (1836), we received in the form of historical essays what had probably been acquired industriously as materials for romance. Two romances from Spanish history, *Leila* and *Calderon*, published in 1838, aimed at a less realistic treatment, and, with all their purely literary excellences, were not so popular. In *Ernest Maltravers* (1837) and its sequel *Alice, or The Mysteries* (1838), the novelist returned to English ground and psychological and social problems—"the affliction of the good, the triumph of the unprincipled." Critics to whom he failed to make the full purpose of these works apparent in the execution complained of the low tone of their morality, a fair complaint concerning most exhibitions of vice as a warning.

To his other literary labours Bulwer superadded for some time the editorship of a magazine. He succeeded Campbell as editor of *The New Monthly* in 1833. In 1838 he projected a magazine called *The Monthly Chronicle*, and contributed to it as a serial story the fantastic romance "Zicci." The magazine expired before the story was completed, and it was afterwards developed into *Zanoni*, a romance of which he was himself especially proud, and which suffered in public estimation from being tried by realistic standards.

During the most productive period of his literary life Bulwer was an eminent member of parliament. He was returned for St Ives in 1831, and sat for Lincoln from 1832 to 1841. He spoke in favour of the Reform Bill, and took the leading part in obtaining the reduction, after vainly trying to procure the repeal, of the newspaper stamp duties. His support of the Whigs in parliament, and by a pamphlet on "the crisis" when they were dismissed from office in 1834, was considered so valuable that Lord Melbourne offered him a place in the administration. His intimacy with Radical leaders at this period exposed him to an undeserved charge of tergiversation when later in life he was a member of a Conservative Government. Charles Buller and Charles Villiers were among his friends at Cambridge; he was an admiring student of Bentham; Mill's *Essay on Government* was the text-book on which was founded "Pelham's" instruction by his uncle in the principles of politics; J. S. Mill contributed the substance of the appendices to *England and the English*, on Bentham and Mill; Godwin suggested to him the subject and some part of the plot of *Eugene Aram*; he even succeeded in winning the good opinion of Miss Martineau; but we have only to read his speech in favour of the Reform Bill to see that it was the situation that had changed and not the man when he assailed the repeal of the corn laws, and took office under Lord Derby. Bulwer's leading political aim, like his leading artistic aims, was early formulated, and the formula governed all his political reasoning: it was to "aristocratize the community," "to elevate the masses in character and feeling to the standard which conservatism works in aristocracy," a standard not of wealth or pedigree but of "superior education, courteous manners, and high honour." Hence it was "social reforms" from first to last that enlisted his interest, and he sought the motive power for these reforms in the public spirit of the classes enfranchised by the Reform Act of 1832.

There was a slight break in Bulwer's career as a novelist between 1838 and 1847. During this interval he applied himself enthusiastically to play writing,—Macready's management of Covent Garden having inspired men of letters with the hope of reconciling poetry with the stage. In 1836 he had produced *The Duchess of La Vallière*. It was a failure. But in 1838 and the two following years he produced three plays which have kept the stage ever since—*The Lady of Lyons*, *Richelieu*, and *Money*. In his plays as in his novels definite theory preceded execution. The principles on which he wrote his plays were laid down in his chapter on the drama in *England and the English*. For many of the details of stagecraft, all-important to success under any principles, he is said to have been indebted to Macready. No Englishman not himself an actor has written so many permanently successful plays as Bulwer Lytton, and this is another instance of his extraordinary plasticity of mind and practical insight. Thirty years afterwards, in 1869, he turned his thoughts again to writing for the stage, recast an old failure with a new title *The Rightful Heir*, and produced a new comedy, *Walpole*. Neither was a success.

From 1841 to 1852 Bulwer (he assumed his mother's name of Lytton on succeeding to her estates in 1843) had no seat in parliament. But the issue of novels and romances was not so rapid as it had been in the full energy of his youth. Before 1849, when he opened a new vein with *The Caxtons*, he produced five works in his familiar vein:—*Night and Morning* (1841, in which the influence of Dickens is traceable), *Zanoni* (1842), *The Last of the Barons* (1843, the most historically solid, and perhaps the most effective of his romances), *Lucretia, or the Children of the Night* (1847; moral purpose—to exhibit the horrors caused by the worship of money; popular effect—disgust at these horrors, and indignation at the author's sentiment as morbid), *Harold, The Last of the Saxon Kings* (1848).

The cause of the comparative infertility of this period in prose fiction probably was that Lytton was now making a determined effort to win high rank as a poet. He published a volume of poems in 1842, a volume of translations from Schiller in 1844, *The New Timon*, a satire, in 1845.[1] Then came the work on which mainly Lytton rested his pretensions, *King Arthur*, a romantic epic. "I am unalterably convinced," he said, "that on this foundation I rest the least perishable monument of those thoughts and those labours which have made the life of my life." But *King Arthur* fell flat. The verse, the six-lined stave of elegiac quatrain and couplet, lacks charm and variety; the incidents are monotonous, the personages uninteresting, the plot unexciting, and the allegory obscure. *St Stephen's*, a gallery of parliamentary portraits from the time of Queen Anne, was a kind of metrical composition that lay more within his powers. In this the satire is keen-edged, the admiration just and generous. It was published in 1860. The *Lost Tales of Miletus* (1866) and a translation of Horace's *Odes* (1869) were Lytton's last essays in verse.

In the skill with which he sustained a new style in *The Caxtons* (1848) Lytton gave a more convincing proof of his versatility. This imitation of Sterne (by no means a servile imitation, rather an adaptation of Sterne's style and characters to the circumstances of the 19th century) appeared anonymously in *Blackwood's Magazine*, and made a reputation before the authorship was suspected. *My Novel* (1853) and *What will He Do with It?* (1858) continued in the same strain. The sub-title of *My Novel*, "Varieties of English life," shows still operative the same purpose that we find in *Pelham*, but the criticism of the "Varieties" is more polemical in spirit. There is more than a shade of defiance in his praise of the virtues of a territorial aristocracy, and a strong spice of hostility to the vulgarities of the manufacturers who threatened to push them from their stools. There is a blindness to defects in the one case and to merits in the other quite foreign to the broad sympathies of the dandy Pelham; Caxton paints the ideal best of the one class and the ideal worst of the other. In these, as in all Lytton's novels, the characters are placed on the stage and described; they are not left to reveal themselves gradually in action.

Lytton returned to parliament in 1852 as member for Hertfordshire, and sat on the Conservative side. Early in life he had decided in his mind against the reduction of the corn duties, and, unchanged in 1851, he addressed a "Letter to John Bull," enlarging on the dangers of their repeal. Incapable of failure in any intellectual exercise that he set his mind to, he was an effective speaker; but the effort was against nature: he could speak only under extreme excitement or after laborious preparation, and he never took a high place among parliamentary orators. He was colonial secretary in Lord Derby's Government from 1858 to 1859, and threw himself industriously into the duties of his office. He was raised to the peerage as Baron Lytton in 1866.

That he had not forgotten his power of moving the sense of melodramatic and romantic mystery when he adopted the more subdued style of *The Caxtons*, Lytton proved by *A Strange Story*, contributed to *All the Year Round* in 1862. A serial story of the kind made a new call on his resources, but he was equal to it, and fairly rivalled the school of Dickens in the art of sustaining thrilling interest to the close.

When he died, in January 1873, after a short painful illness, two works of high repute, *The Coming Race* and *The Parisians*, were not acknowledged, and were only vaguely suspected to be his. They had freshness enough to be the work of youth, and power enough to shame no veteran. These two books, the fable and the novel, are classed by Lytton's son and successor in the the title with the romance of *Kenelm Chillingly*, left completed at his death, as forming a trilogy, animated by a common purpose, to exhibit the influence of "modern ideas" upon character and conduct. The moulding force whose operation is traced in *The Parisians* is the society of imperial and democratic France, in *Chillingly* the society of England in relation to its representative institutions. The leading purpose is kept well in view throughout both works, and the tendencies to corruption analysed and presented with admirable skill; but the theorist has omitted from his problem certain important regenerating and safeguarding factors in the large world outside the pale of society. Problems and theories apart, these last works show no falling off of power; he is as vivid as ever in description, as fertile as ever in the invention of humorous and melodramatic situation. If he had been content to abandon his purpose in *Chillingly*, and end with the first volume by some such commonplace contrivance as giving "motive power" to his hero in the love of Cecilia Travers, it would have been the most perfect of his works in unity of humorous sentiment. The veteran author died in harness,—two novels all but completed; another, an historical romance, *Pausanias the Spartan*, outlined and partly written.

The fact that in the fiftieth year of his authorship, after publishing at least fifty separate works, most of them popular, Lord Lytton had still vigour and freshness enough to make a new anonymous reputation with *The Coming Race* would seem to indicate that critics had not fairly gauged his versatility, and also that an erroneous fixed idea had been formed of his style. The explanation probably is that even after the publication of *The Caxtons* he was thought of in connexion with that school of melodramatic romance of which he was indisputably the leader, if not the founder, and that heavily loaded rhetorical style which was made ridiculous by his imitators. "Every great genius," one of his characters is made to say, "must deem himself alone in his conceptions. It is not enough for him that these conceptions should be approved as good, unless they are admitted as inventive." Invention and originality are matters of degree, and, though no one can deny that Lytton possessed great inventive powers, he did not put that individual stamp on his work without which no writer is entitled to a place in the foremost rank. He was not self-centred enough; he was too generally emulous to win the highest individual distinction. But his freshness of thought, brilliancy of invention, breadth and variety of portraiture, gave him a just title to his popularity, and, with all allowance for superficial affectations, his generous nobility of sentiment made his influence as wholesome as it was widespread. (W. M.)

[1] A feeble attack in the last on Mr Tennyson's poetry provoked a brusque but powerful reply from the enraged laureate, aimed at his assailant's person.

M

M. THE letter M denotes a nasal sound, which varies little, if at all, in different languages.

Nasal sounds are produced as follows. The breath—turned into voice at its passage through the glottis—does not pass out wholly through the mouth. Part of it is diverted behind the soft palate, and so through the nostrils; the remainder passes through the mouth-cavity, and is there completely checked at some point of its course. When that check is taken away, we hear, not the sonant which would have been produced if all the breath had passed through the mouth, but a nasal varying in nature according to the part of the cavity where the check of the tongue or the lips has been applied. There may be as many definite nasal sounds in any language as there are recognized classes of consonants, as guttural, palatal, dental, labial. In Sanskrit there were even five nasal sounds so clearly differentiated that each had a special symbol to denote it; the cerebral class of sounds (produced by turning the tip of the tongue slightly back against the middle of the palate) had its nasal as well as each of the other four classes above mentioned. In English we have three sounds, but only two simple symbols, *m* and *n*; for the guttural nasal heard in *sing*, &c., we employ the digraph *ng*. Spanish has a palatal nasal.

The nasal sound denoted by M is the labial nasal. It corresponds to the sonant *b*-sound; for each of them the lips are completely closed, and if no voice were diverted through the nostrils a *b*-sound only would be heard when the lips are opened; all the organs of the mouth are in exactly the same position for one sound as for the other, but, the soft palate being lowered, the voice is divided in its egress. Hence we see why a man who has a cold pronounces *m* as *b*; the voice cannot get through the nostrils, which are blocked up; it must therefore escape mainly or entirely through the lips, and so produce a *b*-sound. Therefore, instead of "talking through his nose," as the phrase goes, such a person tries to talk through his nose, but cannot.

The symbol M stands in numeration for 1000. See Alphabet.

MAAS. See Meuse.

MABILLON, Jean (1632–1707), the learned and discriminating historian of the Benedictine order, was born at the village of Saint Pierremont, Champagne (now in the department of Ardennes), on November 23, 1632. He received his early education from an uncle who held the post of village curé in the neighbourhood, and afterwards he went to Rheims, where, in 1653, he entered upon his noviciate in the Benedictine Abbey of Saint Remy, taking the vows in the following year. The following four years were spent at various houses of the order, to which he was sent on account of his health, impaired by excessive study. From 1658 to 1663 he was at Corbie, and in 1664 he assisted Chantelon at Saint Denis in the preparation of a new edition of the works of St Bernard. Shortly afterwards he was removed to Saint-Germain-des-Prés, and charged with the task of editing materials which had already been amassed for a general history of the Benedictine order. While engaged on this work (*Acta Sanctorum ordinis S. Benedicti in sæculorum classes distributa*), the publication of which, in 9 vols. folio, extended from 1668 to 1701, he made several journeys, for literary research, into Germany and Italy, as well as into the provinces of France; amongst the more important of the numerous monographs to which his investigations gave rise, the work *De Re Diplomatica*, which appeared in 1681, deserves special mention (see Diplomatics). Mabillon died at Saint-Germain-des-Prés, on December 27, 1707.

For a complete list of his works reference may be made to Bayle's *Dictionnaire*, or to the *Biographie Générale*. They include, besides those mentioned above, *Vetera Analecta*, 1675–85 (a work similar in character to the *Miscellanea* of Baluze); *Animadversiones in Vindicias Kempenses*, 1677 (in which he claims the *Imitatio* for Gersen); *De Liturgia Gallicana*, 1685; *Museum Italicum*, 1687–89; and *Annales Ordinis S. Benedicti*, 6 vols. fol., 1703–39.

MABUSE. See Gossart.

MACAO (A-Ma-ngao, "Harbour of the goddess A-Ma"; Portuguese, *Macau*), a Portuguese settlement on the coast of China, in 22° N. lat. and 132° E. long., consists of a tongue of land 1½ square miles in extent, running south-south-west from the island of Hiang Shang (Portuguese, Ançam) on the western side of the estuary of the Canton river. Bold and rocky hills about 300 feet in height occupy both extremities of the peninsula, the picturesque-looking city, with its flat-roofed houses painted blue, green, and red, lying in the far from level stretch of ground between. The forts are effective additions to the general view, but do not add much to the real strength of the place. Along the east side of the peninsula runs the Praya Grande, or Great Quay, the chief promenade in Macao, on which stand the governor's palace, the administrative offices, the consulates, and the leading commercial establishments. The church of St Paul, erected between 1594 and 1602, the seat of the Jesuit college in the 17th century, was destroyed by fire in 1835. The Hospital da Misericordia (1569) was rebuilt in 1640. The Camoens grotto—where the exiled poet found leisure to celebrate the achievements of his ungrateful country—lies in a secluded spot to the north of the town, which has been partly left in its native wildness strewn with huge granite boulders and partly transformed into a fine botanical garden. In 1871 there were in Macao 5375 persons of European birth or extraction, 53,761 Chinese living on land and 10,268 in boats. Half-castes are very numerous. Though most of the land is under garden cultivation, the mass of the people is dependent more or less directly on mercantile pursuits; for, while the exclusive policy both of Chinese and Portuguese which prevented Macao becoming a free port till 1845–46 allowed what was once the great emporium of European commerce in eastern Asia to be outstripped by its younger and more liberal rivals, the trade of the place is still of very considerable extent. Since the middle of the century indeed much of it has run in the most questionable channels: the nefarious coolie traffic gradually increased in extent and in cruelty from about 1848 till it was prohibited in 1874, and much of the actual trade is more or less of the nature of smuggling. The total value of exports and imports was in 1876–77 upwards of £1,536,000. Commercial intercourse is most intimate with Hong-Kong, Canton, Batavia, and Goa. The preparation and packing of tea is the principal industry in the town. The colonial revenue, which is largely recruited by a tax on the notorious gambling tables, increased from 104,643 dollars in 1856–57 to 380,012 in 1872–73, while the expenditure rose from 69,757 to 266,344.

In 1557 the Portuguese were permitted to erect factories on the peninsula, and in 1573 the Chinese built the wall across the isthmus which still cuts off the barbarian from the rest of the island. Jesuit missionaries established themselves on the spot, and in 1580 Gregory XIII. constituted a bishopric of Macao. A senate was organized in 1583, and in 1628 Jeronimo de Silveira became first royal governor of Macao. Still the Portuguese remained largely under the control of the Chinese, who had never surrendered their territorial rights and maintained their authority by means of mandarins,—these insisting that even European criminals should be placed in their hands. Ferreira do Amaral, the Portuguese governor, put an end to this state of things in 1849, and left the Chinese officials no more authority in the peninsula than the representatives of other foreign nations; and, though his antagonists procured his assassination (August 22d), his successors have succeeded in carrying out his policy. The Chinese Government has hitherto refused (notably in 1862) to recognize the territorial claims of the Portuguese; but the European powers treat Macao as *de facto* a colonial possession, and not only the governor, the president of the courts, and other Portuguese officials, but even the Chinese magistrates, are directly appointed by the king of Portugal. For a short time in 1802, and again in 1808, Macao was occupied by the English as a precaution against seizure by the French.

MACARONI (from dialectic Italian *maccare*, "to bruise or crush") is a preparation of wheat originally peculiar to Italy, in which country it is an article of food of national importance. The same substance in different forms is also known as vermicelli, pasta or Italian pastes, taglioni, fanti, &c. These substances are prepared from the hard semi-translucent varieties of wheat which are largely cultivated in the south of Europe, Algeria, and other warm regions, and which are distinguished by the Italians as *grano duro* or *grano da semolino*. Hard wheats are much richer in gluten and other nitrogenous compounds than the soft or tender wheats, and their preparations are more easily preserved, to which conditions their suitability for the manufacture of Italian pastes are mainly due. The various preparations are met with in the form of fine thin threads which constitute vermicelli, so called from its thread-worm like appearance, thin sticks and pipes (macaroni), small lozenges, stars, disks, ellipses, &c. (pastes), and ribbons, tubes, and other fanciful forms. These various forms are prepared in a uniform manner from a granular meal of hard wheat which itself, under the name of semolina or semola, is a commercial article. The semolina is thoroughly mixed and incorporated into a stiff paste or dough with boiling water, and in the hot condition it is placed in a strong metallic cylinder, the end of which is closed with a thick disk pierced with openings which correspond with the diameter or section of the article to be made. Into this cylinder an accurately fitting plunger or piston is introduced, and by very powerful pressure it causes the stiff dough to squeeze out through the openings in the disk in continuous threads, sticks, or pipes, as the case may be. When pipe or tube macaroni is being made, the openings in the disk are widened internally, and mandrels, the gauge of the tubes to be made, are centred in them. In making pastes the cylinder is laid horizontally, the end is closed with a disk pierced with holes having the sectional form of the pastes, and a set of knives revolves close against the external surface of the disk, cutting off the paste in thin sections as it exudes from each opening. Macaroni is dried rapidly by hanging it in long sticks or tubes over wooden rods in stoves or heated apartments through which currents of air are driven. It is only genuine macaroni, rich in gluten, which can be dried in this manner; spurious fabrications made with common flour and coloured to imitate the true material will not bear their own weight. Imitations must therefore be laid out flat and dried slowly, during which they very readily split and break up, while in other cases they become mouldy on the inside of the tubes. True macaroni can be distinguished by observing the flattened mark of the rod over which it has been dried within the bend of the tubes; it has a soft yellowish colour, is rough in texture, elastic, and hard, and breaks with a smooth glassy fracture. In boiling it swells up to double its original size without becoming pasty or adhesive, maintaining always its original tubular form without either rupture or collapse. It can be kept any length of time without alteration or deterioration, and it is on that account, in many circumstances, a most convenient as well as a highly nutritious and healthful article of food. In its various forms it is principally used as an ingredient in soups, and for the preparation of puddings, with cheese, &c. Many of the good qualities of genuine macaroni may be obtained by enriching the flour of common soft wheat with gluten obtained in the preparation of wheaten starch, and proceeding as in the case of semolina. Such imitations, and others of inferior quality, are extensively made both in France and Germany.

MACARTNEY, George Macartney, Earl of (1737–1806), was descended from an old Scotch family, the Macartneys of Auchinleck, who had settled in 1649 at Lissanoure, Antrim, Ireland, where he was born May 13, 1737. After graduating at Trinity College, Dublin, in 1759, he became a student of the Inner Temple, London. Appointed envoy-extraordinary to Russia in 1764, he succeeded in negotiating an alliance between England and that country. After for some time occupying a seat in the English parliament, he was in 1769 returned for Armagh in the Irish parliament, in order to discharge the duties of chief secretary for Ireland. On resigning this office he received the honour of knighthood. In 1775 he became governor of Granada, in 1780 governor of Madras, and in 1785 he was appointed governor-general of Bengal, but, his health demanding his return to England, he declined to accept office. After being created earl of Macartney in the Irish peerage, he was appointed in 1792 the first envoy of Britain to China. On his return from a confidential mission to Italy he was raised to the English peerage in 1796, and in the end of the same year was appointed governor of the newly acquired territory of the Cape of Good Hope, where he remained till ill health compelled him to resign in November 1798. He died at Chiswick, Surrey, 31st March 1806.

An account of Macartney's embassy to China, by Sir George Staunton, was published in 1797, and has been frequently reprinted. See also *Life and Writings of Lord Macartney*, by Barrow, 2 vols., London, 1807.

MACASSAR. See Celebes, vol. v. p. 288.

MACAULAY, Thomas Babington Macaulay, Lord (1800–1859), was born at Rothley Temple, Leicestershire, on the 25th of October 1800. His father, Zachary Macaulay, had been governor of Sierra Leone, and was in 1800 secretary to the chartered company who had founded that colony. Happy in his home, the boy at a very early age gave proof of a determined bent towards literature. Before he was eight years of age he had written a *Compendium of Universal History*, which gave a tolerably connected view of the leading events from the creation to 1800, and a romance in the style of Scott, in three cantos, called the *Battle of Cheviot*. At a little later time the child composed a long poem on the history of Olaus Magnus, and a vast pile of blank verse entitled *Fingal, a Poem in Twelve Books*.

The question between a private and a public school was anxiously debated by his parents, and decided in favour of the former. The choice of school, though dictated by theological considerations, was a fortunate one. Mr Preston of Little Shelford enjoyed the confidence of Mr Simeon, but was himself a judicious tutor; and at his table, where master and pupil dined in common, not only the latest Cambridge topics were mooted, but university ambitions and ways of thought were brought home to the boys.

In October 1818 young Macaulay went into residence at Trinity College, Cambridge. Here he revelled in the possession of leisure and liberty, which he could not forego for the sake of those university honours which at that day were only to be obtained by a severely exclusive course of mathematical study. But he succeeded in obtaining the prize which in his eyes was the most desirable that Cambridge had to give, viz., a fellowship at Trinity. A trifling college prize for an essay on the character of William III. was awarded to an essay by young Macaulay, which may be regarded as the first suggestion and the earnest of his future *History*.

In 1826 Macaulay was called to the bar and joined the northern circuit. But after the first year or two, during which he got no business worth mention, he gave up even the pretence of reading law, and spent many more hours under the gallery of the House of Commons than in the court. His first attempt at a public speech, made at an anti-slavery meeting in 1824, was described by the *Edinburgh Review* as "a display of eloquence of rare and matured excellence." His first considerable appearance in print was in No. 1 of Knight's *Quarterly Magazine*, a periodical which enjoyed a short but brilliant existence, and which was largely supported by Eton and Cambridge. In August 1825 began Macaulay's connexion with the periodical which was to prove the field of his literary reputation. The *Edinburgh Review* was at this time at its height of power, not only as an organ of the growing opinion which leant towards reform, but as a literary tribunal from which there was no appeal. The essay on Milton, though so crude that the author said of it that "it contained scarcely a paragraph such as his matured judgment approved," created for him at once a literary reputation which suffered no diminution to the last, a reputation which he established and confirmed, but which it would have been hardly possible to make more conspicuous. Murray declared that it would be worth the copyright of *Childe Harold* to have Macaulay on the staff of the *Quarterly Review*. Robert Hall, writhing with pain, and well-nigh worn out with disease, was discovered lying on the floor employed in learning by aid of grammar and dictionary enough Italian to enable him to verify the parallel between Milton and Dante. The family breakfast table was covered with cards of invitation to dinner from every quarter of London.

The sudden blaze of popularity kindled by a single essay, such as are now produced every month without attracting any notice, is partly to be explained by the dearth of literary criticism in England at that epoch. For, though a higher note had already been sounded by Hazlitt and Coleridge, it had not yet taken hold of the public mind, which was still satisfied with the feeble appreciations of the *Retrospective*, or the dashing and damnatory improvisation of Wilson in *Blackwood* or Jeffrey in the *Edinburgh*. Still, after allowance made for the barbarous partisanship of the established critical tribunals of the period, it seems surprising that a social success so signal should have been the consequence of a single article. The explanation is to be found in the fact that it had been discovered at the same time that the writer of the article on Milton was, unlike most authors, also a brilliant converser. There has never been a period when an amusing talker has not been in great demand at London tables; but at the date at which Macaulay made his début witty conversation was studied and cultivated as it has ceased to be in the more busy age which has succeeded. At the university Macaulay had been recognized as pre-eminent for talk and companionship among a circle of young men of talents so brilliant as were Charles Austin, Romilly, Praed, Villiers, and others. He now displayed these gifts on a wider theatre. Crabb Robinson's diary, under date 1826, records the judgment of one who had been in the constant habit of hearing the best talk of the London of his day. Such as he was in 1826 Macaulay continued to be to the end. In Lord Carlisle's journal, under date 27th June 1843, we read—"Breakfasted with Hallam, John Russell, Macaulay, Everett, Van de Weyer, Hamilton, Mahon. Never were such torrents of good talk as burst and sputtered over from Macaulay and Hallam." Again, 11th October 1849, "the evening went off very pleasantly, as must almost always happen with Macaulay. He was rather paradoxical, as is apt to be his manner, and almost his only social fault. The greatest marvel about him is the quantity of trash he remembers." In March 1850 Lord Carlisle records—"Macaulay's flow never ceased once during the four hours, but it is never overbearing."

Thus launched (1825) on the best that London had to give in the way of society, Macaulay accepted and enjoyed with all the zest of youth and a vigorous nature the opportunities opened for him. He was courted and admired by the most distinguished personages of the day. He was admitted at Holland House, where Lady Holland listened to him with deference, and scolded him with a circumspection which was in itself a compliment. Rogers spoke of him with friendliness, and to him with affection, and ended by asking him to name the morning for a breakfast party. He was treated with almost fatherly kindness by "Conversation" Sharp.

Thus distinguished, and justifiably conscious of his great powers, it was not unnatural that Macaulay's thoughts should take the direction of politics, and his ambition aspire to a political career. But the shadow of pecuniary trouble early began to fall upon his path. When he went to college his father believed himself to be worth £100,000, and declared his intention of making him, in a modest way, an eldest son. But commercial disaster overtook the house of Babington and Macaulay, and the son now saw himself compelled to work for his livelihood. His Trinity fellowship of £300 a year became of great consequence to him, but it expired in 1831; he could make at most £200 a year by writing; and a commissionership of bankruptcy, which was given him by Lord Lyndhurst in 1828, and which brought him in about £400 a year, was swept away, without compensation, by the ministry which came into power in 1830. Macaulay now found himself a poor man, and was reduced to such straits that he had to sell his Cambridge gold medal.

In February 1830 the doors of the House of Commons were opened to him in the only way in which a man without fortune could enter them, through what was then called a "pocket borough." Lord Lansdowne, who had been struck by two articles on Mill (James) and the Utilitarians, which appeared in the *Edinburgh Review* in 1829, offered the author the seat at Calne. The offer was accompanied by the express assurance that the noble patron had no wish to interfere with his freedom of voting. He thus entered parliament at one of the most exciting moments of English domestic history, when the compact phalanx of reactionary administration which for nearly fifty years had commanded a crushing majority in the Commons was on the point of being broken by the growing strength of the party of reform. Macaulay made his maiden speech on 5th April 1830, on the second reading of the bill for the removal of Jewish disabilities. In July the king died and parliament was dissolved; the revolution took place in Paris. Macaulay, who was again returned for Calne, visited Paris, eagerly enjoying a first taste of Continental travel. On 1st March 1831 the Reform Bill was introduced, and on the second night of the debate Macaulay made the first of his reform speeches. It was a signal success. Sir Robert Peel said of it that "portions were as beautiful as anything I have ever heard or read."

Encouraged by this first success, Macaulay now threw himself with ardour into the life of the House of Commons, while at the same time he continued to enjoy to the full the social opportunities which his literary and political celebrity had placed within his reach. For these reasons he dined out almost nightly, and spent many of his Sundays at the suburban villas of the Whig leaders, while he continued to supply the *Edinburgh Review* with a steady series of his most elaborate articles. On the triumph of Earl Grey's cabinet, and the passing of the Reform Act in June 1832, Macaulay, whose eloquence had signalized every stage of the conflict, became one of the commissioners of the Board of Control, and applied himself to the study of Indian affairs. His industry was untiring, and the amount of intellectual product which he threw off very great. Giving his days to India and his nights to the House of Commons, he could only devote a few hours to literary composition by rising at five when the business of the House had allowed of his getting to bed in time on the previous evening. Between September 1831 and December 1833 he furnished the *Review* with the following articles:—"Boswell's Life of Johnson": "Lord Nugent's Hampden"; "Burleigh and his Times"; "Mirabeau"; "Horace Walpole"; "Lord Chatham"; besides writing his ballad on the Armada for one of the Albums, annual publications of miscellanies then in fashion.

In the first reform parliament, January 1833, Macaulay took his seat as one of the two first members for Leeds, which up to that date had been unrepresented in the House of Commons. He replied to O'Connell in the debate on the address, meeting the great agitator face to face, with high, but not intemperate, defiance. In July he defended the Government India Bill in a speech of great power, and to his aid was greatly due the getting the bill through committee without unnecessary friction. When the abolition of slavery came before the House as a practical question, Macaulay had the prospect of being placed in the dilemma of having to surrender office or to vote for a modified abolition, viz., twelve years' apprenticeship, which was proposed by the ministry, but condemned by the abolitionists. He was prepared to make the sacrifice of place rather than be unfaithful to the cause to which his father had devoted his life. He placed his resignation in Lord Althorp's hands, and spoke against the ministerial proposal. But the sense of the House was so strongly expressed as unfavourable that, finding they would be beaten if they persisted, the ministry gave way, and reduced apprenticeship to seven years, a compromise which the abolition party accepted; and Macaulay remained at the Board of Control.

While he was thus growing in reputation, and advancing his public credit, the fortunes of the family were sinking, and it became evident that his sisters would have no provision except such as their brother might be enabled to make for them. Macaulay had but two sources of income, both of them precarious—office and his pen. As to office, the Whigs could not have expected at that time to retain power for a whole generation; and, even while they did so, Macaulay's resolution that he would always give an independent vote made it possible that he might at any moment find himself in disagreement with his colleagues, and have to quit his place. As to literature, he wrote himself to Lord Lansdowne (1833), "it has been hitherto merely my relaxation; I have never considered it as the means of support. I have chosen my own topics, taken my own time, and dictated my own terms. The thought of becoming a bookseller's hack, of spurring a jaded fancy to reluctant exertion, of filling sheets with trash merely that sheets may be filled, of bearing from publishers and editors what Dryden bore from Tonson and what Mackintosh bore from Lardner, is horrible to me." Though pennyless, Macaulay could never be accused of playing the game of politics from selfish considerations. But it was impossible that, circumstanced as he was, he should not look with anxiety upon his own future and that of his sisters,—sisters who had been, and who had deserved to be, the intimate confidants of all his thoughts and doings, and to whom he was attached by the tenderest affection. He was therefore prepared to accept the offer which was made him of a seat in the supreme council of India, a body which had been created by the India Act he had himself been instrumental in passing. The salary of the office was fixed at £10,000, an income out of which he calculated to be able to save in five years a capital of £30,000. His sister Hannah accepted his proposal to accompany him, and in February 1834 the brother and sister sailed for Calcutta.

Macaulay's appointment to India occurred at the critical moment when the government of the company was being superseded by government by the crown. His knowledge of India was, when he landed, but superficial. But at this juncture there was more need of statesmanship directed by general liberal principles than of a practical knowledge of the details of Indian administration. Macaulay's presence in the council was of great value; his minutes are models of good judgment and practical sagacity. The part he took in India has been described as "the application of sound liberal principles to a government which had till then been jealous, close, and repressive." He vindicated the liberty of the press; he maintained the equality of Europeans and natives before the law; and as president of the committee of public instruction he inaugurated that system of national education which has since spread over the whole of the Indian peninsula.

A clause in the Indian Act of 1833 occasioned the appointment of a commission to inquire into the jurisprudence of our Eastern empire. Macaulay was appointed president of that commission. The draft of a penal code which he submitted became, after a revision of many years, and by the labour of many experienced lawyers, that criminal code under which law is now administered throughout the empire. Of this code Sir James Stephen says that "it reproduces in a concise and even beautiful form the spirit of the law of England, in a compass which by comparison with the original may be regarded as almost absurdly small. The Indian penal code is to the English criminal law what a manufactured article ready for use is to the materials out of which it is made. It is to the French Code Pénal, and to the German code of 1871, what a finished picture is to a sketch. It is simpler and better expressed than Livingston's code for Louisiana; and its practical success has been complete."

As might be expected, Macaulay's enlightened views and measures drew down on him the abuse and ill-will of Anglo-Indian society in Calcutta and the Mofussil. Fortunately for himself he was enabled to maintain a tranquil indifference to political detraction by withdrawing his thoughts into a sphere remote from the opposition and enmity by which he was surrounded. Even amid the excitement of his early parliamentary successes literature had balanced politics in his thoughts and interests. Now in his exile, for such he felt it to be, he began to feel more strongly each year the attraction of European letters and European history. He writes to his friend Ellis, "I have gone back to Greek literature with a passion astonishing to myself. I have never felt anything like it. I was enraptured with Italian during the six months which I gave up to it; and I was little less pleased with Spanish. But when I went back to the Greek I felt as if I had never known before what intellectual enjoyment was." In thirteen months he read through, some of them twice, a large part of the Greek and Latin classics. The attention with which he read is proved by the pencil marks and corrections of press errors which he left on the margin of the volumes he used.

The fascination of these studies produced their inevitable effect upon his view of political life. He began to wonder what strange infatuation leads men who can do something better to squander their intellect, their health, and energy on such subjects as those which most statesmen are engaged in pursuing. He was already, he says, "more than half determined to abandon politics and give myself wholly to letters, to undertake some great historical work, which may be at once the business and the amusement of my life, and to leave the pleasures of pestiferous rooms, sleepless nights, and diseased stomachs to Roebuck and to Praed."

In 1838 Macaulay and his sister Hannah, who had now become Lady Trevelyan, returned to England. He at once entered parliament as member for Edinburgh. In 1839 he became secretary at war, with a seat in the cabinet in Lord Melbourne's ministry. His acceptance of office diverted him for a time from prosecuting the plan he had already formed of a great historical work. But only for a time. In less than two years the Melbourne ministry fell, and Macaulay was liberated from having to support a Government wretchedly weak, and maintaining its struggle for bare existence.

He returned to office in 1846, in Lord John Russell's administration. But it was in an office which gave him leisure and quiet rather than salary and power—that of paymaster-general. His duties were very light, and the contact with official life and the obligations of parliamentary attendance were even of benefit to him while he was engaged upon his *History*. In the sessions of 1846–47 he spoke only five times, and at the general election of July 1847 he lost his seat for Edinburgh upon issues which did not reflect credit upon that constituency. Over and above any political disagreement with the constituency, there was the fact that the balance of Macaulay's faculties had now passed to the side of literature. Lord Cockburn wrote in 1846, "the truth is, Macaulay, with all his knowledge, talent, eloquence, and worth, is not popular. He cares more for his *History* than for the jobs of constituents, and answers letters irregularly and with a brevity deemed contemptuous." At an earlier date he had relished crowds and the excitement of ever new faces; as years went forward and absorption in the work of composition took off the edge of his spirits, he recoiled from publicity. He began to regard the prospect of business as worry, and had no longer the nerve to brace himself to the social efforts required of one who represents a large constituency.

Macaulay retired into private life, not only without regret, but with a sense of relief. He gradually withdrew from general society, feeling the bore of big dinners, and country-house visits, but he still enjoyed close and constant intercourse with a circle of the most eminent men that London then contained. At that time social breakfasts were in vogue. Macaulay himself preferred this to any other form of entertainment. Of these brilliant reunions nothing has been preserved beyond the names of the men who formed them,—Rogers, Hallam, Sydney Smith, Lord Carlisle, Lord Stanhope, Nassau Senior, Charles Greville, Milman, Panizzi, Lewis, Van de Weyer. His biographer thus describes Macaulay's appearance and bearing in conversation: "Sitting bolt upright, his hands resting on the arms of his chair, or folded over the handle of his walking-stick, knitting his eyebrows if the subject was one which had to be thought out as he went along, or brightening from the forehead downwards when a burst of humour was coming, his massive features and honest glance suited well with the manly sagacious sentiments which he set forth in his sonorous voice and in his racy and intelligible language. To get at his meaning people had never the need to think twice, and they certainly had seldom the time."

But, great as was his enjoyment of literary society and books, they only formed his recreation. In these years he was working with unflagging industry at the composition of his *History*. His composition was slow, his corrections both of matter and style endless; he spared no research to ascertain the facts. He sacrificed to the prosecution of his task a political career, House of Commons fame, the allurements of society. The first two volumes of the *History of England* appeared in December 1848. The success was in every way complete beyond expectation. The sale of edition after edition, both in England and the United States, was enormous.

In 1852, when his party returned to office, he refused a seat in the cabinet, but he could not bring himself to decline accepting the compliment of a voluntary amende which the city of Edinburgh paid him in returning him at the head of the poll at the general election in July of that year. He had hardly accepted the summons to return to parliamentary life before he was struck down by the malady which in the end proved fatal. This first betrayed itself in deranged action of the heart; from this time forward till his death his strength continued steadily to sink. The process carried with it dejection of spirits as its inevitable attendant. The thought oppressed him that the great work to which he had devoted himself would remain a fragment. Once again, in June 1853, he spoke in parliament, and with effect, against the exclusion of the Master of the Rolls from the House of Commons, and at a later date in defence of competition for the Indian civil service. But he was aware that it was a grievous waste of his small stock of force, and that he made these efforts at the cost of more valuable work.

In November 1855 vols. iii. and iv. of the *History* appeared. No work, not being one of amusement, has in our day reached a circulation so vast. During the nine years ending with the 25th June 1857 the publishers (Longmans) sent out more than 30,000 copies of vol. i.; in the next nine years more than 50,000 copies of the same volume; and in the nine years ending with June 1875 more than 52,000 copies. Within a generation of its first appearance upwards of 140,000 copies of the *History* will have been printed and sold in the United Kingdom alone. In the United States no book except the Bible ever had such a sale. On the Continent of Europe, the sale of Tauchnitz editions was very large, a sale which did not prevent six rival translations in German. The *History* has been published in the Polish, Danish, Swedish, Hungarian, Russian, Bohemian, Italian, French, Dutch, Spanish languages. Flattering marks of respect were heaped upon the author by the foreign Academies. His pecuniary profits were on a scale commensurate with the reputation of the book: the cheque for £20,000 has become a landmark in literary history.

In May 1856 he quitted the Albany, in which he had passed fifteen happy years, and went to live at Holly Lodge, then, before it was enlarged, a tiny bachelor's dwelling, but with a lawn whose unbroken slope of verdure gave it the air of a considerable country house. In the following year (1857) he was raised to the peerage by the title of Baron Macaulay of Rothley. "It was," says Lady Trevelyan, "one of the few things that everybody approved; he enjoyed it himself, as he did everything, simply and cordially." It was a novelty in English life to see eminence which was neither that of territorial opulence nor of political or military services recognized and rewarded by elevation to the peerage.

The distinction came just not too late. Macaulay's health, which had begun to give way in 1852, was every year visibly failing; in May 1858 he went to Cambridge for the purpose of being sworn in as high steward of the borough, to which office he had been elected on the death of Earl Fitzwilliam. When his health was given at a public breakfast in the town-hall, he was obliged to excuse himself from speaking on the ground of inability. His nephew, who was in attendance upon him on the occasion, records that "it was already apparent that a journey across Clare Bridge and along the edge of the great lawn at King's, performed at the rate of ½ mile in the hour, was an exertion too severe for his feeble frame." In the Upper House he never spoke. Absorbed in the prosecution of his historical work, he had grown indifferent to the party politics of his own day. Gradually he had to acquiesce in the conviction that, though his intellectual powers remained to him unimpaired, his physical energies would not carry him through the reign of Anne; and, though he brought down the narrative to the death of William III., the last half volume wants the finish and completeness of the earlier portions.

The winter of 1859 was very severe, and hastened the end. He died on 28th December, and on 9th January 1860 was buried in Westminster Abbey, in Poet's Corner, near the statue of Addison.

Lord Macaulay was never married. A man of warm domestic affections, he found their satisfaction in the attachment and close sympathy of his sister Hannah, the wife of Sir Charles Trevelyan. Her children were to him as his own. Macaulay was a steadfast friend, and a generous enemy. No act inconsistent with the strictest honour and integrity has ever been imputed to him. When a poor man, and when salary was of consequence to him, he twice resigned office rather than make compliances for making which he would not have been severely blamed. In 1847, when his seat in parliament was at stake, he would not be persuaded to humour, to temporize, even to conciliate. He took a lofty tone, and haughtily rebuked the Edinburgh constituency for their bigotry. He had a keen relish for the good things of life, and desired fortune as the means of obtaining them; but there was nothing mercenary or selfish in his nature. When he had raised himself to opulence, he gave away with an open hand, not seldom rashly. His very last act was to write a letter to a poor curate, enclosing a cheque for £25. The purity of his morals was not associated, as it not unfrequently is, with a tendency to cant, or parade of religious phrases.

The lives of men of letters are often records of sorrow or suffering. The life of Macaulay was eminently happy. Till the closing years 1857–59, when his malady had begun to tell upon his strength, he enjoyed life with the full zest of healthy faculty, happy in social intercourse, happy in the solitude of his study, and equally divided between the two. For the last fifteen years of his life he lived for literature, as none of our eminent men since Gibbon have done. His writings were remunerative to him far beyond the ordinary measure, yet he never wrote as the professional author writes. He lived in his historical researches; his whole heart and interest were unreservedly given to the men and the times of whom he read and wrote. His command of literature was imperial. Beginning with a good classical foundation, he made himself familiar with the imaginative, and then with the historical, remains of Greece and Rome. He went on to add the literature of his own country, of France, of Italy, of Spain. He learnt Dutch enough for the purposes of his history. He read German, but for the literature of the northern nations he had no taste, and of the erudite labours of the Germans he had little knowledge and formed an inadequate estimate. The range of his survey of human things had other limitations more considerable still. All philosophical speculation was alien to his mind; nor does he seem aware of the degree in which such speculation has influenced the progress of humanity. A large —the largest—part of ecclesiastical history lay outside his historical view. Of art he confessed himself ignorant, and even refused a request which had been made him to furnish a critique on Swift's poetry to the *Edinburgh Review*. Lessing's *Laocoon*, or Goethe's criticism on Hamlet, "filled" him "with wonder and despair."

Of the marvellous discoveries of science which were succeeding each other day by day he took no note; his pages contain no reference to them. It has been told already how he recoiled from the mathematical studies of his university. These deductions made, the circuit of his knowledge still remains very wide,—as extensive perhaps as any human brain is competent to embrace. His literary outfit was as complete as has ever been possessed by any English writer; and, if it wants the illumination of philosophy, it has an equivalent resource in a practical acquaintance with affairs, with administration, with the interior of cabinets, and the humour of popular assemblies. Nor was the knowledge merely stored in his memory; it was always at his command. Whatever his subject, he pours over it his stream of illustration, drawn from the records of all ages and countries. "Figures from history, ancient and modern, sacred and secular; characters from plays and novels, from Plautus down to Walter Scott and Jane Austen; images and similes from poets of every age and every nation; shrewd thrusts from satirists, wise saws from sages, pleasantries caustic or pathetic from humorists,—all these fill Macaulay's pages with the bustle and variety of some glittering masque and cosmoramic revel of great books and heroical men. His style is before all else the style of great literary knowledge." His *Essays* are not merely instructive as history; they are, like Milton's blank verse, freighted with the spoils of all the ages. They are literature as well as history. In their diversified contents the *Essays* are a library by themselves; for those who, having little time for study, want one book which may be a substitute for many, we should recommend the *Essays* in preference to anything else.

As an historian Macaulay has not escaped the charge of partisanship. He was a Whig; and in writing the history of the rise and triumph of Whig principles in the latter half of the 17th century he identified himself with the cause. But the charge of partiality, as urged against Macaulay, means more than that he wrote the history of the Whig revolution from the point of view of those who made it. When he is describing the merits of friends and the faults of enemies, his pen knows no moderation. He has a constant tendency to glaring colours, to strong effects, and will always be striking violent blows. He is not merely exuberant, but excessive. There is an overweening confidence about his tone; he expresses himself in trenchant phrases, which are like challenges to an opponent to stand up and deny them. His propositions have no qualifications. Uninstructed readers like this assurance, as they like a physician who has no doubt about their case. But a sense of distrust grows upon the more circumspect reader as he follows page after page of Macaulay's categorical affirmations about matters which our own experience of life teaches us to be of a contingent nature. We inevitably think of a saying attributed to Lord Melbourne, "I wish I were as cock-sure of any one thing as Macaulay is of everything." Macaulay's was the mind of the advocate, not of the philosopher; it was the mind of Bossuet, which admits no doubts or reserves itself and tolerates none in others, and as such was disqualified from that equitable balancing of evidence which is the primary function of the historian. It was a fortunate circumstance that rhetoric so powerful was enlisted in the constitutional cause,—that Macaulay was, as he himself has said of Bishop Burnet, "a strong party man on the right side."

Macaulay, the historian no less than the politician, is always on the side of justice, fairness for the weak against the strong, the oppressed against the oppressor. But though a Liberal in practical politics, he had not the reformer's temperament. The world as it is was good enough for him. The glories of wealth, rank, honours, literary fame, the elements of a vulgar happiness, made up his ideal of life. A successful man himself, every personage and every cause is judged by its success. "The brilliant Macaulay," says Emerson, "who expresses the tone of the English governing classes of the day, explicitly teaches that 'good' means good to eat, good to wear, material commodity." Macaulay is in accord with the average sentiment of orthodox and stereotyped humanity on the relative values of the objects and motives of human endeavour. And this commonplace materialism is one of the secrets of his popularity, and one of the qualities which guarantee that that popularity will be enduring.

Macaulay's whole works have been collected by his sister, Lady Charles Trevelyan, in eight volumes. The first four volumes are occupied by the *History*; the next three contain the *Essays*, and the *Lives* which he contributed to the *Encyclopædia Britannica*. In vol. viii. are collected his *Speeches*, the *Lays of Ancient Rome*, and some miscellaneous pieces. His life has been written by his nephew, George Otto Trevelyan (2 vols., London, 1878), and is one of the best biographies in the language. His diary remains in MS. in the hands of his family. It is to be hoped that measures will be taken to secure this valuable record from the fate that has overtaken so many private diaries, and thus impoverished the sources of English history. (M. P.)

MACAW, or, as formerly spelt, MACCAW,[1] the name given to some fifteen or more species of large, long-tailed birds of the Parrot Family, natives of the Neotropical Region, and forming a very well-known and easily-recognized group to which the generic designation *Ara* is usually applied by ornithologists, though some prefer for it *Macrocercus* or *Sittace*. Most of the Macaws are remarkable for their gaudy plumage, which exhibits the brightest scarlet, yellow, blue, and green in varying proportion and often in violent contrast, while a white visage often adds a very peculiar and expressive character.[2] With one exception the known species of *Ara* inhabit the mainland of America from Paraguay to Mexico, being especially abundant in Bolivia, where no fewer than seven of them (or nearly one half) have been found (*Proc. Zool. Soc.*, 1879, p. 634). The single extra-continental species, *A. tricolor*, is one of the most brilliantly coloured, and is peculiar to Cuba, where, according to Dr Gundlach (*Ornitologia Cubana*, p. 126), its numbers are rapidly decreasing, so that there is every chance of its becoming extinct.[3]

It will perhaps be enough here to dwell on the best known species of the group, and first the Blue-and-yellow Macaw, *A. ararauna*, which has an extensive range in South America from Guiana in the east to Colombia in the west, and southwards to Paraguay. Of large size, it is a bird to be seen in almost every zoological garden, and is very frequently kept alive in private houses, for its temper is pretty good, and it will become strongly attached to those who tend it. Its richly-coloured plumage, sufficiently indicated by its common English name, has the additional recommendation of supplying feathers which are eagerly sought by salmon-fishers for the making of artificial flies. Next may be mentioned the Red-and-blue Macaw, *A. macao*, which is even larger and more gorgeously clothed, for, besides the colours expressed in its ordinary appellation, yellow and green enter into its adornment. It inhabits Central as well as South America as far as Bolivia, and is also a common bird in captivity, though perhaps less often seen than the foregoing. The Red-and-yellow species, *A. chloroptera*, ranging from Panama to Brazil, is smaller, or at least has a shorter tail, and is not quite so usually met with in menageries. The Red-and-green, *A. militaris*, smaller again than the last, is not unfrequent in confinement, and presents the colours of the name it bears. This has the most northerly extension of habitat, occurring in Mexico and thence southwards to Bolivia. All the other species are comparatively rare in a reclaimed condition. Four of them, *A. hyacinthina*, *A. leari*, *A. glauca*, and *A. spixi*, are almost entirely blue, while in *A. manilata* and *A. nobilis* the prevailing colour is green, and *A. severa* is green and blue.

As is the case with most Neotropical birds, very little is known of the life history of Macaws in a state of nature. They are said to possess considerable power of flight, rising high in the air and travelling long distances in search of their food, which consists of various kinds of fruits; but of any special differences of habit we are wholly ignorant. The sexes appear in all cases to be alike in colouring, and the birds, though constantly paired, are said to live in companies. As with others of the Order *Psittaci*, the nest is made in a hollow tree, and the eggs, asserted to be two in number, are white without any lustre. Of the habits of these birds in confinement it is needless to speak, as they are so extremely well known. If caged, their long tail-feathers are sure to suffer, but chained by the leg to a perch, Macaws seem to enjoy themselves as well as any captive can, and will live for many years.

In our present state of ignorance as to the best mode of classifying Parrots, it would be premature to hazard any guess as to the place occupied in the Order by the genus *Ara*. (A. N.)

[1] Thus Willughby, *Ornithologia*, p. 73 (1676); but an earlier form of the word is found in the "great blew and yellow Parrat called the *Machao*, or *Cockatoon*" of Charleton, *Onomasticon*, p. 66 (1668). Its derivation is shown by De Laet, who, in his description of certain Brazilian birds (*Novus Orbis*, ed. 1633, p. 556), has "inter alios [*sc.* Psittacos] excellunt magnitudine & pulchritudine, quos barbari *Araras* & *Macaos* vocant," and again (*loc. cit.*) "Tertium locum meretur *Araruna* vel *Machao*." Webster, in his dictionary, says that Macaw, "written also Macao," is "the native name in the Antilles," but gives no authority for his statement, which, considering that one West Indian island only is known to possess a Macaw (and that in that island the bird is known as *Guacamayo*), is very unlikely. Some of the older writers, Buffon (*Oiseaux*, vi. p. 278) for instance, say that *Makavouanne* was the name given by natives of Guiana to one species of Macaw found in that country; but the Antillean origin of the name cannot at present be accepted.

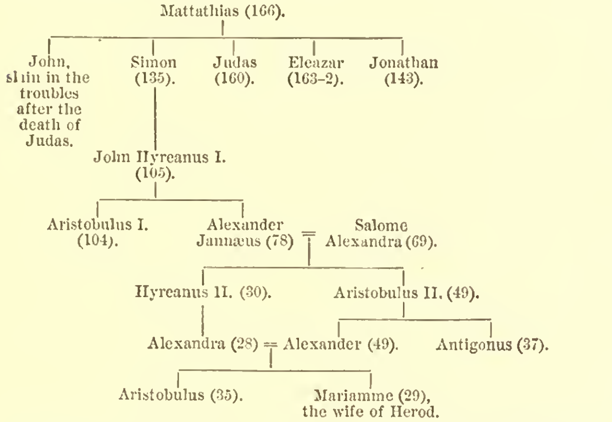
[2] This serves to separate the Macaws from the long-tailed Parrakeets of the New World (*Conurus*), to which they are very nearly allied.

[3] There is some reason to think that Jamaica may have formerly possessed a Macaw (though no example is known to exist), and if so it was most likely a peculiar species. Sloane (*Voyage*, ii. p. 297), after describing what he calls the "Great Maccaw" (*A. ararauna*, to be spoken of above), which he had seen in captivity in that island, mentions the "Small Maccaw" as being very common in the woods there, and Mr Gosse (*Birds of Jamaica*, p. 260) gives, on the authority of Robinson, a local naturalist of the last century, the description of a bird which cannot be reconciled with any species now known, though it must have evidently been allied to the Cuban *A. tricolor*.

MACBETH, MACBETHAD, or MACBEDA, son of Finnlaech, was king of Scotland from 1040 to 1057. He had previously been "mormaer" of Moravia or Moray; and his predecessor on the throne was Duncan, son of Crinan, and grandson of Malcolm, whom he slew (according to some accounts at "Bothgowan," said to have been near Elgin). Macbeth's wife was Gruoch, a descendant of the royal house. Of the events of his reign almost nothing is known. The ecclesiastical records of St Andrews bear that he and his wife, "rex et regina Scotorum," made over certain lands to the Culdees of Lochleven; and in 1050 he appears to have visited Rome, perhaps to obtain absolution for the murder of Duncan. The sons of Duncan, who had taken refuge with their uncle Siward, earl of Northumberland, brought about an invasion of Scotland in 1054; a battle was fought at Dunsinnane with indecisive results, but three years afterwards Macbeth fell at Lumphanan in Aberdeenshire (August 15, 1057). The war was continued for some time in the interests of a certain Lulach, the son of Queen Gruoch by a former marriage; but he too was slain in Strathbogie in March 1058, and Malcolm, the son of Duncan, ascended the throne.

See Skene, *Celtic Scotland*, vol. i. chap. 8; and compare Burton (*History of Scotland*, vol. i. chap. 10 *ad fin.*), who gives special prominence to the circumstance that when the genealogy of the Scottish kings is traced upwards the first break in the hereditary succession occurs when Macbeth is reached; the break of continuity at this point becomes all the more prominent when it is found that the father of Macbeth's successor had occupied the throne. "This had to be accounted for, and the easiest way was by treating the intruder as a 'usurper.' The loyal monks of the 15th century looked on a usurper with horror. Being so placed in the seat of political infamy, we have perhaps the reason why so many events, natural and supernatural, came to cluster round the career of Macbeth." It is most probable that Shakespeare's only source for the tragedy of *Macbeth* was the *Chronicles* of Holinshed (derived from John of Fordun and Hector Boece).

MACCABEES. The name Maccabee (Μακκαβαῖος) is properly and originally the distinguishing surname of Judas, son of Mattathias, the first great hero of the Jewish revolt against Antiochus Epiphanes. The source of the name is uncertain, but it is most natural to connect it with מַקָּב, "hammer," and so the Syriac writes the name with ק not כ. Ewald (*Gesch.*, iv. 403) is doubtless right in arguing from 1 Mac. vi. 43, &c., that the surnames of the sons of Mattathias were simply distinguishing epithets which they bore in ordinary life, and in this light "hammerman" appears as a natural surname enough, the occasion of which it would be vain to inquire into.[1] From Judas the name was in later times extended to the whole family, or to the party it represented, or even, as in the title of 3 Maccabees, to other contenders or sufferers for the faith of Israel in the Greek period. The more correct name of the family was Hasmoneans, Ἀσ[σ]αμωναῖοι, בית חשמונאי (Tgm. Jon. on 1 Sam. ii. 4). According to Josephus, *Ant.*, xii. 6, § 1, this name is taken from Asamonæus, the grandfather of Mattathias. Modern writers have suggested a connexion with the town Heshmon (Josh. xv. 27) or with חַשְׁמַנִּים, *magnates*, in Psalm lxviii. 31 [32]. The history of the Hasmoneans is given in Israel (vol. xiii. p. 421 *sq.*); in the appended genealogical tables (after Schürer) the dates are those of the death of each individual in years B.C.



The chief authorities are 1 and 2 Maccabees (see next article) and Josephus. For details as to other sources see Schürer's *Neutestamentliche Zeitgeschichte*, which gives also a good summary of the history. Of other works subsequent to Ewald's *Geschichte*, vol. iv., it is enough to name Derenbourg, *Histoire de la Palestine* (1867), and Wellhausen's *Pharisäer and Sadducäer* (1874). For the coins of the Hasmoneans see Madden, *Coins of the Jews*, 1881.

MACCABEES, Books of. Two books of this name are included among the Apocrypha of the English Bible, as they had formerly been in the Vulgate, and were accepted as canonical by the council of Trent. A third book is usually included in editions of the Septuagint, and is found in common with books iv. and v. in the Syriac, but never took a place in Latin Bibles; a fourth is found in some MSS. of the Septuagint (including the Sinaitic and Alexandrian—the Vatican does not contain the Maccabee books) and also in MSS. of Josephus, and has been printed in both connexions.

1 *Maccabees* was originally written in Hebrew, as appears, not only from the testimony of Jerome (*Prol. Gal.*), who had seen the Hebrew text, but from internal evidence. Josephus, however, already used the Greek,[2] and no trace of the Semitic original survives except the problematical title recorded by Origen (*ap.* Eus., *H. E.*, vi. 25).[3] The book gives the history of the national movement in Judæa from the accession of Antiochus Epiphanes (175 B.C.) to the murder of Simon (135 B.C.), in a plain and honest style, and evidently from good information. When the book was written there already existed a history of the reign or high priesthood of John Hyrcanus, to which the author refers for the continuation of his narrative. On the other hand, the friendly tone in which he always speaks of the Romans seems to justify the inference that he wrote before 63 B.C.[4]

2 *Maccabees*, covering the history from 176 B.C. to the victory over Nicanor (160 B.C.), is much inferior in value. It begins with two epistles which are certainly forgeries, and then proceeds to the task of summarizing in one book the five books of a certain Jason of Cyrene on the war of liberation against Antiochus Epiphanes. The narrative is a useful supplement to that in the first book, but is not nearly so trustworthy, and can never claim the preference where the two are in conflict. Geiger has shown that in 2 Maccabees the history is coloured and distorted by sympathy with the Pharisees, who became the bitter enemies of the Hasmoneans (*Urschrift und Uebers.*, book i. § 4).

3 *Maccabees* records a persecution of the Alexandrian Jews by Ptolemy IV. Philopator, with the ultimate repentance of the tyrant. It is quite unhistorical, and the local feast of the Alexandrian Jews, of which it professes to explain the origin (vi. 36), is connected by Josephus (*Cont. Ap.*, ii. 5) with an event that took place under Ptolemy Physcon. Ewald's conjecture that the story contains a hidden reference to the emperor Caius (*Gesch.*, iv. 611 *sq.*) has found considerable favour. It seems strange that this book should ever have found entrance in Christian circles. It had, however, considerable acceptance in the Eastern Church.

4 *Maccabees*, also known by the title περὶ αὐτοκράτορος λογίσμου, "on the sovereignty of reason," was ascribed to Josephus by Eusebius and Jerome. This opinion is now given up, and nothing certain can be said of its origin. It is a not uninteresting specimen of a Jewish philosophical theme composed under Stoic influence. The author illustrates the sovereignty of pious reason over the passions by historical examples, and is thus led to give anecdotes from the time of the Maccabees.

Fritzsche's edition of the Apocrypha (1871) is the best, and contains the four books of Maccabees. Grimm's commentary on 1 Mac. appeared in 1853, on the other three books in 1857. There is also a commentary on 1 Mac. by Keil, 1875. On 4 Mac. there is an elaborate study by Freudenthal, *Die Fl. Josephus beigelegte Schrift Ueber die Herrschaft der Vernunft*, Breslau, 1869. For further literature see Schürer, *NTliche Zeitgeschichte* (1874), pp. 19, 650 *sq.*, and his excellent article "Apokryphen" in Herzog-Plitt, *R.E.*, vol. i. An Arabic "Book of Maccabees," giving a compend of Jewish history from the affair of Heliodorus to the last part of Herod's reign, is printed in the Paris and London Polyglotts. A so-called "Fifth Book of Maccabees" is also contained in the great Ambrosian Peshito. It is in fact the sixth book of Josephus *De Bello Judaico*.

MACCLESFIELD, a municipal and parliamentary borough and market-town of Cheshire, England, is situated on a declivity near the borders of what is still known as the Macclesfield Forest, 17 miles south-south-east of Manchester, and 37 east-north-east of Chester. It consists

[1] One theory which has had much acceptance is that the name is made up of the initials of the first words of Exod. xv. 11. This is a pure guess, and requires the spelling מכבי or מכבאי found in the late work of Jos. ben Gorion. Equally unproved is the guess of S. J. Curtiss, resting on the Latin spelling Machabæus, that the word is properly from כבה, Isa. xliii. 17, the "quencher" or "queller" (*The Name Machabee*, Leipsic, 1876).

[2] Such at least is the current view (see Grimm, p. XXVIII *sq.*). J. D. Michaelis in his German translation of 1 Mac. argued that Josephus used the original; and a modified form of this view, viz., that he used an anonymous source resting on the original, has been put forth by Destinon (*Quellen des Fl. Josephus*, Kiel, 1882).

[3] This title is usually given σαρβὴθ σαρβανὲ ἔλ, and the attempts at decipherment, none of which are satisfactory (see Grimm's *Com.*, p. XVII; Derenbourg, *La Palestine*, p. 450 *sq.*), proceed from it. Heinichen, however, reads σαρβὴθ σαβαναιέλ, on overwhelming MS. authority, and in the Nitrian MS. used by Lagarde for his edition of the Syriac Apocrypha (*cf.* Wright's *Cat.*, i. 98), the title runs ספרא קדמיא דמקביא דמתקרין לות עבריא סרבסת סבעא איל. This seems to confirm Heinichen's reading (ע and נ being easily interchanged in Syrian MSS.). The sense may be "the prince of the house which God hath built up."

[4] Ewald (*Gesch.* iv. 436) and before him Whiston conjectured that Josephus did not possess the last part of the book. Destinon (*ut supra*, p. 80 *sq.*) develops this conjecture, and believes that the book originally ended with the liberation of Judæa under Simon, and that the interval between this book and the annals of Hyrcanus was filled up later.

of four principal streets, which meet in the market-place, and within the last twenty years has undergone great improvements. The old church of St Michael, on the brow of the hill, was founded by Eleanor, queen of Edward I., in 1278, and in 1740 was partly rebuilt and greatly enlarged. The lofty steeple by which its massive tower was formerly surmounted was battered down by the parliamentary forces during the civil war. Connected with the church there are two chapels, one of which, Rivers Chapel, belonged to a college of secular priests founded in 1501 by Thomas Savage, afterwards archbishop of York. Both the church and chapels contain several ancient monuments. For the free grammar school, originally founded in 1502 by Sir John Percival, and refounded in 1552 by Edward VI., a new building was erected in 1856 at a cost of £3000. A commercial school was erected in 1840 out of the funds of the grammar school. Among the other public buildings are the town-hall in the Grecian style (1823–24), with a new frontage (1869–70), the union workhouse (1843–44), the county lunatic asylum (1868–71), and the infirmary (1872). The neighbouring castle of the duke of Buckingham was the residence of Duke Humphrey in the 15th century. Originally the trade of Macclesfield was principally in twist and silk buttons, but this has been completely superseded by the manufacture of all kinds of silk. The first mill for silk-throwing was opened in 1756, and the manufacture of broad silks was introduced in 1790. Besides this staple trade, there are various textile manufactures and extensive breweries. The population of the municipal borough (3235 acres) in 1871 was 35,540, and of the parliamentary borough (3272 acres) 35,570. In 1881 the numbers were 37,514 and 37,620.

Previous to the Conquest, Macclesfield constituted a portion of the royal demesne of the earls of Mercia. At Domesday it was included in the earldom of Chester, and after the abolition of that jurisdiction it relapsed to the crown. In 1261 it was made a borough, and in 1678 it obtained incorporation from Charles II. It has returned two members to parliament since the first Reform Act, and its boundary was enlarged in 1868.

M'CLURE, Sir Robert John Le Mesurier, the discoverer of the North-West Passage, was born at Wexford, January 28, 1807, and died in London, October 17, 1873. He was the posthumous son of one of Abercrombie's captains, and spent his childhood under the care of his godfather, General Le Mesurier, hereditary governor of Alderney. Schooled in Arctic exploration by his service under Captain Back on board the "Terror," he was first lieutenant of the "Enterprise" during the Franklin search expedition (1848–49), and in 1850 was placed in command of the expedition which, battling with the frozen sea for four years, succeeded in passing from ocean to ocean to the north of the American continent. M'Clure was knighted on his return, and received gold medals from the English and the French geographical societies. During the Canadian insurrections of 1836–38 he had performed some gallant exploits on the lakes,—on one occasion, in the eagerness of pursuit, infringing the territory of the United States; and between 1856 and 1861 he rendered good service in the Chinese war at the storming of Canton, &c. His latter years were spent in a quiet country life. He was appointed Commander of the Bath in 1859, and had attained the rank of vice-admiral on the retired list. See Admiral Sherard Osborn, *The Discovery of a North-West Passage.*

M'CRIE, Thomas (1772–1835), was born at Dunse or Duns in Berwickshire, Scotland, November 1772. He studied in Edinburgh University, and thereafter in the divinity hall at Whitburn. In 1796 he was ordained minister of the Second Associate Congregation, Edinburgh, the place of worship being in the Potterrow.

At an early period in its history the Secession Church in Scotland had been divided by a controversy about the burgess oath into Burghers and Antiburghers; but towards the close of the century the Antiburgher Synod, to which M'Crie belonged, showed symptoms of a disposition to qualify adherence to the subordinate standards of the Church of Scotland on such points as the magistrate's power *circa sacra* and national covenanting, and a new historical manifesto was prepared called *The Narrative and Testimony*, which was adopted as a term of communion by the general synod in 1804. M'Crie was one of those who protested against this departure, as they deemed it, from Secession principles, and, declining to acknowledge the jurisdiction of the synod, constituted themselves into a presbytery under the name of "The Constitutional Associate Presbytery." M'Crie was in consequence deposed by the Associate Synod, and his congregation withdrew with him to a place of worship in the south side of the town, in which he officiated to the close of his life.

From the time of his settlement in Edinburgh, M'Crie devoted himself to historical investigations into the history, constitution, and polity of the churches of the Reformation; and the first ripe fruits of his study were given to the public in November 1811 in the form of *The Life of John Knox, containing illustrations of the History of the Reformation in Scotland*, which procured for the author the degree of D.D. from his alma mater, an honour conferred then for the first time upon a Scottish dissenting minister. At the solicitation of his friend Andrew Thomson, M'Crie became a contributor to *The Edinburgh Christian Instructor*, and in three successive numbers for 1817 he subjected Sir W. Scott's *Tales of my Landlord* to a criticism which took the form of a *Vindication of the Covenanters.* Preserving the continuity of his historical studies, he followed up his first work with *The Life of Andrew Melville*, 1819. Negotiations for union between the Burghers and Antiburghers resulted, in 1820, in the formation of the United Secession Synod, and called forth from Dr M'Crie *Two Discourses on the Unity of the Church, her Divisions, and their Removal*, in which what he considered to be the fallacious and unscriptural character of the plan for union adopted by the United Synod is pointed out. Several of his former brethren among the Antiburghers, dissatisfied with the union of 1820, had formed themselves into a separate synod, and between these and the Constitutional Presbytery a union was formed in 1827, the uniting bodies assuming the name of the Associate Synod of Original Seceders, of which branch of the Secession in Scotland M'Crie continued through the rest of his life the best known representative. In 1827 he published a *History of the Progress and Suppression of the Reformation in Italy in the 16th century*, and in 1829 a similar *History of the Reformation in Spain.*

Great as was his absorption in historical research, it did not prevent his taking a lively interest in the leading questions of the day; in pamphlets and on the platform he maintained his convictions, not always popular, on such matters as Greek independence, Catholic emancipation, the "Marrow" and "Voluntary" controversies, Irish education, and church patronage. His evidence on the last-named matter before a committee of the House of Commons is contained in the parliamentary publications of 1834.

The latest literary undertaking of M'Crie was a life of John Calvin. Although he had been gathering material for this project for several years, it was not till a late period of his life that, stimulated by the assistance of his son John, then in Geneva, he seriously addressed himself to the task. Only three chapters of the work were completed when the writer was struck down by apoplexy. He died on the 5th of August 1835.

In addition to the works the titles of which have been already given, Dr M'Crie published the following:—(1) *The Duty of Christian Societies towards each other, a Sermon*, 1797 (afterwards suppressed by the author, now extremely scarce); (2) *Statement of the Difference between the Profession of the Reformed Church of Scotland and the Profession contained in the New Testimony adopted by the General Associate Synod*, 1807; (3) *Free Thoughts on the late Religious Celebration of the Funeral of the Princess Charlotte*, 1817; (4) *Memoirs of Veitch and Brysson*, 1825; (5) *What Ought the General Assembly to do at the Present Crisis?* 1833. The posthumous publications are—(1) *Sermons*, 1836; (2) *Lectures on the Book of Esther*, 1838; (3) *Miscellaneous Writings*, 1841; (4) *The Early Years of John Calvin, a Fragment*, 1880.

An estimate of the services and a graphic description of the personal appearance of Dr M'Crie are to be found in *The Headship of Christ* (pp. 77–129), and in *My Schools and Schoolmasters* (chap. xvi.), both by Hugh Miller.

MACCULLAGH, James (1809–1846), one of the most elegant geometers of modern times, was born in 1809, near Strabane, Ireland. After an exceptionally brilliant undergraduate career in Trinity College, Dublin, he was elected fellow in 1832. From 1832 to 1843 he held the chair of mathematics; and during his tenure of this post, for which he was specially fitted, he improved in a most marked manner the position of his university as a mathematical centre. In 1843 he was transferred to the chair of natural philosophy, for which he was not nearly so well qualified. Overwork, mainly on subjects beyond the natural range of his powers, induced mental disease; and he died by his own hand in 1846. His *Works* have been published in a collected form (Dublin University Press Series, 1880). Their distinguishing feature is the geometry,—which has rarely been applied either to pure space problems or to known physical questions such as the rotation of a rigid solid or the properties of Fresnel's wave-surface with such singular elegance. In this respect his work takes rank with that of Poinsot. No higher praise could be given. One specially remarkable geometrical discovery of Maccullagh's is that of the "modular generation of surfaces of the second degree"; and a noteworthy contribution to physical optics is his "theorem of the polar plane." But his methods, which, in less known subjects, were almost entirely tentative, were altogether inadequate to the solution of the more profound physical problems to which his attention was mainly devoted, such as the theories of double refraction, of crystalline reflexion, &c. Here not only are the utmost powers of analysis required, but also the highest physical knowledge; and in consequence Maccullagh's work was entirely overshadowed by that of contemporaries, such as Cauchy and Green. See, on this point, Stokes's "Report on Double Refraction" (*B. A. Report*, 1862). The story of his later days painfully suggests the comparison of a high-bred but slight racer tearing itself to pieces in the vain endeavour to move a huge load, which a traction-engine could draw with ease and promptitude. He wasted, on problems altogether beyond his strength, powers of no common order, which, had they only been suitably directed, might have immensely extended our knowledge. Such, at least, is the estimate which we cannot avoid forming from a perusal of his published works. He had "conical refraction" in his hand for years without knowing its value. The reader who wishes to see the other side of the question (Maccullagh represented as standing to Fresnel in the same relative position as Newton to Kepler) is referred to the *Proceedings of the Royal Society*, vol. v. p. 712 (1847).

MACCULLOCH, Horatio (1805–1867), Scotch landscape painter, was born in Glasgow in 1805. An early friendship with Sir Daniel Macnee, and William Leitch, the water-colourist, was the means of turning the lad's attention to art, which he studied for a year under John Knox, a Glasgow landscapist of some repute, with whom Macnee was apprenticed at the time. After leaving the studio of Knox, we find him engaged at Cumnock, painting the ornamental lids of snuff-boxes in the manufactory of the Messrs Smith, and afterwards he was employed in Edinburgh by Lizars, the engraver, to colour the illustrations in Selby's *British Birds* and similar works. Meanwhile he was diligently prosecuting his studies in higher walks of art, and working unweariedly from nature, greatly influenced in his early practice by the water-colours of H. W. Williams,—"Grecian Williams" as he was called,—whose works had a charm for the young painter after the drier and more elaborate method of his first master. Returning to Glasgow in some four or five years, he was employed by Mr Lumsden, the lord provost, on several large pictures for the decoration of a public hall which he had erected in St George's Place, and he did a little as a theatrical scene-painter in Kilmarnock and other provincial towns. About this time he was greatly impressed with a picture by Thomson of Duddingston, and upon the works of this artist, the greatest Scottish landscapist that had yet appeared, the art of Macculloch may be said to have been founded. Gradually he asserted his individuality, and formed his own style on a closer study of nature than had been possible to his predecessor, and his works form an interesting link of connexion between the old world of Scottish landscape and the new. By its love of elaborate and balanced compositions, by its choice of noble and exceptional scenes, his art connects itself with that of sixty years ago; by its brilliant and varied colouring, by its care for detail, it differentiates itself from the quietude and the stately abstraction of the older landscape. In 1829 Macculloch first figured in the Royal Scottish Academy's exhibition, with a View of the Clyde, and, year by year, till his death on the 24th of June 1867, he was a liberal contributor to its displays. In 1838 he was elected a member of the Scottish Academy, and came to reside in Edinburgh, where his genial manners gathered round him a large and appreciative circle of the artists and litterateurs of the city.

Among the more important of the long series of landscapes which he produced, subjects almost exclusively from Scottish scenery, may be mentioned—Moonlight Deer Startled, 1840; Moor Scene, Sunset, 1841; A Dream of the Highlands, 1844; Inversnaid Ferry, Loch Lomond, 1847; A Highland Deer Forest, 1856; Ben Venue from Silver Strand, 1862; and Bothwell Castle, 1863. Several works by Macculloch were engraved by William Miller and William Forrest, and a volume of photographs from his landscapes, with an excellent biographical notice of the artist by Alexander Fraser, R.S.A., was published in Edinburgh in 1872.

MACCULLOCH, John (1773–1835), one of the most eminent geologists of his time, descended from the Maccullochs of Nether Ardwell in Galloway, was born in Guernsey, 6th October 1773, his mother being a native of that island. Having displayed remarkable powers as a boy, he was sent to study medicine in the university of Edinburgh, took his diploma there, and entered the army as assistant surgeon. Attaching himself to the artillery, he became chemist to the Board of Ordnance (1803), and thus began relations with the Government which materially affected his future career. He still continued, however, to practise for a time as a physician, and then resided at Blackheath. In the year 1811 he communicated his first papers to the Geological Society. They were devoted to an elucidation of the geological structure of Guernsey, of the Channel Islands, and of Heligoland. The evidence they afforded of his capacity, and the fact that he already had received a scientific appointment, probably led to his being selected by Government to make some geological and mineralogical investigations in Scotland. He was asked to report upon stones adapted for use in powder-mills, upon the suitability of the chief Scottish mountains for a repetition of the pendulum experiments previously conducted by Maskelyne and Playfair at Schiehallion, and on the deviations of the plumb-line along the meridian of the Trigonometrical Survey. In the course of the explorations necessary for the purposes of these reports he made extensive observations on the geology and mineralogy of Scotland. He formed also a collection of the mineral productions and rocks of that country, which he presented to the Geological Society in 1814. At that time comparatively little had been done in the investigation of Scottish geology. Finding the field so entirely his own, and so full of promise, he devoted himself to its cultivation with great ardour. One of his earliest and most important labours was the examination of the whole range of islands along the west of Scotland, at that time not easily visited, and presenting many obstacles to a scientific explorer. The results of this survey appeared (1819) in the form of his *Description of the Western Islands of Scotland, including the Isle of Man* (2 vols. 8vo, with an atlas of plates in 4to), which forms one of the classical treatises on British geology. He continued to write papers, chiefly on the rocks and minerals of Scotland, and had at last gathered so large an amount of information that the Government was prevailed upon in the year 1826 to employ him in the preparation of a geological map of Scotland. From that date up to the time of his death he returned each summer to Scotland and traversed every district of the kingdom, inserting the geological features upon Arrowsmith's map, which was the only one then available for his purpose. He lived to complete this great labour, and to prepare also a small volume explanatory of the map, but he died before these were published in 1836. Among his other works the following may be mentioned :—*A Geological Classification of Rocks, with Descriptive Synopses, comprising the Elements of Geology*, 1 vol. 8vo, 1821 ; *The Highlands and Western Islands of Scotland*, in a series of letters to Sir Walter Scott, 4 vols. 8vo, 1824 ; *A System of Geology, with a Theory of the Earth and an examination of its Connexion with the Sacred Records*, 2 vols. 8vo, 1831. His versatility of acquirement was shown by the publication also of works on malaria, remittent and intermittent diseases, the art of making wines, natural and revealed religion, besides numerous memoirs in various departments of natural history and antiquities. During a visit to Cornwall he was killed by being dragged along in the wheel of his carriage, 21st August 1835.

Dr Macculloch's name will ever be regarded with honour as one of the pioneers of geology in Britain. Essentially a mineralogist and petrographer, he was the first to trace out with some approach to truth the general distribution of the various rock-formations of Scotland. His temperament unhappily led him to look with jealousy and mistrust upon the labours of some of his more illustrious contemporaries, and even to ignore them in his published writings. In particular he appears to have been irritated by the rapid advances made by palæontological geology, and the increasingly large place given to that department of the science, while his own favourite domain of minerals and rocks was proportionately neglected. His feelings of dissent were strongly expressed in the posthumous memoir to accompany his map of Scotland ; but their bitterness may in part be attributed to the influence of failing health. Much hostile criticism was expended on his description of the manners and customs of the Highlanders, which were certainly amusing and picturesque, though sometimes his love of an effective period seems to have led him to exaggeration. The way in which he was appointed to conduct a geological survey of Scotland, unknown to the public bodies of that country, also led to considerable opposition. But the solid services rendered by Macculloch to the progress of geology must be regarded as far outweighing any objections that have been made to his literary work or peculiarities of character.

M'CULLOCH, John Ramsay (1779–1864), a distinguished writer on political economy and statistics, was born on 1st March 1779, at Whithorn in Wigtownshire. His family belonged to the class of "statesmen," or small landed proprietors. Having received his early education from his maternal grandfather, a Scotch clergyman, he came to Edinburgh, and was for some time employed there as a clerk in the office of a writer to the signet. But, the *Scotsman* newspaper having been established at the beginning of 1817, M'Culloch sent a contribution to the fourth number, the merit of which was at once recognized ; he soon became connected with the management of the paper, and during 1818 and 1819 acted as editor. Most of his articles in the *Scotsman* related to questions of political economy, and he delivered lectures in Edinburgh on that science. He now also began to write on subjects of the same class in the *Edinburgh Review*, his first contribution to that periodical being an article on Ricardo's *Principles of Political Economy* in 1818. Within the next few years he gave both public lectures and private instruction in London on political economy, and had amongst his hearers or pupils many persons of high social position, and some who were important in the political world. In 1823 he was chosen to fill the lectureship established by subscription in honour of the memory of Ricardo. A movement was set on foot in 1825 by Jeffrey and others to induce the Government to found in the university of Edinburgh a chair of political economy, separate from that of moral philosophy, the intention being to obtain the appointment for M'Culloch. This project fell to the ground ; but in 1828 he was made professor of political economy in the London University. He then fixed his residence permanently in London, where he continued his literary work, being now one of the regular writers in the *Edinburgh Review.* Indeed it appears from a letter of his to Macvey Napier in 1830 that he regarded himself, though Napier did not admit the justice of the claim, as entitled to be the sole contributor of economical articles to the *Review.* In 1838 he was appointed comptroller of Her Majesty's Stationery Office ; the duties of this position, which he held till his death, he discharged with conscientious fidelity, and introduced important reforms in the management of the department. Sir Robert Peel, in recognition of the services he had rendered to political science, conferred on him a literary pension of £200 per annum. He was elected a foreign associate of the Institute of France (Academy of Moral and Political Sciences). He died, after a short illness, on 11th November 1864, in the seventy-sixth year of his age. To his personal character and social qualities very favourable testimony is borne by those who knew him best. In general politics he always remained a Whig pure and simple ; though he was in intimate relations with James Mill and his circle, he never shared the Radical opinions of that group.

M'Culloch cannot be regarded as an original thinker on political economy. He did not contribute any new ideas to that science, or introduce any noteworthy correction of the views, either as to method or doctrine, generally accepted by the dominant school of his day. But the work he did must be pronounced, in relation to the wants of his time, a very valuable one. It was at an important crisis that he appeared in the field of economical discussion. The principles of free trade had been powerfully asserted before the public in the celebrated petition of the merchants of London, drawn up by Mr Tooke and presented to parliament by Mr Alexander Baring in 1820. Political economy, to which the bullion controversy had previously attracted much attention, was more and more engaging the minds of political writers and of statesmen. But the new views had to encounter fierce and sometimes unscrupulous opposition. The *Edinburgh Review* was the principal organ of the reformers, and was maintaining, when M'Culloch became a writer in it, an energetic warfare against the policy founded on the mercantile theory of wealth. Naturally endowed with strong sense and sagacity, and possessing a rare capacity for arduous and prolonged mental exertion, he threw himself, with the ardour of conviction, into the great struggle. There can be no doubt that his labours on the whole contributed largely to the diffusion of just ideas on the economic questions then under debate, and to the right direction of the national legislation with respect to them. It must at the same time be admitted that his treatment of the subjects with which he dealt is not marked by any special breadth or elevation. He adopted too hastily the theoretic exaggerations of some of Smith's successors, and exhibited in full measure their habitual deadness, in the study of social questions, to all but material considerations. In his evidence before the parliamentary committee on the state of Ireland in 1825 he stated opinions, afterwards more fully asserted in the *Edinburgh Review*, on the subject of Irish absenteeism, which tended to disgust persons of intelligence and right feeling with a science which, as interpreted by him, seemed to lead to practical absurdities, and in other quarters had, it is to be feared, the effect of supplying a plausible excuse for carelessness on the part of the rich and great with respect to the inferior classes of society. These opinions could not be justified even on strictly economic grounds, as has since been shown by Longfield and Senior. M'Culloch had in him an element of intellectual wilfulness or perverse self-assertion, compared by his friends and admirers to the despotic dogmatism of Johnson, which both in conversation and in his writings led him into the enunciation and defence of paradoxes; a notable example of this is furnished by the obstinacy with which to the last, in the teeth of evidence, he clung to the doctrine of the impolicy of cheap postage. M'Culloch was deficient in literary taste, and never attained any high degree of excellence in style. His expression is often slipshod, and a certain coarseness in his images sometimes throws an air of vulgarity over his pages. His name will probably be less permanently associated with anything he has written on economic science, strictly so called, than with his great statistical and other compilations. His *Dictionary of Commerce and Commercial Navigation* and his *Statistical Account of the British Empire*—however they may be expanded and altered, as they have already been, in successive editions—will long remain imposing monuments of his extensive and varied knowledge and his indefatigable industry. Another useful work of reference, also the fruit of wide erudition and much labour, is his *Literature of Political Economy*. Though weak on the side of the foreign literature of the science, it is very valuable as a guide to British writers, and, in relation to its entire field, has not yet been superseded by any English book.

The following is as complete a list of his publications as it has been found possible to form:—*An Essay on the Reduction of the Interest on the National Debt*, 1816; *An Essay on the question of Reducing the Interest on the National Debt*, 1816; *A Discourse on the Rise, Progress, Peculiar Objects, and Importance of Political Economy*, 1824; the article POLITICAL ECONOMY in the supplement to the 6th edition of the *Encyclopædia Britannica*, afterwards enlarged into *The Principles of Political Economy, with a sketch of the Rise and Progress of the Science*, 1830, and again 1843, 1849 (translated into French by Augustin Planche, 1851); *Dictionary, Practical, Theoretical, and Historical, of Commerce and Commercial Navigation*, 1832; *Statistical Account of the British Empire*, 1837; *Dictionary, Geographical, Statistical, and Historical, of the various Countries, Places, and Natural Objects in the World*, 1841–42 (several editions of the last three have since appeared, and the first two of them have been reprinted in the United States, and translated into foreign languages); *Statements illustrative of the Policy and probable Consequences of the proposed Repeal of the existing Corn-Laws and the Imposition in their stead of a moderate Fixed Duty on Foreign Corn*, 1841; *Memorandums on the proposed Importation of Foreign Beef and Live Stock*, 1842; *A Treatise on the Principles and Practical Influence of Taxation and the Funding System*, 1845; *The Literature of Political Economy*, 1845; *A Treatise on the Succession to Property Vacant by Death*, 1848; *Treatise on the Circumstances which determine the Rate of Wages and the Condition of the Labouring Classes*, 1851 (an earlier edition had appeared anonymously in 1826); *Considerations on Partnership with Limited Liability*, 1856; perfaces and notes to a select collection, in 4 vols. of scarce and valuable economical tracts, reprinted at Lord Overstone's expense, 1856–59. He united in one volume (2d ed., 1859) a number of his minor *Treatises and Essays on subjects connected with Economic Policy*, many of which had appeared as articles in the *Encyclopædia Britannica*. He also printed, for private distribution amongst his friends, a catalogue of his library,—which contained a fine collection of books on his own special subjects,—adding critical and biographical notices. He had edited in 1828 Smith's *Wealth of Nations*, with a life of the author, an introductory discourse, notes, and supplemental dissertations; this work he greatly enlarged and improved in the editions of 1838 and 1850. In 1846 he edited Ricardo's works, with a notice of the life and writings of the author. (J. K. I.)

MACDONALD, ÉTIENNE-JACQUES-JOSEPH-ALEXANDRE (1765–1840), duke of Taranto, and marshal of France, was born at Sancerre on November 17, 1765. His father came of an old Jacobite family, which had followed James II. to France, and was a near relative of the celebrated Flora Macdonald (1722–1790), the heroine whose courage and fidelity were at one critical period the sole means by which Prince Charles Edward was enabled to elude his enemies after the defeat of Culloden in 1746. In 1784 Macdonald joined the legion raised by the second Marshal Maillebois to support the revolutionary party in Holland against the Prussians, and after it was disbanded he received a commission in the regiment of Dillon. On the breaking out of the Revolution, the regiment of Dillon remained eminently loyal, nearly all its officers emigrating with the princes, with the exception of Macdonald, who was in love with a Mademoiselle Jacob, whose father was enthusiastic for the doctrines of the Revolution. His love was successful, and directly after his marriage he was appointed aide-de-camp to General Dumouriez. He also distinguished himself at Jemmapes, and was promoted colonel in 1794. He refused to desert to the Austrians with Dumouriez, and as a reward was made general of brigade, and appointed to command the leading brigade in Pichegru's invasion of Holland. His knowledge of the country proved most useful, and he was instrumental in the capture of the Dutch fleet by the French hussars. In 1797 he was made general of division, and transferred first to the army of the Rhine and then to that of Italy. When he reached Italy, the peace of Campo Formio had been signed, and General Bonaparte had returned to France; but, under the direction of Berthier, Macdonald first occupied Rome, of which he was made governor, and then in conjunction with Championnet he defeated General Mack, and revolutionized the kingdom of Naples under the title of the Parthenopæan Republic. When Suwaroff invaded northern Italy, and was winning back the conquests of Bonaparte, General Macdonald collected all the troops in the peninsula and moved northwards. With but 30,000 men he attacked, at the Trebbia, Suwaroff with 50,000, and after three days' fighting, during which he held the Russians at bay, and gave time for Moreau to come up, he retired in good order to Genoa. After this gallant behaviour he was made governor of Versailles, and acquiesced in, if he did not co-operate in, the events of the 18th Brumaire. In 1800 he received the command of the army in Switzerland which was to maintain the communications between the armies of Germany and of Italy. He carried out his orders to the letter, and at last, in the winter of 1800–1, he was ordered to march over the Splügen Pass. This achievement is fully described by Mathieu Dumas, who was chief of his staff, and is at least as noteworthy as Bonaparte's famous passage of the Saint Bernard before Marengo, though followed by no such successful battle. On his return to Paris he married the widow of General Joubert, and was appointed French plenipotentiary in Denmark. Returning in 1805 he associated himself with Moreau, and incurred the dislike of Napoleon, who did not include him in his first creation of marshals. Till 1809 he remained without employment, but in that year Napoleon, hard pressed at Aspern, gave Macdonald the command of a division in the army of the viceroy of Italy which was to march from Italy to his help. He led the army from Italy till its junction with Napoleon, and at Wagram commanded the attack on the Austrian centre which won the victory. Napoleon made him marshal of France on the field of battle, and presently created him duke of Taranto. In 1810 he served in Spain, and in 1812 he commanded the left wing of the grand army for the invasion of Russia. After sharing in the battles of Lützen and Bautzen, he was ordered to invade Silesia, where Blücher defeated him with great loss at the Katzbach. After the terrible battle of Leipsic he was ordered with Prince Poniatowski to cover the evacuation of Leipsic, and after the blowing up of the bridge, he managed to swim the Elster, while Poniatowski was drowned. During the defensive campaign of 1814 Macdonald again distinguished himself, and was one of the marshals sent by Napoleon to take his abdication in favour of his son to Paris. When all were deserting their old master, Macdonald remained faithful to him. Macdonald was directed by Napoleon to give in his adherence to the new régime, and was presented by him with the sabre of Murad Bey for his fidelity. He was made a peer of France at the Restoration, and, having once passed his word to the new order of things, remained faithful during the Hundred Days. In 1816 he became chancellor of the Legion of Honour, a post he held till 1831, and took a great part in the discussions in the House of Peers. In 1823 he married Mademoiselle de Bourgony, and at last had a son, Alexander, who succeeded on his death in 1840 as duke of Taranto. From 1830 his life was spent in retirement at his country place Courcelles.

Macdonald had none of that military genius which distinguished Davoust, Masséna, and especially Ney, nor of that military science conspicuous in Marmont and St Cyr, but nevertheless his campaign in Switzerland gives him a rank far superior to such mere generals of division as Oudinot and Dupont. This capacity for independent command made Napoleon, in spite of his defeats at the Trebbia and the Katzbach, trust him with large corps d'armée till the end of his career. As a man, his character cannot be spoken of too highly; no stain of cruelty or faithlessness rests on him. He retained always the frank honour of a soldier of fortune; but he never forgot that he was a gentleman, or disgraced the new nobility of Napoleon by ridiculous pretensions.

Macdonald was especially fortunate in the accounts of his military exploits, Mathieu Dumas and Ségur having been on his staff in Switzerland. See Dumas, *Événements Militaires*; and Ségur's rare tract, *Lettre sur la campagne du Général Macdonald dans les Grisons en* 1800 *et* 1801 (1802). Also consult Pelet's excellent *Campagne de* 1809, and Ségur's *Éloge* (1842).

MACDONALD, Lawrence (1798–1878), sculptor, was born at Gask, Perthshire, Scotland, in 1798, and in early life served as a mason's apprentice. Having shown an aptitude for stone carving, he went while still a youth to Edinburgh as an art student at the Trustees' Academy, finding at the same time a good deal of occasional employment in carving coats of arms and other ornamental figures on the gateways or walls of country houses. By the help of friends he was enabled to visit Rome, whence, after a stay of two or three years, he returned to Edinburgh in 1826. During the next few years he executed a considerable number of commissions for busts, and also devoted a good deal of time to the designing of ideal subjects, in which branch of his art, however, the public interest was comparatively slight. From 1832 until his death on March 4, 1878, his home was in Rome; during the long period of forty-six years his chisel never rested, and the number of works that issued from his studio, chiefly in the department of portrait sculpture, was very great. Among his ideal works may be mentioned Ulysses and his Dog Argos, Andromeda chained to the Rock, Eurydice, Hyacinth, a Siren, and a Bacchante. His busts, while excellent as likenesses, are remarkable for purity and dignity of style; and the ideal works are at once full of grace and carefully correct in form, design, and treatment.

Plate III. MACEDONIA, when that name is taken in its widest signification, is the country between Thrace on the east and Illyria on the west, bounded on the S. by Thessaly and the Ægean Sea, and on the N. by the lands which belong to the basin of the Danube. The most definite limit in its physical geography is that towards Illyria, where the Scardus range, which still bears the name of *Schar*, forms a continuous barrier between the two countries; on the side of Thessaly also, Mount Olympus and the Cambunian mountains constitute a well-marked frontier. In the other two directions its natural limits are less clearly defined. Towards the east, during the greater part of its history, the river Strymon was regarded as its proper boundary; but after the foundation of the city of Philippi it encroached on Thrace, and extended as far as the river Nestus, or even Mount Rhodope. With regard to the features of the country immediately to the north of Macedonia a misconception long prevailed, which has only of late years been dispelled by geographical research. Owing to a misinterpretation of a passage in Strabo (vii. fragm. 10; *cf.* vii. 5, 1), it was long believed that the country between the Danube and the Ægean was divided in the middle by a lofty range of mountains, which formed a continuation of the main chain of the Alps as far as the Euxine; and this mistake is perpetuated in many of our maps at the present day. But since this district has been explored, first by Grisebach, and afterwards by Von Hahn, it has been known that along one important portion of this supposed line, directly to the north of Macedonia and south-east of the modern principality of Servia, the hills do not rise to any considerable elevation, and that affluents of the Margus (Morava), which flows into the Danube, and of the Axius (Vardar), which runs to the Ægean, rise close together in the upland plain of Kossova, the scene of the great battle in which the Servian monarchy was overthrown by Sultan Amurath I. in 1389. This watershed may be regarded as the northern boundary of Macedonia. But the extended limits which have here been given did not belong to the district that bore that name in early times. The original Macedonia was confined to the inland region west of the Axius, between that river and the Scardus mountains, and did not include the northern portion, which was known as Pæonia, or the coast-land which, together with the eastern districts, was inhabited by Thracian tribes, and was regarded by the Greeks at the time of the Peloponnesian war as part of Thrace. The people of this country were not Hellenic, though its rulers ultimately succeeded in claiming that title for themselves, at the time when Alexander I. was admitted as a competitor at the Olympic games. The same thing may be said of the land itself, the appearance of which presents many points of contrast to that of Greece proper. Instead of the delicate, bright, and varied scenery of that country, with its clear atmosphere and sharp outlines, we find in Macedonia broad masses of mountains, extensive sweeps of lowland, and uniformity of colour. The climate of the inland regions also is severe, so that the cypress and other trees which flourish in Greece will not grow there.

The river Axius divides Macedonia into two parts, the eastern of which resembles the neighbouring country of Thrace in the irregularity of its surface; but in the western part there is a succession of valley-plains, generally elevated themselves, though deeply sunk among the rocky walls that surround them. These lie under the flanks of Mount Scardus, and differ in a still more striking manner from the country of Illyria on the further side of that chain, which is made up of a number of irregular, and usually narrow, river-valleys, separated from one another by rugged mountains. The characteristics of these valley-plains are the well-defined basins in which they lie, their rich alluvial soil, and the river which waters each of them respectively, and in each case makes its exit through a narrow passage, which is its only means of escape. The northernmost and smallest of these is now called the Tettovo, and from it the main stream of the Axius issues. At the southern extremity of this a branch detaches itself from the Scardus, and bending southward forms an important secondary chain, which is continued until, under the name of Bermius, it approaches Mount Olympus. This branch, in the upper part of its range, forms the eastern boundary of the second and most important valley-plain, that of Pelagonia (now the plain of Monastir), from which the Erigon (Czerna) forces its way to join the Axius. This plain, which is 40 miles in length by 10 in breadth, and 1500 feet above the sea, was one of the primitive seats of the Macedonian race, and was suited for developing a hardy yet thriving population which might afterwards become a great people. Here is laid the scene of the story of the foundation of the Macedonian monarchy, which Herodotus has related (viii. 137, 138). According to this, three brothers of the family of the Temenidæ of Argos, having entered the service of the king of the country, and having been defrauded by him of their wages, made their escape in a romantic manner, the narrative of which contains numerous fabulous incidents, and ultimately conquered all Macedonia. The southern part of this plain was called Lyncestis, and was the scene of the encounter between Brasidas and the Illyrians, which Thucydides has described (iv. 124–28); the famous retreat of that general was made by the pass at its south-eastern extremity.

W & A K Johnston Edinburgh.

Between Lyncestis and the lowlands, near the coast, is a lake district of somewhat inferior elevation, which bore the name of Eordæa. Again, to the southward of Pelagonia is another extensive plain, from which the Haliacmon (Vistritza) draws its waters; that river ultimately breaks through the Bermian range behind Berrhœa (Verria), and flows into the Thermaic Gulf. The coast district between the Haliacmon and Olympus, as well as the sea-slopes of that mountain, formed Pieria, the original home of the Muses. The chief cities of Pieria were Pydna, where Perseus, the last king of Macedon, was defeated by the Romans, and Dium. From this neighbourhood to the head of the Thermaic Gulf a vast maritime plain extended, which was intersected by the Lydias and the Axius, as well as the Haliacmon.

The Scardus chain, which has been spoken of as separating Macedonia from Illyria, is the northern continuation of Pindus, and the two together form a well-defined backbone, which may be compared to the *spina* of an ancient circus. At its northern extremity, where it rises from the plain of Kossova, stands a lofty peak, which, to carry out the comparison, may be called the *meta* or goal of the circus. This summit, which reaches a height of between 7000 and 8000 feet, had no name in antiquity, but is now known by the Slavonic appellation of Liubatrin, or the "Lovely Thorn." The mountain wall which starts from it presents a most imposing appearance from every point of view, and is broken through at only one point, where the river now called Devol, rising on its eastern side, divides it to its base as it flows to the Adriatic. Here the chain of Scardus ends, and that of Pindus commences. Northward of this it is crossed by two passes,—one near the headwaters of the Axius, between the modern towns of Prisrend and Calcandele; the other farther to the south, leading from the head of the Lacus Lychnitis (Lake of Ochrida) into the Pelagonian plain. At the southern end of this plain another chain diverges from Scardus, and takes an easterly direction through Macedonia; in the region between the Strymon and Nestus this was called Orbelus, and between it and the sea lies Mount Pangæus, which was famed for its gold and silver mines.

The rivers of this country, notwithstanding that they are larger than any that are found in Greece proper, can hardly be called navigable, though barges are floated down them at the present day. The Axius, which is the most important, is celebrated by Homer, on account of its fertilizing water, as "the fairest stream that flows in all the earth" (*Il.*, ii. 850), and the valley in which it runs must always have formed a line of communication between the barbarous districts of the interior and the sea. The point of demarcation between the uplands and the lowlands is marked by the Stena, or, as it is now called, the Iron Gate (Demir Kapu) of the Vardar. Here the river cuts through at right angles the mountains that join the Scardus and Orbelus ranges, and forms a deep ravine, through which it rushes in rapids for the distance of a quarter of a mile, beneath steep cliffs that rise to the height of 600 or 700 feet above; and traces of groovings in the rocks are visible, where a passage has been made in ancient times. At the point in its upper course where it receives its northern tributaries, and begins to bend towards the south, stood the town of Scupi, the name of which was changed by the Byzantines into Scopia, or "the look-out place," and has now been corrupted into Uskiub. The importance of this consisted in its neighbourhood to the pass over the Scardus, by which the barbarian tribes to the west used to descend into the more level and fertile country, and in its commanding the principal line of traffic. Between Scupi and the Stena, at the confluence of the Axius and the Erigon, was Stobi, the ruins of which have recently been discovered by M. Heuzey, of the French "Mission de Macédoine." This town was in Roman times the meeting-point of four great roads—one from the Danube by Scupi; another from Sardica, near the modern Sophia, to the north-east; a third from Heraclea (Monastir) to the south-west; and a fourth from Thessalonica. The Strymon (Struma) follows a direction nearly parallel to the Axius in eastern Macedonia, and, after passing through the chain of Orbelus, enters the rich plain of Serrhæ (Seres), and flows into the Lake of Prasias or Cercinitis, shortly after emerging from which it reaches the sea. On the shores of the Lake Prasias were a number of lacustrine habitations which Herodotus has described, corresponding in their general features to those of which so considerable remains have recently been discovered in Switzerland and elsewhere. At the point where the Strymon leaves the lake was built the important town of Amphipolis, which was surrounded on three sides by the river, thus occupying a very strong position. It was founded by the Athenians in 437 B.C., and was valuable on account of its neighbourhood to the mines of Pangæus, and as furnishing a large supply of timber. Its port, at the mouth of the Strymon, was called Eion. The ancient capital of Macedonia, Ægæ or Edessa (Vodena), stood at the point where the passes from Lyncestis and Eordæa emerge into the lower country. Its situation seems to suggest dominion; for, while it has at its back all the resources of the richest districts, the view from it embraces the wide maritime plain, the mighty mass of Olympus, and a portion of the Thermaic Gulf. The site, which resembles that of Tivoli, is one of extreme beauty, for below the level table of land on which the city is built the rock falls some 200 feet in steep precipices, and the river which passes through it, a tributary of the Lydias, divides into a number of smaller streams, which plunge at various points in cascades down the cliffs. When Philip of Macedon transferred the seat of government to Pella, Edessa continued to be the national hearth of the race, and the burial-place of their kings. Pella, the later capital, occupied a much inferior position, being on low hills at the edge of an extensive marsh in the middle of the maritime plain. This was naturally an unhealthy site, and its only strength lay in its swampy surroundings; so that its nearness to the sea must have been its chief recommendation. The place is now deserted, but the name of Pel is still attached to its vicinity. In Roman times Thessalonica became the chief centre of these parts, which at all times it deserves to be, for it is admirably placed for purposes of communication and trade, as it lies on the innermost bay of the Thermaic Gulf, and forms the natural point of transit for exports and imports. Its appearance recalls that of Genoa, from the way in which the houses rise from the water's edge, and ascend the hill-sides behind. This city was the terminus of the Via Egnatia, the great Roman road which joined the Adriatic and the Ægean, and formed the main line of communication between the West and the East. Starting from Dyrrhachium, it threaded the defiles of Illyria, and, passing the Lacus Lychnitis, crossed the Scardus by the southernmost of its two passes, which descends on Heraclea; thence it traversed Lyncestis and Eordæa, till it reached Edessa, and finally crossed the plain to Thessalonica.

It remains to speak of the maritime district of Macedonia, called Chalcidice, which projects like a trident into the north of the Ægean between the Thermaic and Strymonic Gulfs. When seen on the map, it strikingly resembles the Peloponnese in miniature, from its three southern promontories, with deep intervening bays, and the massive breadth of ground from which these spring. This resemblance is still further borne out in the form of the mountains and their vegetation; and in most respects it corresponds so well to what the Greeks desired for their settlements that we cannot be surprised at finding its shores fringed with Hellenic colonies. Several of these were founded from Chalcis in Eubœa, which city gave its name to the district; but the important town of Potidæa was a Corinthian colony. The most eastern of the three peninsulas, that of Acte, is far the highest, and rises from its isthmus until it forms a steep central ridge, which gradually attains the height of 4000 feet, and finally throws up the vast conical peak of Mount Athos (6400 feet). The isthmus, which is about a mile and a half broad, still shows traces of the canal made by Xerxes for the passage of his fleet, in order to avoid the dangers of shipwreck on the rocks of Athos, which had destroyed the expedition of Mardonius. On the land side of the isthmus stood the city of Acanthus. Separated from Acte by the Singitic Gulf was the promontory of Sithonia, with the town of Toronė; and still farther to the west, beyond the Toronaic Gulf, was that of Pallene. The former of these, though of lower elevation than Acte, is intersected by a well-marked ridge; but the latter is almost level, and from the traces of volcanic action that are found there was called by the Greeks Phlegra, and was said to have been the scene of the conflict between the giants and the gods. On the southern side of Pallene were the towns of Mende and Scione, and its isthmus was occupied by Potidæa, near which, at the head of the Toronaic Gulf, stood Olynthus. The Greek cities on this coast were a continual thorn in the side of the Macedonian monarchs, and caused them to take part against Athens during the Peloponnesian War. The northern part of Chalcidice is mountainous, and beyond these mountains is a considerable depression, in which lies the Lake of Bolbe.

Macedonia first comes into notice in history in the reign of Amyntas (about 500 B.C.) and in that of his son Alexander, who was king at the time of Xerxes's invasion of Greece. But whatever historical interest attaches to it is due rather to the great empire which sprang from it than to the importance of the country itself. During the Peloponnesian War we notice it chiefly as it affects the principal contending parties, but in the time of Demosthenes it attracts our attention as furnishing the keynote of the policy of that statesman, and being the proximate cause of the overthrow of Greek liberty. After the MACEDONIAN EMPIRE (*q.v.*) was subjugated by the Romans in 168 B.C., the country was left with a nominal autonomy, but lost its national unity by being divided into four districts, which were separated from one another by rigid political and social limitations. Before long it was reduced to the form of a province, and this, at the division of the provinces in the time of Augustus, was assigned to the senate. Thenceforward it followed the fortunes of the Roman empire, and, after the partition of that dominion, of the eastern branch of it. In the time of Alaric it was frequently plundered by the Goths, and in the interval which elapsed between Justinian I. and Heraclius a considerable part of it was colonized by Slavonians. During the prosperous period of the great Bulgarian monarchy in the 10th century a large portion of Macedonia was included in that kingdom. After that age extensive depopulation must have ensued, for in the 11th and 12th centuries colonies of various tribes of Asiatic origin—Uzes, Turks, and Patzinaks—were established there by the emperors of Constantinople. In the partition of the Eastern empire, which followed the capture of that city by the Latins at the time of the fourth crusade, in 1204, Macedonia was assigned to Boniface, marquis of Monferrat, who assumed the title of king of Saloniki. This kingdom in turn was brought to an end in 1224 by the Greek despot of Epirus, Theodore I., and by him a Greek empire of Thessalonica was founded, which for a time seemed likely to become the heir of the Byzantine power, but afterwards was merged in that of Nicæa, and on the recapture of Constantinople by Michael Palæologus once more formed part of a united Greek empire. In the latter half of the 14th century the greater part of Macedonia was in the possession of the Servians, whose kingdom was now at the height of its power; but before the middle of the 15th it had passed into the hands of the Ottoman Turks, by whom it has been held ever since. At the present day the population of the inland part of the country is mainly composed of Bulgarian Christians, mixed with Turks, while the Greeks occupy the coasts, the whole of Chalcidice, the plain of Seres, and some other districts. (H. F. T.)

MACEDONIAN EMPIRE, THE. The attention of the Greeks was drawn at an early time to the danger that the northern tribes might combine to invade the south. Sitalces, king of Thrace, spread great alarm by an inroad during the Peloponnesian War, but the real peril was from Macedonia rather than from Thrace. The Macedonians had been gradually pushing their way down towards the coast, and, though Alexander I. was a vassal of Xerxes, the retreat of the Persians, 478 B.C., left these hardy tribes free. They were still in a primitive state, mountain shepherds, ill clothed and ill housed, many of them clad only in skins. They wore the kausia or broad-brimmed hat; they ate and drank from wooden platters and cups; they differed little from what they had been when the first Perdiccas came to the country, when the king's wife baked cakes with her own hand on the hearth. But the peasants were freemen, not serfs like the Penestæ of Thessaly. It was still necessary for the young warrior to slay a foe before he could take his place in the tribe; and Cassander had to sit instead of reclining at the banquet of his father Antipater, because he had not yet killed a wild boar. The drunken bouts at these banquets led to some of the deeds which are a blot on the fame of both Philip and Alexander. The king held large domains, and had a choice body of "companions" around him, but the warriors used much freedom of speech towards him, and the chiefs could only be condemned by the assembled host. When, however, any one was thus convicted of treason, his kindred were also put to death. If any blood guilt was incurred, a dog was cut in two and the soldiers passed between the halves laid out in the open air, that so they might be purified. There were still but few towns, or even strongholds, to which the people could fly when the Illyrians came in over Mount Bermius from the west, or the Thracians across the Strymon from the east, or the Pæonians down the river Axius from the north. The western tribes too were at this time being pushed onward into Macedonia by a migration of the Gauls. Archelaus, son of Perdiccas II., however, built forts, cut straight roads, and collected horses and arms. The cavalry of the richer landowners was good; but the foot soldiers were armed only with wicker shields and rusty swords. Archelaus also courted the friendship of leading Athenian statesmen, philosophers, and poets; and later on the Athenian general Iphicrates did essential service to the royal house.

But the advance made by Archelaus, who died 399 B.C., was almost all lost before Philip II. came to the throne, and the kingdom was reduced to a narrow district round Edessa, shut out from the sea by Greek cities. Olynthus, the chief of these cities, had in the reign of Philip's father, Amyntas II., induced many places to make themselves independent of the king, but the jealousy of Sparta proved fatal to the Olynthian confederacy, and destroyed what would have been a bulwark against the barbarians of the north (379).

Philip himself had the best of all trainings, that of adversity. During the reign of his eldest brother Alexander II., Pelopidas took hostages for the fidelity of Macedonia, and among them was Philip, then about fifteen years old. He remained two or three years at Thebes, profiting by literary training, and above all by the living example of Epaminondas, the ablest organizer and most scientific tactician of the age, who had trained the soldiers that broke through the Spartan line at Leuctra. When Philip returned home, his brother Perdiccas III. entrusted him with the government of a district, where he organized a force on the Theban model. On the death of Perdiccas, though he left an infant son Amyntas, Philip was called to the throne (359), for the reign of a child in an early state of society means anarchy. Philip's energy soon made itself felt. He fortified a new capital, Pella, safe amidst its lake-like marshes, from which he could act against the coast. Greece was at the moment completely disorganized. Sparta had lost, not only her supremacy over the other Greek states, but the control over Messenia and Arcadia, which leant on Thebes for defence against her revenge. Thebes had incurred odium from her conduct towards the free cities of Bœotia, was at feud with Athens, and had but a precarious hold over Phocis and Thessaly; while Thessaly itself, after the fall of the tyrants of Pheræ, was a prey to internal feuds. Athens was the first to come into collision with Philip, owing to her holding possessions on the coast of Macedonia and Thrace, whence she procured ship timber and naval stores. Philip had conciliated her for the time by withdrawing his troops from Amphipolis, her old colony in the bend of the river Strymon, while he was driving off the Illyrians and reducing the tribes to the west as far as the Lake Lychnitis. But Athens was at this moment threatened by the revolt of her allies which led to the Social War, and so lost the chance of reoccupying Amphipolis while Philip was busied in the interior. The moment his hands were free, he retook the place, which was all-important to him, as it was not only the most convenient maritime station in Thrace, but also threw open to him all the country east of the Strymon, and especially the gold region near Mount Pangæus, the productive country facing the island of Thasos; and to secure his conquests he founded a new city in the interior called Philippi. His gold coins, struck on the Attic standard, soon became well known, and even the early gold coins of distant Britain copied the types of the Macedonian money. He also took Pydna and Potidæa, thus depriving Athens of her hold on the Thermaic Gulf, while the occupation of Methone opened the way into Thessaly. Moreover, the Social War had not yet ended when the disastrous Sacred War began, which added religious to political enmity, and benefited only the aggressor from the north. The Amphictyonic League was called into activity to crush the Phocians, who in their despair seized Delphi, and by the use of its treasures collected troops enough to hold Thebes in check for some years. It was the misfortune of Greece that there had arisen mercenary bands, like the condottieri of mediæval Italy, who hired themselves out to any one that would employ them. The citizens became more averse to service as civilization increased, and the work of war was now done by alien hands. Only a standing army could face the standing army of Macedonia, but the industrious and refined citizens naturally disliked continuous service, and it was long before even Demosthenes could arouse Athens to the necessity of the struggle. He was opposed by the old statesmen, by honest men such as Phocion (whose peace policy, however expedient after Chæronea, was impolitic during most of Philip's reign), and by others whom Philip had bribed—for he loved to "plough with a silver ploughshare." The Sacred War gave Philip a pretence for interfering on behalf of the Delphic god. He drove the Phocian mercenaries from Thessaly, incorporated the excellent Thessalian cavalry in his army, and gained a good naval position on the Gulf of Pagasæ (Volo), the great inlet and outlet for the trade of the country. This also opened the way to Eubœa, for the possession of which, however, Athens struggled hard. It was on the Gulf of Pagasæ that Demetrias was afterwards founded, which, with Chalcis and Corinth, became the "fetters of Greece." Philip also laid a strong hand on Epirus, occupied Acarnania, won over the Ætolians by the gift of Naupactus, and thus hemmed in Athens on the land side. It is true that, when he marched on Thermopylæ, B.C. 352, a sudden effort of the Athenians enabled them to reach the pass in time to arrest his progress, and save the Phocians for a while; but Philip had now a large seaboard, and he proceeded to increase his fleet, to extend his dominion in Thrace on both sides of the Hebrus, and secure it by the foundation of Philippopolis, Calybe, Berœa, and Alexandropolis, while the Greek colonies along the Euxine up to Odessus sought his alliance. There was worse to come, for Philip by the year 347 had destroyed Olynthus and thirty-one other free cities in Chalcidice, and sold their inhabitants as slaves, a calamity such as had not happened since the invasion of Xerxes. This struck terror into all the south country, and we find Isocrates, once the champion of Panhellenic freedom, proclaiming Philip the arbiter of Greece, and advising him to use his power for the purpose of conquering Persia. He found himself bitterly deceived, and "that dishonest victory at Chæronea, fatal to liberty, killed with report that old man eloquent." The Thebans were still unwilling to combine with Athens, and even called in Philip to end the Sacred War. This gave him the command of Thermopylæ, and the means of marching into Bœotia and Attica, while the destruction of the Phocians spread the terror still more widely. Philip now became the recognized religious leader of the Amphictyonic League, and began to interfere authoritatively in the Peloponnese. He was also preparing to master the Bosphorus and the Hellespont, the outlets from the Euxine into the Ægean, through which the main supplies of corn came from the country north of the Euxine to Athens, which therefore laid great stress on the possession of the Chersonese. Once again Athens gained a success when she sent Phocion to relieve Byzantium from his attack (339). The Greek cities began again to lean on her, and her trade increased owing to the destruction of Olynthus by Philip, and of Sidon by the Persian king Ochus. The Greeks too began to see that Philip's allies were being swallowed up one by one. Philip himself, when returning through the passes of Hæmus from an attack on the Scythian king, who ruled between the mountains and the Danube, suffered heavily from a surprise by the Triballi. But a second Sacred War against the Locrians of Amphissa, caused by Æschines's troublesome activity, again brought Philip into the heart of Greece. He fortified Elatea in Phocis, and demanded a passage through Bœotia to attack Athens. On this Demosthenes won his greatest triumph, when he induced Thebes to join in the struggle for freedom and independence; and, though the patriots were defeated at Chæronea, 338 B.C., yet their blood was not shed in vain; their example has told on all future time. Philip used his victory moderately, for he wished to leave Greece quiet behind him when he crossed into Asia to assail the great king. He garrisoned the citadel of Thebes, and demanded from Athens an acknowledgment of his leadership in the national war against Darius; and a congress at Corinth recognized him as its chief, and arranged what contingents were to be sent from each state. His assassination in 336, at the early age of forty-seven, hardly delayed the execution of the plan, for he was succeeded by Alexander, who combined the qualities of a king of the heroic ages with all that Greek training could give. Though the Macedonians had a dialect of their own, yet they had neither language for communicating with others nor any literature except what they derived from Greeks, and Philip had taken care to give his son even a better training than he had received himself. Alexander was also as prompt and cruel as his father. He at once rid himself of his cousin and brother-in-law Amyntas and other kinsmen and possible competitors for the throne, or persons otherwise dangerous. Then he dealt some heavy blows against the barbarians east, north, and west, some of whose chiefs he took for further security with him into Asia. He was just south of Lake Lychnitis, on the western side of the range of Scardus or Pindus, when the news reached him that the exiles had roused Thebes to arms, and were besieging his garrison in the Cadmeia or citadel. Striking through a cleft in the main range of mountains, through which the Devol flows, and marching south along the Haliacmon and over the Cambunian ridge, which joins Pindus to Olympus, he reached Bœotia in less than a fortnight, stormed Thebes, sold the citizens as slaves, and destroyed the place. The citadel alone remained as a Macedonian fortress, until Cassander rebuilt the city. Amidst the general terror, Alexander thought it wisest to follow his father's policy here also, and be content with his election as captain-general by the congress of Corinth.

He left Antipater as regent, and at once crossed the Hellespont to Sestus in the spring of 334, before the Persian fleet was ready to intercept him, or the main Persian army had been embodied. What information had he as to the regions beyond the Taurus and beyond the Tigris, and still more as to the great table-land of Asia extending from Persia to the Indus? He had the *Anabasis* of Xenophon, and perhaps the Persian history of Ctesias, but he must have relied mainly on information derived from Greeks who had been in the Persian service, or who had traded in the interior. But he knew one thing for certain, that no force in Asia could resist Philip's veteran army. Philip had formed the local battalions of militia into the phalanx, arrayed sixteen deep, and armed with long two-handed pikes (*sarissæ*); and this steady body of pikemen, with the veterans in the front ranks, had borne down on the open plain of Chæronea the resistance of the Greek hoplites, who were only armed with a much shorter spear. The phalanx was supported on the flanks by the light infantry of the guard (*hypaspists*), by targeteers (*peltasts*) trained after the plan of Iphicrates, by light lancers, and by a strong body of heavy cavalry, headed by the king's companions, and fighting with the short thrusting pike. It was the charge of the cavalry led by Alexander in person, at the head of the "agema" or royal squadron, that decided all his battles. It seems strange, however, to us to hear that the men had neither saddles nor stirrups, nor were the horses shod. The fine native army was largely reinforced by barbarian archers, darters, and slingers, and by regiments of Greek mercenaries; and this systematic combination of different arms and kinds of troops was supported by field and siege artillery of an improved type. Later on, when the main Persian army was broken up, Alexander added to the number of light troops, and made the regiments smaller and more flexible. Philip had moulded his country into a military monarchy, and turned the nobles into a caste of officers. All its strength was devoted to the one object of war, and it became for the time an overmatch for all its neighbours. On the other hand, Persia had deprived the subject peoples of national life and spirit; the retreat of the Ten Thousand had shown how useless her native levies were, and now her defence rested almost entirely on a force of Greek troops under the able Rhodian general Memnon. The Orientals fought mainly with missiles, and were little suited for close combat hand to hand. The Persian satraps, however, had around them some choice horsemen, armed with missile javelins and with scimitars; and they insisted, against Memnon's advice, on fighting at the Granicus, which flows northward from Ida into the Propontis, but is everywhere fordable. A sharp cavalry action at the passage of the river (334 B.C.) gave Alexander all Asia Minor, and the completeness of his victory might seem to justify Livy's saying that he "did but dare to despise an empty show," and the words attributed to his uncle, Alexander of Epirus, that he himself had found the men's chamber in Italy while his nephew had found the women's in Asia. The Greeks had long been conscious of their superiority. "They might," said Aristotle, "govern the world, could they but combine in one political society." Agesilaus of Sparta and Jason of Pheræ had already planned the attack on Persia, and the liberation of the Asiatic Greeks; and Alexander acted in the full consciousness that he was extending Greek rule and civilization over the East. At the news of the battle on the Granicus, Sardis surrendered. It was the centre to which all the routes converged, but Alexander did not (like Cyrus the younger) at once push on into the heart of the empire along the great road that led from Sardis to Susa. His object was to secure a firm base of operations, by occupying the line of coast round the Ægean, and forcing the Phœnician fleet in the Persian service to retire. The Greek colonization of Asia Minor had prepared the way for him; the Greek cities along the western and southern coast threw open their gates, and Alexander restored their popular constitutions. He even recognized the Lycian confederation. Memnon was only able to organize a resistance at Miletus and Halicarnassus. But his real plan was to put troops on board his ships and raise Greece against the Macedonian yoke, especially as the Athenian fleet was still more than a match for that of Alexander. But when Memnon died there was no one left to carry out this able plan, and Darius threw away his best chance by recalling the troops. Then Alexander marched up northwards from Lycia through Pisidia and Phrygia to Gordion on the Sangarius, whence the main road led east across the Halys and through Cappadocia to Cilicia, between the passes of Mount Taurus and those of Mount Amanus. Here Darius tried to throw his army across the Greek line of communication with their supplies, but his host, crowded together in the narrow ground on the river Pinarus near Issus, was hopelessly defeated. The modern name of the Gulf of Issus, "Iskenderun," still preserves the memory of Alexander. Then Parmenio, Alexander's second in command, pushed on and took Darius's treasures and stores at Damascus. Again, however, Alexander deferred his march inland till he had mastered Phœnicia and Egypt, and so gained the command of the sea in the eastern basin of the Mediterranean. Only the brave freemen of two fortified cities, Tyre and Gaza, held out; and when the Phœnician and Cyprian fleet transferred its allegiance to the invader their only effective weapon was wrested from the hands of the Persians. The occupation of Cyprus and Egypt had been one of the boldest conceptions of the age of Pericles and Cimon, and its success would have secured the supremacy of Greek commerce. As the Persians had persecuted the Egyptians for their worship of animals, Egypt welcomed the deliverer, and recognized him as the son of Ammon; while the Greek colonies of Cyrene and its Pentapolis sent to tender submission. Alexandria was founded on the seaboard as a new centre of commerce, from which it was easy to communicate with the Government and with all parts of the empire. The protecting island of Pharos gave the means of forming two good harbours on a coast elsewhere harbourless; while Lake Mareotis, communicating by canals with the Nile, enabled produce to be easily brought down from the interior.

At last the time was come for delivering the final blow to Persia. Alexander passed the Euphrates at Thapsacus ("the passage"), and then marched north-east through the hilly country by Nisibis, to avoid the hot desert of Mesopotamia. He crossed the Tigris unopposed, and defeated Darius's hosts at Gaugamela. The long struggle of two hundred years between Greece and Persia was at an end. The victory converted Alexander into the great king, and Darius into a fugitive pretender; and Babylon and Susa submitted. At Babylon Alexander sacrificed to the native gods, as he had done elsewhere, and this admixture of the religions of all countries largely influenced the later phases of heathenism. The priests recognized the Greek kings, and the later cuneiform inscriptions commemorate Seleucus and Antiochus. When Euemerus's view spread, that the gods were only deified men, a fusion of religions became still easier. The worship of the Sun-god and of Osiris, the god of the dead (especially under his Grecized form at Sinope as Serapis), extended far and wide. In administering these countries, Alexander separated the civil, military, and financial functions, and, where natives were left in office, entrusted taxation and military command to Macedonians. The great power of the satraps had weakened the central government of Persia, and Alexander adopted a wiser plan, but his generals restored the old system after his death. The Persian treasures, dispersed by the conquest, gave a fresh stimulus to commerce, especially as Persia was rich in gold, which was scarce in the West. Alexander had already prepared the way for a universal currency by coining silver didrachms and tetradrachms after the Attic standard, which became current coinage over most of the East; the Ptolemies, however, adopted the Phœnician standard for Egypt. Up to this point the countries conquered admitted of being more or less assimilated and Hellenized; but, when Alexander penetrated through the passes that led up to Persepolis in Persia, and thence to Ecbatana in Media, and again north to secure the defiles that led down to the Caspian, and so skirting the southern flank of the range of Elburz to Hecatompylus in Parthia, the centre of the roads leading to Hyrcania (at the south-east of the Caspian), to Bactria, and to Ariana, and then from Kandahar northwards to Cabul, and through the mighty range of the Hindu-Kush to Bactria (Balkh) south of the Oxus, and Sogdiana (Bokhara) between that river and the Jaxartes, and at last as far as the Indus and the Punjab, his route lay through tribes that still possessed their native strength and power of resistance to foreign influence, though for the moment overborne by the superiority of the Western arms. Alexander saw the danger, and met it by settling Greek colonists in new cities which were to serve as military posts, depôts of commerce, and centres from which to Hellenize the country districts; and many of them are still important points in the East, though the desert has spread, and robber hordes have stopped some of the old caravan routes. Such places are Merv, Herat, Kandahar, Cabul, Samarkand, Khojend. Bactria and Sogdiana were to serve as a frontier against the wild hordes of the north, and thus Alexander's measures determined the fortune of Transoxiana for centuries. Some native rulers also were left to form a sort of barrier in front of the empire to the north and east. Alexander laid the main stress on securing the great rivers, the Euphrates and the Tigris, the Oxus and Jaxartes, the Indus and Hydaspes. In Greece itself the Macedonian kings upheld tyrants or oligarchies, but here freer municipal constitutions were allowed to attract colonists. Alexander further planned to fuse the noble Persian race with the Greeks by intermarriage, and by giving the Persians equal rights in the army and the administration. Common service in these was the best means for Hellenizing the natives. This was a more generous plan than Aristotle's advice as to the way of ruling barbarians would have led to; but Alexander saw that the Eastern peoples were not barbarians like the Illyrians. The culture of Egypt reached far back; the astronomy and art of Babylon could not be despised; the religions of Persia and India afforded matter of interest to Greek inquiry. These lands of ancient civilization might teach as well as learn something from Greece. The Eastern nations responded to the touch, and Persian legend to this day preserves the name of Iskander among the names of their national heroes. Alexander's conquests were to be justified by the result, by the union of East and West, and the diffusion of Western civilization over Asia. Even India should feel something of the new influence. Alexander would have made the nations into one. An old writer says, "The elements of the nations' lives were mixed together as in a love cup, and the nations drank of the same cup, and forgot their old enmity and their own weakness" (Plut., *De Fort. Alex.*, i. 6). There is, it is true, a reverse to the picture. The oppressive conduct of many of the Macedonians thus suddenly put into power was an evil omen of what might happen if their chief was removed; and, if the East was becoming Hellenized, yet Alexander became in turn Orientalized. Could he remain a Western king and also an Oriental despot? a Greek and a Persian? It might be good policy, but Philip's old generals could not help showing their disgust, and Clitus and others paid for it with their lives. The Greek states also felt the difference. Just before his death Alexander required them to worship him as a god, and, without any regard to the rules agreed on at the congress of Corinth, forbade the federal meetings of the Achæans and Arcadians, and issued a decree restoring all exiles to the various states. Greece became practically a province of the Eastern empire, and the patriots who had maintained the fight for freedom were more than justified by the ruin that came on Greece through Alexander's successors. Even if he himself had not been spoilt by success and absolute power, yet he was but a lucky accident. And, though the Hellenizing influence spread over much of the East in a way to which there has been but one parallel, the mixture of German and Roman elements when the barbarians invaded the empire, yet Alexander's conquests, while they Hellenized Asia, tended to Asiatize Hellas; they put an end to the genuine Hellenic spirit, to its productive genius and consummate literary and artistic excellence, as well as to its political freedom. The New Comedy shows how national life and public interests had died out; with all its fine psychological analysis it does but dwell on the characters and situations of daily life and purely domestic feelings. But the braggart soldier is now a common character in the play, and slavery plays a greater part than ever. Last of all, Alexander marched along the Cabul river, and through the pass of Jellalabad to the passage of the Indus by Attock; but when he reached the Hyphasis (Sutlej) the weary troops refused to cross it and press on to the Ganges. He then sent Nearchus down the Indus, to sail round to the mouth of the Euphrates, and explore a route for traffic across the Indian Ocean. Nearchus profited by the monsoons, which thus became known to the Greek sailors. The king himself went down the river to see the great southern ocean with its strange tides, and he planned that an Alexandria on the Indus should communicate with the Alexandria of the Nile valley by an intermediate harbour on the Euphrates. He further planned the circumnavigation of Arabia, if not of Africa also, and a voyage to the north of the Caspian. At the same time Pytheas of Marseilles was exploring the British and Baltic seas. This enlarged and systematic exploration of the earth, combined with increased means of communication among its inhabitants, was beneficial to civilization, if we may define growth in civilization as growth in the amount of services rendered to each other in civil society. The record kept by Alexander's quarter-masters (*bematistæ*) of the length of his marches gave succeeding geographers important information; and it was more useful to Eratosthenes than the vague descriptions in the historians, who were striving after literary effect, and some of whose accounts were very legendary, for legends soon clustered round the name of the great conqueror. Alexander seems also to have had a description (*anagraphe*) of the empire drawn out. After his return through the desert of Baluchistan, along the Indian Ocean, he devoted himself to consolidating the internal administration and checking the oppression exercised by his officers; but he was planning new conquests in the West, from all parts of which he had received ambassadors, when he died of marsh fever at Babylon (323 B.C.), at the early age of thirty-two.

All attempts to keep his empire together inevitably failed, but his work was done, since, whether for good or evil, the Hellenizing of the East determined the whole course of history. The army resolved that his child (not yet born) by his Bactrian wife Roxane, and his imbecile half-brother, Philip Aridæus, should bear rule jointly. First Perdiccas was named regent, but the generals began to combine against him, and he perished in trying to reduce to obedience Ptolemy, the satrap of Egypt, the man who saw most clearly and earliest the tendency of events. Then Antipater, who had with difficulty defeated the gallant attempt of the Greeks under the leadership of Athens to regain their freedom in the Lamian War, was made regent. On his deathbed he transferred the office to Polysperchon, who soon proved unequal to his task, and even gave up Phocion, the leader of the Macedonian party at Athens, to death. Antigonus, the commander-in-chief in Asia, destroyed Eumenes, who was faithful to the royal house but was a Greek from Cardia and not a Macedonian. He then tried to reunite the satrapies; but Ptolemy of Egypt, Lysimachus of Thrace, and Seleucus of Babylon combined with Cassander of Macedon against him, and he fell (301 B.C.) at the battle of Ipsus in Phrygia. This decided the final break up of the empire. Several native princes retained their dominions and formed a kind of neutral zone between the new kingdoms, and the Getæ on the Danube maintained themselves against Lysimachus. The customary feuds in the royal house, and its intrigues with the generals, soon led it to destruction. Roxane, the mother of the child Alexander, began by murdering Alexander's other wife Statira, the daughter of Darius. Alexander's Epirote mother Olympias killed Philip Aridæus and his wife Eurydice, and Cassander killed Olympias herself, and afterwards Roxane with her son. There were similar feuds and murders in the houses of all Alexander's successors, except the early Antigonids. Their marriages, like those of Philip and Alexander, were of a very Oriental character; and "in these families," says Plutarch, "murders of sons, mothers, and wives were frequent, murders of brothers were even common as a necessary precaution for safety." The generals assumed the title of king after Demetrius's defeat of Ptolemy off Cyprus (307 B.C.), and their example was followed by Agathocles at Syracuse, and Dionysius at Heraclea on the Euxine. Demetrius, after his father's death at Ipsus, fled to Greece, and occupied much of the country. His viceroy in Bœotia was the historian Hieronymus of Cardia, the friend and fellow-citizen of Eumenes. Demetrius for a time even gained Macedonia, but his Oriental rule disgusted the people, and he had to fly to Seleucus, who married his daughter Stratonice. Seleucus detained him under honourable guard till his death, perhaps with some idea of using his help if the balance of power should again be threatened. When an empire breaks up, old geographical relations make themselves felt, the great masses and divisions of the land exert their influence and affinities of race begin to show their old power, the natural boundaries of mountain and river tend to reappear; and so it proved now. After Cassander's death, and the defeat of Lysimachus by Seleucus, Seleucus reorganized Asia by breaking up the twelve large satrapies into more than seventy districts of a more manageable size. He then crossed to Europe to reunite Macedonia to Asia, but was murdered by Ptolemy Ceraunus, eldest son of Ptolemy of Egypt—who had chosen his second son Philadelphus as his heir instead of the wild Ceraunus. Seleucus's death ended the generation of Alexander's generals. A new state of things followed. Ceraunus fell in battle against the invading Gauls, whose migrations gave a final blow to the old system. Part of the Gauls passed on into Greece, where the free states destroyed them, while others crossed into Asia and occupied the country named from them Galatia, 276 B.C. Lastly, after Pyrrhus of Epirus, whose sister Deidamia married Demetrius, had more than once nearly gained possession of Macedonia, Antigonus Gonatas, the son of Demetrius, finally secured the succession, and restored the wasted realm to the position of one of the great kingdoms by the side of Egypt and Syria. The last struggle of Athens against him in the war of Chremonides (a pupil of Zeno of Citium) proved fruitless. He also regained the Macedonian frontier on the side of Epirus as it had been in Philip's time, and the Aous became the boundary towards the Dardanians on the north-west. Of the kingdom thus restored his family retained possession till Perseus was overthrown by the Romans at the battle of Pydna (168 B.C.), but the later kings wasted their strength in useless wars instead of doing what might have been done, conquering and Hellenizing the country up to the Danube. The Epirote kings Alexander and Pyrrhus had striven to found a new military empire in Italy, but in vain. The Apennines can be seen from the coast of Epirus, and these kings were always stretching eager hands over the sea to the new lands in the West, but their power proved unequal to the task, and Pyrrhus's position in history is mainly important because his expedition brought Greece and Italy into close connexion. His geniality of character impressed his contemporaries, and has left its impress on Roman and Greek legend.

In Asia Seleucus had in vain tried to preserve the most easterly provinces, for the Eastern nature had at once begun to react against the Macedonian conquest, and the Seleucid kingdom had no true centre or natural limits. Sandracottus, a native chief, founded a great kingdom in India with Indian and "Javanic" (Ionian, *i.e.*, Greek) support; and Seleucus, after one campaign, gave up the eastern districts as far as the Paropamisadæ west of Cabul. Sandracottus was perhaps supported by the Brahmans whom Alexander had opposed, but the Punjab has witnessed more than one revolt against the system of caste, which had its stronghold in the valley of the Ganges; and Buddhism soon became predominant in the new kingdom. The edicts of Asoka, the second successor of Sandracottus, which made Buddhism the state religion (though Brahmanism was tolerated), mention Antiochus Ptolemy and Antigonus (see INDIA, vol. xii. p. 787, for a full account); and Buddhist missionaries began to spread the faith westwards as well as to the south, and some knowledge of the cycle of Eastern story and fable was communicated to the Greeks. But we have not the materials for estimating the influence exercised in Asia by the Greeks on the new kingdom. Similarly a Græco-Bactrian kingdom, which was made independent by Theodotus or Diodotus about 256 B.C., lasted for two centuries. Many of its coins have been found with legends at first purely Greek, but becoming gradually barbarized. Some of the early ones resemble the gold coins of Antiochus II. of Syria, who ruled just before Diodotus made the new state independent. After the first five kings, however, the legends are in Prakrit as well as in Greek. The caravan routes were long kept open, and in this way trade with China was maintained, and silk and other Chinese commodities reached Europe. Farther west native Persian chiefs became practically independent, such as Atropates in the Median district, called from him Atropatene, and elsewhere; for the clan system was suited to these districts, and they preserved the system of Zoroaster till Artaxerxes (Ardshir) restored the Persian monarchy, 226 A.D. (see PERSIA). But even here Greek influence lasted on; nor when Arsaces, about 250 B.C., had set up the kingdom of Parthia and made Hecatompylus his capital, did that influence die out in Parthia. Even the new cities founded by the Parthian kings, such as Dara, were on the Greek model, and largely inhabited by Greeks; and some of the chief cities retained Greek municipal constitutions, such as Ctesiphon, which took the place of Seleucia on the Tigris as Seleucia had taken the place of the old capital Babylon—

> "Of later fame,
> Built by Emathian or by Parthian hands,
> The great Seleucia, Nisibis, and there
> Artaxata, Teredon, Ctesiphon."

So again in Asia Minor native chiefs began to rule in Armenia, Bithynia, Cappadocia, Paphlagonia, and Pontus; and some of them, such as the Cappadocian princes of the Mithridatic family, who afterwards ruled at Amasia, claimed descent from the royal Achæmenid house of Persia, or from leading Persian houses. They, as well as the princes of Pontus, intermarried with the house of Seleucus, to which their help was important. Bithynia and Pontus had an era of independence, from which they reckoned their dates just as the Syrian kings did from the return of Seleucus to Babylon. The independence of Judæa under the Maccabees was established at a later time (see ISRAEL). All these were subject to the Hellenizing influence of the Greek towns; and the Greek language spread everywhere, even among the Galatians, as we see by the inscriptions. Nicomedes of Bithynia founded Nicomedea in 264 B.C., as a Greek town; it soon rivalled Nicæa in importance, and we owe to it Arrian, the historian of Alexander. The barbaric princes often took wives, ministers, officers, engineers, literati, artists, actors, and intermediate agents of all kinds from some neighbouring Greek city, a custom which had begun before the time of Alexander, as we see in the case of Mausolus of Caria. In Pergamon, about 238 B.C., Philetærus, by the help of the royal treasure, made himself independent, and under Eumenes and Attalus the little state showed much political skill in trimming the balance of power between the neighbouring dynasties. Attalus took the title of king after a victory over the Galatians on the Caicus, and this victory was commemorated by the Gigantomachia around the famous altar lately discovered at Pergamon (see Conze, *Beschreibung der Pergamenischen Bildwerke*; Overbeck, *Geschichte der Griechischen Plastik*, 3d ed.). He also sent commemorative statues to Athens; one of which, long celebrated as the Dying Gladiator, is now seen to be the portraiture of a dying Gaulish chief. Greek art, transplanted from Athens and the Peloponnese to Pergamon and Rhodes, though it had acquired a somewhat florid tinge, was yet not unworthy of its descent from the schools of Phidias and Lysippus, and owing to the close alliance of these two cities with Rome, as against Macedon and Syria, this revived Greek art found its way to Italy. Pergamon also became a centre of Greek learning only second to Alexandria; and, when Ptolemy cut off the supply of papyrus from Egypt, Crates of Mallus in Cilicia (whose name was only second to that of Aristarchus) is said to have revived the old Asiatic use of "parchment"—a name which itself preserves the memory of Pergamon. Papyrus, it is true, remained the usual material for books till about the 4th century, when the Christian Church finally adopted the new material due to the invention of Crates (see Birt, *Das antike Buchwesen*).

All along the coast also a number of Greek cities acquired practical independence owing to the division of power among the princes, Greek as well as native, who were further kept in check by the invading Gauls. Such were the cities of Byzantium, Cyzicus, Heraclea, Sinope, and Olbia on the north-west of the Black Sea, and Panticapæum or Bosporus between that sea and the Palus Mæotis. The true Greek spirit survived above all in Rhodes, as it did also at Massalia in the West. All the more did the Syrian kings strive to maintain their power by founding cities under their own rule, which were made attractive to new colonists by something of municipal independence, with the right to bear arms, to coin money, and to manage their own judicial affairs. Each city had its demus, senate, archons, and generals. There were four of these great cities in Syria itself:—two inland, Antioch on the Orontes, the greatest commercial entrepôt in the East, and Apamea, the military centre of the kingdom; two on the coast, Seleucia, with its rock fortress to serve as a refuge in time of trouble, and farther south Laodicea on the sea, among its rich vineyards. They were all named after the royal family. Other towns were named from places in Greece or Macedonia, such as Achaia, Amphipolis, Apollonia, Arethusa, Astacus, Berœa, Callipolis, Chalcis, Edessa, Heræa, Larissa, Maronea, Oropus, Pella, Perinthus, Tegea; for the oppressed Greeks of Greece itself and of Magna Græcia here found an outlet for their energy. Some military colonies were planted on the west and south of Galatia, to keep the Gauls in check, and guard the roads leading from Phrygia, the centre of the commerce of Asia Minor, to the towns on the coast; such were Antioch in Pisidia, Apamea Cibotus, Synnada, and Thyatira. Even Palestine, notwithstanding the temporary success of the Maccabees, was full of Greek towns like the later Cæsarea, and the manufacturing population used the Greek language. We have some traces of the state of things in the *Economics*, a work of this period, though falsely attributed to Aristotle; and the later political literature shows that men had a clear idea of the aims and means of the politics of the day, and that diplomacy and international law had considerably developed. Thus a large influx of new Hellenic blood was poured into the lands on this side of the Tigris, into Asia Minor, Mesopotamia, and Syria; during the century after Alexander's death nearly two hundred cities were founded, and the Greek race became predominant in western Asia, though of course it was differentiated by the various peoples which it undertook to assimilate, and by which it could not but be influenced in turn, especially as the princes found it necessary to conciliate them. The historians of the time are mostly lost; but many inscriptions survive which show what a blending of populations took place. One gives us a rescript of Antigonus on incorporating the people of Lebedus with the Teians. Another shows that Magnesia became absorbed in Smyrna, now restored after it had long lain waste. Others tell us that places like Erythræ and Iasus recovered something like independence owing to the needs of the Syrian kings. Amidst the feuds of the great powers the Ionian states recovered their freedom, and were able to form a kind of federal union. Similarly we hear of the community (*κοινόν*) of Bithynia, of Asia, and the like. A new life of a somewhat different kind from the old Greek life in politics, religion, and science dates from the revolution effected by Alexander's conquests, though in the lower strata of the country population old beliefs still had some hold, as is evident by what Pausanias found existing even in his day in Greece itself. But old distinctions tended to vanish away, only that between poor and rich acquired still greater force, material interests became predominant. We see also that in the manufacturing towns the workmen had formed benefit societies, and secret or public associations of various kinds. And it was in these commercial centres, with their somewhat cosmopolite character, free from old prejudices and ideas, that Christianity found an early home. Greek freedom made a great impression in the East. The Greeks had no system of castes, no close priesthood, no sacred books like those of India to limit their development; their views may almost be called cosmopolitan, and the distinction between "Greek" and "barbarian" already tended to disappear, as Alexander perhaps had wished. Attic speech became the basis of the new written language, and, with Attic customs, prevailed at the courts of Alexandria and Babylon, of Bactra and Pergamon. Attic plays were acted at Ctesiphon down to Roman times; and the later rhetoricians and sophists imitated the masters of Attic oratory. The Greek view as to Philip and Alexander was thus enabled to hold its own against the prevailing Macedonian tone on these matters, especially when Macedonia lost its leading position, for that country produced only soldiers—with the exception of Marsyas of Pella, and of King Ptolemy, who wrote with true military brevity an account of Alexander's campaigns, which Arrian wisely preferred to the more romantic account of Clitarchus. But, though the towns became Hellenized, yet the Hellenistic populations did not possess the highest qualities of the Greek mind, as the surrounding elements and the climate naturally wrought some alteration. Polybius looked with surprise at the Greeks settled in Alexandria. The living forces of Greece —its productive genius, self-organizing power, and active spirit of political life—were weakened and gradually lost their energy. The Attic language became the Hellenistic, Attic eloquence received a florid Asiatic tinge (though Æschines himself taught at Rhodes), but true eloquence can only flourish, as Tacitus points out, in a free state. Literature and art lost their connexion with a true national life. Architecture took another character, and the plastic art of Pergamon, though derived from Athens, and that of Rhodes, though derived from the Sicyonian school, through Chares of Lindus (who modelled the Sun-god, known as the "Colossus"), had lost the self-restraint and dignity of the highest Greek art. But the suppression of political freedom turned the force of the Greek mind all the more strongly into other channels, and science and criticism, and speculation and literary history, made a great advance. Considerable schools were opened at Tarsus and other centres of commerce. As the free state lost its power over the mind, men had recourse to philosophy, and regained in mental fortitude and independence the outward freedom they had lost. Then this feeling reacted on politics, and a generation of patriots like Philopœmen arose, worthy to represent Greece in these her last days. The new teaching of freedom came forth, as was right, from Athens; it was the followers of Arcesilaus, the founder of the new Academy, who freed Megalopolis from its tyrant. The later developments of philosophy were mainly due to Zeno of Citium in Cyprus, and to Epicurus, who finally taught at Mytilene and Lampsacus; but Athens was still the chief home of their teaching. The writings of the great philosophers of this age, however, are mostly lost to us, as well as those of the historians, and after Aristotle there is a strange gap in the tradition up to the Christian era. The Greeks now wished to know the early history of the East, and the Eastern peoples wished to make their history known to the great literary nation. Hence Berosus wrote the history of Babylon for Antiochus II., from the archives in the temple of Belus, Manetho that of Egypt for Ptolemy Philadelphus, Menander of Tyre that of Phœnicia, and Jewish writers the history of their race and religious views, which are finally summed up for us by Philo and Josephus. The sacred books of Egypt, Palestine, and Persia were to be found in the Alexandrian library, and the religious syncretism that resulted from the mixture of races prepared the way for monotheism and for Christianity. The astrology, however, and divination of the East in turn made their way among the Greeks, and led to curious superstitions, and a whole literature of Sibylline books and similar forgeries sprang up. Christianity itself spread chiefly in the Hellenized towns; the country districts were much longer in feeling the new influence.

It was in Egypt, however, that Hellenism was perhaps most highly developed. The Ptolemies gained Cyrene and Cyprus, and struggled hard with the Syrian kings for the possession of Phœnicia; Palestine was as of old the battle-field for the king of the north and the king of the south. The Ptolemies even held Seleucia at the mouth of the Orontes for some time. The history of these times is lost in its detail; the only thing certain is the spread of the Hellenistic spirit in the East. Many Jews were transplanted to Alexandria and Cyrene, occupied large quarters of those cities, and had full civil rights. The Ptolemies also pushed south into Ethiopia, and the African elephants which they trained for war enabled them to oppose the Syrian army with its Indian elephants. A Greek inscription at Adulis, though of later origin, commemorates the conquests of the third king of this line. These kings also secured the route down the Red Sea, reopened the old canal of Necho leading from the Nile into that sea, founded Arsinoe and other important towns, and made discoveries on the route to India. The new information thus gained was recorded in the geographical works of Agatharcides of Cnidus and Artemidorus of Ephesus. The old trade of Egypt had chiefly consisted in the export of corn; now the wares of Arabia, South Africa, and India came through Egypt to Europe, and ships of Alexandria became frequent visitors to the western waters. Even in Asia Minor Egypt won influence as Syria lost it, and a court poet (perhaps Theocritus) was justified in praising the Egyptian king who was master of the sea. The carrying trade had fallen largely into the hands of Egypt from the time when the war between Seleucus and Antigonus stopped the trade of the caravans by land, and the import and export duties formed a large part of the Egyptian revenues. After the return of Pyrrhus from Italy, Philadelphus even made a treaty with Rome. The Sicilian Greeks might be rivals in trade, but the Italians were good customers, and produced the excellent wool which was invaluable for the Egyptian manufactures, as the cultivation of cotton in Egypt had but begun. Puteoli, the first really good port to the south of Rome, was the chief centre of the trade even at this early time. The Egyptian trade was concentrated in Alexandria, which thus became one of the greatest cities on the earth. Science flourished there, and men like Archimedes came thither to study. Much of what was done was done for ever. No mathematician has to redemonstrate the problems of Euclid. Geography was founded by Eratosthenes of Cyrene on a mathematical and astronomical basis; he first calculated the magnitude of the earth by measuring an arc of the meridian, the process employed at the present day. Modern astronomy too is the natural development of the work of Hipparchus and Ptolemy. Erasistratus and Herophilus investigated the structure and functions of the valves of the heart, and the nerves of sensation and motion, and a close connexion was thus formed between anatomy and medicine. The Múseum, a sort of college, numbered Eratosthenes, Callimachus, Aristophanes, and Aristarchus among its members. They fixed the text of the classical writers on critical principles; and grammar assumed the form it kept for centuries. Poetry itself had a kind of second summer with Callimachus and Apollonius Rhodius, and, under Sicilian influences, with

Theocritus, Bion, and Moschus. All the knowledge of the past was treasured up for transmission to a future age.

There was no more unity among the Macedonian monarchies than there had been among the free cities of Greece, and the kings were even less able to combine against Rome than the republics against Philip. When Philip V. tried to keep the Romans out of Greece, he met with no support from Antiochus the Great, and was defeated by Flamininus at Cynoscephalæ, 197 B.C. Antiochus in turn had no help from Philip when Scipio crossed into Asia and defeated the Syrian army at Magnesia, 190 B.C. Last of all, Perseus was overthrown at Pydna (168 B.C.), while Antiochus Epiphanes was trying to plunder Egypt; and Macedonia was divided into four districts, like those out of which the kingdom had been originally formed—Amphipolis, Thessalonica, Pella, Pelagonia. The Romans in many respects carried on the work of spreading Greek culture. They gave the Greek cities of Asia a freer scope for their action on the country; they united the whole Greek race, east and west, under one rule, and opened out the world to their enterprise. We meet with many great names in this later age, such as Posidonius at Rhodes, Galen at Pergamon, Strabo at Amasia. Epictetus was a Greek slave from Phrygia. Cappadocia became so thoroughly Greek that the church itself owed to it such men as Basil and Gregory. The Greek influence even spread to Palmyra in the desert, and its ruin in the third century marks the first great check sustained by Hellenism. But under the rule of Rome it may almost be said that the primitive unity of the Græco-Italian race was restored, and the work of the Macedonian conqueror completed in western Asia.

This article is mainly based on Grote's *Greece*, and Droysen's *Hellenismus*, 2d ed., 1877. For more detailed accounts and for the personal history see ALEXANDER, ANTIGONUS, ANTIOCHUS, ANTIPATER, &c. The original authorities are collected in Didot's *Historici Græci*, and his *Arrianus*, 1877. (C. W. BO.)

MACEDONIUS, a deacon, was raised to the patriarchate of Constantinople as successor of Eusebius of Nicomedia by the Arian bishops in 341 A.D., while the orthodox party elected Paul, whom Eusebius had superseded. The partisans of the two rivals involved the city in a tumultuous broil, murdered Hermogenes, the general whom Constantius II., during his own absence, had empowered to preserve order, and were not quelled until the emperor himself returned to the city and banished Paul. Macedonius was recognized as patriarch in 342. In that year Paul again returned, and was again banished, and Macedonius, amid much tumult and bloodshed, was forcibly installed in his see by the imperial troops. Compelled by the intervention of Constans in 348 to confine his authority again to one church, and to resign the patriarchate in favour of his former opponent, he was reinstalled in 350. He then took vengeance on his opponents by a general persecution of the adherents of the Nicene creed. In 356 he occasioned a disastrous and bloody tumult in Constantinople by causing the ashes of Constantine the Great to be removed from the dilapidated church of the Apostles to that of St Acacius. In 359, on the division of the Arian party into Acacians (or pure Arians) and semi-Arians, Macedonius adhered to the latter, and in consequence was expelled from his see by the council of Constantinople in 360. He now became avowed leader of the sect of Pneumatomachi, Macedonians, or Marathonians, whose distinctive tenet was that the Holy Spirit is but a divine influence pervading the universe and not a person distinct from the Father and the Son. He did not long survive his deposition.

MACEIO, or MACAYO, a city of Brazil, the chief town of the province of Alagoas, and one of the ports open to foreign trade, is situated about 150 miles south of Pernambuco, in 9° 39′ S. lat., on an eminence about a mile from the shore, in the midst of luxuriant vegetation. It possesses a fine cathedral and an elegant house of assembly, as well as a cotton inspection office and a custom-house. As its harbour at Jagudra on the coast is but slightly protected by reefs and a small peninsula, and the water deepens slowly from the sandy beach, vessels cannot approach the piers (of which there are several), and have to be discharged and loaded by lighters. Trade, however, is on the increase, and will develop largely on the completion of the railway to the interior. In 1880 44 British and 35 foreign vessels entered, with a burden respectively of 17,624 and 10,482 tons; and cotton and sugar were exported to the amount of 4181 and 27,810 tons. In 1839 the town became the provincial capital instead of Alagoas. The population is about 20,000.

MACERATA, a city of Italy, the chief town of a province, a bishop's see, and the seat of a court of appeal, lies 22 miles south of Ancona, and 17 miles by road west of Civita Nova, the nearest station on the East Coast Railway. Crowning the top of a hill about 1300 feet in height with a picturesque mass of buildings enclosed by walls and towers, Macerata looks out over the Adriatic and the valleys of the Potenza and the Chienti. The cathedral is a modern structure of but little interest; but some of the churches, and especially some of the palaces,—Palazzo dei Torri, Palazzo Bonaccorsi, &c.,—are fine pieces of architecture; and at a short distance from the town stands the beautiful S. Maria delle Vergini, designed by Galasso da Carpi, but often attributed to Bramante. Besides the university, Macerata contains a communal library founded by Leo XII., and, in the municipal buildings, a collection of antiquities from Helvia Ricina. Its infant schools were the first established in the papal states. Glass and pottery are among the manufactures, and three fairs are held yearly. The population of the commune has increased from 19,283 in 1861 to 20,219 in 1881; that of the town was 10,065 at the former date.

Macerata, as well as Recanati, was founded by the inhabitants of Ricina after the destruction of their city by Alaric in 408. During the Lombard period it was a flourishing town; but it was from comparative insignificance that it was raised by Nicholas IV. to be the seat of the governors of the March. By the viceroy of Frederick II. it was enclosed in the 13th century by a new line of walls more than 2½ miles in circuit; and in the troubles of the next two hundred years it had frequent occasion to learn their value. For the most part it remained faithful to the popes, and in return it was rewarded by a multitude of privileges. Though in 1797 the inhabitants opened their gates to the French, two years afterwards, when the country people took refuge within the walls, the city was taken by storm and delivered to pillage. The bishopric of Macerata dates from the suppression of the see of Recanati (1320). Crescimbeni, the poet of the 13th century, his namesake the founder of the Arcadian Academy at Rome, and Matteo Ricci, the Chinese missionary and scholar, were natives of the city.

MACGILLIVRAY, WILLIAM (1796-1852), a writer on several branches of natural science, but best known as an ornithologist, was born in 1796. He studied as an arts student in King's College, Aberdeen, graduating M.A. in 1815, and also studied medicine, but did not complete the latter course. In 1823 he became assistant to the professor of natural history in Edinburgh University; and in 1831 he was appointed curator of the museum of the Royal College of Surgeons in Edinburgh. In 1841 he became professor of natural history and lecturer on botany in Marischal College, Aberdeen. He died in 1852. He possessed a wide and comprehensive knowledge of natural science in its various departments, gained no less from personal observations in the course of frequent excursions through different parts of Scotland than from a study of the collections under his charge in Edinburgh and of books. His industry and extensive knowledge are amply shown in his published works. He contributed numerous articles on the zoology, botany, and geology of Scotland to the scientific journals in Edinburgh, to the *Magazine of Botany and Zoology*, and to the *Transactions of the British Association.* He also assisted Audubon in his classical works on the *Birds of America*; and he edited Withering's *British Botany.*

His larger works are numerous, and include biographies (of Humboldt, and of zoologists from Aristotle to Linnæus), *Text-books of Botany*, *of Geology*, and *of Conchology*, a *History of British Quadrupeds*, a *History of the Mollusca of Aberdeen, Banff, and Kincardine*, a *Manual of British Ornithology*, and a *History of British Birds*, in 5 vols., 1837–52. The last work holds a high rank from the excellent descriptions of the structure, habits, and haunts of birds, and from the use in classification of characters afforded by their internal organs. In 1850 he spent some time in the Highlands of Aberdeenshire. The results are embodied in the *Natural History of Deeside*, published after his death by command of the queen.

He made considerable collections, alike for the instruction of his students and to illustrate the zoology, botany, and geology of the parts of Scotland examined by him, especially around Aberdeen. His success in enlisting the interest and co-operation of his students is shown by the assistance acknowledged by him in his work on the mollusca of that district. His devotion to his favourite sciences made him apt to be careless of risk to health, and seems to have led to the illness that proved fatal. Though his reputation rests chiefly on his works on birds and on mollusca, his other writings are also of interest and value. In some respects he was in advance of most of his contemporaries, *e.g.*, in the opinions in regard to species published in his *Text-book of Botany* (pp. 210, 211) in 1840.

His reputation might have been greater as a specialist had he restricted his investigations within narrower limits, but this he was prevented from doing as much by the wide range of subjects that he had to teach as by his natural inclination. He had to encounter great difficulties in ascertaining what had been already accomplished by naturalists elsewhere from the want of a good library and of named collections for reference. To this fact may be traced a tendency to regard as undescribed and to name whatever animals he was unable to identify from books within his reach, as well as occasional apparent neglect of work done by others and some peculiar views on nomenclature and classification.

Throughout his life pecuniary difficulties, in part arising from the publication of his books, pressed on him; and to this it was probably due, at least in part, that, despite an amiable nature, he at times expressed himself in controversy in a way that made him keen opponents. His books show that from all troubles he found relief in tracing the proofs of wisdom and of goodness in nature. Throughout his was a laborious life, and just before his death he completed his *History of British Birds*, an enduring and worthy memorial of an earnest and true-hearted naturalist.

His family inherited a taste for similar pursuits. One son, John, contributed several articles to magazines on the natural history of Scotland, and published an account of the voyage round the world of H.M.S. "Rattlesnake," on board which he was naturalist. Another son, Paul, published an *Aberdeen Flora* in 1853.

MACHIAVELLI, Niccolò (1469–1527), was born at Florence on the 3d of May 1469. His ancestry claimed blood relationship with the lords of Montespertoli, a fief situated between Val di Pesa and Val d'Elsa, at no great distance from the city. In 1393 the castle of Montespertoli became the property of Niccolò's great-grandfather. At this date the Machiavelli, like other nobles of the Florentine *contado*, had been absorbed into the body of the burghers, and had begun to seek distinction as officers of the republic. They counted numerous priors and gonfaloniers of justice in the generations which preceded the illustrious secretary. Niccolò's father, Bernardo, who was born in 1428, followed the profession of a jurist. He held landed property, chiefly near the village of San Casciano, which was worth, according to a recent calculation, something like £250 a year of our money. His son, though not wealthy, was never wholly dependent upon official income.

Of Niccolò's early years and education little is known. He is said to have studied under the grammarian Marcello Virgilio Adriani; and his works show wide reading in the Latin and Italian classics. But it is almost certain that he had not mastered the Greek language. In that age of humanistic erudition, it is noticeable that the three most eminent writers of the Renaissance—Machiavelli, Ariosto, and Guicciardini—owed their training to the literature of their own nation. To the defects of Machiavelli's education, as it appeared to men of Giovio's stamp, we may, in part at least, ascribe the peculiar vigour of his style and his speculative originality. He is free from the scholastic trifling and learned frivolity which tainted the rhetorical culture of his century. He made the world of men and things his study, learned to write his mother-tongue with idiomatic conciseness, and nourished his imagination on the masterpieces of the Romans. Machiavelli shared the enthusiasm of his race and period for antiquity; but the antiquity he worshipped was confined to the commonwealth of Rome. Not the arts, the letters, and the philosophy of the Greeks, but the Latin histories in which the statecraft and organization of the Romans are described, arrested his attention. His habit of thought is marked throughout by a strong Latin bias.

The year 1494, the year of Charles VIII.'s invasion and of the Medici's expulsion from Florence, saw Machiavelli's first entrance into public life. He was appointed clerk in the second chancery of the commune under his old master Marcello Virgilio Adriani. Early in 1498 Adriani became chancellor of the republic, and Machiavelli received his vacated office with the rank of second chancellor and secretary. This post he retained till the year 1512. The masters he had to serve were the Dieci di Libertà e Pace, who, though subordinate to the signoria, exercised a separate control over the departments of war and the interior. They sent their own ambassadors to foreign powers, transacted business with the cities of the Florentine domain, and controlled the military establishment of the commonwealth. The next fourteen years of Machiavelli's life were fully occupied in the voluminous correspondence of his bureau, in diplomatic missions of varying importance, and in the organization of a Florentine militia. It would be tedious and uninstructive to follow him through all his embassies to petty courts of Italy, the first of which took place in 1499, when he was sent to negotiate the continuance of a loan to Catherine Sforza, countess of Forlì and Imola. A more important mission followed in 1500, when Machiavelli travelled into France, to deal with Louis XII. about the affairs of Pisa. It is enough to say in general that these embassies were the school in which Machiavelli formed his political opinions, and gathered views regarding the state of Europe and the relative strength of nations. They not only introduced him to the subtleties of Italian diplomacy, but also extended his observation over races very different from the Italians in their social and constitutional development. He thus, in the course of his official business, gradually acquired principles and settled ways of thinking which he afterwards expressed in writing. He was at no time a philosopher or man of letters by profession, and when he came to write he gave to the world the condensed result of practical experience, combined with meditations on the Latin historians, rather than a methodical system.

His office obliged him from time to time to draw up proposals and memorials on questions of the day, which he presented to the Dieci. One of these, on the affairs of Pisa, belongs to 1499; a second, on the condition of Pistoia, to 1501; a third, of more general importance, on the right way of dealing with the rebels of Valdichiana, to 1502. In this last-named document some of the points of view which stamp his later works with a distinctive character emerge into prominence. We find him seeking parallels and precepts in Roman history, laying down the axiom that human nature is identical throughout the ages, exposing the futility of half measures, and finally appealing to Cesare Borgia as a model of political sagacity. It is clear from this brief and early composition that Machiavelli had already formed the habits of thought which distinguish him. He has begun to idealize Borgia's policy. He interweaves historical reflexions with contemporary analysis, using the past to illustrate the present, and expounding practical doctrine from texts derived from Livy. There is also noticeable the uncompromising spirit of the man, who was destined afterwards in the *Principe* to subordinate all minor considerations of morality and conduct to the one object of political attainment.

In the year 1502 Machiavelli married Marietta Corsini, the wife who bore him several children, with whom, in spite of his own infidelities, he lived on good terms, and who survived him twenty-six years. In the same year Piero Soderini was chosen gonfalonier for life, in accordance with certain changes in the constitution of the state, which were intended to bring Florence closer to the Venetian type of government. This was an important event in Machiavelli's career, for he now became intimately connected with Soderini, assisted him in carrying out his policy, suggested important measures of military reform which Soderini adopted, and finally was involved in ruin by his fall. Machiavelli, it may be said in passing, had the qualities of a good servant and a practical official. He remained faithful to Soderini through the difficulties of his later years of power, and spoke well of him subsequently. Yet he was a severe critic, blaming the gonfalonier for weakness of administration and half measures; and, when he died, he indulged in a sarcastic epigram on his old master which does less honour to his loyalty than to his wit.

The year 1502 was marked by yet another decisive incident in Machiavelli's life. In October he was sent, much against his will, as envoy to the camp of Cesare Borgia, or duke of Valentino, as he was now called. The duke was then in Romagna, and it was Machiavelli's duty to wait upon and watch him. He was able now to observe those intricate intrigues which culminated in Cesare's seizure of Sinigaglia and the treacherous murder of his disaffected captains. From what remains of Machiavelli's letters to the Dieci during this period, and from his tract upon the *Modo tenuto dal Duca Valentino nell' ammazzare Vitellozzo Vitelli*, we are able to appreciate the actual relations which existed between the two men, and the growth in Machiavelli's mind of a political ideal based upon his study of the duke's character. Machiavelli was a mere spectator and critic, by no means an adviser of the duke. He seems to have been even weary and uneasy in the network of hypocrisy and crime in which he found himself,—refreshing his spirits with jocular letters to his private friends, and with the study of a Plutarch which they sent him. He was also able to stigmatize the Borgia's conduct from a conventional point of view, as is proved by his calling him a "basilisk" and "hydra" in his *Decennali*. Yet he conceived the strongest admiration for his combination of audacity with diplomatic prudence, for his adroit use of cruelty and fraud, for his self-reliance, avoidance of half measures, employment of native troops, and firm administration in conquered provinces. More than once, in letters to his friend Vettori, no less than in the pages of the *Principe*, he afterwards expressed his belief that Cesare Borgia's behaviour in the conquest of provinces, the cementing of a new state out of scattered elements, and the dealing with false friends or doubtful allies, was worthy of all commendation and of scrupulous imitation. Hydra and basilisk were terms, not of reproach, but of panegyric, on the lips of the writer who warned his prince to acquire the nature of the fox and of the lion, who spoke familiarly of *frodi onorevoli, scelleratezze gloriose*, and whose conception of *Virtù* was self-reliant ability. As he watched Cesare Borgia at this, the most brilliant period of his adventurous career, the man became idealized in his reflective but imaginative mind. Round him, as a hero, he allowed his own conceptions of the perfect prince to cluster. There was so much in the conduct of the duke which exactly fitted with those conceptions, so much of that ideal had conversely been derived at first hand from the duke himself, that the hero and the adventurer were, as it were, confounded. That Machiavelli separated the actual Cesare Borgia, whom he afterwards saw, ruined and contemptible, at Rome, from this radiant creature of his political fancy, is probable. That the Cesare of history does not exactly match the Duca Valentino of Machiavelli's writings is certain. Still the fact remains that henceforth Machiavelli cherished the ideal image of the statesman which he had modelled upon Cesare, and called this by the name of Valentino.

On his return to Florence early in January 1503, Machiavelli began to occupy himself with a project he had long since formed, and which his recent attendance upon Cesare Borgia had strengthened in his mind. The duties of his office obliged him to study the conditions of military service as they then existed in Italy. He was familiar with the disadvantages under which republics laboured when they engaged professional captains of adventure and levied mercenary troops. The bad faith of the condottiere Paolo Vitelli (beheaded at Florence in 1499) had deeply impressed him. In the war with Pisa he had observed the insubordination and untrustworthiness of soldiers gathered from the dregs of different districts, serving under egotistical and irresponsible commanders. His reading in Livy taught him to admire the Roman system of employing armies raised from the body of the citizens; and Cesare Borgia's method of gradually substituting the troops of his own duchy for aliens and mercenaries showed him that this plan might be adopted with success by the Italians. He was now determined, if possible, to furnish Florence with a national militia. The gonfalonier Soderini entered into his views. But obstacles of no small magnitude arose. First came the financial difficulties in which the Government was then involved. The suspicion and jealousy of the Florentines had also to be encountered. Some of them feared lest Soderini, if he armed the commonwealth, would aspire to tyranny. All alike were adverse to arming the population of subject cities like Arezzo and Cortona; for it must be remembered that an Italian republic ruled its province with the despotism of an autocrat, and the towns beneath its sway were always panting for independence. The question of money was immediately pressing. Early in 1503 Machiavelli drew up for Soderini a speech, *Discorso sulla provisione del Danaro*, in which the duty and necessity of liberal expenditure for the protection of the state were expounded upon principles of sound political philosophy. Between this date and the last month of 1506 Machiavelli laboured at his favourite scheme, working out memorials on the subject for his office, and suggesting the outlines of a new military organization. On the 6th of December 1506 his plan was approved by the signory, and a special ministry, called the *Nove di Ordinanza e Milizia*, was appointed. Machiavelli immediately became their secretary. The country districts of the Florentine dominion were now divided into departments, and levies of foot soldiers were made in order to secure a standing militia. A commander-in-chief had to be chosen for the new troops. Italian jealousy shrank from conferring this important office on a Florentine, lest one member of the state should acquire a power dangerous to the whole. The choice of Soderini and Machiavelli fell, at this juncture, upon an extremely ineligible person, none other than Don Micheletto, Cesare Borgia's cut-throat and assassin. It is necessary to insist upon this point, since it serves to illustrate a radical infirmity in Machiavelli's genius. While forming and promoting his scheme, he was actuated by principles of political wisdom and by the purest patriotism. But he failed to perceive that such a ruffian as Micheletto could not inspire the troops of Florence with that devotion to their country and that healthy moral tone which should distinguish a patriot army. Here, as elsewhere, he revealed his insensibility to the ethical element in human nature. Knowing that Don Micheletto had worked well for Cesare Borgia, accustomed to disregard private morality as insignificant in public conduct, he was satisfied to entrust the discipline and education of his raw militia to a notorious villain. His indifference to personal ethics led him now into a practical blunder, as it afterwards vitiated his political writings with a philosophical error.

Meanwhile Italy had been the scene of memorable events, in most of which Machiavelli took some part. Alexander VI. had died suddenly of fever. Julius II. had ascended the papal chair. The duke Valentino had been checked in mid-career of conquest. Machiavelli was sent to Rome during the conclave, when he renewed his intercourse with Cesare Borgia. On this occasion he seems to have felt nothing but contempt for the hero of his dreams, who had sunk into insignificance and almost abject submission. The collapse of the Borgias threw Central Italy into confusion; and Machiavelli had, in 1505, to visit the Baglioni at Perugia and the Petrucci at Siena. In the following year he accompanied Julius upon his march through Perugia into the province of Emilia, where the fiery pope subdued in person the rebellious cities of the church. Upon these embassies Machiavelli represented the Florentine Dieci in quality of envoy. It was his duty to keep the ministry informed by means of frequent despatches and reports. All this while the war for the recovery of Pisa was slowly dragging on, with no success or honour to the Florentines. Machiavelli had to attend the camp and provide for levies amid his many other occupations. And yet he found time for private literary work. In the autumn of 1504 he began his *Decennali*, or *Annals of Italy*, a poem composed in rough terza rima, and now remembered only for one line describing the courage of Piero Capponi, when he defied Charles VIII. to his face in 1495 :—

> "Lo strepito dell' armi e de' cavalli,
> Non potè far che non fosse sentita
> La voce d'un Cappon fra cento Galli."

About the same time he composed a comedy on the model of Aristophanes, which is unfortunately lost. It seems to have been called *Le Maschere*. Giuliano de' Ricci tells us it was marked by stringent satire upon great ecclesiastics and statesmen, no less than by a tendency to "ascribe all human things to natural causes or to fortune." That phrase accurately describes the prevalent bias of its author's mind.

The greater part of 1506 and 1507 was spent in organizing the new militia, corresponding on the subject, and scouring the country on enlistment service. But at the end of the latter year European affairs of no small moment diverted Machiavelli from these humbler duties. Maximilian was planning a journey into Italy in order to be crowned emperor at Rome, and was levying subsidies from the imperial burghs for his expenses. The Florentines thought his demands excessive. Though they already had Francesco Vettori at his court, Soderini judged it advisable to send Machiavelli thither in December. He travelled by Geneva, all through Switzerland, to Botzen, where he found the emperor.

This journey was an important moment in his life. It enabled him to study the Swiss and the Germans in their homes; and the report which he wrote on his return, *Rapporto di Cose della Magna*, reckons among his most effective political studies. Instead of confining his attention to the analysis of parties or the portraits of eminent persons in the countries he had traversed, Machiavelli strove to estimate the essential elements of national success or failure. The antique sobriety of the Swiss, their absolute equality and independence, their efficient national militia, inspired him with such admiration that henceforth the Swiss appeared to him the model of modern nations and the most formidable among the neighbours of the Italians. He pointed out that the strength of Germany lay in the free cities, while the emperor was weakened, not only by his own indecisive character and want of funds, but by the jealousy of the feudal princes. The German princes, the burghs, and the empire being ill-accorded, and the Swiss being hostile to all alike, this vast nation lacked the force which its excellent morality, sober living, and vigorous military organization ought to have secured it. What is most remarkable in Machiavelli's report is his concentrated effort to realize the exact political weight of the German nation, and to penetrate the causes of its strength and weakness. He attempts to grasp the national character as a whole, and thence to deduce practical conclusions. Certain mistakes he undoubtedly made. He treated the Swiss, for example, too much as though they were a part of Germany. He exaggerated the simplicity and sobriety of the race at large, seemingly inspired by Tacitus, and inflamed in his own imagination by sympathy with a people who realized his cherished dreams of national health. His indifference to ecclesiastical questions prevented him from discerning the crisis of the Reformation, which was on the verge of precipitating Germany into the discord of religious wars. Yet, allowing for these drawbacks, we are astonished by the insight into details and the co-ordinating faculty which enabled this Italian to draw so discriminating and animated a portrait of the Germans for the benefit of his republic.

The same great qualities are noticeable in his *Ritratti delle Cose di Francia*, which he drew up after an embassy to Louis XII. at Blois in 1510. These notes upon the French race are more scattered than the report on German affairs. But they reveal no less acumen combined with imaginative penetration into the very essence of national existence. He points out that the special strength of France lies in her centralization. The monarch is surrounded by obedient feudal vassals, the most powerful of whom are of the royal blood. They in their turn draw their wealth from the people. Feudalism, an element of discord in Germany, has been converted into monarchy, and become the cohesive bond of society in France. On the other hand, this centralization contains a grave element of danger for the future of France. The people are ground down and have no liberty. Machiavelli points out how, in these circumstances, the pith of the French army is its chivalry, and why the king is always obliged to hire German and Swiss infantry for his wars. The *Ritratti* abound in pointed observations upon the French character which is well contrasted with that of the Spaniards. But what constitutes the originality of this tract is Machiavelli's determination to realize to himself and to his readers the political value of the French people as a whole, and thus to form a solid basis for judging of its probable behaviour in the future. In this case, as in the case of Germany, he attempts to estimate the physical, moral, and intellectual capacity of an antagonist with whom his country has to grapple. It may be said that, with France as with Germany, he wholly omits the possibilities of religious perturbation.

While engaged upon this topic, it may be well to mention that Machiavelli displayed exactly the same force of analysis in laying bare the central causes of weakness in Italy itself. The disarmament of the population by selfish despots and indolent republics; the consequent growth of a vicious mercenary system; the dismemberment of the nation into petty, mutually jealous parcels, due for the most part to the selfishness of Rome; the loss of antique sobriety in manners, and the almost total corruption of the people, fostered and encouraged by their debauched spiritual leaders,—these, he says, are the causes which have made Italy "more enslaved than the Hebrews, more downtrodden than the Persians, more disunited than the Athenians." This is not the place to discuss his policy for the Italians. Suffice it to say that the same method which he applied to Germany and France supplied him with general conclusions about Italy, and enabled him to view with a truly terrible clairvoyance that desperate disease of his country for which he afterwards invented remedies as desperate.

Machiavelli returned from Germany in June 1508. The rest of that year and a large part of 1509 were spent in the affairs of the militia and the war of Pisa. Chiefly through his exertions the war was terminated by the surrender of Pisa in June 1509. Meanwhile the league of Cambray had disturbed the peace of Italy, and Florence found herself in a perilous position between Spain and France. Soderini's Government grew weaker. The Medicean party lifted up its head. To the league of Cambray succeeded the Lega Santa. The battle of Ravenna was fought, and the French retired from Italy. The Florentines had been spectators rather than actors in these great events. But they were now destined to feel the full effects of them. The cardinal Giovanni de' Medici, who was present at the battle of Ravenna, brought a Spanish army into Tuscany. Prato was sacked in the August of 1512. Florence, in extreme terror, deposed the gonfalonier, and opened her gates to the princes of the house of Medici.

The Government on which Machiavelli depended had fallen, never to rise again. The national militia in which he placed unbounded confidence had proved inefficient to protect Florence in the hour of need. He was surrounded by political and personal enemies, who regarded him with jealousy as the ex-gonfalonier's right hand man. Yet at first it appears that he still hoped to retain his office. He showed no repugnance to a change of masters, and began to make overtures to the Medici. The Nove della Milizia were, however, dissolved; and on November 7, 1512, Machiavelli was deprived of his appointments. He was exiled from Florence and confined to the dominion for one year, and on November 17 was further prohibited from setting foot in the Palazzo Pubblico. Ruin stared him in the face; and, to make matters worse, he was implicated in the conspiracy of Pier Paolo Boscoli in February 1513. Machiavelli had taken no share in that feeble attempt against the Medici, but his name was found upon a memorandum dropped by Boscoli. This was enough to ensure his imprisonment. He was racked, and only released upon Giovanni de' Medici's election to the papacy in March 1513. When he left his dungeon, he retired to a farm near San Casciano, and faced the fact that his political career was at an end.

Machiavelli now entered upon a period of life to which we owe the great works that have rendered his name immortal. But it was one of prolonged disappointment and annoyance. He had not accustomed himself to economical living; and, when the emoluments of his office were withdrawn, he had but barely enough to support his family. The previous years of his manhood had been spent in continual activity. Much as he enjoyed the study of the Latin and Italian classics, literature was not his business; nor had he looked on writing as more than an occasional amusement. He was now driven in upon his books for the employment of a restless temperament; and to this irksomeness of enforced leisure may be ascribed the production of the *Principe*, the *Discorsi*, the *Arte della Guerra*, the comedies, and the *Storia Fiorentina*. The uneasiness of Machiavelli's mind in the first years of this retirement is brought before us by his private correspondence. The letters with Vettori paint a man of vigorous intellect and feverish activity, dividing his time between studies and vulgar dissipations, seeking at one time distraction in low intrigues and wanton company, at another turning to the great minds of antiquity for solace. It is not easy for a modern gentleman to understand the spirit in which the author of the *Principe* sat down to exchange obscenities with the author of the *Sommario della Storia d'Italia*. Nor can it be urged that Machiavelli plunged into dissipation at this crisis to escape from care, or that he penned filth because he had no other occupation for his thoughts. From the camp of Borgia in 1502, when his mind was on the stretch, and he was watching history in the making, he had written similar trash to his acquaintances at home. At the same time this coarseness of taste did not blunt his intellectual sagacity. His letters on public affairs in Italy and Europe, especially those which he meant Vettori to communicate to the Medici at Rome, are marked by extraordinary fineness of perception, combined, as usual in his case, with philosophical breadth. In retirement at his villa near Percussina, a hamlet of San Casciano, Machiavelli completed the *Principe* before the end of 1513. This famous book is an analysis of the methods whereby an ambitious man may rise to sovereign power. It appears to have grown out of another scarcely less celebrated work, upon which Machiavelli had been engaged before he took the *Principe* in hand, and which he did not finish until some time afterwards. This second treatise is the *Discorsi sul primo libro delle Deche di Tito Livio*, which will henceforth be mentioned in this article as the *Discorsi*.

Cast in the form of comments on the history of Livy, the *Discorsi* are really an inquiry into the genesis and maintenance of states,—how states come into being, prosper, and decline—in what forms they can be modelled and maintained. The *Principe* is an offshoot from the main theme of the *Discorsi*, setting forth Machiavelli's views at large and in detail upon the nature of principalities, the method of cementing them, and the qualities of a successful autocrat. Being more limited in subject and more independent as a work of literary art, this essay detaches itself from the main body of the *Discorsi*, and has attracted far more attention. We feel that the *Principe* is inspired with greater fervency, as though its author had more than a speculative aim in view, and brought it forth to serve a special crisis. The moment of its composition was indeed decisive. Machiavelli judged the case of Italy so desperate that salvation could only be expected from the intervention of a powerful despot. The unification of Italy in a state protected by a national army was the cherished dream of his life; and the peroration of the *Principe* shows that he meant this treatise to have a direct bearing on the problem. We must be careful, however, not to fall into the error of supposing that he wrote it with the sole object of meeting an occasional emergency. Together with the *Discorsi*, the *Principe* contains the speculative fruits of his experience and observation combined with his deductions from Roman history. The two works form one coherent body of opinion, not systematically expressed, it is true, but based on the same principles, involving the same conclusions, and directed to the same philosophical end. That end is the analysis of the conception of the state, studied under two main types, republican and monarchical. Up to the date of Machiavelli, modern political philosophy had always presupposed an ideal. Mediæval speculation took the church and the empire for granted, as divinely appointed institutions, under which the nations of the earth must flourish for the space of man's probation on this planet. Thinkers differed only as Guelfs and Ghibellines, as leaning on the one side to papal on the other to imperial supremacy. In the revival of learning, scholarship supplanted scholasticism, and the old ways of mediæval thinking were forgotten. But no substantial philosophy of any kind emerged from humanism; the political lucubrations of the scholars were, like their ethical treatises, for the most part rhetorical. Still the humanists effected a delivery of the intellect from what had become the bondage of obsolete ideas, and created a new medium for the speculative faculty. Society in Europe had outgrown the conditions of the Middle Ages, and this new humanistic atmosphere corresponded to the new phase upon which the modern nations were entering. Simultaneously with the revival, Italy had passed into that stage of her existence which has been called the age of despots. The yoke of the empire had been shaken off. The church had taken rank among Italian tyrannies. The peninsula was, roughly speaking, divided into principalities and sovereign cities, each of which claimed autocratic jurisdiction. These separate despotisms owned no common social tie, were founded on no common *jus* or right, but were connected in a network of conflicting interests and changeful diplomatic combinations. A keen and positive political intelligence emerged in the Italian race. The reports of Venetian and Florentine ambassadors at this epoch contain the first germs of an attempt to study politics from the point of view of science. At this moment Machiavelli intervenes. He was conscious of the change which had come over Italy and Europe. He was aware that the old strongholds of mediæval thought must be abandoned, and that the decaying ruins of mediæval institutions furnished no basis for the erection of solid political edifices. He felt the corruption of his country, and sought to bring the world back to a lively sense of the necessity for reformation. His originality consists in having extended the positive intelligence of his century from the sphere of contemporary politics and special interests to man at large regarded as a political being. He founded the science of politics for the modern world, by concentrating thought upon its fundamental principles. Much that is unnatural in the forced severance of politics from ethics, much that we know now to be untrue in the conception of national development, much that offends our moral sense in the justification of iniquity for public ends, much that the experience of the last three centuries has shown to be mistaken in the theory of the state considered as a work of plastic art, much that belongs to the Renaissance, and has perished with that period of transition, much that is wrongly applied from the experience of Italian diplomacy to politics in general, can be noted by the students of Machiavelli. We feel the want in him of a thorough philosophical education, the continual oscillation between speculative and practical points of view, the lack of system and the negligence of stringent definition. We surmise that, had he studied Plato's *Republic* or the first chapters of Aristotle's *Politics* and *Ethics*, he might perhaps have avoided what has been the stumbling-block to generous readers—his indifference to moral righteousness as indispensable to states no less than individuals. We regret his unqualified inculcation of the doctrine that means are justified by ends,—a doctrine rendered odious by Jesuitry to the modern mind, and incompatible with any sound science of humanity. We know that ethics cannot be severed, as he severed them, from politics; that, though national differs from private duty, both are based upon the same immutable principles; that the former tends, with the growth of the race, to approach ever more nearly to the former; and that it is the function of the political philosopher to keep this steadily in view. We have learned to regard nations, not merely as materials to be moulded by a lawgiver, but as total organisms, which, however modified by men of genius, obey their own laws of evolution. We have outgrown his admiration of antiquity, and do not believe that modern states should seek to model themselves upon the type of Rome. We perceive that his ideal of a prince, working by force, fraud, cruelty, dissimulation to a certain end, was the creature of circumstances, which caused him to advocate the opposition of violence to anarchy as the only possible resort. These are deductions to be made from Machiavelli's teaching, regarded as final, or as instructive for the times in which we live. But, when we have made these deductions, there remains the fact of his achievement. He began to study men, not according to some preconception, but as he found them,—men, not in the isolation of one century, but as a whole in history. He drew his conclusions from the nature of mankind itself, "ascribing all things to natural causes or to fortune." In this way he restored the right method of study, a method which had been neglected since the days of Aristotle. He formed a conception of the modern state, which marked the close of the Middle Ages, and anticipated the next phase of European development. His prince, abating those points which are purely Italian or strongly tinctured with the author's personal peculiarities, prefigured the monarchs of the 16th and 17th centuries, the monarchs whose motto was *L'état c'est moi!* His doctrine of a national militia foreshadowed the system which has given strength in arms to France and Germany. His insight into the causes of Italian decadence was complete; and the remedies which he suggested, in the perorations of the *Principe* and the *Arte della Guerra*, have since been applied in the unification of Italy. Lastly, when we once have freed ourselves from the antipathy engendered by his severance of ethics from the field of politics, when we have once made proper allowance for his peculiar use of phrases like "frodi onorevoli" or "scelleratezze gloriose," nothing is left but admiration for his mental attitude. That is the attitude of a patriot, who saw with open eyes the ruin of his country, who burned above all things to save Italy and set her in her place among the powerful nations, who held the duty of self-sacrifice in the most absolute sense, whose very limitations and mistakes were due to an absorbing passion for the state he dreamed might be reconstituted. It was Machiavelli's intense preoccupation with this problem—what a state is and how to found one in existing circumstances—which caused the many riddles of his speculative writings. Dazzled, as it were, with the brilliancy of his own discovery, concentrated in attention on the one necessity for organizing a powerful coherent nation, he forgot that men are more than political beings. He neglected religion, or regarded it as part of the state machinery. He was by no means indifferent to private virtue, which indeed he judged the basis of all healthy national existence; but in the realm of politics he postponed morals to political expediency. He held that the people, as distinguished from the nobles and the clergy, were the pith and fibre of nations; yet this same people had to become wax in the hands of the politician,—their commerce and their comforts, the arts which give a dignity to life and the pleasures which make life liveable, neglected,—their very liberty subordinated to the one tyrannical conception. To this point the segregation of politics from every other factor which goes to constitute humanity had brought him; and this it is which makes us feel his world a wilderness, devoid of atmosphere and vegetation. Yet some such isolation of the subject-matter of this science was demanded at the moment of its birth, just as political economy, when first started, had to make a rigid severance of wealth from other units. It is only by a gradual process that social science in its whole complexity can be evolved. We have hardly yet discovered that political economy has unavoidable points of contact with ethics.

From the foregoing criticism it will be perceived that all the questions whether Machiavelli meant to corrupt or to instruct the world, to fortify the hands of tyrants or to lead them to their ruin, are now obsolete. He was a man of science—one who by the vigorous study of his subject-matter sought from that subject-matter itself to deduce laws. The difficulty which remains in judging him is a difficulty of statement, valuation, allowance. How much shall we allow for his position in Renaissance Italy, for the corruption in the midst of which he lived, for his own personal temperament? How shall we state his point of departure from the Middle Ages, his sympathy with prevalent classical enthusiasms, his divination of a new period? How shall we estimate the permanent worth of his method, the residuum of value in his maxims?

After finishing the *Principe*, Machiavelli thought of dedicating it to one of the Medicean princes, with the avowed hope that he might thereby regain their favour and find public employment. He wrote to Vettori on the subject, and Giuliano de' Medici, duke of Nemours, seemed to him the proper person. The choice was reasonable. No sooner had Leo been made pope than he formed schemes for the aggrandizement of his family. Giuliano was offered and refused the duchy of Urbino. Later on, Leo designed for him a duchy in Emilia, to be cemented out of Parma, Piacenza, Reggio, and Modena. Supported by the power of the papacy, with the goodwill of Florence to back him, Giuliano would have found himself in a position somewhat better than that of Cesare Borgia; and the Borgia's creation of the duchy of Romagna might have served as his model. Machiavelli therefore was justified in feeling that here was an opportunity for putting his cherished schemes in practice, and that a prince with such alliances might even advance to the grand end of the unification of Italy. Giuliano, however, died in 1506. Then Machiavelli turned his thoughts towards Lorenzo, duke of Urbino. The choice of this man as a possible Italian liberator reminds us of the choice of Don Micheletto, as general of the Florentine militia. To Lorenzo the *Principe* was dedicated, but without result. The Medici, as yet at all events, could not employ Machiavelli, and had not in themselves the stuff to found Italian kingdoms.

Machiavelli, meanwhile, was reading his *Discorsi* to a select audience in the Rucellai gardens, fanning that republican enthusiasm which never lay long dormant among the Florentines. Towards the year 1519 both Leo X. and his cousin the cardinal Giulio de' Medici were much perplexed about the management of the republic. It seemed necessary, if possible, in the gradual extinction of their family, to give the city at least a semblance of self-government. They applied to several celebrated politicians, among others to Machiavelli, for advice in the emergency. The result was his *Discorso sopra il Riformar lo Stato di Firenze*, a treatise in which he deduces practical conclusions from the past history and present temper of the city, blending these with his favourite principles of government in general. He earnestly admonishes Leo, for his own sake and for Florence, to found a permanent and free state system for the republic, reminding him in terms of noble eloquence how splendid is the glory of the man who shall confer such benefits upon a people. The year 1520 saw the composition of *I sette Libri dell' Arte di Guerra*, and of the *Vita di Castruccio*.

The first of these is a methodical treatise, setting forth Machiavelli's views on military matters, digesting his theories respecting the superiority of national troops, the inefficiency of fortresses, the necessity of relying upon infantry in war, and the comparative insignificance of artillery. It is strongly coloured with his enthusiasm for ancient Rome; and specially upon the topic of artillery it displays a want of insight into the actualities of modern warfare. We may regard it as a supplement or appendix to the

Principe and the *Discorsi*, since Machiavelli held it for a fundamental axiom that states are powerless unless completely armed in permanence. The peroration contains a noble appeal to the Italian liberator of his dreams, and a parallel from Macedonian history, which, read by the light of this century, sounds like a prophecy of Piedmont.

The *Vita di Castruccio* was composed at Lucca, whither Machiavelli had been sent on a mission. This so-called biography of the mediæval adventurer who raised himself by personal ability and military skill to the tyranny of several Tuscan cities must be regarded in the light of an historical romance. Dealing freely with the outline of Castruccio's career, as he had previously dealt with Cesare Borgia, he sketched his own ideal of the successful prince. Cesare Borgia had entered into the *Principe* as a representative figure rather than an actual personage; so now conversely the theories of the *Principe* assumed the outward form and semblance of Castruccio. In each case history is blent with speculation in nearly the same proportions. But Castruccio, being farther from the writer's own experience, bears weaker traits of personality.

In the same year, 1520, Machiavelli, at the instance of the cardinal Giulio de' Medici, received commission from the officers of the Studio Pubblico to write a history of Florence. They agreed to pay him an annual allowance of 100 florins while engaged upon the work. The next six years were partly employed in its composition, and he left a portion of it finished, with a dedication to Clement VII., when he died in 1527. In the *Istorie Fiorentine* Machiavelli quitted the field of political speculation for that of history. But, having already written the *Discorsi* and the *Principe*, he carried with him to this new task of historiography the habit of mind proper to political philosophy. In his hands the history of Florence became a text on which at fitting seasons to deliver lessons in the science he initiated. This gives the work its special character. It is not so much a chronicle of Florentine affairs, from the commencement of modern history to the death of Lorenzo de' Medici in 1492, as a critique of that chronicle from the point of view adopted by Machiavelli in his former writings. Having condensed his doctrines in the *Principe* and the *Discorsi*, he applies their abstract principles to the example of the Florentine republic. His favourite topics reappear—the dismemberment of Italy by the papacy (bk i. 9, 23); the ruin of her national militia (bk. i. 34, 38; bk. v. 1; bk. vi. 1); the enervation of her commonwealths by commerce (bk. i. 39; bk. ii. 42); her corrupt morality (bk. iii. 1); the reference of Italian circumstances to Roman precedents (bk. iii. 1); the theory of the intervenient "nomothetes" in states (bk. iv. 1); and the theory of human vicissitudes (bk. v. 1). This gives to his history a deductive and illustrative quality which men of less imaginative mind, like Guicciardini, or the exact students of our own days may criticize. But the *History of Florence* is not a mere political pamphlet. It is the first example in Italian literature of a national biography, the first attempt in any literature to trace the vicissitudes of a people's life in their logical sequence, deducing each successive phase from passions or necessities inherent in preceding circumstances, reasoning upon them from general principles, and inferring corollaries for the conduct of the future. In his prooemium Machiavelli taxes Poggio and Lionardo Bruni with having neglected civic affairs for the record of wars and alliances. It is to the analysis of the republic's inner life that he directs attention, showing how her acts were the phenomena of this organic force. At the same time he does not omit the narrative of external events, but places the portrait of Florence in the centre of an animated group of pictures drawn from Italian history. Approaching his own times, he enlarges on the part played by the Medici; for it was one of the conditions of the task imposed on him that he should celebrate the ancestors of Giulio. This portion of the work is executed in no servile spirit, and the subsequent destiny of Florence fully justified the prominence here given to the elder Cosimo and Lorenzo. In point of form the *Florentine History* is modelled upon Livy. In contains speeches in the antique manner, which may be taken as partly embodying the author's commentary upon situations of importance, partly as expressing what he thought dramatically appropriate to prominent personages. The style of the whole book is nervous, vivid, free from artifice and rhetoric, obeying the writer's thought with absolute plasticity. Machiavelli had formed for himself a prose style, equalled by no one but by Guicciardini in his minor works, which was far removed from the emptiness of the Latinizing humanists and the trivialities of the Italian purists. Words in his hands have the substance, the self-evidence of things. It is an athlete's style, all bone and sinew, nude, without superfluous flesh or ornament.

It would seem that from the date of Machiavelli's discourse to Leo on the government of Florence the Medici had taken him into consideration. Writing to Vettori in 1513, he had expressed his eager wish to "roll stones" in their service; and this desire was now gratified. In 1521 he was sent to Carpi to transact a petty matter with the chapter of the Franciscans, the chief known result of the embassy being a burlesque correspondence with Francesco Guicciardini. Four years later, in 1525, he received a rather more important mission to Venice. But Machiavelli's public career was virtually closed; and the interest of his biography still centres in his literary work. We have seen that already, in 1504, he had been engaged upon a comedy in the manner of Aristophanes, which is now unfortunately lost. A translation of the *Andria*, and three original comedies from his pen are extant, the precise dates of which are uncertain, though the greatest of them was first printed at Rome in 1524. This is the *Mandragola*, which may be justly called the ripest and most powerful single play in the Italian language.

The plot is both improbable and unpleasing. But, having granted this, literary criticism is merged in admiration of the wit, the humour, the vivacity, the satire of a piece which brings before us the old life of Florence in a succession of brilliant scenes. If Machiavelli had any moral object when he composed the *Mandragola*, it was to paint in glaring colours the corruption of Italian society. It shows how a bold and plausible adventurer, aided by the profligacy of a parasite, the avarice and hypocrisy of a confessor, and a mother's complaisant familiarity with vice, achieves the triumph of making a gulled husband bring his own unwilling but too yielding wife to shame. The whole comedy is a study of stupidity and baseness acted on by roguery. About the power with which this picture of domestic immorality is presented there can be no question. But the perusal of the piece obliges us to ask ourselves whether the author's radical conception of human nature was not false. The same suspicion is forced upon us by the *Principe*. Did not Machiavelli leave good habit, as an essential ingredient of character, out of account? Men are not such absolute fools as Nicia, nor such compliant catspaws as Ligurio and Timoteo; women are not such weak instruments as Sostrata and Lucrezia. Somewhere, in actual life, the stress of craft and courage acting on the springs of human vice and weakness fails, unless the hero of the comedy or tragedy, Callimaco or Cesare, allows for the revolt of healthier instincts. Machiavelli does not seem to have calculated the force of this recoil. He speculates a world in which *Virtù*, unscrupulous strength of character, shall deal successfully with frailty. This, we submit, was a deep-seated error in his theory of life, an error to which may be ascribed the numerous stumbling-blocks and rocks of offence in his more serious writings.

Some time after the *Mandragola*, he composed a second comedy, entitled *Clizia*, a portion of the plot of which is borrowed from the *Casina*. Though modelled on the art of Plautus, the *Clizia* is even homelier and closer to the life of Florence than its predecessor. It contains incomparable studies of the Florentine housewife and her husband, a grave business-like citizen, who falls into the senile folly of a base intrigue. The device by which Nicomaco is brought back to a sense of duty is presented in scenes of solid humour which recall the manner of Ben Jonson. On the whole, the *Clizia* is a pleasanter and wholesomer play than the *Mandragola*. It served as model to a school of later playwrights. There remains a short piece without title, the *Commedia in Prosa*, which, if it be Machiavelli's, as internal evidence of style sufficiently argues, might be accepted as a study for both the *Clizia* and the *Mandragola*. It seems written to expose the corruption of domestic life in Florence, and especially to satirize the friars in their familiar part of go-betweens, tame cats, confessors, and adulterers. The Fra Alberigo of this comedy is a vigorous piece of realistic portraiture, anticipating, if not surpassing, the Fra Timoteo of the *Mandragola*.

Of Machiavelli's minor poems, sonnets, capitoli, and carnival songs, there is not much to say. Powerful as a comic playwright, he was not a poet in the proper sense of the term. The little novel of *Belfagor* claims a passing word, if only because of its celebrity. It is a good-humoured satire upon marriage, the devil being forced to admit that hell itself is preferable to his wife's company. That Machiavelli invented it to express the irritation of his own domestic life is a myth without foundation. The story has a mediæval origin, and it was almost simultaneously treated in Italian by Machiavelli, Straparola, and Giovanni Brevio.

In the spring of 1526 Machiavelli was employed by Clement VII. to inspect the fortifications of Florence. He presented a report upon the subject, and in the summer of the same year received orders to attend Francesco Guicciardini, the pope's commissary of war in Lombardy. Guicciardini sent him in August to Cremona, to transact business with the Venetian provveditori. Later on in the autumn we find him once more with Guicciardini at Bologna. Thus the two great Italian historians of the

16th century, who had been friends for several years, were brought into relations of close intimacy. It would be interesting to know the topics of their conversation, and to possess some fragments of the debates they undoubtedly held upon the grave affairs of Italy at this decisive juncture. In the next year Rome was destined to be sacked by an imperial army. Florence was to rise in rebellion against the Medici. Four years later Charles V. was to lay the iron hand of Spain upon the remnants of Italian liberty. But nothing survives of Machiavelli's and Guicciardini's discourse. We can only form an opinion of what it must have been from the commentaries written by the latter on the political philosophy of Machiavelli—commentaries which sufficiently explain the different methods of the two great thinkers. Guicciardini, more positive even than Machiavelli in his criticism, averse to theory, satisfied with a policy of public temporizing and expediency, accepting Italian decadence with the tranquillity of egotism, looked on Machiavelli as a dreamer. "Nothing," he says, "can cure the diseases of our century but the knife of Lycurgus, and the knife of Lycurgus may not be expected." Machiavelli was always hoping against hope that this knife in the hands of some superior Cesare might still be used. Guicciardini, as events proved, had taken a sounder view of the situation; or rather it was men like Guicciardini who made the situation. Machiavelli to the last remained a patriot, with darkly bright impracticable visions in his brain.

After another visit to Guicciardini in the spring of 1527, Machiavelli was sent by him to Civita Vecchia. It seemed that he was destined to be associated in the papal service with Clement's viceroy, and that a new period of diplomatic employment was opening for him. But soon after his return to Florence he fell ill. His son Piero said that he took medicine on the 20th of June which disagreed with him; and on the 22d he died, having received the last offices of the church. There is no foundation for the legend that he expired with profane sarcasms upon his lips. Yet we need not run into the opposite extreme, and try to fancy that Machiavelli, who had professed paganism in his life, proved himself a believing Christian on his death-bed. That he left an unfavourable opinion among his fellow-citizens is very decidedly recorded by the historian Varchi. The *Principe*, it seems, had already begun to prejudice the world against him; and we can readily believe what Varchi sententiously observes, that "it would have been better for him if nature had given him either a less powerful intellect or a mind of a more genial temper." There is in truth a something crude, unsympathetic, cynical in his mental attitude toward human nature, for which, even after the lapse of more than three centuries, we find it difficult to make allowance. The force of his intellect renders this want of geniality repulsive. We cannot help objecting that one who was so powerful could have been kindlier and sounder if he willed. We therefore do him the injustice of mistaking his infirmity for perversity. He was colour-blind to commonplace morality; and we are angry with him because he merged the hues of ethics in one grey monotone of politics. In person Machiavelli was of middle height, black-haired, with rather a small head, very bright eyes, and slightly aquiline nose. His thin close lips often broke into a smile of sarcasm. His activity was almost feverish. When unemployed in work or study, he was not averse to the society of boon companions, gave himself readily to transient amours, and corresponded in a tone of cynical bad taste. At the same time he lived on terms of intimacy with worthy men. Varchi says of him that "in his conversation he was pleasant, obliging to his intimates, the friend of virtuous persons." Those who care to understand the contradictions of which such a character was capable should study his correspondence with Vettori. It would be unfair to charge what is repulsive in their letters wholly on the habits of the times; for wide familiarity with the published correspondence of similar men at the same epoch brings one acquainted with little that is so disagreeable.

For complete editions of Machiavelli's works, that of Italia, 8 vols., 1813, and the more comprehensive by Usigli, Florence, 1853, may be cited. The best biography is by Professor Pasquale Villari, 3 vols., Florence, 1877–82. This work contains a copious critique of all the most important studies which have been made of Machiavelli's works. An English translation of this life, finished by Madame Villari under the guidance of Professor Villari, is being published. (J. A. S.)

MACHINE TOOLS. The very small degree of antiquity to which machine tools can lay claim appears forcibly in the sparse records of the state of the mechanical crafts a century ago. A few tools of a rude kind, such as tilt-hammers, and a few special ones which aimed at accuracy, but were of very limited application, such as "mills" for boring cannon, or "engines" for cutting the teeth of clock wheels, were almost their only representatives. Machine tools of the modern type indeed would not then have been likely to have found much favour even if they had been invented, owing to the difficulty of providing sufficient power for driving them, except in the comparatively few positions where water-power was available. The transmission of power was unthought of, except for the very limited distances which were possible with the ill-fitted "gudgeons" and "lanterns and trundles" of the old millwrights.

The steam-engine, however, changed all this. On the one hand the hitherto unheard-of accuracy of fit required by its working parts created a demand for tools of increased power and precision, and on the other it rendered the use of such tools possible in almost any situation. Thus, acting and reacting on each other, machine tools and steam-engines have grown side by side, till our workshops have become peopled with a race of giants, capable of uncomplainingly performing tasks altogether beyond the powers of the easily wearied hands which have brought them into existence. But the first steps in the process were costly and difficult to a degree which it is not now easy to realize. James Watt, for instance, in 1769, was fain to be content with a cylinder for his "fire-engine" of which, though it was but 18 inches in the bore, the diameter in one place exceeded that at another by about $\frac{3}{8}$ (·375) of an inch; its piston was not unnaturally leaky, though he packed it with "paper, cork, putty, pasteboard, and old hat." In the bore of a cylinder of 120 inches there would not now be admitted an error of $\frac{1}{100}$ of an inch, and the leakage past the piston is practically *nil*. Even this must by no means be taken to represent the extreme limit attainable in respect of size and accuracy.

Machine tools present so many points of difference that no classification of them will be attempted beyond a broad division into general and special tools,—those included under the latter head being such as are intended to perform repeatedly one single operation (or one of a small number of varieties of that operation), or are mainly employed in particular processes or manufactures.

As an instance of special tools working successively in a series,—which is a frequent arrangement with special tools,—the *block machinery*, for making ships' blocks at Portsmouth dockyard, may be mentioned. Erected in 1807 by Mr H. Maudslay from designs by Mr (afterwards Sir Marc) Brunel, on the recommendation of Sir S. Bentham, it enabled ten men to do in a superior manner work which previously required one hundred and ten, and effected in the annual expenditure of the nation a saving of about £24,000. Into the particulars of the beautifully arranged sawing, mortising, shaping, and other machines by which this was accomplished we cannot enter, but they are of great interest, not only from their intrinsic merits, but also as being, if not the very first, certainly superior to any which had previously been used. Our limited space, however, will be more profitably devoted to giving a few examples of the general tools used in engineers' workshops.

The *Steam-Hammer*, which in some respects may be regarded as the most important of machine tools, has already been noticed (see HAMMER, vol. xi. p. 425). Second only to it in importance, and long anterior to it in date, stands the *lathe.* At what exact point of its development from the simple foot lathe it first became entitled to rank as a machine tool we will not stop to inquire, for the origin of this, as of most of the mechanical legacies which have been handed down to us by successive inventors and improvers, is involved in much obscurity. But as far as tools laying any claim to precision are concerned it appears certainly to have been the first to come into existence. On the Continent, mechanism to be used in conjunction with it for oval turning, and for producing mouldings oblique to the axis of the work, had been devised as early as 1569, in which year one Jacques Besson published drawings of two lathes so arranged. Whether much additional beauty was obtained by thus departing from the circular sections producible with the simple lathe, and converting them into distorted ones, such as that sketched in fig. 1 (reduced from Besson), may perhaps be questioned, but the taste for this "swash" work, as it is called, ere long extended also to England. Moxon, the first English writer on the subject, gives a drawing of a very similar lathe, and he mentions the name of an established London maker whose oval engines and swash engines, and all other engines, were "excellently well made," so they were apparently in some demand at the time of his writing (1680).

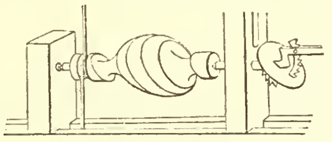


FIG. 1.—Swash Work.

Screw cutting in the lathe was another problem—and a more worthy one—which occupied the attention of inventors at the same early period. A curious but mechanically very imperfect arrangement for accomplishing it (with which, however, threads either right or left handed could be cut on tapered and oval as well as on cylindrical work) is given in another of Besson's engravings. In this the tool is entirely supported and its movements are controlled by the machine instead of being held in the hand,—an arrangement of which the great advantage appears to have been but tardily appreciated, though it contains the germ of the principle which, applied first in the slide-rest of the lathe, and subsequently in machine tools of almost every type, has enabled tasks of constantly increasing severity to be successfully dealt with.

Nearly two centuries seem to have elapsed before what we now know as the *slide-rest* became a recognized adjunct to the turning lathe, though in the meantime arrangements had been devised for controlling the motion of the tool by attaching it to some portion of the mechanism in some special cases,—as in that of two curious lathes for turning hyperbolic, spherical, or plane mirrors for optical purposes, of which engravings were published at Rome in 1648. Its first definite appearance in print occurs in the great French *Encyclopédie*, published in 1772. Detail drawings of an admirable slide-rest are given in one, and evidence of its being then in regular use occurs in several of the very interesting engravings of that ponderous work, which gives so clear an insight into the methods then employed in France in the various crafts. The description, however, by no means settles the question of its origin.

It is pretty certain that the slide-rest was reinvented in England by the ingenious Henry Maudslay, when he was employed in Mr Bramah's workshop in London, where "Maudslay's go-cart" (as it was at one time derisively called) was first set to work in 1794. That he had not previously seen the drawings just mentioned cannot of course be proved, but the high price at which the *Encyclopédie* was published makes it very probable that no copy of it had at that time come under the notice of a hard-working English mechanic. The intrinsic differences of the two slide-rests tend towards a similar conclusion. Whoever may have been its first inventor, the slide-rest has certainly proved itself to be the most invaluable of all the additions made to the turning lathe. Its indispensability to the modern power-lathe will be readily appreciated from the following examples.

An engraving of a simple slide-rest for use with a foot lathe has already been given (see LATHE), and its effect in reducing the labour of the turner was then pointed out. The *self-acting slide-rest* (fig. 2) carries this reduction still farther; and, by deriving from the lathe itself the small "feed" movement necessary for bringing the tool to bear on successive portions of the work, it dispenses wholly with the need for physical exertion on the part of the workman, and does not even demand his continuous supervision. One result of this is that the slide lathe (for so complete is the union between the slide-rest and the lathe that they must now be regarded as one machine) affords a complete solution of the screw-cutting problem, since, by varying the extent to which the rest traverses the lathe bed during each revolution of the mandrel, a screw thread of any desired pitch can be cut with a single tool.

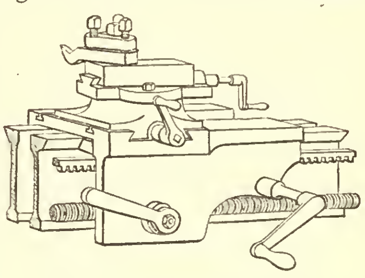

FIG. 2.—Self-Acting Slide-Rest.

In fig. 3, which shows a self-acting *screw-cutting lathe* with double-geared headstock, of a type now well established, the arrangements for obtaining and varying this traversing motion may be observed. A steel *leading screw* runs along the front of the lathe bed, and with it the slide-rest can be connected at pleasure. Two or more *change wheels*, properly proportioned as to the number of their teeth, connect the head of the screw with the hinder end of the mandrel.

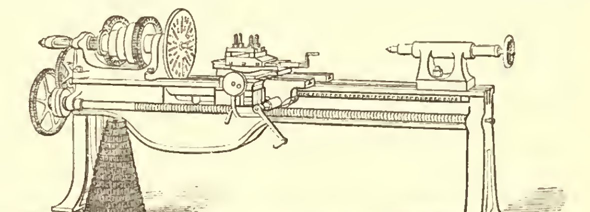

FIG. 3.—Self-Acting Screw-Cutting Lathe.

Although a leading screw is not the only nor in all cases the best mode of rendering a lathe self-acting, ordinary screw-cutting lathes are very largely used for other purposes than that implied by their name. The advantage of perfect regularity in the feed is very great even for plain turning, and this can only be secured when it is independent of human vigilance. The feed in a direction transverse to the bed is also very commonly rendered automatic by means into which we cannot here enter, lathes so provided being distinguished as self-acting *surfacing* lathes. In this case, however, the varying diameter of the successive cuts introduces serious objections to a uniform rate of feed. These were remedied as long ago as 1827 by that excellent mechanician Joseph Clement, —who was one of the greatest improvers of the power lathe; but his arrangement has never come into general use.

To enable a comparatively small lathe to be used for surfacing work of larger diameter than it would naturally admit, a portion of the bed is frequently made removable so as to leave a "gap" close to the fixed headstock. An 8-inch *gap lathe*, for instance, such as fig. 3, can thus admit an article of 26 inches diameter instead of 16 inches only.

Break lathes, such as fig. 4, carry the same principle still farther, so that they can take in work of considerable length as well as of large diameter,—the treble-geared headstock and all other parts being in their case made of sufficient strength to bear the heavy strains which result from the increased size and weight of the work, a quality

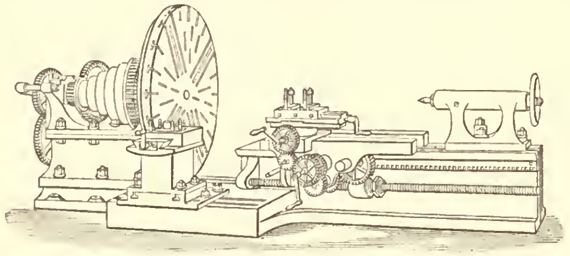

Fig. 4.—Self-Acting Break Lathe.

in which gap lathes are not unfrequently deficient. Lathes of this kind were made by Mr (now Sir Joseph) Whitworth as long ago as 1840, and the type is still the accepted one for general heavy turning. The face plates on which large work is chucked in these lathes are sometimes as much as 15 feet in diameter.

Face lathes, of which the main duty is surfacing articles whereof the diameter is great but the length small, are very similar to the foregoing minus the entire right-hand portion of the bed and all that it carries. They have occasionally been made for work of very large diameter,—such as turning the roller paths of 40 feet railway turntables,—though it is now found preferable to turn such things in a horizontal position, in lathes of which the mandrels are vertical.

But the point to which the growth of power-lathes has now attained will be best illustrated by the following interesting particulars of two which have been quite recently designed and made in the Royal Gun Factories at Woolwich. Each of these can take in a piece of work having a maximum diameter of 12 feet and a total length of 36 feet,—which represents a truly appalling weight of metal to have to deal with,—their main dimensions, &c., being

Height of centre of mandrel above the bed	6 ft.
Total length of bed....................................	60 ,,
Length of fixed headstock..........................	12 ,,
Diameter of front bearing of mandrel in do. ...	18 in.
Length of do. do.	36 ,,
Length of leading screw over all............... ...	52 ft. 3 in.
Diameter of do. do.	7 in.
Weight of fixed headstock, about..................	55 tons
Do. movable do., about..................	18 ,,
Do. slide-rest and saddle, about...........	15½ ,,
Total weight, nearly..................................	300 ,,

In lathes of this enormous size—as in all machine tools of the heaviest class—great weight and a proper disposal of it on a thoroughly secure foundation are necessary for obtaining the rigidity which is a first essential to success. When, however, this and all other conditions have been fulfilled, and the tool and the speed have been suitably adjusted, the operation of paring off great shavings from the revolving mass becomes one of such apparent facility that it is almost difficult for a stranger to believe that it is not lead or even some yet softer substance, rather than wrought iron or steel, which is under treatment.

It has been found that in heavy turning the best results are obtained by taking deep cuts at a low rate of speed, fast driving bringing no corresponding increase in the amount of work got through. Various other means have therefore been devised for accelerating operations. Each of the Woolwich lathes just mentioned is furnished with two slide-rests, so that two independent cuts can be taken at once at different parts of the work. The *duplex system* effects the same thing in a different way, two slide-rests (one in front and the other at the back of the lathe) being mounted on one saddle and adjusted simultaneously by a single right and left handed screw,—a plan which has the advantage of subjecting the work to two opposite strains which either wholly or partially balance each other. In some instances both the above advantages are combined by using two duplex rests at different parts of the bed. A *quick hand traverse* is another time-saving arrangement, now common to almost all screw cutting lathes. It enables the slide-rest to be run quickly back from the end of one cut to the starting point of the next. In turning up a number of similar articles upon each of which several different tools have to be used in succession, the time which would be lost in changing the tools is sometimes saved by employing a *capstan rest*, in which the whole series of tools is so fixed once for all that each in turn can be brought to bear upon the work without further adjustment.

Three examples of turning tools are given in fig. 5, the middle one being an ordinary *hook tool*, suited for outside work on wrought iron or steel, and the one above it a *left-hand tool* which can be used also for inside. Their cutting edges are of course forged and ground straighter or more pointed or otherwise varied according to circumstances, and for cast iron or brass the angle of the edge is made much less acute, as in the lowest of the three in the engraving. The size of the steel from which they are made also varies, 2 inches square being by no means exceptionally large, so that the weight of it uselessly employed in the shanks is very considerable, and altogether disproportionate to that required for the cutting edges. The plan of fixing a short steel cutter in an iron tool-holder, suggested many years ago by Mr Babbage (which has already been mentioned in connexion with foot lathes), has, however, not found the favour which at first sight might have been expected for it, in spite of the saving which it effects in this respect.

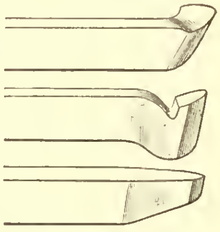

Fig. 5.—Slide-Rest Tools.

For chasing long or coarse-threaded screws the above-mentioned screw-cutting lathes leave little or nothing to be desired. But for producing the large number of screwed bolts, studs, &c., now required in mechanical workshops more rapid methods must be had recourse to, and special machines for forging, turning, screwing, and finishing them have accordingly come into common use. Of these one example only can be given—the *screwing machine*, fig. 6—with which the threads of bolts or nuts are cut to the "standard pitch" which now (happily) is almost universally accepted. Immense loss and inconvenience were formerly caused by the absence of uniformity in this respect, but, thanks to the persevering manner in which the efforts of Maudslay and Clement to put an end to this evil have been followed up by Whitworth, it has now almost ceased to exist, and any bolt or nut can be substituted for any other of a like size, however different the processes by which the two have been manufactured. The machine (fig. 6) is in fact a lathe with a few special features, such as the hollow mandrel, which enables it to operate upon a bar of any length. Dies mounted on a modified form of slide-rest cut the thread to the full depth at a single traverse, and a simple arrangement enables nuts to be tapped with equal facility. In some other varieties of screwing machines, more particularly those intended for hand power only, the outward resemblance to the turning lathe is less apparent, but if their action is looked into it will be found that in them as in almost all machine tools it is the principle of the slide which is mainly conducive to their success.

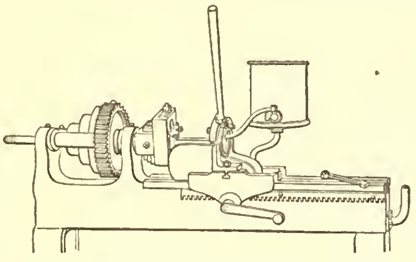

Fig. 6.—Screwing Machine.

Second only to the lathe in its importance stands the *planing machine*. Just as the slide lathe renders it easy to turn a cylindrical surface true from end to end, a task which before its introduction had been one of extreme difficulty, even for the most highly skilled workman, so the planing machine supersedes, by a method giving vastly superior results, the difficult and costly process of hand chipping and filing, by which flat surfaces of metal were formerly produced. Although it is a comparatively modern invention, its real origin is obscure. No drawings or description of any planing machine at all resembling those now in use were published in England previously to those of one made by Clement in 1825, which appeared in the *Transactions of the Society of Arts*. With this beautiful machine, which was of considerable size, being capable of admitting articles measuring as much as 6 feet in height or width, he obtained results which would satisfy all ordinary requirements at the present day.

The ordinary self-acting planing machine is shown in fig. 7. Its action bears no resemblance to the familiar

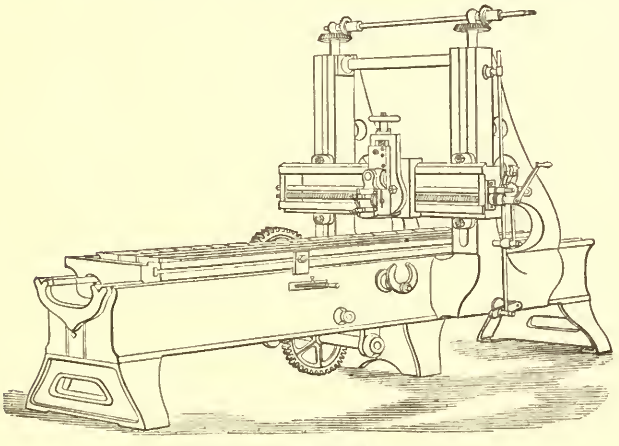

Fig. 7.—Planing Machine.

process of wood planing, but is analogous to that by which the successive cuts of a narrow tool produce a cylindrical surface in a slide lathe. A traversing table carries the work and forces it against the tool, which is stationary while making its cut, but between the cuts has a slight "feed" motion along its horizontal slide. Perfectly parallel cuts are thus taken from every portion of the work in succession, the result being a surface, not indeed perfectly smooth and free from scores, but (what is generally far more important) possessing a general flatness and freedom from twist which can be obtained only with a great expenditure of time and trouble by hand labour. The extent to which machinery has cheapened work of this kind will be appreciated from the fact that in 1826 the cost of rendering a square foot of surface true by hand chipping and filing was 12s., whereas in 1856 it could be done in the planing machine at a cost of less than one penny.

Planing machines, equally with lathes, are required not only to give good results but to give them quickly. Provision is therefore made for regulating the traverse of the table to suit the length of the cut, and for utilizing or accelerating its return journeys. The former is sometimes done by fixing the tool in a *revolving tool-holder* or "jim crow," so that its face can be always turned towards its cut, and for accomplishing the latter there are various arrangements which give a "quick return" to the table. It is also a common practice to use two tools at once, as in turning. It will be observed that the size of the work which can be treated in a planing machine, such as fig. 7, is strictly limited by the clear width between the standards, and the height of the horizontal slide above the table when at its highest point. Although these dimensions are very considerable in the larger sizes, which can occasionally take in articles over 9 feet in width and height and 50 feet in length, yet it is sometimes desirable to be able to exceed them, and in these large machines the weight of the table and the power consumed in driving and reversing it become a serious consideration. It is therefore mechanically preferable to keep the work at rest when it is large or heavy, and to give all the requisite movements to the tool. This view is now gradually gaining favour, and the makers of some recent machines have adopted a form of construction entirely different from the above, which has the advantage of enabling cuts either horizontal or vertical to be taken from any piece of work which can be secured to the base-plate, so that its full size is almost immaterial.

An ordinary *vertical drilling machine* is represented in fig. 8, one of comparatively small size and single-geared having been chosen rather than a larger example with greater complication. When once properly started, this machine is self-acting, but for each hole the work has to be adjusted by hand so as to bring the required portion exactly under the drill spindle, and the small size of the table prevents its being at any great distance from the edge. These objections are remedied in larger machines, either by making the table capable of horizontal adjustment,—a good way of doing this being to pivot a circular table at the end of an arm which can revolve round the main standard of the machine,—or by mounting the drill spindle on a radial arm, and enabling its distance from the standard to be varied. In the first case the tool is than distinguished as a "pillar" and in the second as a "radial" drilling machine. Either of these methods enables the drill to be brought to bear exactly upon the desired spot

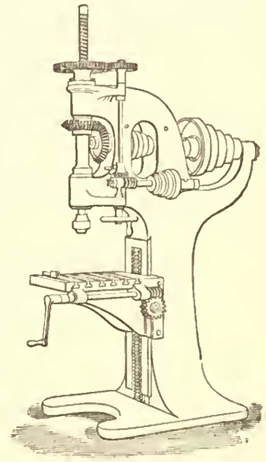

Fig. 8.—Vertical Drilling Machine.

(within certain limits as to distance from the edge, &c.), the first by adjusting the work below the drill, the second by adjusting the drill over the work. A *wall drill* dispenses with a table altogether, and gives great facilities for operating on large pieces of work, especially if the means of adjustment is secured by the radial arm just mentioned. *Multiple* drilling machines, with which a series of holes can be drilled at once, are serviceable tools for some purposes, mainly on account of the saving of time which they effect. Three drills are shown in fig. 9, the first the old, bad, but not yet quite superseded pattern, which is incapable of making a straight or clean hole of any considerable depth, and which loses its original diameter both in wear and in sharpening; the second the *twist drill*, which compares favourably with it in every one of these respects; and the third a *pin drill*, for enlarging a hole already existing.

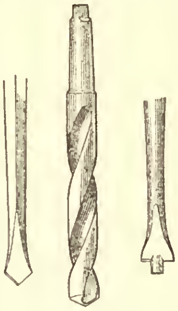

Fig. 9.—Drills.

Boring machines deal chiefly with apertures of large diameter, for which great straightness and accuracy are required, such as the cylinders of pumps, steam-engines, &c., or the bores of guns. The latter object brought them very early into existence, as already mentioned, and the general principle upon which the rude machinery of more than a century ago bored out the old cast iron mortars is still used for the powerful weapons of our own day. It consists in the employment of a *boring bar* formed by mounting a series of cutters (or a combination of guides and cutters) round the periphery of a cylindrical "head" somewhat less in diameter than the required bore. Fig. 10 will render evident the great similarity which exists between the oldest and the most recent gun-boring heads, the one being taken from the *Encyclopédie* already referred to, and the other from a drawing of a boring-bar used for a similar purpose at Woolwich. The head may be either a fixture at the end of its bar, in which case it forms a kind of drill with several cutting edges, or it may be so arranged as to traverse the bar to a small extent at each revolution,—a plan which is generally preferred for all open-ended cylinders, &c., and which admits of the work being kept stationary throughout the operation. The bar when in use is mounted either vertically or horizontally, according to circumstances, in a lathe or boring machine. The excellent results obtainable in this manner will be appreciated from the fact that with the gun-boring machinery at Woolwich a hole 10 inches in diameter and 10 feet deep can be bored in solid steel at a single operation, and holes have been carried to a depth of 24 feet with a variation of less than $\frac{1}{100}$ of an inch in the diameter. The accuracy of modern machine work indeed not unfrequently brings into prominence sources of error which were previously unsuspected. The boring of large cast iron cylinders affords an instance of this, for it has been found that, however true the boring tool may be, the distortion of the cylinder itself, through being laid on its side, is sufficient to mar the results obtained with it; consequently it has been found necessary always to bore a large cylinder in the vertical position which it will occupy when in use.

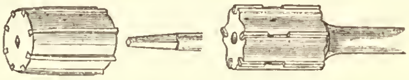

Fig. 10.—Gun-Boring Heads.

In the construction of modern machinery, &c., it is often necessary to depart from the simple geometric forms to the production of which the tools which have thus far occupied our attention are mainly adapted. We will now glance at some of the labour-saving contrivances applicable to other cases.

The *slot-drilling machine* effects (by a method said to have been first used about the year 1848) the conversion of the circular cavity producible with an ordinary drilling machine into an elongated "slot" or slit. The extent of the elongation can be varied by increasing or diminishing the reciprocating movement of the slide which carries the rotating drill. An example of it is given in fig. 11, and the cutting end of a *roughing drill* is shown to an enlarged scale. Where smoothness of the sunken surface is required this is followed by a *rose* or some other *finishing tool.*

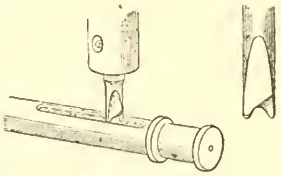

Fig. 11.—Slot Drilling.

The *slotting machine* (fig. 12) also cuts grooves and slots, but in an entirely different manner. Those who are acquainted with the wood mortising machine, from which the idea of this tool was derived by Roberts of Manchester, will at once understand its principle, and will appreciate the good service which can be rendered by this powerful paring tool. A large proportion of the shaping, &c., required in heavy work is now done in these machines, which are sometimes of great size and power. The table on which the work is placed is pivoted and mounted on a compound slide, and a self-acting horizontal transverse or circular movement can thus be given to it.

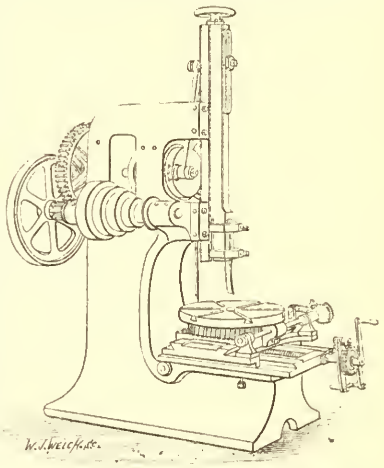

Fig. 12.—Slotting Machine.

For work of moderate size *shaping machines*, which are more of recent introduction than either slotting or planing machines, both of which they resemble in their action, are in some respects more convenient. The slide which carries the tool is in their case horizontal, and its short but variable strokes are in a direction transverse to the bed, along which it can travel, just as a slide-rest travels along a lathe bed. Curved surfaces, either convex or concave, as well as flat ones, can generally be worked up automatically in these machines, one of which is shown in fig. 13, but their details and arrangements vary considerably. For operating upon small surfaces, especially those of complicated outline, the plan of employing a revolving cutter, resembling a circular file, is now gaining favour. It is interesting to note that this is but a return to a system which is stated to have been devised by Dr Hooke in 1664, and which was certainly used in some of the early "engines" for cutting the teeth of wheels. One such cutter or *milling tool* is shown in fig. 14. Others are of a plain cylindrical form, or are varied in outline to any extent to suit the particular purpose for which they are intended, amongst which purposes may be mentioned that of cutting the teeth of other milling tools. When mounted on a compound slide and used in a *milling machine*, a tool of this kind is a labour-saving contrivance of a very efficient kind, and it should be observed that it may in some cases be employed for finishing metal surfaces possessing a double curvature, to which none of the foregoing planing or shaping machines could be applied.

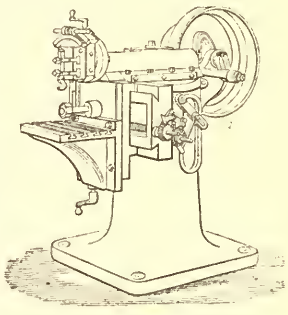

Fig. 13.—Shaping Machine.

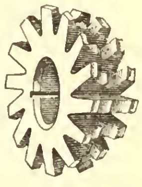

Fig. 14.—Milling Tool.

Profiling or *edge-milling machines* are a still more recent application of the milling-tool system. They enable the curved or complicated outline of a previously prepared templet to be reproduced with certainty any number of times in succession. They are in fact copying machines, acting in a similar manner to Jordan's carving machine or Blanchard's copying lathe, in both of which the form of the copy is derived from the original pattern by causing this pattern to control the movements of the revolving tool.

Another class of machine tools, which has sprung up of late years and is rapidly extending, is that of *emery grinders*. One thing which has given much impetus to these is the now not unfrequent necessity for turning or shaping steel in a more or less hard condition, for doing which these and natural grinding-stones are the only substances practically available on a large scale, while the rapid wear of the latter unfits them for many of the purposes to which the artificial preparations of emery can be applied with great advantage. Accordingly *emery wheels* are now mounted for use in a great many different ways,—either on slide-rests as turning tools, in *emery planers* and *emery shaping machines* (such as fig. 15), and various others in which they take the place of steel cutters, or as *tool grinders* either general or special, in which the rival material, so far from supplanting steel, does much towards increasing its efficiency, by enabling the process of grinding to be applied to many cutting tools which could previously be sharpened only with much greater labour and cost by other methods. Saws, grooved rimers and screw taps, and twist drills are familiar instances of this application. A high rate of speed is essential for obtaining the full effect of an emery wheel, half a mile a minute being by no means an unusual or excessive rate of travel for its cutting surface. A considerable amount of heat is consequently developed at the point of contact with the work, and the composition of the wheel must be such that it can endure this without injury. Some which could not fulfil this requirement have long been used by native workmen in India, but others which could fulfil it were patented in England in 1842, though for years after this they were but little known or used.

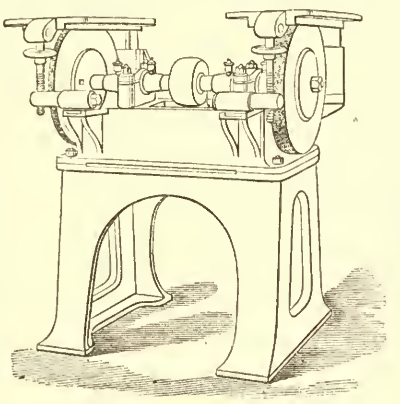

Fig. 15.—Emery Shaping Machine.

Punching and shearing machinery holds the same isolated position amongst machine tools that punches and shears occupy amongst cutting tools used by hand—if indeed either the one or the other can be regarded as cutting tools at all. Yet, for performing rapidly and in many cases without any waste of material, shears can often claim superiority to any other means available for accomplishing the same ends. The diagram (fig. 16) shows the old arrangement known as *cropping shears*, still in use at many iron-works, where early appliances seem to enjoy a remarkable vitality. An example of a self-contained *shearing and punching machine* is given in fig. 17. The apparent ease with which machines of this kind, acting with a slow quiet stroke, shear or perforate plates of iron, even when of considerable thickness, gives an altogether false impression of the amount of power which the operation requires. Arrangements for obviating the difficulty of placing the work exactly in the correct position for each one of a series of holes to be punched in it were devised by Maudslay ; his plan, which is the one now usually adopted, being to place a traversing table in front of the machine, from some part of which it is moved to a distance depending on the "pitch" of the holes after each stroke of the punch. Another system, by which the holes could be arranged in any required pattern, was subsequently invented by Roberts.

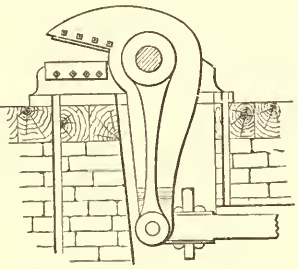

Fig. 16.—Cropping Shears.

The above examples of workshop tools have been confined to those to which the requisite power is transmitted from an independent steam-engine or some other prime mover—the usual mode of transmission being by lines of *shafting* carrying *pulleys* or *drums*. Belts pass from these to similar pulleys, which may be observed on many of the machines in the engravings. But this is not the invariable method. The prime mover may itself form part of the machine, as it does in the case of a steam-hammer. Or steam may be dispensed with and water confined under a high pressure substituted,—which constitutes the *hydraulic system* of distribution, now largely applied to the working of cranes and many other purposes, and to some extent also to machine tools. Punches and shears lend themselves readily to this system on account of their slow movements ; so, too, do *riveting machines*. The distribution of power by hydraulic means, and also by compressed air, was patented by Mr Bramah in 1796. Another formidable rival to steam also has now sprung up in the shape of *electricity*, and the results from it which are promised to us—and which indeed seem likely to be obtained—will go far towards revolutionizing all our present ideas as to the difficulty of transmitting power to a distance, and will work a complete transformation in the aspect of the machine tools of the future.

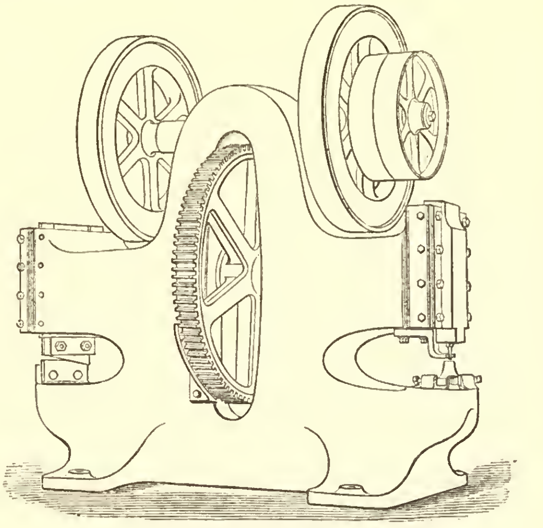

Fig. 17.—Punching and Shearing Machine.

One other class of machines must be mentioned before concluding, viz., *measuring machines*. The greatly increased accuracy of modern work has rendered necessary the recording of very minute dimensions, such as are quite beyond the measuring powers of ordinary rules and callipers. Difference engines, *i.e.*, machines which can measure minute differences between two articles—such as a standard gauge and an intended copy of it—have thus found a place in engineers' works. To their arrangement and manufacture, as well as to that of *standard measuring bars* and *gauges*, Sir J. Whitworth has paid great attention, and he has achieved such success that in his workshop measuring machines a difference of $\frac{1}{10000}$ part of an inch is readily appreciable. At the standards department of the Board of Trade there is one of these machines, used for the verification of standard gauges, which reads to the $\frac{1}{100000}$ of an inch ; and with his most sensitive machines—which, however, require great care and special precautions in their use—the $\frac{1}{1000000}$ part of an inch can be detected.

The social influence of machine tools we cannot discuss, though it is a subject upon which the diffusion of correct ideas is greatly needed. The days of mill-burning and implement-breaking mobs indeed are past, but the effect of the introduction of the machinery of which these tools are the parents is one which is still much misunderstood. More particularly is this the case amongst the hand-working classes in England, who see clearly the local and temporary hardships which its introduction occasionally causes, but are blind to the greatly preponderating advantages which they reap from it in an especial degree. (C. P. B. S.)

MACKENZIE, Sir Alexander (1755–1820), a Canadian explorer, was a native of Inverness. Having emigrated at an early age to Canada, he was for a number of years engaged in the fur trade at Fort Chipewyan, on the north side of the Lake of the Hills, and it was there that his schemes of travel were formed. His first journey (3d July to 27th September 1789)—for which he had prepared himself by a year's study in England of astronomy and navigation—was from Fort Chipewyan along the Great Slave Lake and down the river which now bears his name to the Frozen Ocean ; and his second (October 1792 to July 1793) from Fort Chipewyan up the Peace river across to the Columbia river, and thence westward to the coast of the Pacific at Cape Menzies, opposite Queen Charlotte Islands. The narrative of these expeditions (*Voyages through North America to the Frozen and Pacific Oceans*, London, 1801) is of considerable interest from the information it contains about the native tribes ; and it is prefaced by an historical dissertation on the Canadian fur trade. Mackenzie was rewarded for his discoveries by the honour of knighthood in 1801.

MACKENZIE, Sir George (1636–1691), of Rosehaugh, knight, a prominent Scottish lawyer, was the grandson of Kenneth, first Lord Mackenzie of Kintail, and the nephew of Colin and George, first and second earls of Seaforth; his mother was a daughter of Dr Andrew Bruce, principal of St Leonard's College, St Andrews. He was born at Dundee in 1636, and, having passed through the grammar school there, was sent at an early age to college at Aberdeen, and afterwards at St Andrews, graduating at sixteen. He then engaged for three years in the study of the civil law at Bourges; on his return to Scotland he was called to the bar in 1656, and before the Restoration had risen into considerable practice. Immediately after the Restoration he was appointed a "justice-depute," and it is recorded that he and his colleagues in that office were ordained by the parliament in 1661 "to repair, once in the week at least, to Musselburgh and Dalkeith, and to try and judge such persons as are there or thereabouts delate of witchcraft." In the same year he acted as counsel for the marquis of Argyll; soon afterwards he was knighted, and he represented the county of Ross during the four sessions of the parliament which was called in 1669. He succeeded Sir John Nisbet as king's advocate in August 1677, and in the discharge of this office became implicated in all the worst acts of the Scottish administration of Charles II., earning for himself an unenviable distinction as "the bloody Mackenzie." His refusal to concur in the measures for dispensing with the penal laws against Catholics led to his removal from office in 1686, but he was reinstated in February 1688. At the Revolution, being a member of convention, he was one of the minority of five in the division on the forfeiture of the crown. King William was urged to declare him incapacitated for holding any public office, but refused to accede to the proposal. When the death of Dundee (September 1689) had finally destroyed the hopes of his party in Scotland, Mackenzie betook himself to Oxford, where, admitted a student by a grace passed on June 2, 1690, he was allowed to spend the rest of his days in the enjoyment of the ample fortune he had acquired, and in the prosecution of his literary labours. One of his last acts before leaving Edinburgh had been to pronounce (March 15, 1689), as dean of the faculty of advocates, the inaugural oration at the foundation of the Advocates' Library. He died at Westminster on May 8, 1691, and was buried in Greyfriars churchyard, Edinburgh.

While still a young man Sir George Mackenzie appears to have aspired to eminence in the domain of pure literature, his earliest publication having been *Aretina, or a Serious Romance* (anon., 1660); it was followed, also anonymously, by *Religio Stoici, a Short Discourse upon several Divine and Moral Subjects* (1663), *A Moral Essay, preferring Solitude to Public Employment* (1665), and one or two other disquisitions of a similar nature. None of these earlier efforts are now read, if they ever were; and perhaps Mackenzie's strongest claim to be remembered at all in connexion with belles lettres is that which rests upon Dryden's grateful reminiscence of some stimulating conversation held with "that noble wit of Scotland, Sir George Mackenzie," about 1673. (See Dryden's "Discourse on the Origin and Progress of Satire," prefixed to his *Juvenal* in 1693.) His most important legal works are entitled *A Discourse upon the Laws and Customs of Scotland in Matters Criminal* (1678), *Observations upon the Laws and Customs of Nations as to Precedency, with the Science of Heraldry* (1680), *Institutions of the Law of Scotland* (1684), and *Observations upon the Acts of Parliament* (1686); of these the last-named is the most important, the *Institutions* being completely overshadowed by the similar work of his great contemporary Stair. In his *Jus Regium; or the Just and Solid Foundations of Monarchy in general, and more especially of the Monarchy of Scotland, maintained* (1684), Mackenzie appears as an uncompromising advocate of the highest doctrines of prerogative. His *Vindication of the Government of Scotland during the reign of Charles II.* is valuable as a piece of contemporary history. The collected *Works* were published at Edinburgh (2 vols. fol.) in 1716–22; and *Memoirs of the Affairs of Scotland from the Restoration of King Charles II.*, from previously unpublished MSS., in 1821. It may be well to add that the subject of this notice must not be confounded with Dr George Mackenzie, the author of *Lives and Characters of the Most Eminent Writers of the Scots Nation* (1708–22).

MACKENZIE, Henry (1745–1831), was born at Edinburgh in August 1745. His father was Dr Joshua or Josiah Mackenzie, a successful physician, who also cultivated letters in a small way. Mackenzie got the ordinary education of a youth in his position at the high school and university of Edinburgh, and was afterwards articled to Mr Inglis, who was then attorney for the crown in the management of exchequer affairs. To this comfortable post the author in due time succeeded, and perhaps knew as little as any of that tribe ever did about the struggles and sorrows of a literary career. For his work's sake it would have been better if he had travelled some of life's rougher paths, or else been content to write about what he had actually seen in the Scottish world of that day. There was plenty of material there if he had had the open eye to see it, as Walter Scott showed by and by; and it is a pity that Mackenzie did not try his hand at it, having been more in the heart of it than Scott could ever have been. As it is, his stories are clearly not the fruit of his experience, but rather the echo of his reading. He could write graceful enough sentences, somewhat artificial, yet smooth and pointed; but the men he describes are mere shadows, and the life altogether unreal. His first and best-known work, *The Man of Feeling*, was published anonymously when he was only twenty-six years of age, and soon became highly popular. It was a droughty season in Scottish literature, and therefore any little blossom, however sickly, was welcome for its rarity. Hume and Robertson and Smith had left the scene; Burns was just learning to think of the daisy he turned up with his ploughshare, and Fergusson had lately closed his brief and troubled career. Mackenzie had the field all to himself, and got the attention which is given to a solitary figure. He had read the *Sentimental Journey*, as one can see from expressions here and there, as well as from the affectation of writing his story in a fragmentary form; but he had not a gleam of Sterne's humour to relieve the sentimentality. He had read Richardson too, but he had none of that writer's subtle insight into character. Perhaps Goldsmith was his real model, but the likeness was as that between a firefly and a star. The "man of feeling" is a weak foolish creature, possessed with a futile benevolence, who goes up to London, where his friends should never have let him go, and meets a variety of sharpers, and comes out of their hands pretty much as Goldsmith makes the vicar's son do, only without the fun that clings to poor Moses. For this book is all in one key, sentimental and lachrymose, and the hero dies at last, from no particular cause, in a highly tragic fashion beside his fainting mistress. His next work, *The Man of the World*, is the picture of a born villain, a rogue in grain, who begins his rascality at school, perhaps earlier, and carries it through with entire consistency to the end. The man is unnaturally bad, and the incidents are badly unnatural; and such a book at present would only find a place in some third-rate penny paper, if even there. *Julia de Roubigné*, his only other novelette, was meant to depict the misfortunes of a number of quite blameless people—to be, in short, a tragedy without a villain, an *Othello* without an Iago. But, as it has no insight, and does not even try to have any insight, into the mystery of such calamities, the result is insipid and tedious. All these works had great popularity in their day; but that day is long past, and what life they now have is only a tradition.

Mackenzie also wrote several dramas, mostly of the tragic sort, for in that tone he had won his successes, such as they were. But one who had no conception of distinct character, of human individuality, was not likely to succeed in the drama, which depends more on that than on anything; and hence it was not our author's good fortune to deliver his country from the stigma of never having produced a genuine tragedy. Of *The Spanish Father*, *The Prince of Tunis*, and *The Shipwreck*, the second was brought on the stage, and managed to live for six nights; the other two were stillborn, and probably no man living has ever read them, unless for purely critical purposes.

But Mackenzie, if nowise a great writer, but quite otherwise essentially a small writer, with a knack of making sentences indeed, but having nothing particular of his own to say, was not therefore altogether a useless man in his day. That he did well for himself, and perhaps for the exchequer too, is quite likely, even though he toiled in the high-Tory service of Dundas, and wrote tracts meant to "broom" out of the country the tide of French Revolutionary notions. At any rate he became in his old age a kind of literary centre and social power in Edinburgh, when that was really needed and useful. He had known John Home and blind Dr Blacklock, and wrote lives of them; but, what is of more consequence, he was among the first to recognize the genius of Robert Burns, as editor of *The Lounger*, which he and a group of young men with some literary tastes wrote and printed for some years. Yet, though he once breakfasted with Johnson, and certainly met Burns more than once, he has told us nothing about either of them, though a page of Burns's talk would have been worth all *The Man of Feeling* twice told. It was so far good, however, that he hailed the peasant poet cordially, which we could hardly have hoped so artificial a writer would do, and even better that he noticed the dawn of German literature when Lessing and Schiller rose above the horizon, and not only wrote some account of them, taken from French sources, but boldly set to the study of German that he might really know them at first hand. How far he went in that study we do not know, only he set young Walter Scott on the scent, with results such as he himself could never have imagined. So he lived on, a kind of small king in the Edinburgh literary world, till 1831, dying in his eighty-sixth year, with a wonderful new world around him, which had not yet begun to criticize, but only to admire and honour him.

MACKEREL. Mackerels are pelagic fishes, belonging to a small family, *Scombridæ*, of which the tunny, bonito, albacore, sucking-fish (*Echeneis*), and a few other tropical genera are members (see ICHTHYOLOGY, vol. xii. p. 690). Although the species are fewer in number than in the majority of other families of fishes, they are widely spread and extremely abundant, peopling by countless schools the oceans of the tropical and temperate zones, and approaching the coasts only accidentally, occasionally, or periodically. The mackerels proper (genus *Scomber*) are readily recognized by their elegantly shaped, well-proportioned body, shining in iridescent colours. Small, thin, deciduous scales equally cover nearly the entire body. The dorsal fin extends over a great part of the back, and consists of several portions: the anterior, composed of feeble spines which can be laid backwards in a groove; the posterior, of rays only, of which the five or six hindmost are detached, forming isolated "finlets." The shape of the anal fin is similar to that of the rayed dorsal. The caudal fin is crescent-shaped, strengthened at the base by two short ridges on each side. The mouth is wide, armed above and below with a row of very small, fixed teeth.

No other fish shows finer proportions in the shape of its body. Every "line" of its build is designed and eminently adapted for rapid progression through the water; the muscles massed along the vertebral column are enormously developed, especially on the back and the sides of the tail, and impart to the body a certain rigidity which interferes with abruptly sideward motions of the fish. Therefore mackerel generally swim in a straightforward direction, deviating sidewards only when compelled, and rarely turning about in the same spot. They are in almost continuous motion, their power of endurance being equal to the rapidity of their motions. Mackerel, like all fishes of this family (with the exception, perhaps, of *Echeneis*, which has not yet been examined in this respect), have a firm flesh; that is, the muscles of the several segments are interlaced, and receive a greater supply of blood-vessels and nerves than in other fishes. Therefore the flesh, especially of the larger kinds, is of a red colour; and the energy of their muscular action causes the temperature of their blood to be several degrees higher than in other fishes.

All fishes of the mackerel family are strictly carnivorous; they unceasingly pursue their prey, which consists principally of other fish and pelagic crustaceans. The fry of clupeoids, which likewise swim in schools, are followed by the mackerel until they reach some shallow part of the coast, which their enemies dare not enter.

Mackerels are found in almost all tropical and temperate seas, with the exception of the Atlantic shores of temperate South America, where they have not hitherto been met with. The distinctive characters of the various species have not yet been fully investigated; and there is much confusion in the discrimination of the species. So much is certain that the European mackerel are of two kinds, of which one, the common mackerel, *Scomber scomber*, lacks, while the other possesses, an air-bladder. The best-known species of the latter kind is *Scomber colias*, the "Spanish" mackerel;[1] a third, *Scomber pneumatophorus*, is believed by some ichthyologists to be identical with *S. colias*. Be this as it may, we have strong evidence that the Mediterranean is inhabited by other species different from *S. scomber* and *S. colias*, and well characterized by their dentition and coloration. Also the species from St Helena is distinct. Of extra-Atlantic species the mackerel of the Japanese seas are the most nearly allied to the European, those of New Zealand and Australia, and still more those of the Indian Ocean, differing in many conspicuous points. Two of these species occur in the British seas: *Scomber scomber*, which is the most common there as well as in other parts of the North Atlantic, crossing the ocean to America, where it abounds; and the Spanish mackerel, *Scomber colias*, which is distinguished by a somewhat different pattern of coloration, the transverse black bands of the common mackerel being in this species narrower, more irregular or partly broken up into spots, while the scales of the pectoral region are larger, and the snout is longer and more pointed. The Spanish mackerel is, as the name implies, a native of the seas of southern Europe, but single individuals or small schools reach frequently the shores of Great Britain and of the United States.

The home of the common mackerel (to which the following remarks refer) is the North Atlantic, from the Canary Islands to the Orkneys, and from the Mediterranean and the Black Sea and the coasts of Norway to the United States.

Towards the spring large schools approach the coasts. Two causes have been assigned of this migration: first, the instinct of finding a suitable locality for propagating their species; and, secondly, the search and pursuit of food, which in the warmer season is more abundant in the neighbourhood of land than in the open sea. It is probable that the latter is the true and only cause, for the following reasons:—mackerel are known to increase much more rapidly in size while in the neighbourhood of land than in the months during which they lead a roving pelagic life in the open sea; and, further, one-year and two-year-old fishes, which have not yet attained maturity, and therefore do not travel land-

[1] The term "Spanish mackerel" is applied to a very different fish in America, viz., *Cybium maculatum*.

wards for the purpose of spawning, actually take the lead in the migration, and are followed later on by the older and mature fishes. Finally, according to the observations made by Sars, vicinity of land or shallow water are not necessary conditions for the oviposition of mackerel; they spawn at the spot which they happen to have reached during their wanderings at the time when the ova have attained their full development, independently of the distance of the land or of the depth of water below them, as the ova float and the embryo is developed on the surface of the water.

In the month of February, or in some years as early as the end of January, the first large schools appear at the entrance of the English Channel, and are met by the more adventurous of the drift-net fishers many miles west of the Scilly Islands. These early schools, which, as we mentioned above, consist chiefly of one-year and two-year-old fishes, yield sometimes enormous catches, whilst in other years they escape the drift-nets altogether, passing them, for some hitherto unexplained reason, at a greater depth than that to which the nets reach, viz., 20 feet. As the season advances, the schools penetrate farther northwards into St George's Channel or eastwards into the English Channel. The fishery then assumes proportions which render it next in importance to the herring and cod fisheries. In Plymouth alone a fleet of some two hundred boats assembles; and on the French side of the Channel no less capital and labour are invested in it, the vessels employed being, though less in number, larger in size than on the English side. Simultaneously with the drift-net the deep-sea-seine and shore-seine are used, which towards June almost entirely supersede the drift-net. Towards the end of May the old fish become heavy with spawn, and are in the highest condition for the table; and the latter half of June or beginning of July may be regarded as the time at which the greater part of mackerel spawn.

Mackerel are scarcely less abundant in the German Ocean; probably some of the schools never leave it, and this resident stock (if we are allowed to apply this term to a fish which is ever shifting its quarters) is increased by the schools coming from the Atlantic through the English Channel or round the north coast of Scotland. The schools approach the coasts of the German Ocean somewhat later in the season, partly owing to the greater severity of the weather, which detains the resident fishes in the open sea, and partly owing to the greater distance which the Atlantic shoals have to travel. On the Norwegian coast mackerel fishing does not begin before May, whilst on the English coasts large catches are frequently made in March. Large cargoes are now annually imported in ice from Norway to the English market.

After the spawning the schools break up into smaller companies which are much scattered, and offer for two or three months employment to the hand-line fishermen. They now begin to disappear from the coasts and return to the open sea. Single individuals or small companies are found, however, on the coast all the year round; they may have become detached from the main bodies, and be seeking for the larger schools which have long left on their return migration.

Although, on the whole, the course and time of the annual migration of mackerel are marked with great regularity, their appearance and abundance at certain localities are subject to great variations. They may pass a spot at such a depth as to evade the nets, and reappear at the surface some days after farther eastwards; they may deviate from their direct line of migration, and even temporarily return westwards. In some years between 1852 and 1867 the old mackerel disappeared off Guernsey from the surface, and were accidentally discovered feeding at the bottom. Many were taken at 10 fathoms and deeper with the line, and all were of exceptionally large size, several measuring 18 inches, and weighing nearly 3 lb; these are the largest mackerel on record.

The mackerel most esteemed as food is the common species, and individuals from 10 to 12 inches in length are considered the best flavoured. In more southern latitudes, however, this species seems to deteriorate, specimens from the coast of Portugal, and from the Mediterranean and Black Sea, being stated to be dry and resembling in flavour the Spanish mackerel (*S. colias*), which is not esteemed for the table. See also Fisheries. (A. C. G.)

MACKINTOSH, Sir James (1765–1832), publicist, historian, statesman, and philosopher, was born at Aldourie, 7 miles from Inverness, in 1765. He came of old Highland families both through his father and his mother. Of the former, who was an officer in the army, and was mostly on duty abroad, he saw but little, and he spent his early years under the care of his mother and her relatives. At a very early age young James bore the reputation of a prodigy for multifarious reading and learning. His schooling he received at Fortrose, whence he went in 1780 to college at Aberdeen. As a student in the arts faculty there his reading extended far beyond the bounds of the curriculum; but the influence that most powerfully formed his mind was the companionship of Robert Hall, afterwards so famous as a pulpit orator, with whom he ardently beat the usual round of vexed questions. In 1784 he proceeded for the study of medicine to Edinburgh, where he found a still more congenial field for his opening mind, at a time when Hume had been dead just eight years, while Adam Smith, Dr Black the father of chemistry, Dr Cullen, Robertson, Ferguson, and other eminent men, were resident there. Mackintosh participated to the full in the intellectual ferment, but did not quite neglect his medical studies, and took his degree, though with characteristic unpunctuality he kept the professors waiting for a considerable time on the examination morning.

In 1788 Mackintosh removed to London, then agitated by the trial of Hastings and the king's first lapse into insanity. He was much more interested in these and other political events than in his professional prospects; and his attention was specially directed to the events and tendencies which caused or preceded the Revolution in France. In the year of his removal to London his father died, and he succeeded to the family estate, which, being small and burdened, brought very little income; and, as he made no headway in his profession, his financial outlook was not very bright. It was under these circumstances that he wedded his first wife Catherine Stuart. Yet his marriage was a happy event for him. His wife's prudence was a corrective to his own unpractical temperament, and his efforts in journalism soon became fairly profitable. Mackintosh was soon absorbed in the question of the time; and in April 1791, after long meditation, he published his *Vindiciæ Gallicæ*, a reply to Burke's *Reflections on the French Revolution*. It was the only worthy answer to Burke that appeared. It placed the author in the front rank of European publicists at the age of twenty-five, and won him the friendship of some of the most distinguished men of the time, including Burke himself. About the same time he became honorary secretary of the association of the Friends of the People. The success of the *Vindiciæ* finally decided him to give up the medical for the legal profession. He was called to the bar in 1795, and gained a considerable reputation there as well as a tolerable practice. During this period his greatest public efforts were his lectures (1799) at Lincoln's Inn on the law of nature and nations, of which the introductory discourse was published, and his eloquent defence (1803) of Jean Peltier, a French refugee, tried at the instance of the French Government for a libel against the first consul. In 1804 he was created knight, and received the post of recorder at Bombay, where he spent the next seven years of his life. The spoilt child of London society was not at home in Bombay. He did seek to interest himself in India, and in imitation of Sir William Jones founded the Literary Society of Bombay; but the current literature of Europe was far more engrossing than the old Indian life, and the packet with the latest tidings from Europe and the newest development of the Napoleonic drama was infinitely more interesting than either. In spite of his scholarly and historic sympathies, his heart always was with the new era, and he was glad to return to England, where he arrived in 1812. True to his old faith, he courteously declined the offer of Perceval to resume political life under the auspices of the dominant Tory party, though tempting prospects of office in connexion with India were opened up. He entered parliament in the Whig interest as member for Nairn. He sat for that county, and afterwards for Knaresborough, till his death. In London society, and in Paris during his occasional visits, he was a recognized favourite for his genial wisdom and his great conversational power. On Madame de Staël's visit to London he was the only Englishman capable of representing his country in talk with that phenomenal woman. His parliamentary career was marked by the same wide and candid liberalism as his private life. He opposed the repressive and reactionary measures of the Tory Government, supported and afterwards succeeded Romilly in his efforts for reforming the criminal code, and took a leading part both in Catholic emancipation and in the Reform Bill. But he was too little of a partisan, too widely sympathetic and candid, as well as too elaborate, to be a telling speaker in parliament, and was consequently surpassed by more practical men whose powers were incomparably inferior. From 1818 to 1824 he was professor of law and general politics in the East India Company's College at Haileybury.

In the midst of the attractions of London society and of his parliamentary avocations Mackintosh felt that the real work of his life was being neglected. His great ambition was to write a history of England. His studies both in English and foreign speculation led him to cherish the design also of making some worthy contribution to philosophy. There is real pathos in the fact that it was not till 1828, when he was sixty-three years of age, and even then only at the instance of Macvey Napier, editor of the *Encyclopædia Britannica*, that he set about the first task of his literary ambition. This was the *Dissertation on the Progress of Ethical Philosophy*, prefixed to the seventh edition of the *Encyclopædia*. The dissertation, written mostly in ill-health and in snatches of time taken from his parliamentary engagements, was published in 1831. About the same time he wrote for the *Cabinet Cyclopædia* a "History of England from the Earliest Times to the Final Establishment of the Reformation." His more elaborate *History of the Revolution*, for which he had made great researches and collections, was not published till after his death. Already a privy councillor, Mackintosh was appointed commissioner for the affairs of India under the Whig administration of 1830. He died in 1832.

Mackintosh was undoubtedly one of the most cultured and catholic-minded men of his time. His studies and sympathies embraced almost every human interest, except pure science. But it was the width of his intellectual sympathies joined to a constitutional indecision and *vis inertiæ* that prevented him from doing more enduring work. Thus it was that his actual achievements came so far short both of his real power and of the promise given in his early efforts. The works of Mackintosh which have the best claim to permanent value are the *Vindiciæ Gallicæ*, the *Dissertation*, and the *History of the English Revolution*. Of the three the first is the greatest both in ability and historical significance. It is the verdict of a philosophic Liberal on the development of the French Revolution up to the spring of 1791, and is at the same time a sympathetic estimate of its causes, principles, and tendencies. While respectful to his great opponent, he is firm and manly in his assertion of the rights and interests of man so deeply concerned in the Revolution. Its excesses compelled him a few years after to express his entire agreement with the opinions of Burke; but few will now deny that his early judgment was the more correct. The *Dissertation* is a sketchy and fragmentary work, redeemed by catholic criticism and ingenious suggestion. It was a great undertaking, for which half a lifetime would hardly have been sufficient, attempted at a time when the study of the history of philosophy had hardly been begun. Yet his suggestions as to the formation of conscience are valuable. The *History of the Revolution in England in 1688*, which is only a posthumous fragment of a long meditated history of England beginning with the Revolution, is written in a style of calm and lofty impartiality. It is wanting in colouring, in movement, in the concrete and picturesque, and could never have been a popular history. It gives the history only of three years (1685–88), breaking off at the point where William of Orange is preparing to intervene in the affairs of England. The account of the early career of the prince is a noble and striking piece of work, showing that, if the author could have resisted the charms of society and applied himself resolutely to historical composition, he might have achieved something really great in that department.

See the *Memoirs of Sir James Mackintosh's Life*, edited by his son; also Macaulay's *Essay* on Sir J. Mackintosh.

MACLAURIN, Colin (1698–1746), one of the most eminent among the mathematicians and philosophers that Great Britain has produced, was the son of a clergyman, and born at Kilmodan, Argyllshire, in 1698. At the early age of eleven years he entered the university of Glasgow, where he graduated as master of arts in his sixteenth year. While at the university he exhibited a decided genius for mathematics, more especially for geometry; and it is said that before the end of his sixteenth year he had discovered many of the theorems afterwards published in his *Geometria Organica.*

In 1717 he was elected professor of mathematics in Marischal College, Aberdeen, as the result of a competitive examination. Two years later he was admitted a fellow of the Royal Society, and in a visit to London made the acquaintance of Newton, whose friendship and esteem he afterwards enjoyed. In 1719 he published his *Geometria Organica, sive descriptio linearum curvarum universalis.* This work was inspired by the beautiful discoveries of Newton on the organic description of conic sections. In it Maclaurin introduced the well-known method of generating conics which bears his name, and showed that many species of curves of the third and fourth degrees can be described by the intersection of two movable angles. In 1721 he wrote a supplement to the *Geometria Organica*, which he afterwards published, with extensions, in the *Philosophical Transactions* for 1735. This paper is principally based on the following general theorem, which is a remarkable extension of Pascal's hexagram:—"If a polygon move so that each of its sides passes through a fixed point, and if all its summits except one describe curves of the degrees m, n, p, &c., respectively, then the free summit moves on a curve of the degree $2mnp$ . . . . which reduces to mnp . . . when the fixed points all lie on a right line."

In 1722 Maclaurin travelled as tutor and companion to the eldest son of Lord Polwarth, and after a short stay in Paris resided for some time in Lorraine, where he wrote an essay on the percussion of bodies, which obtained the prize of the French Academy of Science for the year 1724. The following year he was elected professor of mathematics in the university of Edinburgh on the urgent recommendation of Newton. After the death of Newton in 1728, his nephew, Mr Conduitt, applied to Maclaurin for his assistance in publishing an account of Newton's life and discoveries. This Maclaurin gladly undertook, but before the account was written the death of Mr Conduitt put a stop to the project. It was not until many years afterwards, and subsequently to Maclaurin's death, that this account of Newton's philosophical discoveries was published (1748).

In 1740 Maclaurin obtained the high distinction of dividing with Euler and Daniel Bernoulli the prize offered by the French Academy of Science for an essay on the flux and reflux of the sea. This important memoir was subsequently revised by him, and inserted in his *Treatise on Fluxions*, which was published at Edinburgh in 1742, in two volumes. In the preface he states that the work was undertaken in consequence of the attack on the method of fluxions made by Berkeley in 1734, under the title of *The Analyst.* Maclaurin's object was to found the doctrine of fluxions on geometrical demonstration, after the manner of Archimedes and the ancient mathematicians, and thus to answer all objections to its method as being founded on false reasoning and full of mystery. He thus laid down the grounds of the fluxional method, regarding fluxions as velocities, after Newton. He proceeded to give an extensive application of the method to curves, surfaces, and the other subjects usually discussed in works on the differential and integral calculus, his treatment being almost exclusively geometrical; but the most valuable part of the work is that devoted to physical applications, in which he embodied his essay on the tides, as stated above.

In this he investigated the attraction of an ellipsoid of revolution, and showed that a homogeneous fluid mass revolving uniformly round an axis under the action of gravity ought to assume the form of an ellipsoid of revolution. The importance of this investigation in connexion with the theory of the tides, the figure of the earth, and other kindred questions has always caused it to be regarded as one of the great problems of mathematical physics. Thus Clairaut, D'Alembert, Lagrange, Legendre, Laplace, Gauss, Ivory, Poisson, Jacobi, Chasles, and other eminent mathematicians have successively attacked the problem, and in doing so have declared their obligations to Maclaurin as the creator of the theory of the attraction of ellipsoids. Lagrange's statement as to Maclaurin's discoveries deserves to be especially cited: after observing that the attraction of a spheroid of revolution is one of the problems in which the method of the ancients has advantages over that of modern analysis, he adds that Maclaurin's investigation is "un chef d'œuvre de géométrie qu'on peut comparer à tout ce qu' Archimède nous a laissé de plus beau et de plus ingénieux" (*Mém. de l'Acad. de Berlin*, 1773). It may be added that Maclaurin was the first to introduce into mechanics, in this discussion, the important conception of *surfaces of level*, namely, surfaces at each of whose points the total force acts in the normal direction. He also gave in his *Fluxions*, for the first time, the correct theory for distinguishing between maxima and minima in general, and pointed out the importance of the distinction in the theory of the multiple points of curves.

In 1745, when the rebels, having got between Edinburgh and the king's troops, were marching on that city, Maclaurin took a most prominent part in preparing trenches and barricades for its defence. This occupied him night and day, and the anxiety, fatigue, and cold to which he was thus exposed, affecting a constitution naturally weak, laid the foundation of the disease to which he afterwards succumbed. As soon as the rebel army got possession of Edinburgh, Maclaurin fled to England, to avoid making the submission to the Pretender which was demanded of all who had defended the town. He accepted the invitation of Dr Herring, then archbishop of York, with whom he remained until it was safe to return to Edinburgh. From that time his health was broken, and he died of dropsy on June 14, 1746, at Edinburgh, in his forty-eighth year. Maclaurin was married in 1733 to Anne, daughter of Walter Stewart, solicitor-general for Scotland. His eldest son, John, born in 1734, was distinguished as an advocate, and appointed one of the judges of the Scottish Court of Session, with the title of Lord Dreghorn. He inherited an attachment to scientific discovery, and was one of the founders of the Royal Society of Edinburgh, in 1782.

After Maclaurin's death his account of Newton's philosophical discoveries was published, and also his algebra in 1748. As an appendix to the latter appeared his work, *De linearum geometricarum proprietatibus generalibus tractatus*, a treatise of remarkable elegance. Of the more immediate successors of Newton in Great Britain Maclaurin is probably the only one who can be placed in competition with the great mathematicians of the Continent at the time, and his name will ever be held in remembrance in connexion with his important discoveries. Among his publications in the *Philosophical Transactions* the following should be noticed:—

(1) "Tractatus de curvarum constructione et mensura, ubi plurimæ series curvarum infinitæ vel rectis mensurantur, vel ad simpliores curvas reducantur," May 1718. The series of curves here treated are what are now styled "pedal" curves, which hold an important place in the modern discussion of curves. Maclaurin established many geometrical properties connecting a curve with its pedal. He investigated the properties of the successive pedals of a circle with respect to a point on its circumference, also those of the pedals of curves for which the perpendicular on the tangent varies as some power of the radius vector drawn to the point of contact. (2) "Nova methodus universalis curvas omnes cujuscunque ordinis mechanice describendi sola datorum angulorum et rectarum ope," January 1719. This and the preceding memoir were subsequently enlarged and incorporated by Maclaurin in his *Geometria Organica*. (3) "On Equations with Impossible Roots," May 1726. (4) On "Continuation of the Same," March 1729. In these papers he gave a proof of Newton's rule for the discovery of the number of imaginary roots of an equation. He added some general results on the limits to the roots, and gave the well-known method of finding equal roots by aid of the first derived equation. (5) "Observation of the Eclipse of the Sun of February 18, 1737," January 1738. (6) "On the Bases of the Cells where Bees Deposit their Honey," November 1743.

French translations of his *Treatise on Fluxions* and that on Newton's philosophical discoveries were published at Paris in 1749. His algebra was also translated into French, in 1753. (B. W.)

M'LENNAN, JOHN FERGUSON, LL.D. (1827-1881), one of the most original of modern inquirers into the constitution of early society, was born at Inverness 14th October 1827. He studied at King's College, Aberdeen, where he graduated with great distinction in 1849, and then proceeded to Cambridge, where he remained till 1855, but did not take his degree. After some years spent in literary work and legal studies in London and Edinburgh, he joined the Scottish bar (January 1857). In 1865 he published an epoch-making study on *Primitive Marriage*, in which, starting from the prevalence of the symbolical form of capture in marriage ceremonies, and combining with great argumentative power a variety of phenomena of primitive society previously quite obscure, he developed an intelligible picture of the growth of the marriage relation and of systems of kinship (see FAMILY) according to natural laws. Continuing his studies on allied topics, M'Lennan published in 1866 (*Fortnightly Review*, April and May 1866) an essay on "Kinship in Ancient Greece," in which he proposed to test by early Greek facts the theory of the history of kinship set forth in *Primitive Marriage*, and, three years later, a series of essays on "Totemism" (*Fortnightly Review*, 1869-70) (the germ of which had been contained in the paper just named), which mark the second great step in the systematic study of early society, to which the energies of his life were now devoted. A reprint of *Primitive Marriage*, with "Kinship in Ancient Greece" and some other essays not previously published, appeared in 1876 under the title of *Studies in Ancient History*. The new essays contained in this volume were mostly critical, but one of them, in which perhaps his guessing talent is seen at its best, on "The Divisions of the Irish Family," is an elaborate discussion of a problem which has long puzzled both Celtic scholars and jurists; and in another, "On the Classificatory System of Relationship," he propounded a new explanation of a series of facts which, he thought, might be made to throw a flood of light upon the early history of society, at the same time putting to the test of those facts the theories he had set forth in *Primitive Marriage*. Papers on "The Levirate and Polyandry," following up the line of his previous investigations, appeared in the following year (*Fortnightly Review*, 1877), and were the last work he was able to publish. From 1872 to 1875 his literary plans were much interrupted by his duties as parliamentary draftsman for Scotland, and when he retired from this office his health was broken; his last years were chiefly spent abroad, and in spite of the self-denying assistance of his second wife (his first wife, a daughter of M'Culloch the political economist, died in 1870, and he married again in 1875) the vast materials which he had accumulated for a comprehensive work on his favourite subjects were left only partially worked up, though the publication of his remains may still be looked for. He died 14th June 1881. In private life M'Lennan was distinguished by his remarkable powers of conversation, by an uncompromising sense of duty, especially of duty to truth, by a warm and affectionate disposition, and by his readiness to help all workers in science, especially young men of promise. Besides the works already cited, M'Lennan wrote *Life of Thomas Drummond* (Edinburgh, 1867). His later labours had for immediate object the solution of the origin of exogamy—that is, of laws prohibiting the marriage of relations (laws of incest); and in connexion with this he had prepared materials for a description of the social state of the less advanced races of men (keeping totemism in view as it bore on the history of society rather than the history of religion), which, he believed, would throw much light on the history of marriage and the family, of kinship, and laws of inheritance.

MACLEOD, Norman (1812-1872). There were three Norman Macleods, all ministers of the Church of Scotland, and all men of some note in their day. The first was settled in Morven, the "Highland parish," looking out on the Sound of Mull, of which his grandson has given us so many pleasant and sunny reminiscences. The second was minister of Campbeltown, afterwards of Campsie, and finally of St Columba's Gaelic Church in Glasgow, an able Celtic scholar and popular preacher, with a dash of dry humour in him, and general Highland "pawkiness." The third Norman was born in Campbeltown on June 3, 1812, and, like his father, he too could tell a good story, only his humour was not of the pawky kind, but verged on caricature, when it had not, as it mostly had, a vein of pathos in it; for he had received, probably from his mother, Agnes Maxwell, a richer blood and a larger life than we can trace in his more purely Celtic ancestry.

A sunny, light-hearted youth, full of jest and song, given to miscellaneous literature rather than to accurate scholarship or professional learning, would hardly seem to have been the kind of training to prepare for the life of an eloquent preacher and earnest pastor. Yet the broad human sympathies which were thus fostered were, after all, more serviceable for the work that lay before him than a knowledge of the Greek drama or of Dutch divinity; and, though he was never much of a scholar or a theologian, he was out and out a man, which is of more consequence in the long run. He had also moved about, and seen a good deal of the world in Highland Morven, in Glasgow, in Edinburgh, in England, and in Germany, when in 1838, on the recommendation of Dr Chalmers, he was presented by the dowager marchioness of Hastings to the parish of Loudoun, and began his ministry among a curious combination of Davie Deanses and Silas Marners—covenanting small farmers and Chartist hand-loom weavers. There, in the small rural parish, his work had the same characteristic features as in the larger sphere which afterwards opened up to him in the Barony church and in general literature. He carefully prepared for his pulpit, yet he was most eloquent when most spontaneous, for he was naturally more of a speaker than a writer. Courteous and chivalrous, yet also homely and ready-witted, he was as much liked by the radical weavers as he was honoured and trusted by the marchioness and her family. And if his natural gaiety of heart, which now and then amounted to rollicking animal spirits, gave him an occasional twinge of conscience which is duly recorded in his secret diary, that only shows that his genuine piety had not yet harmonized his whole nature, as it afterwards did, blending the grave and gay in one beautiful human service.

When he began his ministry, the troubles in the Scottish Church were already gathering to a head, and he found himself compelled to look around, and choose his ground. He wanted to get for the church all that Chalmers and his friends wanted. He felt that the best men, both lay and cleric, were with them, and against himself. He had no love for lay patronage, and he wished the church to be free to do its proper work. But more than all else he clung in those days to the idea of a national Established Church; and it was not without a sinking of heart that he saw the long array file out of the Assembly of 1843 after Drs Welsh and Chalmers. Yet he girded himself up for the task that had now to be done with courage and wisdom. It was a heavy job to fill four hundred and thirty pulpits with such materials as came to hand, mostly men who had already failed, and practically given up the profession. For years Macleod, and those who worked with him, toiled almost despairingly to inspire them with any living interest in the real business of the Christian Church. But in the long run his labours were crowned with a large measure of success, though his own brethren to the last hardly gave him the credit for it which was due almost to him alone—to him, at any rate, above all others. With his broad sympathies he flung himself upon the masses, and taught the working men to feel that the Church of Scotland was still as interested in their wellbeing as any denomination. Discerning also that the harder forms of Calvinism had no longer the hold on their minds that they once had, he made room for the thoughtful teachings of his cousin, Dr John Macleod Campbell, whom the Evangelical party had formerly cast out as a heretic, gaining by this means not a little influence with the young and inquiring intellects of the country. And finally, by his efforts to diffuse a wholesome religious literature through the land, he so identified his church with the growing spirit of the age that at length he lived to see it, not indeed the strong and united community which in his youth practically controlled the nation, but yet once more a great power, dear to the hearts of many of the people, and doing good Christian service to the land.

It may be doubted if the work which Norman Macleod did for Scotland could have been done in his day without the disruption of the church. For the Evangelical party, using that word in its technical sense, had not only gained the confidence of the people by much faithful service, but also had confirmed their power by somewhat sharp treatment of all who differed from them. It needed a different kind of church to tolerate the views of Macleod Campbell; but as these were now, more or less, identified with the living element in the kirk, with those who were most diligent in parochial work, and most zealous in mission enterprise, they gradually established their right to be preached in Calvinistic pulpits. Norman Macleod, of course, was not long left to expend his energies on the weavers of Loudoun. Removing first to Dalkeith, he was finally, in 1851, called to the Barony church, Glasgow, where the rest of his days were passed, in honour and influence, as the foremost of its citizens. There the more liberal theology rapidly made way among a people who judged it more by its fruits than its arguments. And, as they heard his eloquent voice pleading on behalf of churches and schools for the poor, penny savings banks, foreign missions, and every likely scheme for doing good to men, they learned to look without suspicion at opinions which yielded such Christian results.

Two other events also helped not a little to increase his influence. These were his position as editor of *Good Words*, and his relation to the queen and the royal family.

In 1860 a magazine was projected which was to deal with subjects common to all, only with a decidedly religious tone. It was not for Sunday only, nor was it for Christians only; but it was to be broadly human, and at the same time clearly pious. For the conducting of such a magazine Macleod was singularly well qualified. Not that he had yet attained any great literary position, or indeed was ever likely to do so. He had written some ecclesiastical pamphlets, amusing but not weighty. He had edited the *Edinburgh Christian Magazine*, without achieving any marked success. His best work as yet was the life of his friend and brother-in-law, John Mackintosh. But nothing human was foreign to him, and "good words," on things in general, were just the words that he could make quick and powerful. Very soon *Good Words* came to be by far the most popular magazine of the day. Nearly all his own literary work, by which he will be judged in other times, appeared in its pages,—sermons, stories, travels, novels, poems,—all of them honest "good words" which it was wholesome to read. But they hardly give him a name in literature,—at least, not such a name in the future as he had while he was still alive. They were too much the hurried productions of a life busy with many affairs. The short stories, like "Wee Davie" and "Billy Buttons," are those which are most likely to retain a place in letters, on account of their mingled humour and pathos. Of his more studied works "The Starling" is perhaps the best; but, while he could tell a brief tale admirably, he could not sustain a long narrative, with its play of varied character and incident; and, instead of leaving his art to read its own lesson, he preached a sermon by means of a story. Always, indeed, it is evident that he was more of an orator than a writer. The best of his poems is the hymn "Trust in God and do the right," though the "Curling" song has the right ring of the stones rattling over the ice. Altogether, his work was honest and good, not the highest in point of literary finish, but wholesomer than much that is more perfect in its form.

While *Good Words* made his name widely known, and helped the cause he had so deeply at heart, his relations with the queen and the royal family strengthened yet further his position in the country. Never since Principal Carstairs had any Scotch clergyman been on such terms with his sovereign; and their friendship was felt to be alike honourable to both, resting, on her part, on esteem for his work and character, and on his, on a loyal desire to serve his queen as a Christian minister may. All this helped not a little to increase his influence in the councils of the church, and to restore its prestige, which had for a time been nearly overthrown; and yet, while his popularity was in full swing, one unlucky piece of honesty made him for a time the man in all Scotland most profoundly distrusted.

Scotch Sabbatarian ideas had been a good deal disturbed by the running of Sunday trains and by other novelties, and in 1865 the presbytery of Glasgow issued a pastoral letter on the subject to be read from all the pulpits there. Macleod, of course, loved the day of rest as much as any of them, but he did not like the grounds on which they rested it, nor yet the spirit in which they would have it observed. Therefore he resolved to deliver his mind on the subject to his brethren. Like St Paul, he refused to let any man judge him concerning "new moons and Sabbaths." His speech was not at first well reported, those parts only being printed which were most likely to startle the religious public; and in consequence it was, for a while, greatly misunderstood. Old friends shrunk from him. His house seemed to be shunned as if plague-stricken. His brethren in the presbytery threatened a "libel" for heresy. And he needed all his courage to bear up against the outcry which assailed him on all hands. A more correct version of the speech was issued, however, and the good sense and Christian intelligence of the people soon learned to form a juster estimate of its real bearing. The threatened prosecution broke down. Truer ideas of Sabbath observance got a lodgment in men's minds. And, four years after, the church, which at one time seemed ready to cast him from her bosom, accorded him the highest honour in her power to give, by choosing him as moderator of her General Assembly.

Before that, however, he had already gained her confidence so far as to be sent, along with Dr Archibald Watson, to India to inquire into the state of her mission there. He had always taken a deep interest in the India mission, and had been for some time convener of the committee which took charge of its interests. When asked to undertake this duty, he was already labouring under the disease which afterwards shortened his days; his medical advisers were not without grave anxieties as to the effect of the climate on his constitution, and it was with clear consciousness of the risk he ran that, in 1867, he sailed for the East. He returned fully resolved to devote the rest of his days largely to the work of rousing the church to her duty in carrying out "the marching orders" of her Commander. But he was not destined to do much more for the cause that lay so near his heart than to make one or two stirring appeals to the conscience of the church. His health was now broken, and his old energy flagged. Always his habits of work had been somewhat irregular; properly, indeed, he had no fixed habits, but only tremendous fits of labour and periods of exhaustion. Now neither body nor brain could stand this strain, and with reluctance and pain he had to give up the charge of the India mission. His speech in doing so was the last and greatest he ever made. It was as if he had gathered up his failing powers for one final effort, and spent his life on it. Shortly after his return from the Assembly of May 1872, his disease showed some fresh symptoms that alarmed the doctors. And on Sunday the 16th of June, shortly after completing his sixtieth year, Norman Macleod peacefully fell asleep, the country hardly knowing how it had loved him till he was borne to his quiet resting-place in Campsie churchyard.

Memoir of Norman Macleod, D.D., by his brother, the Rev. Donald Macleod, 2 vols., appeared in 1876. (W. C. S.*)

MACLISE, DANIEL (1806 or 1811–1870), subject and history painter, was born at Cork, the son of a Highland soldier.[1] His education was of the plainest kind, but he was eager for culture, fond of reading, and anxious to become an artist. His father, however, placed him, in 1820, in Newenham's Bank, where he remained for two years, and then left to study in the Cork school of art. In 1825 it happened that Sir Walter Scott was travelling in Ireland, and young Maclise, having seen him in a bookseller's shop, made a surreptitious sketch of the great man, which he afterwards lithographed. It was exceedingly popular, and the artist became celebrated enough to receive many commissions for portraits, which he executed, in pencil, with very careful treatment of detail and accessory. Various influential friends perceived the genius and promise of the lad, and were anxious to furnish him with the means of studying in the metropolis; but with rare independence he refused all aid, and by careful economy saved a sufficient sum to enable him to leave for London. There he made a lucky hit by a sketch of the younger Kean, which, like his portrait of Scott, was lithographed and published. He entered the Academy schools in 1828, and carried off the highest prizes open to the students, including, in 1829, the gold medal for the best historical composition. In the same year he exhibited for the first time in the Royal Academy. Gradually he began to confine himself more exclusively to subject and historical pictures, varied occasionally by portraits of Campbell, Miss Landon, Dickens, and other of his celebrated literary

[1] The year of his birth is uncertain; he himself used to assert that the 25th of January 1811 was the correct date, but research in the register of the old Presbyterian church in Cork seems to prove that he was born on 2d February 1806.

friends. In 1833 he exhibited Snap Apple Night, or All Hallow Eve in Ireland, and Mokanna Unveiling his Features to Zelica, which greatly increased his reputation, and were followed in the succeeding year by the powerfully dramatic subject of the Installation of Captain Rock, and in 1835 by the Chivalric Vow of the Ladies and the Peacock, a work which procured his election as associate of the Academy, of which he became full member in 1840. The years that followed were occupied with a long series of figure pictures, deriving their subjects from history and tradition, and from the works of Shakespeare, Goldsmith, and Le Sage. He also designed illustrations for Moore's *Irish Melodies*, Lytton's *Pilgrims of the Rhine*, and several of Dickens's Christmas books, and for *The Story of the Norman Conquest* and Shakespeare's *Seven Ages*, published by the Art Union. Between the years 1830 and 1836 he contributed to *Fraser's Magazine*, under the *nom-de crayon* of Alfred Croquis, a very remarkable series of portraits of the literary and other celebrities of the time,—character studies, etched or lithographed in outline, and touched more or less with the emphasis of the caricaturist, which have been since reproduced and published in a volume. In 1858 Maclise commenced one of the two great monumental works of his life, the Meeting of Wellington and Blücher, on the walls of Westminster Palace, where he had previously painted his Spirit of Religion and his Spirit of Chivalry. It was begun in fresco, a process which proved unmanageable. The artist wished to resign the task; but, encouraged by Prince Albert, he studied in Berlin the new method of "water-glass" painting, and carried out the subject and its companion, the Death of Nelson, in that medium, completing the latter painting in 1864. The intense application which he gave to these great historic works, and the various depressing and discouraging circumstances connected with the commission, had a serious effect on the artist's health. He began to shun the company in which he formerly delighted; his old buoyancy of spirits was gone; and when, in 1865, the presidentship of the Academy was offered to him, he declined the honour. In 1868 he exhibited the Sleep of Duncan, and in 1869 his King Cophetua and the Beggar Maid. Having finished the Earls of Desmond and Ormond, he was attacked by acute pneumonia, which carried him off, after a brief illness, on the 25th April 1870.

The works of Maclise are distinguished by powerful intellectual and imaginative qualities, but most of them are marred by harsh and dull colouring, by metallic hardness of surface and texture, and by frequent touches of the theatrical in the action and attitudes of the figures. His fame rests most securely on his two greatest works at Westminster. A memoir of the artist by his friend W. J. O'Driscoll was published in 1871.

MACLURE, William (1763–1840), the pioneer of American geology, was born at Ayr in Scotland in 1763. After a brief visit to New York he began active life as a partner in the firm of Miller, Hart, & Co., London. Four years later (1796) business affairs brought him again to America, which he thereafter made his home. In 1803 he visited France as one of the commissioners appointed to settle the claims of American citizens on the French Government for spoliations committed during the Revolution; and during the few years then spent in Europe he applied himself with enthusiasm to the study of geology. On his return home he commenced the self-imposed task of making a geological survey of the United States. Almost every State in the Union from the St Lawrence to the Gulf of Mexico was traversed and mapped by him, the Alleghany mountains being crossed and recrossed some fifty times. The results of his unaided labours were submitted in a memoir to the American Philosophical Society (1809), and published in the Society's *Transactions* (vol. vi.), together with a geological map, which thus antedates William Smith's great geological map of England by six years. Subsequent survey has corroborated the general accuracy of Maclure's observations, so far at least as the Primary and Secondary formations are concerned. From 1817 to his death Maclure was president of the Academy of Natural Sciences of Philadelphia, and much of the prosperity of the institution was due to his devoted services. In 1819 he visited Spain, and attempted to establish an agricultural college near the city of Alicante; but with the overthrow of the short-lived Liberal constitution his plans became hopelessly deranged. Returning to America in 1824, he settled for some years at New Harmony, Indiana, endeavouring, but with small success, to develop his scheme of the agricultural college. Failing health ultimately constrained him to relinquish the attempt, and to seek (in 1827) a more congenial climate in Mexico. There, at San Angel, he died March 23, 1840.

His great geological memoir was issued separately, with some additional matter, in 1817; and in 1837 he published a collection of essays, in 2 vols., mainly on political economy, entitled *Opinions on Various Subjects*. His other original papers, including observations on the geology of the West Indies and of Mexico, and remarks on the origin and arrangement of rocks, were published in the *Journal of the Academy of Natural Sciences* (Philadelphia), in Silliman's *American Journal of Science and Arts*, and in the French *Journal de Physique*.

MACNEE, Sir Daniel (1806–1882), portrait painter, was born in 1806 at Fintry in Stirlingshire. He was educated in Glasgow, and at the age of thirteen apprenticed, along with Horatio Macculloch and Leitch the water-colour painter, to John Knox, a landscapist of some repute at the time. He afterwards worked for a year as a lithographer, was employed by the Messrs Smith of Cumnock to paint the ornamental lids of the planewood snuff-boxes for which their manufactory was celebrated, and, having studied in Edinburgh at the "Trustees' Academy," supporting himself meanwhile by designing and colouring book illustrations for Lizars the engraver, he established himself as an artist in Glasgow. At first he was occupied a good deal with figure pictures, but the increasing demands on his time as a fashionable portrait painter eventually left him little leisure for this branch of art. He was one of the twenty-four associates of the Royal Institution who, in 1829, were admitted members of the Royal Scottish Academy; and on the death of Sir George Harvey in 1876 he was elected president, and received the honour of knighthood, and the degree of LL.D. from the Glasgow University. From this period till his death, on the 18th of January 1882, he resided in Edinburgh, where his genial social qualities and his inimitable powers as a teller of humorous Scottish anecdote rendered him popular. Among his portraits may be mentioned those of Lord Brougham, Viscount Melville, Lord Inglis, and Mrs Bough. His Dr Wardlaw obtained a gold medal at the Paris International Exhibition of 1855.

MACNEILL, Hector (1746–1818), a minor Scottish poet, born near Roslin, October 22, 1746, died at Edinburgh, March 15, 1818. The son of an impoverished army captain, he spent several years of his boyhood on a farm which his father had taken on the banks of Loch Lomond, and was sent to Bristol at the age of fourteen to enter on a mercantile career. Soon afterwards he was despatched to the West Indies, where he remained many years without ever enjoying even a moderate prosperity. When about forty he returned to Scotland with the intention of devoting himself to a literary life, but his ill fortune still pursued him, and he was obliged to go back to Jamaica. The kindness of two friends enabled him soon to come home again to Scotland, and on the journey he finished *The Harp, a Legendary Tale*, published at Edinburgh in 1789. After six years spent at Edinburgh, rendered miserable by shattered health and depressed spirits, he retired to the house of a friend at Stirling, where he wrote most of his songs and his *Scotland's Skaith, or the History of Will and Jean*, a narrative poem intended to show the deteriorating influences of whisky and pot-house politics, which appeared in 1795, and at once made its author popular, having passed through fourteen editions within the year. A sequel, *The Ways of War*, appeared next year, and in 1799 *The Links of Forth, or a Parting Peep at the Carse of Stirling*, a somewhat feeble descriptive poem, intended as a parting tribute to his kind host before his own departure for Jamaica. Not long after his arrival an early friend settled on him an annuity of £100, which enabled the poet to return soon afterwards to Scotland, and so close his long struggle against adversity with fifteen years of comparative comfort at Edinburgh.

In 1800 he published *The Memoirs of Charles Macpherson, Esq.*, a novel understood to be a close narrative of his own hardships and adventures. His later works, which added little to his fame, were —*The Pastoral or Lyric Muse of Scotland*, 1809; two anonymous works in verse entitled *Town Fashions, or Modern Manners Delineated*, and *Bygone Times and Latecome Changes*, and *The Scottish Adventurers*, a novel. He left behind an autobiography still unpublished, but of which an abstract appeared in *Blackwood's Magazine* for December 1818. A complete edition of the poems he wished to own appeared in 1812, and it is on these that his fame will rest. His songs, "Mary of Castlecary," "Come under my plaidy," "My boy, Tammy," "O tell me how for to woo," "I lo'ed ne'er a lassie but ane," "The plaid amang the hether," and "Jeanie's black e'e," will live, spite of Allan Cunningham, for their sweetness and simplicity, while his *Will and Jean*, quite apart from its excellent intention and tendency, will maintain a place among the most characteristic productions of the Doric Muse in Scotland.

MACON, the capital of Saône-et-Loire, France, occupies a gently sloping site on the right bank of the Saône, 41 miles north of Lyons. It is connected by a bridge of twelve arches with the suburb of St Laurent on the opposite bank of the river. The site is sheltered and the climate mild, but the locality is subject to sudden changes of temperature. Of the public buildings of Macon the most prominent is the old church of St Pierre, reconstructed in 1866,—a three-naved basilica, 328 feet in length, with two fine spires. Of the old cathedral, destroyed at the Revolution, nothing remains but the façade, portions of the two towers, and a narthex of the 12th century, now used as a chapel. The old episcopal palace, which has been rebuilt, is now used as the prefecture. The hospital is from designs by Soufflot; the lyceum bears the name of Lamartine (a native of Macon, to whom there is a statue). The town house contains a library of 7000 volumes, and a museum. Macon is a railway centre of considerable importance, being the point at which the line from Paris to Marseilles is joined by that from Mont Cenis and Geneva, as well as by a branch from Digoin. The industries of the place include brass-founding, the manufacture of agricultural implements, weighing-machines, and the like, printing, dyeing, and the production of faience. The principal articles of commerce are wine, barrels and hoops, and grain. The population in 1876 was 17,570.

Macon (*Matisco*) was an important town of the Ædui, but under the Romans it was supplanted by Autun and Lyons. It suffered a succession of disasters at the hands of Germans, Burgundians, Vandals, Huns, Hungarians, and even of the Carlovingian kings. In 1228 it was sold to the king of France, but more than once afterwards passed into the possession of the dukes of Burgundy, until the ownership of the French crown was fixed in the time of Louis XI. In the 16th century Macon became a stronghold of the Huguenots, sided with the League, and did not yield to Henry IV. until 1594. The bishopric, created by King Childebert, was suppressed in 1790.

MACON, a city of the United States, the chief town of Bibb county, Georgia, is situated on rising ground in the midst of a beautifully wooded country on both sides of the Ocmulgee river, a navigable headwater of the Altamaha, about 80 miles south-east of Atlanta. It is well laid out with tree-bordered streets, often 180 feet wide, and possesses since 1870 a fine central park, on the formation of which $125,000 were expended. The principal institutions in the town are the State academy for the blind (1852), the Mercer university (a Baptist foundation, 1838), the Wesleyan Female College (1839), the Pio Nono (Roman Catholic) College, and the Southern Botanico-Medical Institute. As an important junction for the Georgia, the Georgia Central, and the South-Western Railways, and communicating with the coast by the direct line to Brunswick, Macon enjoys great facilities for trade; and, besides its extensive railway machine-shops, it has cotton factories, iron foundries, flour-mills, and sash and blind factories. The annual fair held in the Central Park is the great meeting-place of the Georgian planters. From 5720 in 1850 the population has steadily advanced to 8247 in 1860, 10,810 in 1870, and 12,748 in 1880. The foundation of the town dates only from 1823.

MACPHERSON, James (1738–1796), the "translator" of the Ossianic poems, was born at Ruthven, Inverness, Scotland, in 1738, was educated in his native village and at King's College, Aberdeen, and from 1756 taught the school of Ruthven for some time. In 1758 he published a poem entitled the *Highlander*, and about the same period contributed several minor pieces to the *Scots Magazine*. In 1759, while residing with a pupil at Moffat, he became accidentally known to Dr Carlyle of Inveresk and Mr Home, the author of *Douglas*, both of them already interested in the subject of ancient Highland poetry; some fragmentary "translations" from the Gaelic, which in the course of a few days he supplied to Home, were much appreciated in the literary circles of Edinburgh, and in 1760 a volume was published by Macpherson, entitled *Fragments of Ancient Poetry collected in the Highlands of Scotland, and translated from the Gaelic or Erse Language*, with a preface by Dr Blair. A sum of money was now subscribed by the faculty of advocates for the purpose of enabling Macpherson to go to the Scottish Highlands in search of other fragments, and the result of his labours was the publication at London in 1762 of *Fingal, an Epic Poem, in six books, with other lesser Poems*, dedicated to Lord Bute; this was followed in 1763 by *Temora*, in eight books, with several other poems. For the real character of these publications see Celtic Literature, vol. v. p. 313–4. At the time of their appearance they greatly advanced the translator both in fame and fortune; in 1764 he was appointed surveyor-general of the Floridas, and on his return to England two years afterwards he was permitted to retain for life the salary of the office. In 1771 he published *An Introduction to the History of Great Britain and Ireland*, and in 1775 *A History of Great Britain from the Restoration to the Accession of the House of Hanover* (2 vols. 4to) and *Original Papers containing the Secret History of Great Britain* for the same period (also in 2 vols. 4to). His translation of the *Iliad*, published in 1773, was greatly praised by Robertson and others in Scotland, but met with a severe reception in England, and has not stood the test of time. About 1779 he was appointed to the lucrative post of agent for the nabob of Arcot, and from 1780 onwards he sat in parliament for the borough of Camelford. He died at Belleville, an estate which he had recently purchased in Inverness, on February 17, 1796, and was buried in the Poets' Corner at Westminster Abbey. His will had provided for the publication of the Ossianic poems in the original Gaelic, which he is understood to have been preparing for the press at the time of his death; and the work accordingly appeared in 3 vols. 8vo, in 1807, with a literal translation into Latin, by Robert Macfarlane, and a dissertation on the authenticity of the poems, by Sir John Sinclair.

MACREADY, WILLIAM CHARLES (1793-1873), was born in London 3d March 1793, and educated at Rugby. His intention was to proceed to Oxford, but the embarrassed affairs of his father, the lessee of several provincial theatres, called him to share the responsibilities of theatrical management, in which he showed great prudence and address. In 1810 he made a successful debut as Romeo at Birmingham; and the fame which he had acquired in the provinces gave exceptional interest to his appearance in 1816 at Covent Garden, in the character of Orestes in the *Distressed Mother*. In London his choice of characters was at first confined chiefly to the romantic drama, but he showed his capacity for the highest tragic parts when he played Richard III. at Covent Garden in 1819, and in the following year his performance of Virginius, in the new play of Sheridan Knowles, assisted to give solidity to his reputation. Transferring his services to Drury Lane, he gradually rose in public favour, till, on the retirement of Kean and Young, he was regarded as the legitimate successor of these tragedians. In 1826 he completed a successful engagement in America, and in 1828 his performances met with a very flattering reception in Paris. Already he had done something to encourage the creation of a modern English drama through the interest awakened by his performances in *Virginius*, *Gaius Gracchus*, and *William Tell*, and after entering on the management of Covent Garden in 1837 he introduced, besides other new plays, Bulwer's *Lady of Lyons* and *Richelieu*, the principal characters of which were among his most effective parts. Both, however, in his management of Covent Garden, which he resigned in 1839, and of Drury Lane, which he held from 1841 to 1843, he found his designs for the elevation of the stage hampered and finally frustrated by the sordid aims of the proprietors and the absence of adequate public support. In 1843-44 he made a prosperous tour in the United States, but his last visit to that country, in 1849, was marred by a riot at the Astor Opera House, New York, arising from the jealousy of the actor Forrest, and resulting in the death of twenty-two persons, who were shot by the military called out to quell the disturbance. Macready retired from the stage in 1851; and the remainder of his life was occupied chiefly in superintending the education of his family, and in schemes for the welfare of the poorer classes. He died at Cheltenham 27th April 1873.

Macready's performances always displayed fine artistic perceptions developed to a high degree of perfection by very comprehensive culture, and even his least successful personations had the interest resulting from thorough intellectual study. He belonged to the school of Kean rather than of Kemble; but, if his tastes were better disciplined and in some respects more refined than those of Kean, his natural temperament did not permit him to give proper effect to the most characteristic features of the great tragic parts of Shakespeare, *King Lear* perhaps excepted, which in some degree afforded scope for his pathos and tenderness, the qualities in which he specially excelled. With the exception of a voice of good compass and capable of very varied expression, Macready was not in a special degree gifted physically for acting, but the defects of his face and figure cannot be said to have materially influenced his success. He created a considerable number of parts, which still retain their hold on the stage, and, although not by virtue of natural genius worthy of a place among tragedians of the first rank, he is almost entitled to this on account of the high degree of perfection to which he had cultivated his powers, and from the fact that there is no tragedian of the second rank who can be named his equal. See *Macready's Reminiscences*, edited by Sir Frederick Pollock, 2 vols., 1875.

MACROBIUS, AMBROSIUS THEODOSIUS, a Roman grammarian and philosopher, who wrote towards the beginning of the 5th century after Christ. He is described in the superscription of the best MSS. as *vir clarissimus et illustris*; hence it has been supposed that he is the Macrobius who was *præfectus prætorius Hispaniarum* in 399 A.D., proconsul of Africa in 410, and chamberlain (*præpositus sacri cubiculi*) in 422. But the tenure of high office at that date was limited to Christians, and there is no evidence in the writings of Macrobius that he was a Christian. On the contrary, he shows great interest in the deities of paganism; his friends seem to have belonged wholly to the pagan party; and his philosophical views are those of the Neo-Platonists. Hence the identification is more than doubtful. It is possible, but by no means certain, that he was the Theodosius to whom Avianus dedicates his fables. From the date of the persons who are mentioned by him as contemporaries, he appears to have flourished in the time of Honorius.

The most important of his works is the *Conviviorum Saturnaliorum Libri Septem*, containing an account of the discussions held at the house of Vettius Prætextatus during the holiday of the Saturnalia. The latter part of the second book and the beginning of the third, the second half of the fourth book, and the end of the seventh have been lost; otherwise the work is in fairly good preservation. It was written by the author for the benefit of his son Eustachius, and contains a great variety of curious historical, mythological, critical, and grammatical disquisitions, the value of which is much increased by the frequent quotations from earlier writers. The machinery is somewhat cumbrous; for, as in some of Plato's dialogues, the discussions are not directly reported, but a certain Postumianus reproduces, for his friend Decius, the account which he had received from a rhetorician Eusebius, who had been present at them. There is but little attempt to give any dramatic character to the dialogue; in each book some one of the personages takes the leading part, and the remarks of the others serve only as occasions for calling forth fresh displays of erudition. The first book is devoted to an inquiry as to the origin of the Saturnalia and the festivals of Janus, which leads to a history and discussion of the Roman calendar, and to an attempt to derive all forms of worship from that of the sun. The second book begins with a collection of *bons mots*, to which all present make their contributions, many of them being ascribed to Cicero and Augustus; it then appears to have passed into a discussion of various pleasures, especially of the senses; but almost the whole of this is lost. The third, fourth, fifth, and sixth books are devoted to Virgil, dwelling respectively on his learning in religious matters, his rhetorical skill, his debt to Homer (with a comparison of the art of the two) and to other Greek writers, and the nature and extent of his borrowings from the earlier Latin poets. The latter part of the third book is taken up with a dissertation upon luxury and the sumptuary laws intended to check it, which is probably a dislocated portion of the second book, being entirely out of place where it stands. The seventh book is of a more miscellaneous character, consisting largely of the discussion of various physiological questions. The value of the work consists solely in the facts and opinions quoted from earlier writers, for it is purely a compilation, and has little in its literary form to recommend it.

We have also two books of a commentary on the *Somnium Scipionis* narrated by Cicero in his *De Republica*. The nature of the dream, in which the elder Scipio appears to his (adopted) grandson, and describes the life of the good after death and the constitution of the universe from the Stoic point of view, gives occasion for Macrobius to discourse upon many points of physics in a series of essays interesting as showing the astronomical notions then current. The moral elevation of the fragment of Cicero thus preserved to us gave the work a popularity in the Middle Ages to which its own merits have little claim.

There is a good critical edition of Macrobius, with a commentary by L. van Jan (2 vols., Leipsic, 1848-52), and a convenient and excellent edition of the text by F. Eyssenhardt (Leipsic, 1868).

MADAGASCAR

Plate IV.

MADAGASCAR, an important island in the Indian Ocean, and the third largest island in the world, is about 300 miles from the south-east coast of the African continent, from which it is separated by the Mozambique Channel. It is 980 miles in length from north to south, the northern point, Cape Ambro, in 12° S. lat., inclining 16° to the east from the longitude of Cape St Mary, the southernmost point, in 25° 35′ S. lat., so that the main axis of the island runs from north-north-east to south-south-west. The broadest portion of Madagascar is near the centre, where it is nearly 350 miles across, and there it is only 230 miles distant from the African coast. From this part of the island its northern half forms a long irregular triangle, while south of it the average breadth is about 250 miles. Its total area is nearly 230,000 square miles, or not quite four times the extent of England and Wales.

Size and position.

Explora-tion.

Although known to Arab merchants for more than a thousand years past, and frequently visited by Europeans since the beginning of the 16th century, Madagascar is still but imperfectly explored. A careful survey of the coast was made in 1823–25 by Captain W. F. W. Owen, R.N., but all maps of the interior up to about ten years ago were constructed on the most insufficient data. But during the last decade many portions of the island previously unknown have been traversed by missionaries and naturalists, and maps, more or less detailed, have been prepared of a considerable portion of the interior. Conspicuous in this work have been the missionaries of the London Missionary Society and the Friends' Foreign Mission, especially the late Rev. Dr Mullens, whose large map, published in 1879, embodied all that was known up to that date, and also M. Alfred Grandidier, a French traveller and scientist, whose great work on the island is now in process of publication.

Bays.

Madagascar has a very regular and compact form, with but few indentations considering its great extent of shoreline. Along two-thirds of its eastern side the coast is almost a straight line, without any inlet, for Tamatàve and Foule Pointe, which are the most frequented ports on this side of the island, are only open roadsteads protected by coral reefs. North of this, however, is Antongil Bay, a deep and wide inlet running northwards for about 50 miles; farther north is Port Louquez, and at the extreme point of the island is Diego Suarez Bay, one of the finest harbours in the world. The north-western side of Madagascar is broken up by a number of spacious inlets, some of them landlocked and of considerable size. Going southward, these are the bays of Chimpaiky, Pàsandàva, Port Radàma, Narìnda, Majàmbo, Bémbatòka, and Ibòina, as well as the estuaries of some of the rivers. South of Cape St Andrew, the north-west angle of the island, there is nothing else in the shape of a gulf until we reach the estuary of the river Onilàhy, or St Augustine's Bay. Rounding the southern end of the island, we find no other inlet until we come to the small bay of Itapéra near Fort Dauphin, at the southern extremity of the straight line of coast already mentioned.

Islands.

The islands around Madagascar are few and unimportant. The largest are St Marie's, near the eastern coast, a narrow island about 30 miles long, and Nòsibé, larger and more compact in form, opposite Pàsandàva Bay on the north-west coast. Except the Minnow group, north of Nòsibé, the rest are merely rocky islets, chiefly of coral.

Moun-tains.

Much light has been thrown upon the physical geography of Madagascar by recent explorations. In most accounts, up to a very short time ago, a "central mountain chain" is described as running throughout the island as a sort of backbone from north to south; and most maps show this, with numerous branches extending in various directions. It is, however, now quite clear that instead of this supposed mountain chain there is an elevated mountainous region, from 3000 to 5000 feet in altitude, occupying from a third to two-fifths of the whole interior, but lying more towards the north and east. Around this upper region are extensive plains, at a much less elevation above the sea, and most developed on the western side of the island, and in its southern portion beyond 23° S. lat. But this lower region is not entirely level, as it is broken up towards the west by three prominent lines of hills running north and south. See Plate IV.

The shores of the greater portion of the southern half of the island are low and flat, but in the northern half much of the coast is bold and precipitous, the high land often approaching the sea. On the eastern side the plains vary from 10 to 50 miles in breadth, but on the western side they often exceed 100 miles across. From these coast plains the ground rises by successive ranges of hills to the high interior land. This elevated region is broken up in all directions by mountains, the highest in the island being centrally situated as regards its length, but more to the eastern side. These are the summits of the basaltic mass of Ankàratra, four of the peaks ranging in elevation from 8100 to 8950 feet above the sea, and from 3900 to 4700 feet above the general level of the surrounding country. The loftiest of these is named Tsi-àfa-jàvona, *i.e.*, "that which the mists cannot climb." Besides these highest points there are a considerable number of mountains in the central provinces, varying in height from 5000 to 7000 feet, the highest as yet measured being Iàvohàika ("the Lofty defying one"), 7100 feet high, about 30 miles west-south-west of Ankàratra, and the highest point of a remarkably rocky and rugged district named Vàvavàto ("Stonemouth"). There are also very many lofty and grand peaks in the Bétsiléo province, some, it is said, nearly 8000 feet high; and in the Bàra country the Isàlo mountains are compared by a recent traveller to the "Church Buttes" and other striking features of the scenery of Utah, on the line of the Pacific Railway. One of the grandest of all the Madagascar peaks is an isolated mountain near the northern point of the island, called Amber or Ambòhitra. This is said to be more than 6000 feet high, and, rising, not as do those before-mentioned, from an elevated plateau, but from plains little above the sea-level, is a remarkably majestic hill as observed from every direction, and is well seen far out to sea.

Valleys and hydro-graphy.

In the elevated region of Madagascar are many fertile plains and valleys. Among these are Bétsimitàtatra in Imérina, and Tsiénimparìhy in Bétsiléo, supplying a large proportion of the rice for the capitals of these two provinces. Still more extensive valleys are the plain of the Antsihànaka country, the valley east of Angàvo, and the Ankày district between the two eastern lines of forest (all of which are one step downwards towards the lower coast plains), and the valley east of the Bémaràha range in the Sàkalàva country. Sections across the central portions of Madagascar show that there is a somewhat saucer-like depression in the centre, the eastern and western edges rising higher than the enclosed space. The eastern ridge is the higher of the two, so that the watershed for a considerable distance is much nearer the eastern than the western side, averaging from 50 to 80 miles from the sea. The country is well watered, even in the highest ranges of the interior, the abundant rainfall giving a perennial supply to the innumerable springs and streams. There are, therefore, no extensive districts that can be called desert, except parts of the west and south-west provinces, where the rainfall is scanty. The extreme southern portion is also reported to be arid, but as yet little is accurately known of this part of the country.

Rivers.

As is necessarily the case from the physical conformation

of the interior, the chief rivers flow to the west and north-west sides of the island. The eastern streams are all less in size, except the Mangòro, which flows for some distance parallel with the coast. Few of them, therefore, are of much service for navigation, except for the light-draught native canoes, and almost all of them are more or less closed at their outlets by sand-bars. Commencing at the southern point and going northward, on the eastern side, the principal rivers are the Mànanàra, Mànambavà, Màtitànana, Mànanjàra, Onivé and Mangòro, Màningòry, and the Anjàhanàmbo at the head of Antongil Bay, besides numerous smaller streams. On the north-west coast, going southward, are the Sofia and Màhajàmba, falling into Majàmbo Bay, the Bétsibòka with the Ikiòpa,—the great drains of the northern central provinces, and forming unitedly the second largest river of the island and falling into Bémbatòka Bay,—the Mànjaray, Mànambòlo, Tsìribìhina or Onimàinty, the largest river of Madagascar, draining by its tributaries the Kitsàmby, Màhajìlo, and Manìa the central parts of the island, the Mòrondàva, Màharìvo, Mangòky, the third largest river, the Màhanòmby, Fiherénana, and Onilàhy.

Of these western rivers the Bétsibòka could be ascended by steamers of light draught for about 90 miles, and the Tsìribìhina is also navigable for a considerable distance. The former is about 300 miles long; the latter is somewhat less, but by its affluents spreads over a greater extent of country. It brings down so large a body of water that the sea is said to be fresh 3 miles from the land. But owing to the height of the interior of Madagascar there is no uninterrupted water-communication with it from the sea by any of the rivers, which are all crossed by rocky bars, and in some cases by grand waterfalls, as on the Manìa. The eastern rivers cut their way through the ramparts of the high land by magnificent gorges, amidst dense forest, and descend by a succession of rapids and cataracts. The Màtitànana, whose falls were first seen by the present writer in 1876, descends at one plunge some 400 or 500 feet.

Lagoons and lakes.

On the eastern side of Madagascar the contest between the fresh water of the rivers and the sea has caused the formation of a long chain of lagoons for nearly three hundred miles. In many parts these look like a river following the coast-line, but frequently they spread out into extensive sheets of water. So short is the distance between these that, by cutting about 30 miles of canal to connect them, a continuous water-way could be formed for 260 miles along the coast. This will doubtless be accomplished at some future time, with great benefit to the commerce of the country. Besides these lagoons, there are few lakes of any size in Madagascar, although there were probably some very extensive ones in a recent geological epoch. Of one of the largest of these the Alàotra Lake in the Antsihànaka plain is the relic; it is about 25 miles long. Next comes Itàsy, in western Imérina, about 8 miles long; and a large lake is reported by the natives to be formed by an expansion of the river Mangòky. Two salt lakes are said to exist near the south-west coast.

Volcanic belt.

Among the many new facts brought to light by recent research in Madagascar is the evidence of very widespread and powerful subterranean action throughout a great part of the island, apparently extending almost unbroken from the south-east to the north-west and extreme north. This volcanic belt is part of a line which has its northern extremity in the Comoro Islands, all of which are volcanic in origin, and where, in Great Comoro, there is a still active vent. There is now no active volcano in Madagascar, but a large number of extinct cones have been observed in various parts of the country. In the central province of Imérina, within an arc of about 90 miles round the mass of Ankàratra, Dr Mullens counted a hundred craters. Others are found farther north, in the Antsihànaka province and the Màndritsàra valley, and on the north-west coast and its islands, the great mountain Ambòhitra being an old volcano. Others have been observed towards the southern extremity of the higher region of the island, as well as columnar basalt, and beds of lava rock, pumice, and ash. Slight shocks of earthquake are felt every year in Madagascar, and other signs of subterranean action are evident in the hot springs which occur at several places in the central and eastern provinces. Several of these are sulphurous and medicinal, and have been found efficacious in skin diseases.

Geology.

The geology of Madagascar has as yet been very imperfectly investigated, for few travellers have possessed the special scientific knowledge requisite to give much value to their observations; and hardly anything has yet been done towards making collections of fossils, or in procuring specimens of rocks and minerals. There are, however, a few facts of a general character which are easily recognizable. In the first place, the upper region of the island already mentioned appears to consist chiefly of Primary and unstratified rocks—granite, gneiss, and basalt—which form the highest points of the hills, and present most varied and picturesque outlines, resembling titanic castles, cathedrals, domes, pyramids, and spires. The general face of the country consists of bare rolling moors, with a great amount of bright red and light brown clays, while the valleys have a rich vegetable soil of bluish-black alluvium. No stratified or fossiliferous rocks have yet been discovered in this upper part of the island, which appears to be very ancient land, and during portions of the Secondary and Tertiary periods probably formed the entire island, then about from a third to two-fifths of its present size, while the extensive southern and western plains were again and again submerged.

Fossils and minerals.

The lower portions of Madagascar do not, as far as is yet known, much exceed from 300 to 600 feet in height above the sea-level (except, of course, the three chains of hills in the south-west). They appear in several localities to consist of strata of the Secondary period, with fossils of the Neocomian age belonging to the genera *Nerinea*, *Turritella*, *Ammonites*, *Terebratula*, *Rhynconella*, *Neritina*, and Echinoderms, and also *Foraminifera* of the genera *Alveolina*, *Orbitoides*, *Triloculina*, &c. There are also beds of a much later age, containing fossils of recently extinct gigantic tortoises, hippopotami, and struthious birds. In addition to the rocks already mentioned as found in the higher portions of the island, there are also slate, mica schist, greywacke, chert, pink and white quartz, and an unstratified limestone deposited by hot springs. Iron exists in great abundance in the central parts of the country, and copper and silver are said to have been found in small quantities, but are not worked. Antimony seems to be plentiful in the north, and rock-salt, iron pyrites, plumbago, and various ochres and coloured earths are among the mineral products. On the north-west coast thin beds of lignite, suitable for steam coal, occur, but no true coal has yet been discovered.

Climate.

The climate varies very much in different parts of the country. In the high interior districts it resembles that of the temperate zones, with no intense heat, and is quite cold during the nights in winter. These parts of the island are therefore tolerably healthy for Europeans. But the coasts are much hotter, especially on the western side; and, from the large amount of marsh and lagoon, malarial fever is prevalent, and frequently fatal both to Europeans and to natives from the interior. The seasons are two—the hot and rainy season from November to April, and the cool and dry season during the rest of the year. Rain indeed falls almost all the year round on the eastern coast, which is exposed to the vapour-laden south-east trade

The Hòva[1] or commoners form the mass of the free population of Imérina. They are composed of a large number of tribes, who usually intermarry strictly among themselves, as indeed do families, so that property and land may be kept together. Hitherto they have also been divided into two great sections—the *bòrozàno* or civilians, and the *miàramìla* or military class; but this distinction does not follow tribal lines, members of the same family belonging to both classes; and the Andriana are also almost all members either of the civilian or the military orders.

The third great division of native society comprises the slave population. Until the year 1877 it was also again subdivided into three classes:—(*a*) the Zàza-hòva, that is, "offspring of the Hòva," or free people who have been reduced to slavery for debt or for political or criminal offences; (*b*) the Andèvo, or slaves proper, mostly the descendants of people of other Malagasy tribes who have been conquered by the Hòva, and thus have become their slaves; and (*c*) the Mozambiques or African slaves, whose ancestors or they themselves have been brought across from the African coast by the Arab slaving dhows. These last, however, were in 1877 formally set free, and will be henceforth mostly reckoned among the Hòva.

Royalty and chieftainship in Madagascar has many peculiar customs connected with it. It still retains a semi-sacred character, the chief being in heathen tribes, while living, the high priest for his people, and after death worshipped as a god; and in its modern development among the Hòva sovereigns it has gathered round it much state and ceremony. There are many curious examples of the *tabu* with regard to actions connected with royalty, and also in the words used which relate to Malagasy sovereigns and their surroundings. These are particularly seen in every thing having to do with the burial of a deceased king or queen.[2]

While the foregoing description of native society applies chiefly to the people of the central province of Imérina, it is more or less applicable, with local modifications, to most of the Malagasy tribes, amongst almost all of whom similar distinctions of rank are found. In modern times a kind of non-hereditary nobility has arisen, derived from military "honours"; and the tendency of recent changes in the native government is to depress the old feudal authority and influence, and to make it subservient to the army and its officers.

Agriculture.

The chief employment of the Malagasy is agriculture, a large portion of their time being spent in the cultivation of rice, their staple food. In this they show very great ingenuity, the *kètsa* grounds, where the rice is sown before transplanting, being formed either on the margins of the streams or in the hollows of the hills in a series of terraces, to which water is often conducted from a considerable distance. In this agricultural engineering no people surpass the Bétsiléo tribes. No plough is used, but all work is done by a long-handled spade; and oxen are only employed to tread out the soft mud preparatory to transplanting. The other processes are very primitive: the rice is threshed by being beaten in bundles on stones set upright on the threshing-floor; and when beaten out the grain is stored by the Hòva in rice-pits dug in the hard red clay, but by the coast tribes in small timber houses raised on posts to protect them from vermin. In preparing the rice for use it is pounded in a wooden mortar to remove the husk, this work being always done by the women. The manioc root is also largely consumed, together with several other roots and many vegetables; but little animal food (save fish and freshwater *Crustacea*) is taken by the mass of the people except at festival times. Rice is used less by the western tribes than by those of the central and eastern provinces, and the former people are more nomadic in their habits than are the others. Large herds of fine humped cattle are kept almost all over the island.

Handicrafts.

The central and eastern peoples have a considerable amount of manual dexterity. The women spin and weave, and with the rudest appliances manufacture a variety of strong and durable cloths of silk, cotton, and hemp, and of ròfia palm, aloe, and banana fibre, of elegant patterns, and often with much taste in colour. They also make from straw and papyrus peel strong and beautiful mats and baskets in great variety, some of much fineness and delicacy, and also hats resembling those of Panama. The people of the south and south-east make large use of soft rush matting for covering, and they also prepare a rough cloth of bark. Their non-employment of skins for clothing is a marked distinction between the Malagasy and the South African races, and their use of vegetable fibres an equally strong link between them and the Polynesian peoples. The ordinary native dress is a loin-cloth or *salàka* for the men, and a *kitàmby* or apron folded round the body from waist to heel for the women; both sexes use over this the *làmba*, a large square of cloth folded round the body something like the Roman *toga*. The Malagasy are skilful in metal working; with a few rude-looking tools they manufacture silver chains of great fineness, and filagree ornaments both of gold and silver. Their iron-work is of excellent quality, and in copper and brass they can produce copies of anything made by Europeans. They display considerable inventive power, and they are exceedingly quick to adopt new ideas from Europeans.

Houses and villages.

There is a considerable variety in the houses of the different Malagasy tribes. The majority of Hòva houses are built of layers of the hard red clay of the country, with high-pitched roofs thatched with grass or rush. The chiefs and wealthy people have houses of framed timber, with massive upright planking, and lofty roofs covered with shingles or tiles. The forest and coast tribes make their dwellings chiefly of wood framing, filled in with the leaf-stalks of the traveller's-tree, with the leaves themselves forming the roof covering. The houses of the Bétsiléo and Sàkalàva are very small and dirty, but those of the coast peoples are more cleanly and roomy. Among the Hòva and Bétsiléo the old villages were always built for security on the summits of lofty hills, around which were dug several deep fosses, one within the other. In other districts the villages and homesteads are enclosed within formidable defences of prickly pear or thorny mimosas.

Commerce.

The country is very deficient in means of communication. There are no roads or wheeled vehicles, so that all goods are carried either by canoes, where practicable, or on the shoulders of bearers along the rough paths which traverse the country, and which have only been formed by the feet of the travellers. Intercourse between distant portions of the island is therefore very limited, but a large quantity of European goods is brought up to the capital city and its neighbourhood, and a good deal of native produce is taken down to the coast. Commerce is gradually increasing, as shown by the consular returns, the chief articles of export being bullocks, rice, hides, ròfia palm cloths (*rabànnas*) and fibre, and also gum-copal and india-rubber, although the yield of these products has latterly much diminished. Coffee is being planted to some extent by creole traders, and is likely to become a staple article of export, and from the natural fertility of the soil almost

[1] This is, of course, a special and restricted use of the word, Hòva in its widest sense being a tribal name, and including all ranks of people in Imérina—royalty, nobles, commoners, and slaves alike.

[2] See Sibree, *The Great African Island*, pp. 185–90, 226, 227, &c.

unlimited quantities of most tropical produce could be obtained—sugar, coffee, rice, cotton, tobacco, indigo, spices, &c. The chief imports are European and American calicoes and prints, hardware, and spirits.[1] On the west coast a sea-going canoe with outrigger is employed, but in the south-east an ingeniously constructed boat, with all the timbers tied together, is used for going through the heavy surf. A considerable number of European traders are scattered along the coasts, especially at Tamatàve and other eastern seaports, and there is a large Arab and Indian community in the north-western ports. There is no native coinage, but the French five-franc piece or dollar is the standard, and all sums under that amount are obtained by cutting up these coins into all shapes and sizes, which are weighed with small weights and scales into halves, quarters, eighths, twelfths, and twenty-fourths of a dollar, and are even reckoned down to the seven-hundred-and-twentieth fraction of the same amount.

Morals. Apart from the modern influence of religious teaching, the people are very immoral and untruthful, disregardful of human life and suffering, and cruel in war. Until lately polygamy has been common among all the Malagasy tribes, and divorce effected in an absurdly easy fashion. At the same time the position of woman is much higher in Madagascar than in most heathen countries; and, since for more than fifty years past there have been (with a few months' exception) only female sovereigns, this has helped to give women considerable influence in native society. Among some of the tribes, as, for instance, the Bàra, there is often a shameless indecency of speech and gesture. The southern and western peoples still practice infanticide as regards children born on several unlucky days in each month. This was formerly the general practice all over the island. The old laws among the Hòva were very barbarous in their punishments, and death in various cruel forms was inflicted for very trifling offences. Drunkenness is very prevalent in many parts of the island (except in Imérina, where it is much restrained by the laws); and it can hardly be said of many of the Malagasy that they are very industrious. But, on the other hand, they are courageous and loyal to their chiefs and tribe, and for short periods are capable of much strenuous exertion. They are affectionate and firm in their friendships, kind to their children and their aged and infirm relatives, very respectful to old age, most courteous and polite, and very hospitable to strangers. Although slavery has existed among them from time immemorial, it bears quite a patriarchal and family character, and is seldom exercised in a cruel or oppressive way. In 1877 all the African slaves who had been brought into the island were formally set free; the other slaves are still retained in servitude, but probably with the advance of Christianity slavery will eventually pass away.

Religion. In their religious notions and practices the Malagasy seem to occupy a middle position among heathen peoples. On the one hand, they have never had any organized religious system or forms of worship; there are no temples, images, or stated seasons of devotion, nor is there a priesthood, properly so called. On the other hand, they have never been without some distinct recognition of a Supreme Being, whom they call *Andriamànitra*, "The Fragrant One," and *Zànahàry*, "The Creator,"—words which are recognized all over the island. They have also retained in their public and oratorical forms of speech many ancient sayings, proverbial in their style, which enforce many of the truths of natural religion as to the attributes of God. With all this, however, there has long existed a kind of idolatry, which in its origin is simply fetichism, the belief in charms—worthless objects of almost any kind—as having power to procure various benefits and protect from certain evils. Among the Hòva in modern times some four or five of these charms had acquired special sanctity and renown, and were each honoured as a kind of national deity, being called god, and brought out on all public occasions to sanctify the proceedings. Together with this idolatry there is also a firm belief in the power of witchcraft and sorcery, in divination, in lucky and unlucky days and times, in ancestor worship, especially that of the sovereign's predecessors, and in several curious ordeals for the detection of crime. The chief of these was the celebrated tangéna poison ordeal, in which there was implicit belief as a test of guilt or innocence, and by which, until its prohibition by an article in the Anglo-Malagasy treaty of 1865, thousands of persons, mostly innocent, perished every year. Sacrifices of fowls and sheep are made at many places at sacred stones and altars, both in thanksgiving at times of harvest, &c., and as propitiatory offerings. Blood and fat are used to anoint many of these stones, as well as the tombs of ancestors, and especially those of the Vazìmba, the supposed aboriginal inhabitants of the central provinces. In some of the southern districts it is said that human sacrifices were occasionally offered. The chief festival among the Hòva, and almost confined to them, is that of the New Year, at which time a kind of sacrificial killing of oxen takes place, and a ceremonial bathing, from which the festival takes its name of *Fandròana* (the Bath). Another and more general feast is at circumcision times. This rite is observed by royal command at intervals of a few years; these are occasions of great rejoicing, but also of much drunkenness and licentiousness. Funerals are also times of much feasting, and at the death of people of rank and wealth numbers of bullocks are killed. Although, as already observed, there was no proper priesthood, the idol keepers, the diviners, the day-declarers, and some others formed a class of people closely connected with heathen customs and interested in their continued observance.

Early political divisions. HISTORY.—From the earliest accounts given of the people of Madagascar by European travellers, as well as from what may be inferred from their present condition over a large portion of the island, they seem for many centuries to have been divided into a number of tribes, each occupying its own territory, and often divided from the others by a wide extent of uninhabited country. Each of these was under its own chief, and was often at war with its neighbours. No one tribe seems to have gained any great ascendency over the rest until about two hundred and thirty years ago, when a small but warlike people

[1] The following tables will give some idea of the imports and exports in English vessels from Tamatàve, the chief eastern port of Madagascar, to Mauritius during the last few years, since the country has been reopened to European trade :—

	Exports.	Imports.
1862	£70,707	£57,714
1865	66,873	40,082
1870	57,922	63,047
1872	154,659	145,258
1875	113,961	113,598
1877	54,882	59,680

The great diminution in the eastern trade during the last four or five years was due to a fearful epidemic of small-pox, which desolated the coast provinces and is said to have carried off 40 per cent. of the population. Of these figures, in the exports, cattle form the largest item, amounting from three-fourths in early years to one-third more recently of the total value; and next to this comes india-rubber, which, in 1872, was exported to the value of £65,000. These figures, however, by no means represent the whole trade of the country, as they do not include French, American, and German commerce, nor do they show what is the trade on the western side of the island. Mr Samuel Procter, the consul for Madagascar in England, says that the west coast has developed very much during the last five or six years, and his opinion is "that the entire foreign trade with Madagascar, import and export, does not fall far short, if at all, of a million pounds sterling." When it is remembered that it is less than thirty years since almost all foreign commerce was excluded, it will be seen that Madagascar trade has developed somewhat rapidly since the reopening of the country.

called Sàkalàva, in the south-west of Madagascar, advanced northward, conquered all the inhabitants of the western half of the island, as well as some northern and central tribes, and eventually founded two kingdoms which retained their supremacy until the close of last century. About that time, however, the Hòva in the central province of Imérina began to assert their own position under two warlike and energetic chieftains, Andrianimpòina and his son Radàma; they threw off the Sàkalàva authority, and after several wars obtained a nominal allegiance from them; they also conquered the surrounding tribes, and so made themselves virtual kings of Madagascar. Since that time the Hòva authority has been retained over the central and eastern provinces, but is only nominal over much of the western side of the island, while in the south-west the people are quite independent, and are still under their own petty kings or chiefs.

Arab intercourse and influence.

While European intercourse with Madagascar is comparatively recent, the connexion of the Arabs with the island dates from a very remote epoch; and in very early times settlements were formed both on the north-west and south-east coasts. In the latter locality there are still traces of their influence in the knowledge of Arabic possessed by a few of the people; and it is asserted that the ruling clans of the Tanàla and other tribes in that district are all of Arab descent. But in these provinces they have almost lost all separate existence, and have become merged in the general mass of the people. It is different, however, in the north-west of the island. Here are several large Arab colonies, occupying the ports of Amòrontsànga, Mòjangà, Màrovoày, and Mòrondàva, and retaining their distinct nationality, together with their own dress, habits, houses, worship, and language. There is also in these districts a Hindu element in the population, for intercourse has also been maintained for some centuries between India and northern Madagascar, and in some towns the Banyan Indian element is as prominent as the Arab one, and Hindu dress, ornament, music, food, and speech are marked features in the social life of these places. In the early times of their intercourse with Madagascar, the Arabs had a very powerful and marked influence upon the Malagasy. This is seen in the number of words derived from the Arabic which are found in the native language. Among these are the names of the months and the days of the week, those used in astrology and divination, some forms of salutation, words for dress and bedding, money, musical instruments, books and writing, together with a number of miscellaneous terms. These form enduring memorials of the influence the Arabs have exerted upon Malagasy civilization, and also on their superstition.

European intercourse and attempted colonization.

The island is mentioned by several of the early Arabic writers and geographers, but mediæval maps show curious ignorance of its size and position. Marco Polo has a chapter upon it, and terms it Madeigascar, but his accounts are evidently confused with those of the mainland of Africa. The first European voyager who saw Madagascar appears to have been a Portuguese captain named Fernando Soares, in command of a squadron of eight ships from the fleet of Don Francisco de Almeida. On his way home from India he sighted the island on the 1st of February 1506. The Portuguese gave names to most of the capes, but made no persistent attempts at colonization. After them the Dutch endeavoured, but with little success, to form colonies; and in the time of Charles I. proposals were made to form an English "plantation," but these were never carried into effect, although for a short time there was a settlement formed on the south-west coast. In the latter part of the 17th and during most of the 18th century the French attempted to establish military positions at various places on the east coast, but with little permanent result. For some time they held the extreme south-east point of the island at Fort Dauphin; but several of their commandants were so incapable and tyrannical that they were frequently involved in war with the people, and more than once their stations were destroyed and the French were massacred. Early in the present century all their positions on the mainland were relinquished, and they now retain nothing but the islands of St Marie on the east coast and Nòsibé on the north-west. No foreign power now holds any portion of Madagascar, for the native Government has jealously reserved all territorial rights to itself, and will suffer no purchase of land by foreigners, allowing it only to be held on short leases.

Radàma I.

The political history of Madagascar as a whole may be said to date from the reign of Radàma I. (1810–28). The ancestors of that king had been merely chiefs of the central provinces, but he was the first to claim by right of conquest to be supreme ruler of the whole island, although actually exercising authority over less than two-thirds of its surface. Radàma was a man much in advance of his age,—shrewd, enterprising, and undeterred by difficulty,—a kind of Peter the Great of his time. He saw that it was necessary for his people to be educated and civilized if the country was to progress; and making a treaty with the governor of Mauritius to abolish the export of slaves, he received every year in compensation a subsidy of arms, ammunition, and uniforms, as well as English training for his troops. He was thus enabled to establish his authority over a large portion of the island, and, although this was often effected with much cruelty, the ultimate results were beneficial to the country as a whole. A number of native youths were sent to Mauritius, and others to England, for education and instruction in some of the arts of civilization, as well as in seamanship. For some years a British agent, Mr Hastie, resided at Radàma's court, and exercised a powerful influence over the king, doing very much for the material advance of the country.

Introduction of Christianity.

At the same period (1820) Christian teaching was commenced in the capital by the London Missionary Society, and by the efforts of its missionaries the language was for the first time reduced to a systematic written form, and the art of printing introduced; books were prepared, the Scriptures were translated, numerous schools were formed, and several Christian congregations were gathered together. The knowledge of many of the useful arts was also imparted, and many valuable natural productions were discovered, and their preparation and manufacture taught to the people. At the same time the power of superstition was greatly broken, a result partly due to the keen good sense of the king, but chiefly to the spread of knowledge and religious teaching.

Rànavàlona I.

The bright prospects thus opening up for the country were clouded by the death of Radàma at the early age of thirty-six, and the seizure of the royal authority by one of his wives, the Princess Rànavàlona. Superstitious and despotic in temper, the new sovereign looked with much suspicion upon the ideas then gaining power among many of her people, and after a few years of temporizing she at length determined to strike a decisive blow at the new teaching. In 1835 the profession of the Christian religion was declared illegal; all worship was to cease, and all religious books were ordered to be given up. By the middle of the following year all the English missionaries were obliged to leave the island, and for twenty-five years the most strenuous efforts were made by the queen and her Government to suppress all opposition to her commands. This, however, only served to show in a very remarkable manner the courage and faith of the Christian Malagasy, of whom about two hundred suffered death in various cruel forms, while many hundreds were punished more or less severely by fine, degradation, imprisonment, and slavery. During the queen's reign the political condition of the country was deplorable; there were frequent rebellions owing to the oppressive nature of the government; many of the distant provinces were desolated by barbarous wars; and for some years all Europeans were excluded, and foreign commerce almost ceased. This last circumstance was partly owing to an ill-managed attack upon Tamatàve in 1846 by a combined English and French force, made to redress the wrongs inflicted upon the foreign traders of that port. But for the leaven of Christianity and education which had been introduced into the country it would have quite reverted to a state of barbarism.

Radàma II.

This reign of terror was brought to a close in 1861 by the death of the queen and the accession of her son Radàma II. The island was reopened to European trade, and missionary efforts were recommenced. A determined attempt was made by some enterprising Frenchmen to gain for their country an overwhelming influence by means of a treaty which they induced the king to sign. But this act, as well as the vices and insane follies into which he was led by worthless foreign and native favourites, soon brought his reign and his life to an end. He was put to death in his palace (1863) after having reigned for less than two years, and his wife was placed on the throne. The new sovereign and her Government refused to ratify the agreement which had been illegally obtained, choosing rather to pay a million francs as compensation to the French company.

Rasohérina.

During the five years' reign of Queen Rasohérina, quiet and steady advances were made in civilization and education, and treaties were concluded with the English, French, and American Governments.

Rànavàlona II.

At the death of Rasohérina in 1868, she was succeeded by her cousin, the present (1882) sovereign, Rànavàlona II. One of the first acts of the new queen was the public recognition of Christianity; and very soon afterwards she and her husband, the prime minister, were baptized, and the erection of a chapel royal was commenced in the palace yard. These acts were followed in the succeeding year by the burning of the royal idols, and immediately afterwards by the destruction of the idols throughout the central provinces, the people generally putting themselves under Christian instruction. Since that time education and enlightenment have made great progress, chiefly through the labours of the London Missionary Society's missionaries, with whom are also associated several agents of the Friends' Foreign Mission Association. About 1200 congregations have been formed, and about 900 schools, in which nearly 50,000 children receive instruction; and there are also normal schools and colleges where teachers, pastors, evangelists, and the sons of the upper classes are well educated. A considerable amount of literature has been prepared, and several printing presses are constantly at work. Very marked advance has been made as regards the morality of the people by the suppression of the grosser and more open forms of vice, the abolition of polygamy, and the restrictions placed upon arbitrary divorce. All the barbarous punishments of the old laws have been done away with; and the only war carried on during the present reign was conducted with such humanity as well as sagacity that peace was speedily restored.

Although these changes have as yet only affected about a fourth part of the whole population, there is reason to believe that the influences at work in the centre of the island will eventually affect all the different tribes. Missionary work is also carried on by English Episcopalians (S. P. G.), Norwegian Lutherans, and French Roman Catholics.

Government. The government of Madagascar during the present century has been and still is monarchical theoretically despotic, but practically limited in various ways. Radàma I. and Rànavàlona I. were much more absolute sovereigns than those before or after them, but even they were largely restrained by public opinion. New laws are announced at large assemblies of the people, whose consent is asked, and always given through the headmen of the different divisions of native society; and this custom is no doubt a "survival" from a time when the popular assent was not a merely formal act, as it has now almost entirely become. The large disciplined army formed by Radàma I. aided much in changing what was formerly a somewhat limited monarchy into an absolute one. The Hòva queen's authority is maintained over the central and eastern portions of Madagascar, and at almost all the ports, by governors appointed by the queen, and supported by small garrisons of Hòva troops. At the same time the chiefs of the various tribes are left in possession of a good deal of their former honours and influence, so long as they acknowledge the suzerainty of the Hòva sovereign, and perform a certain amount of Government service. The present queen and her predecessor have both been married to the prime minister, a man of great ability and sagacity, who, by his position as husband and chief adviser of the sovereign, is the virtual ruler of the country. Chiefly owing to his influence, the last five or six years have been marked by the introduction of several measures tending to modify the government of the country and improve the administration. The purpose of these new laws is to weaken the old oppressive feudal system; to remodel the army; to appoint a kind of local magistracy and registrars; to encourage education; and to form a responsible ministry, with departments of justice, war, education, agriculture, commerce, revenue, &c.

Owing to the conservative habits of the people, considerable time will probably elapse before all these measures are carried into effect, but their mere enactment is a proof of the progress of enlightened ideas. **Army.** Until lately the military service has been very oppressive upon certain classes, being for life, and without any pay; but it is now to be made compulsory upon all, and for short periods only. The Hòva army has been variously estimated at from 30,000 to 40,000 men, although it is popularly termed *ny Fòlo-àlin-dàhy*, *i.e.*, "the Ten ten-thousand men." Military rank is reckoned by numbers, from one "honour," that of a private, to sixteen "honours," the rank of the highest officer; but several of the English words for different ranks are employed, as a sergeant, captain, general, marshal, &c. **Justice.** Justice has hitherto been administered by a number of unpaid judges appointed by the sovereign, and they generally sit in the open air. There appears to be a somewhat small amount of crimes of violence; but cattle-stealing raids made by one tribe upon another are a frequent cause of petty wars away from the Hòva authority. **Revenue.** The revenue of the Government is derived from customs duties, first fruits, fines and confiscation of offenders' property, and a money offering called *hàsina*, presented on a great variety of occasions both to the sovereign in person and to her representatives; and these are supplemented by "benevolences" (in the mediæval sense of the word) levied upon the people for occasional state necessities. Besides these, the Government claims the unpaid service of all classes of the community for all kinds of public work. **Foreign relations.** Consuls appointed by the English, French, and American Governments are accredited to the Malagasy sovereign, and the queen has a consul in England, and a consular agent at Mauritius. During the late Lord Clarendon's tenure of office as foreign secretary an understanding was come to between the English and French Governments by which it was agreed that each power should respect the independence of Madagascar; and, although the intrigues of Jesuit priests have more than once fomented difficulties between the native Government and the French, it may be hoped that the home authorities in France will still refuse to interfere, and will allow the Malagasy—undisturbed by fear of foreign invasion—quietly to advance in that path of progress which they have for some years been following with such happy results. The best prospects for the future of the country would appear to be bound up in the gradual consolidation of the central Hòva authority over the whole island, bringing to every part of it those civilizing and enlightening influences which have already worked such changes in the central provinces.

The capital. Antanànarivo, the capital of Madagascar, is by far the largest city in the island. It has about 100,000 inhabitants, and has been almost rebuilt during the last twelve years, the old timber and rush houses being nearly all replaced by much larger and more substantial ones of sun-dried brick and stone, constructed in European fashion. A group of royal palaces, with lofty roofs and stone-arched verandahs, crowns the summit of the ridge on and around which the city is built, and hardly less conspicuous is the grand new residence of the prime minister. Four handsome stone memorial churches, with spires or towers, mark the spots where the Christian martyrs suffered; and other prominent buildings are the Chapel Royal, the Norwegian and the Roman Catholic churches, the London Missionary College, the London Missionary Society and the Friends' normal schools, mission hospitals, the court of justice, and numerous large Congregational churches of sun-dried brick.

Other towns. Next to the capital in size are the port of Mojangà, on the north-west coast, with about 14,000 inhabitants; Tamatàve, the chief eastern port, and Fianàrantsòa, the chief town of the Bétsiléo, each with about 6000 people; and Ambòhimànga, the old capital of Imérina, with about 5000. There are very few places besides these with as many as 5000 people, and the majority of native towns are small. **Population.** The population is dense in two or three districts only, and the entire island is variously estimated to contain from four to five millions of inhabitants.

Literature.—A considerable number of books have been written upon Madagascar, both in the English and French languages, but many of the latter are of little value. And during the last twenty years a great many papers upon the exploration, natural resources, animal and vegetable life, and political and religious condition of the country have appeared in various periodicals and in the *Proceedings* of the different learned societies, both English and French. In the following lists no attempt is made at completeness, but only to select the most important of each class. As regards the scientific aspects of the country, almost everything worth preserving in previous books and papers will be included in the magnificent work now in course of publication in twenty-eight 4to vols. by M. Alfred Grandidier, entitled, *Histoire Naturelle, Physique, et Politique de Madagascar*. Of this *magnum opus* four volumes are already issued.

Of books treating of the country generally, the following are the most noteworthy:—Hamond, *Madagascar, the Richest and most Frritfull Island in the World*, London, 1643; Boothby, *A Breife Discovery or Description of the most famous Island of Madagascar or St Laurence*, London. 1664; Flacourt, *Histoire de la grande Isle de Madagascar*, Paris, 1658; *Madagascar, or Robert Drury's Journal during Fifteen Years' Captivity on that Island*, London, 1729; *Voyages et Mémoires de Maurice Auguste comte de Benyowski*, Paris, 1791; Rochon, *Voyages à Madagascar*, &c., Paris, an x.; Froberville, *Histoire de Madagascar*, Isle de France, 1809; Copland, *A History of the Island of Madagascar*, London, 1822; Ellis, *History of Madagascar*, London, 1838; Leguevel de Lacombe, *Voyage à Madagascar et aux îles Comores*, Paris, 1840; Guillain, *Documents sur . . . la partie occidentale de Madagascar*, Paris, 1845; Macé Descartes, *Histoire et Géographie de Madagascar*, Paris, 1846; Ellis, *Three Visits to Madagascar*, London, 1859; Oliver, *Madagascar and the Malagasy*, London, 1863; Sibree, *Madagascar and its People*, London. 1870; articles in *Revue des Deux Mondes*, 1872; *Tantara ny Andriana eto Madagascar: Histoire des Rois d'Imérina d'après les manuscrits Malgaches*, Antanànarìvo, 1875; Mullens, *Twelve Months in Madagascar*, London, 1875; Blanchard, *L'Île de Madagascar*, Paris, 1875; Dahle, *Madagaskar og dets Beboere*, Christiania, 1876–78; *The Antanànarìvo Annual*, Nos. i.–v., 1875–81; and Sibree, *The Great African Island*, London, 1880, and "The Arts and Commerce of Madagascar," *Jour. Soc. Arts*, June 4, 1880.

Philology.—Houtman, *Spraak ende woord boek in de Maleische ende Madagaskarsche talen*, Amsterdam, 1603; *Voyage de C. van Heemskerk; vocabulaire de la langue parlée dans l'île Saint-Laurent*, Amsterdam, 1603; Megiser, *Beschreibung der Mechtigen und Weitberhümbten Insul Madagascar*, with dictionary and dialogues, Altenburg, 1609; Arthus, *Colloquia Latino-Maleyica et Madagascarica*, Frankfort, 1613; Challand, *Vocabulaire français-malgache et malgache-français*, Île de France, 1773; Froberville, *Dictionnaire français-madecasse*, 3 vols., Île de France, 1809; Dumont D'Urville, *Voyage de la Corvette l'Astrolabe*, volume on "Philologie," Paris, 1833; Freeman and Johns, *Dictionary of the Malagasy Language* (*Eng.-Mal. and Mal.-Eng.*), Antanànarìvo, 1835; Dalmond, *Vocabulaire et Grammaire pour les langues Malgaches, Sàkalàva et Bétsimisàra*, Bourbon, 1842; R. C. Missionaries' *Dictionnaire Français-Malgache*, Réunion, 1853, and *Dictionnaire Malgache-Français*, Réunion, 1855; Van der Tuuk, "Outlines of a Grammar of the Malagasy Language," *Jour. Roy. Asiat. Soc.*, 1860; Ailloud, *Grammaire Malgache-Hòva*, Antanànarìvo, 1872; W. E. Cousins, *Concise Introduction to the Study of the Malagasy Language as spoken in Imérina*, Antan., 1873; Sewell, *Diksionary Eng. sy Mal.*, Antan., 1875; Marre de Marin, *Grammaire Malgache*, Paris, 1876; Id., *Essai sur le Malgache, ou Étude comparée des langues Javanaise, Malgache, et Malayse*, Paris, 1876; Id., *Le Jardin des Racines Océaniennes*, Paris, 1876; Dahle, *Specimens of Malagasy Folk-lore*, Antan., 1877; and W. E. Cousins, "The Malagasy Language," in *Trans Phil. Soc.*, 1878. Besides these there are several valuable papers by Dahle in the yearly numbers of *The Antanànarìvo Annual* (*ante*), and a number of short vocabularies of coast and other dialects of Malagasy in the notes of various exploratory journeys published at Antanànarivo, noticed below.

Scientific: General and Exploratory.—Vinson, *Voyage à Madagascar*, Paris, 1865; Coignet, "Excursion sur la Côte Nord-est de l'Île de Madagascar," *Bull. Soc. Géog.*, Sept. et Oct., 1867; Grandidier, "Madagascar," *Bull. Soc. Géog.*, August 1871; Id., "Excursion chez les Antanosses émigrés," *Bull. Soc. Géog.*, Feb. 1872; Id., "Madagascar," *Bull. Soc. Géog.*, April 1872; Mullens, "Central Provinces of Madagascar," *Proc. Roy. Geog. Soc.*, January 1875; Sibree, *South-east Madagascar*, Antan., 1876; Houlder, *North-east Madagascar*, Antan., 1877; Richardson, *Lights and Shadows* [South-west Madagascar], Antan., 1877; chap. xi., vol. i., of Wallace's *Geographical Distribution of Animals*, London, 1876; Sibree, "Observations on the Physical Geography and Geology of Madagascar," *Nature*, August 14, 1879; Id., "History of our Geographical Knowledge of Madagascar," *Proc. Roy. Geog. Soc.*, October 1879; chap. xix. in Wallace's *Island Life*, London, 1880; Cowan, *The Bàra Land*, Antan., 1881; Id., "Explorations in South Madagascar," *Proc. Roy. Geog. Soc.*, Sept. 1882. The best general map of Madagascar is that published by Rev. Dr Mullens in 1879, which is to a large scale (12¼ miles to the inch), and includes almost every journey made up to that date, but is somewhat deficient as regards the delineation of the physical geography.

Zoology.—Klug, "Insekten von Madagaskar," in *Kön. Ak. der Wissenschaften*, Berlin, 1832; Boisduval, *Faune Entomologique de Madagascar*, &c., Paris, 1833; Owen, *Monograph on the Aye-aye*, London, 1863; Vinson, *Araneides des Iles Réunion, Madagascar*, &c., Paris, 1863; Bates, "Natural History of Madagascar," *Proc. Zool. Soc.*, 1863; Sclater, "Mammals of Madagascar," *Quart. Jour. Sci.*, April 1864; Pollen and Van Dam, *Recherches sur la Faune de Madagascar et ses Dépendances*, 5 vols., Leyden, 1867 *sq.*; Hartlaub, *Die Vögel Madagascars und der benachbarten Inselgruppen*, Halle, 1877; "Reliquiæ Rutenbergianæ—Zoologie," in the Bremen *Naturwissenschaftliche Verein*, April 1881; also very numerous articles on Madagascar animals, birds, &c., in *Proc. Zool. Soc.*, 1863–81, and in *Ann. and Mag. of Nat. Hist.*, 1863–81.

Botany.—Du Petit Thouars, *Histoire des Végétaux recueillés sur les isles de . . . Madagascar*, Paris, 1804; "Floræ Madagascariensis fragmenta," in *Annales des Sciences Naturelles*, 4 ser., vols. vi., viii., ix.; Davidson, "Account, Historical and Physiological, of the Madagascar Poison Ordeal

(*Tanghinia Veneniflua*)," *Jour. of Anat. and Phys.*, vol. viii.; articles on ferns and flowering plants, in *Linn. Soc. Jour.—Bot.*, for 1864, 1876, 1877, 1880; "Reliquiæ Rutenbergianæ," in the Bremen *Naturwissenschaftliche Verein*, November 1880; Baker on "The Plants of Madagascar," *Nature*, December 9, 1880, and on "Botany of Madagascar," *Proc. of Brit. Assoc.*, 1881.

Anthropology.—Oliver, "The Hovas and other Characteristic Tribes of Madagascar," *Jour. Anthrop. Inst.*, 1868; Wake, "The Race Elements of the Madecasses," *Ibid.*, 1869; Mullens, "On the Origin and Progress of the People of Madagascar," *Ibid.*, 1875; Wake, "Notes on the Origin of the Malagasy," *Ibid.*, 1881; Sibree, "Malagasy Folk-Lore and Popular Superstitions," *Folk-Lore Soc. Record*, 1880; Id., *The Oratory, Songs, Legends, and Folk-Tales of the Malagasy*, 1882.

Religious History.—Freeman and Johns, *Narrative of the Persecutions of the Christians in Madagascar*, London, 1840; Prout, *Madagascar, its Missions and its Martyrs*, London, 1863; Ellis, *Madagascar Revisited*, London, 1867; Id., *The Martyr Church*, London, 1869; "Religion in Madagascar," *Ch. Quart. Rev.*, July 1878; and *Ten Years' Review of Mission Work in Connexion with the London Missionary Society*, 1870-80, Antan., 1880. (J. S., jr.)

MADDALONI, a city of Italy, in the province of Caserta (Terra di Lavoro), about 3½ miles south-east of Caserta, with a station both on the railway from Caserta to Benevento and on that from Caserta to Avellino. It is prettily situated at the base of one of the Tiffata hills, the towers of its mediæval castle and the church of San Michele crowning the heights above. The fine old palace of the Caraffas, once dukes of Maddaloni, the old college now named after Giordano Bruno, and the institute for the sons of soldiers (dating from 1859, and accommodating 500 pupils) are the chief points of interest. In 1871 the population was 18,767. About 2½ miles to the east, at Valle di Maddaloni, the Caroline aqueduct (so called after Charles IV. of Naples), conveying the water of the Tiburno to Caserta (a distance of 19 miles), is carried across the valley between Monte Longano and Monte Gargano by a threefold series of noble arches rising to a height of 178 feet. The work was designed by Lodovico Vanvitelli, and constructed between 1753 and 1759.

Maddaloni (in mediæval documents *Matalonum*, *Madalonum*, and *Magdalonum*) lies on the Appian Way, and is doubtfully identified with Sessucla. Its castle and walls are probably of Lombard origin. The first count of Maddaloni was invested with the fief in 1465, the first duke in 1558. In 1860 General Bixio's volunteers beat the royal Neapolitan forces at Maddaloni. See A. de Reumont, *The Carafas of Maddaloni*, Bohn's series, 1854.

MADDEN, SIR FREDERIC (1801-1873), one of the first palæographers and antiquaries of his time, and for nearly forty years assistant keeper and keeper of manuscripts at the British Museum, was born at Portsmouth on February 16, 1801, the son of an officer of Irish extraction. From his earliest years he displayed a strong bent to linguistic and antiquarian studies. In 1825 he was engaged in collating the text of Cædmon for the university of Oxford, and assisting Dr Bliss in editing Blore's *Monumental Remains*; in the following year he joined Mr Roscoe in preparing a catalogue of the earl of Leicester's MSS. at Holkham, which was completed in eight volumes folio, but remains unpublished. In the same year he was engaged by the British Museum to assist in the preparation of the classed catalogue of printed books at that time contemplated, and in 1828 he became assistant keeper of manuscripts. In 1833 he was knighted, and in 1837 succeeded the Rev. Josiah Forshall as keeper of manuscripts, which office he continued to hold until his retirement in 1866. Notwithstanding his indefatigable attention to his official duties, he found time for a great amount of exceedingly valuable literary work. Between 1828 and 1838 he edited for the Roxburghe Club the old English romances of *Havelok the Dane* (discovered by himself among the Laudian MSS. in the Bodleian) and *William and the Werwolf*, and the old English versions of the *Gesta Romanorum*. In 1839 he edited the ancient metrical romances of *Syr Gawayne* for the Bannatyne Club, and in 1847 Layamon's *Brut*, with a prose translation, for the Society of Antiquaries. In 1850 the magnificent edition of Wickliffe's translations of the Scriptures from the original MSS., upon which he and his coadjutor, Mr Forshall, had been engaged for twenty years, was published by the university of Oxford. In 1866-69 he edited the *Historia Minor* of Matthew Paris for the Rolls series. In 1833 he prepared the literary part of Mr Shaw's work on *Illuminated Ornaments*; and in 1850 he edited the English translation of Silvestre's *Universal Palæography*. He had projected a history of chess in the Middle Ages; ill-health, however, and other causes, prevented the completion of the work. He died on March 8, 1873, bequeathing his journals and other private papers to the Bodleian Library, where they are to remain unopened until 1920.

Sir Frederic Madden's attainments were great, and his services to literature highly distinguished. He was perhaps the first palæographer of his day, and as keeper of manuscripts was most zealous and industrious, imposing a large amount of manual as well as intellectual labour upon himself, and continually, although too often unsuccessfully, exerting himself to enrich the collections committed to his care. He was an acute as well as a laborious antiquary, but rather qualified for critical than for original research, and his unacquaintance with German prevented his ranking high as a philologer, although he paid much attention to the early dialectical forms of French and English. His judgment was shown in the substantial value of the works edited by him. Wickliffe's Bible is the first English version; Layamon's *Brut*, a semi-Saxon paraphrase of the Norman *Brut* of Robert Wace, unites two ages of English poetry, is an inestimable monument of the language at the period of its composition, and possesses no small poetical merit; while *Havelok* is hardly less important in a philological and a metrical point of view. The first volume of his edition of Matthew Paris contains a valuable critical introduction, and the third a biography of the historian, with an estimate of his place in literature. Sir Frederic's minor contributions to antiquarian research were exceedingly numerous: the best known, perhaps, is his dissertation on the orthography of Shakespeare's name, which, mainly on the strength of the Florio autograph, he contends should be "Shakspere." This mode of spelling has been adopted by the New Shakspere Society. It is not generally known that Sir Frederic was the first to discover the "Perkins" forgeries in the duke of Devonshire folio *Shakespeare*, although private considerations induced him to leave the further elucidation of the matter to others. He also promptly detected the fabrications of the Greek Simonides, which had imposed upon some of the first scholars in Germany.

MADDER, or DYER'S MADDER, is the root of *Rubia tinctorum*, L., and perhaps of *R. peregrina*, L., as well, both being European; but *R. cordifolia*, L., and perhaps *Mungista*, Roxb., a native of the mountains of Nepal, Bengal, Japan, &c., supply the Indian madder or *manjit* (see Pickering, *Chron. Hist. of Pl.*, 421; Drury, *Useful Plants of India*, 541). Rubia is a genus of about thirty species of the tribe *Galieæ* of the order *Rubiaceæ*, and much resembles the familiar *Galiums*, *e.g.*, the lady's bedstraw and cleaver of English hedges having similarly whorled leaves, but the parts of the flowers are in fives and not fours, while the fruit is somewhat fleshy. The sole British species is *Rubia peregrina*, L. The use of madder appears to have been known from the earliest times, as cloth dyed with it has been found on the Egyptian mummies. It was the ἐρευθέδανον used for dyeing the cloaks of the Libyan women in the days of Herodotus (Herod., iv. 189). It is the ἐρυθρόδανον of Dioscorides, who speaks of its cultivation in Caria (iii. 160), and of Hippocrates (*De Morb. Mul.*, i.), and the *Rubia* of Pliny (xix. 17), (see Pickering, p. 275). *Rubia tinctorum*, L., a native of western Europe, &c., has been extensively cultivated in South Europe, France, where it is called *garance*, and Holland, and to a small extent in the United States. Large quantities have been imported into England from Smyrna, Trieste, Leghorn, &c. The cultivation, however, is decreasing since alizarin, the red colouring principle of madder, has been made artificially (see ALIZARIN). Madder was employed medicinally by the ancients and in the Middle Ages. Gerard, in 1597, speaks of it as having been cultivated in many gardens in his day, and describes its supposed many virtues (*Herball*, p. 960); but the influence of madder over the system is now believed to be exceedingly slight. Its most remarkable physiological effect is that of colouring red the bones of animals fed upon it, as also the claws and beaks of birds. This appears to be due to the chemical affinity of phosphate of lime for the colouring matter (Pereira, *Mat. Med.*, vol. ii. pt. ii. p. 52). *Rubia chilensis*, Mol., has been used for dyeing red from time immemorial (Pickering, p. 661). The chay-root, which furnishes a red dye in Coromandel and other parts of India, is obtained from *Hedyotis umbellata*, Lam., of the same family as madder (Drury, p. 366).

e III. MADEIRA. The Madeiras, a group of islands in the North Atlantic Ocean belonging to Portugal, consist of two inhabited islands named Madeira and Porto Santo, and three uninhabited rocks named collectively the Desertas. Funchal, the capital of Madeira, is on the south coast of the principal island, in 32° 37′ 45″ N. lat., 16° 55′ 20″ W. long. It is about 360 miles from the coast of Africa, 535 miles from Lisbon, 1215 from Plymouth, 240 from Teneriffe, and 480 from Santa Maria, the nearest of the Azores. Funchal is connected by the Brazilian submarine telegraph, which belongs to a British company, with Lisbon on the one hand, and on the other with Brazil.

Madeira, the largest island of the group, has a length of 30 geographical miles, an extreme breadth of 13 miles, and a coast-line of 80 or 90 miles. Its longer axis lies east and west, in which direction it is traversed by a mountain chain, the backbone of the island, having a mean altitude of 4000 feet, up to which many deep ravines penetrate from both coasts, rendering travelling by land from place to place a very tedious and fatiguing labour. Pico Ruivo, the highest summit, stands in the centre of the island, and has a height of 6100 feet, but some of the adjacent summits are very little lower. The depth and narrowness of the ravines, the loftiness of the rugged peaks that tower above them, the bold precipices of the coast, and the proximity of the sea afford many scenes of picturesque beauty or striking grandeur which are continually changing in character as the traveller advances on his way. The greater part of the interior is uninhabited, for the towns, villages, and scattered huts lie either at the mouths of ravines or upon the lower slopes that extend from the mountains to the coast. The ridges between the ravines usually terminate in lofty headlands, one of which has the height of 1920 feet, and much of the coast is bound by precipices of dark basalt. The north coast, having been more exposed to the erosion of the sea, is on the whole more precipitous than the south coast, and presents everywhere a wilder aspect. On the south there is left very little of the indigenous forest which once clothed the whole island and gave it the name it bears (Madeira, from *materia*, wood), but on the north some of the valleys still contain native trees of fine growth. A long, narrow, and comparatively low rocky promontory forms the eastern extremity of the island, and here is to be seen a tract of calcareous sand, known as the Fossil Bed, containing land shells and numerous bodies resembling the roots of trees, probably produced by infiltration. Upon an islet off this promontory stands the only lighthouse of the group. It has a flashing light visible at the distance of 25 miles in clear weather.

History.—It has been conjectured, but on insufficient evidence, that the Phœnicians discovered Madeira at a very early period. Pliny mentions certain Purple or Mauretanian Islands, the position of which with reference to the Fortunate Islands or Canaries might seem to indicate the Madeiras. There is a romantic story, of doubtful truth, to the effect that two lovers, Robert Machim and Anna d'Arfet, fleeing from England to France in 1346, were driven out of their course by a violent storm, and cast on the coast of Madeira at the place subsequently named Machico, in memory of one of them. On the evidence of a portulano dated 1351, preserved at Florence, it would appear that Madeira had been discovered long previous to that date by Portuguese vessels under Genoese captains. In 1419 two of the captains of Prince Henry of Portugal were driven by a storm to the island called by them Porto Santo, or Holy Port, in gratitude for their rescue from shipwreck. The next year an expedition was sent out to colonize the island, and, Madeira being descried, they made for it, and took possession on behalf of the Portuguese crown. The islands were then uninhabited. For the sixty years intervening between 1580 and 1640, Madeira, with Portugal itself, was under Spanish rule. In 1801 British troops occupied the island for a few months, commanded by General Beresford, and it was again under the British flag from 1807 to 1814. Madeira is now a province and an integral part of the Portuguese kingdom, entitled to send deputies to the Cortes assembling at Lisbon.

Inhabitants.—The inhabitants are of Portuguese descent, with probably some intermixture of Moorish and Negro blood amongst the lower classes. The dress of the peasantry, without being picturesque, is peculiar. Both men and women in the outlying country districts wear the *carapuça*, a small cap made of blue cloth, in shape something like a funnel, with the pipe standing upwards. The men have trousers of linen, drawn tight, and terminating at the knees; a coarse shirt enveloping the upper part of their person, covered by a short jacket, completes their attire, with the exception of a pair of rough yellow boots. The women's outer garments consist of a gaudily coloured gown, made from island material, with a small cape of coarse scarlet or blue woollen cloth. At the end of 1881 the inhabitants of Madeira numbered 131,906 persons, the females exceeding the males by 7060. The population increases, notwithstanding the emigration to Demerara and the Hawaiian Islands that occasionally takes place. There is strong reason for thinking that the islands are too densely peopled, considering the small proportion which cultivable ground bears to the whole, and the general want of capital.

Government.—The administration of affairs is in the hands of a civil governor appointed by the crown, under whom is a military officer in command of the troops, which consist of a battalion of infantry, a detachment of artillery, and some militia. The law of Portugal is administered by four chief judges, each of whom has a separate division (*comarca*) of the island in his jurisdiction, within which he tries both civil and criminal cases with the assistance of a jury. Magistrates elected by the people decide minor cases. For municipal purposes the island is divided into nine districts, called *concelhos* (Porto Santo forming a tenth), each of which has its popularly elected municipal chamber, whose duty it is to repair the roads, light and cleanse the towns and villages, &c. The chief police magistrate of each district is the *administrador*, who is appointed by the central Government. A bishop is at the head of the clergy, his cathedral being at Funchal. There are forty-eight parishes, each with its church and resident priest. Roman Catholicism is the established form of religion, but others are now tolerated.

Education.—By law all children of a certain age should be sent to school, but this regulation is not strictly enforced, and only a small fraction of the total number actually receive instruction. The chief educational establishment is the Lyceo at Funchal, where there are seven professors paid by Government. In 1881 the pupils at this establishment were two hundred and fifty in number. There is a seminary for young priests, and a number of public primary schools are scattered over the island.

Agriculture.—Until recently a considerable portion of the land was strictly entailed in the families of the landlords (*morgados*), but entails have been abolished by the legislature, and the land is now absolutely free. Owing to the irremediable difficulties of the surface, the roads are bad, except in the neighbourhood of the capital. A deficient supply of water is another great obstacle to the proper cultivation of the land, and the rocky nature or steep inclination of the upper parts of the islands is an effectual bar to all tillage. An incredible amount of labour has been expended upon the soil, partly in the erection of walls intended to prevent its being washed away by the rains, and to build up the plots of ground in the form of terraces, so as to lessen their slope. Water-courses, too, have been constructed for purposes of irrigation, without which at regular intervals the island would not produce a hundredth part of its present yield. These water-courses originate high up in the ravines, are built of masonry or driven through the rock, and wind about for miles until they reach the cultivated land. Some of them are brought by tunnels from the north side of the island through the central crest of hill. The water thus conveyed is carefully dealt out according to the rights of each occupier, who takes his turn at the running stream for so many hours in the day or night at a time notified to him beforehand. In this climate flowing water has a saleable value as well as land, for the latter is useless without a supply of the former. The agricultural implements employed are of the rudest kind, and the system of cultivation is extremely primitive. Very few of the occupiers are the owners of the land they cultivate; but they are almost invariably the owners of the walls, cottages, and trees standing thereon, the bare land alone belonging to the landlord. The tenant can sell his share of the property without the consent of the landlord, and if he does not so dispose of it that share passes to his heirs. In this way the tenant practically enjoys fixity of tenure, for the landlord is seldom in a position to pay the price at which the tenant's share is valued. Money rents are rare, the métayer system regulating almost universally the relations between landlord and tenant; that is, the tenant pays to the owner a certain portion of the produce, usually one half or one third. The holdings are usually very small, rarely larger than one man can cultivate with a little occasional assistance. Meadows and pastures are seldom to be met with, the cattle being stall-fed when not feeding on the mountains. Horses are never employed for draught, all labour of that kind being done by oxen, of which there is an ample supply.

The two staple productions of the soil are wine and sugar. The vine was introduced from Cyprus or Crete soon after the discovery of the island by the Portuguese, but it was not actively cultivated until the early part of the 16th century. The vines, after having been totally destroyed by the oidium disease, which made its first appearance in the island in 1852, were replanted, and in a few years wine was again made. The disease is now kept in check by the application of sulphur, which has the effect of increasing the quantity of fruit, whilst it shortens the life of the plant. The phylloxera has also made its way to the island, and every vineyard in Madeira is more or less affected by it. The wine usually termed Madeira, and known in the trade as "London particular," is made from a mixture of black and white grapes, which are also made separately into wines called Tinta and Verdelho, after the names of the grapes. Other high-class wines, known as Bual, Sercial, and Malmsey, are made from varieties of grapes bearing the same names. The exported Madeira is a strong-bodied wine of fine bouquet and excellent quality, but of late years it has gone out of fashion in England, the lighter wines of France and Germany having to a certain extent supplanted it. Taking the four years 1878–1881, the average quantity annually exported was 3045 pipes, each of 92 imperial gallons. It is not usual for the merchant to possess vineyards of his own. The vines are cultivated by the peasants in their small patches of land, and the general rule is for the merchant or wine manufacturer to buy the must from them, and to have it conveyed as it comes from the press direct to his store, where the process of fermentation and the subsequent treatment are carried on from first to last under his own eye.

The sugar cane is said to have been brought from Sicily about 1452, and in course of time its produce became the sole staple of the island. The cultivation languished, however, as the more abundant produce of tropical countries came into the European market, and sugar had long ceased to be made when the destruction of the vines compelled the peasants to turn their attention to other things. Its cultivation was resumed, and sugar machinery imported. In 1881 about 6515 cwts. of sugar, valued at £14,452, were exported. A considerable quantity of spirit is made by the distillation of the juice, or of the molasses left after extracting the sugar, and this is consumed on the island,—not an unmixed benefit to the people, for intemperate habits have greatly increased since they have been subjected to the temptation of cheap spirits. The cane does not flourish here as luxuriantly as within the tropics; still in localities below 1000 feet, where there is a good supply of water, it pays the cultivator well.

The grain produced on the island (principally wheat, barley, and Indian corn) is not sufficient for the consumption of the people. The common potato, sweet potato, and gourds of various kinds are extensively grown, as well as the *Colocasia esculenta*, the *kalo* of the Pacific islanders, the root of which yields an insipid food. Most of the common table vegetables of Europe—cabbages, carrots, onions, beans, pease, &c.—are plentiful. Besides apples, pears, and peaches, all of poor quality, oranges, lemons, guavas, mangos, loquats, custard-apples, figs, bananas, and pine-apples are produced, the last two forming articles of export to the London market. The date palm is occasionally seen, but its fruit is scarcely edible. On the hills large quantities of the Spanish chestnut afford an item in the food of the common people. A little tobacco is grown, and is made up into cigars of inferior quality.

Trade and Commerce.—Excepting sugar and tobacco, the manufactures are insignificant. Coarse linen and woollen articles and boots and shoes are made for island use. A good deal of needlework embroidery is made by the women in and about Funchal for exportation. Baskets, chairs, &c., of wicker work are also exported. According to official returns the total value of exports in 1881 was £134,000, whilst the imports from foreign countries amounted to £175,000 (including £128,500 from the United Kingdom), and the imports from Portugal and the Azores to £112,800. The principal imports were textile fabrics, hardware, grain, salt fish, salt, tea and coffee, tobacco, cask staves, timber, and petroleum (the last three articles coming from America). The duties levied at the custom-house amounted in the same year to about £41,000. In the course of the year 710 merchant vessels entered the port, but more than half of these were English steamers calling on their passage to and from the west coast of Africa, the Cape of Good Hope, or Brazil. The number of Portuguese vessels was only 113.

There is a local bank at Funchal, and also a branch of the Bank of Portugal. The English merchants act as bankers for visitors, and bills or cheques can be negotiated through them. Accounts are made out in reis, an imaginary coin, 4500 of which are equal to the pound sterling, and 1000 form the *mil-rei* or dollar, equal to 4s. 5⅓d. The coins in circulation are of British gold and Portuguese silver, the latter in pieces of 50, 100, 200, and 500 reis, the coinage being decimal. The French decimal system has been established here as in Portugal. Madeira, as a province of Portugal, has the benefit of the regulations of the International Postal Union. Consuls from Great Britain and other European states, as well as from the United States and Brazil, reside at Funchal. Lines of steamers from Liverpool to the British colonies on the west coast of Africa, and from London and Plymouth to the Cape of Good Hope, touch at Madeira, both on their outward and homeward voyages. There is steam communication with Lisbon, and also with Brazil, the Cape Verds, the Canaries, and the Azores (St Michael's), as well as with Antwerp. A large coal depôt for supplying the steamers has been established at Funchal by a firm of British merchants.

Funchal, the capital of the archipelago, lies on the south coast of Madeira, and has a population of about 18,000 persons, the immediate neighbourhood being inhabited by nearly as many more. It is seen to great advantage from the bay, lying on its curving shore, and backed by an amphitheatre of lofty mountains, some of them 4000 feet in height. Numerous country houses (*quintas*) with terraced gardens, and surrounded by vineyards and patches of sugar cane, adorn the slopes and give an air of cheerfulness to the landscape. A small fort on an insulated rock close to the shore commands the bay with its cannon, and there is a much larger fortress on an eminence behind the city. There are no facilities for landing either passengers or goods, nor is there any dock for vessels, which are obliged to remain in the open roadstead, where, however, the anchorage is good. Vessels are protected from all winds except that from the south, which, when blowing with violence, occasionally drives those on shore that do not slip their cables in good time, and take to the open sea. The principal edifices in the city are the cathedral and the churches, none of which deserve much notice, the governor's residence, a semi-castellated building, and the substantial custom-house. The streets are for the most part narrow, but fairly clean, paved with small stones, without side walks, and lighted at night by petroleum lamps. There are two public walks planted with trees, and a garden of small extent, but rendered gay with flowering plants which would need protection in England. There are also fountains of good water, a large hospital, a poor-house, and an unsightly ill-managed jail. The late empress of Brazil built a spacious and handsome hospital close to the town for the reception of twenty-four consumptive patients of Portuguese or Brazilian birth. The entrances of some of the larger houses are through great gates into a paved vestibule, from which a double flight of stairs ascends to the principal rooms. The shops are poor and without display. The windows on the ground floor of the dwelling houses are filled with stout iron bars, which give a prison-like air to the streets. Three streams come down from the hills and run across the town at the bottom of deep channels, which in summer are dry, because the water is diverted higher up for irrigation purposes. Convenient market places have been constructed for the sale of meat, vegetables, and fish. Vegetables and fruit are abundant, but not of the first quality. Fish is plentiful and cheap when fishing is possible, and fresh fish forms with salted cod and herrings an important item in the food of the islanders. Butcher meat is fairly good, with the exception of the mutton, which is very inferior.

The affairs of the city are managed by a municipal chamber of seven persons with a president. Their revenue is derived from imposts on grain and salt imported, and from duties on fresh meat and fish sold in the open market, on wine exported, on houses, and on persons carrying on trade or business. It is expended principally on the lighting and repairing of the streets, and the maintenance of markets and public gardens.

Wheel carriages are not in use; and all heavy articles are transported either on the backs of mules or upon rude wooden sledges drawn by bullocks. When horses are not employed, locomotion is effected either by means of hammocks, or by bullock cars. The hammock is a piece of stout canvas gathered up and secured at each end to a long pole carried by a couple of bearers. In place of cabs, curtained cars on sledges, made to hold four persons, and drawn by a pair of bullocks, are employed. They are convenient enough, but the rate of progress is very slow. The common people carry heavy burdens on the head and shoulders. Such aids as wheelbarrows and trucks are entirely rejected.

A few daily and weekly newspapers are published at Funchal, but they are small sheets, and their circulation is very limited. In a room of the building occupied by the municipal chamber there is a collection of books, numbering about 2800 volumes, accessible to the public. The Portuguese have a club, which has a large house containing a ball room, card rooms, and a billiard room, but no library.

The wine trade attracted several British merchants in the last century to take up their residence at Funchal, where, notwithstanding the decrease of that trade, there was in 1881 a resident British population of 208 persons. A church has been built where a resident chaplain conducts the services of the English Established Church, and the Presbyterians of the Free Church of Scotland have also erected a place of worship. The British community have formed a cemetery, which is kept in admirable order. The English Club, to which strangers can subscribe, has a library of 5000 volumes and a billiard table.

Climate and Meteorology.—The following results have been derived from observations made for a series of eight years at the Government observatory, Funchal, which has a height of 80 feet above the sea. The mean annual barometrical pressure was 30·14 inches. The mean annual temperature was 65°·84 Fahr., the highest point during the eight years having been 90°·3 Fahr. and the lowest 46°·22 Fahr. The two hottest months are August and September, when the mean temperature was 72°·58 Fahr. The three coldest months are January, February, and March, their mean temperature being 60°·6 Fahr. The mean temperature of the six months November to April was 61°·8 Fahr. The mean temperature of winter (December to February) was 61°; of spring (March to May) 62°·64; of summer (June to August) 70°·8; of autumn (September to November) 68°·9. The mean number of days in the year on which rain fell was 80½. The distribution of rain through the months from October to May varies a good deal, but the wettest months are usually November, December, January, and March. Taking a series of twelve years' observations, the mean annual rainfall was 30½ inches, the extremes being 16 and 49·15 inches. The mean daily range of the thermometer from 8 A.M. to 6 P.M. during the six months November to April is about 6°·1 Fahr., but taking the twenty-four hours the mean daily range is about 10°.

The remarkable mildness both in summer and winter of the climate of Madeira, though it lies only 10° north of the Tropic of Cancer, is owing to its being surrounded by a great ocean, from which the atmosphere obtains a large supply of watery vapour. The mean humidity of the air is about 75 (saturation = 100). The prevalent winds are those that blow from the north or from a few points east or west of north, but these winds are much mitigated on the south coast by the central range of mountains. The west wind usually brings rain. That from the east is a dry wind. A hot and dry wind, the *leste* of the natives, occasionally blows from the east-south-east, the direction of the Great Sahara, and causes the hill region to be hotter than below, but even on the coast the thermometer under its influence sometimes indicates 93°. As the thermometer has never been known to fall as low as 46° at Funchal, frost and snow are there wholly unknown, but snow falls on the mountains once or twice during the winter, very seldom, however, below the altitude of 2000 feet. Thunderstorms are rare, and scarcely ever violent.

Madeira has long had a high reputation as a sanatory resort for persons suffering from diseases of the chest. "When we take into consideration," said Sir James Clark in his work on *Climate*, "the mildness of the winter and the coolness of the summer, together with the remarkable equality of the temperature during the day and night, as well as throughout the year, we may safely conclude that the climate of Madeira is the finest in the northern hemisphere." Notwithstanding the ever-increasing competition of other winter resorts, a considerable number of invalids, both English and

German, continue to spend the winter at Funchal, where there are numerous well-conducted hotels and boarding-houses, as well as furnished houses, with gardens, for hire in the neighbourhood, and where English and German physicians practise their profession. The island possesses one great advantage over most other places frequented by invalids in affording cool and comfortable summer quarters on the hills, so that they have no need to make a long journey for the purpose of escaping from the heat.

Zoology.—No species of land mammal is indigenous to the Madeiras. Some of the early voyagers indeed speak of wild goats and swine, but these animals must have escaped from confinement. The rabbit, and those pests the black rat, brown rat, and mouse, have been introduced. The first comers encountered seals, and this amphibious mammal (*Monachus albiventer*) still lingers at the Desertas, but its early extinction is threatened, from the same cause that has brought about its extinction at the Canaries, the persistent attacks of man. Amongst the thirty species of birds which breed in these islands are the kestrel, buzzard, and barn owl, the blackbird, redbreast, wagtail, goldfinch, ring sparrow, linnet, two swifts, three pigeons, the quail, red-legged partridge, woodcock, tern, herring gull, two petrels, and three puffins. Only one species is endemic, and that is a wren (*Regulus madeirensis*), but five other species are known elsewhere only at the Canaries. These are the green canary (*Fringilla butyracea*, the parent of the domesticated yellow variety), a chaffinch (*Fringilla tintillon*), a swift (*Cypselus unicolor*), a wood pigeon (*Columba trocaz*), and a petrel (*Thalassidroma bulwerii*). There is also a local variety of the black cap, distinguishable from the common kind by the extension in the male of the cap to the shoulder. About seventy other species have been seen from time to time in Madeira, chiefly stragglers from the African coast, many of them coming with the *leste* wind.

The only land reptile is a small lizard (*Lacerta dugesii*), which is abundant and is very destructive to the grape crop. The loggerhead turtle (*Caouana caretta*, Gray) is frequently captured, and is cooked for the table, but the soup is much inferior to that made from the green turtle of the West Indies. The only batrachian is a frog (*Rana esculenta*) which has been introduced and has made its way from ravine to ravine.

About 250 species of marine fishes taken at Madeira have been scientifically determined, the largest families being *Scombridæ* with 35 species, the sharks with 24, the *Sparidæ* with 15, the rays with 14, the *Labridæ* with 13, the *Gadidæ* with 12, the eels with 12, the *Percidæ* with 11, and the *Carangidæ* with 10. Many kinds, such as the mackerel, horse mackerel, groper, mullet, braise, &c., are caught in abundance, and afford a cheap article of diet to the people. Several species of tunny are taken plentifully in spring and summer, one of them sometimes attaining the weight of 300 lb. The only freshwater fish is the common eel, which is found in one or two of the streams. (See lists and memoirs by R. T. Lowe and J. Y. Johnson, published by the Zoological Society of London.)

According to the latest writer on the land mollusca of the Madeiras (T. V. Wollaston, *Testacea Atlantica*, 1878), there have been found 158 species on the land, 6 inhabiting fresh water, and 7 littoral species, making a total of 171. A large majority of the land shells are considered to be peculiar, but naturalists do not agree as to the distinctness of the so-called species. Many of the species are variable in form or colour, and some have an extraordinary number of varieties. Of the land mollusca 91 species are assigned to the genus *Helix*, 31 to the genus *Pupa*, and 15 to the genus *Achatina* (or *Lovea*). About 43 species are found both living and fossil in superficial deposits of calcareous sand in Madeira or Porto Santo. These deposits were assigned by Lyell to the Newer Pliocene period. Some 12 or 13 species have not been hitherto discovered alive. As to the marine testaceous mollusca it may be stated that between 300 and 400 species have been collected, but they have been only partially examined, and a large number of forms await identification. Few of them are remarkable for size or colour, and a considerable number are very small. More than 100 species of *Polyzoa* (*Bryozoa*) have been collected, and amongst them are some highly interesting forms.

The only order of insects which has been thoroughly examined is that of the *Coleoptera*. By the persevering researches of the late T. V. Wollaston the astonishing number of 695 species of beetles has been brought to light at the Madeiras (*Insecta Maderensia*, *Cat. of Madeiran Col.*, &c.). The proportion of endemic kinds is very large, and it is remarkable that 200 of them are either wingless or their wings are so poorly developed that they cannot fly, whilst 23 of the endemic genera have all their species in this condition. This fact, Mr Darwin thinks, may be mainly due to the action of natural selection combined with disuse, since those beetles which were much on the wing would incur the risk of being blown out into the sea, whilst those with less-developed wings had the best chance of surviving. With regard to the *Lepidoptera*, 11 or 12 species of butterflies have been seen, all of which belong to European genera. Some of the species are interesting as being geographical varieties of well-known types. Upwards of 100 moths have been collected, the majority of them being of a European stamp, but probably a fourth of the total number are peculiar to the Madeiran group. Thirty-seven species of *Neuroptera* have been observed in Madeira, 12 of them being so far as is known peculiar.

The bristle-footed worms of the coast have been studied by Professor P. Langerhans, who has met with about 200 species, of which a large number were new to science. There are no modern coral reefs at these islands, but several species of stony and flexible corals have been collected, though none are of commercial value. There is, however, a white stony coral allied to the red coral of the Mediterranean which would be valuable as an article of trade if it could be obtained in sufficient quantity. Specimens of a rare and handsome red *Paragorgia* are to be seen in the British Museum and Liverpool Museum.

Botany.—The vegetation of these islands is strongly impressed with a South-European character. Many of the plants in the lower region have undoubtedly been introduced and naturalized since the Portuguese colonization. A large number of the remainder are found at the Canaries and the Azores, or in one of these groups, but nowhere else. Lastly, there are about a hundred plants which are peculiarly Madeiran, either as distinct species or as strongly marked varieties. The late Mr Lowe undertook a description of the vegetation in his *Manual Flora of Madeira*, but unfortunately this valuable work has been left unfinished. The flowering plants found truly wild belong to about 363 genera and 717 species,—the monocotyledons numbering 70 genera and 128 species, the dicotyledons 293 genera and 589 species. The three largest orders are the *Compositæ*, *Leguminosæ*, and *Gramineæ*. Forty-one species of ferns grow in Madeira, three of which are endemic species and six others belong to the peculiar flora of the North Atlantic islands. About 100 species of moss have been collected, and 47 species of *Hepaticæ*. A connexion between the flora of Madeira and that of the West Indies and tropical America has been inferred by the presence in the former of six ferns found nowhere in Europe or North Africa, but existing on the islands of the east coast of America or on the Isthmus of Panama. A further relationship to that continent is to be traced by the presence in Madeira of the beautiful ericaceous tree *Clethra arborea*, belonging to a genus which is otherwise wholly American, and of a *Persea*, a tree laurel, also an American genus. The dragon tree (*Dracæna Draco*) is almost extinct. Amongst the trees most worthy of note are four of the laurel order belonging to separate genera, an *Ardisia*, *Pittosporum*, *Sideroxylon*, *Notelæa*, *Rhamnus*, and *Myrica*,—a strange mixture of genera to be found on a small Atlantic island. Two heaths of arborescent growth and a whortleberry cover large tracts on the mountains. In some parts there is a belt of the Spanish chestnut about the height of 1500 feet. There is no indigenous pine tree as at the Canaries; but large tracts on the hills have been planted with *Pinus pinaster*, from which the fuel of the inhabitants is mainly derived. A European juniper (*J. Oxycedrus*), growing to the height of 40 or 50 feet, was formerly abundant, but has been almost exterminated, as its scented wood is prized by the cabinet-maker. Indeed the flora has been recklessly defaced by the unsparing hand of man. Several of the native trees and shrubs now grow only in situations which are nearly inaccessible, and some of the indigenous plants are of the greatest rarity. There are few remains of the noble forests that once clothed the island, and these are daily becoming less. On the other hand, some plants of foreign origin have spread in a remarkable manner. Amongst these is the common cactus or prickly pear (*Opuntia Tuna*), which in many spots on the coast is sufficiently abundant to give a character to the landscape. As to *Algæ*, the coast is too rocky and the sea too unquiet for a luxuriant marine vegetation, consequently the species are few and poor.

Geology.—The hypothesis that the Madeiras during or since the middle part of the Tertiary epoch formed part of a large tract of land connecting the Canaries in the south and the Azores in the west with south-western Europe and northern Africa has been completely discredited by the discovery of the great depth of the surrounding ocean. The origin of its existing fauna and flora, both of which must have been very different if such a connexion had ever been a fact, is now attributed to the chance arrival from Europe or Africa at distant intervals of the ancestors of the present species, the winds and waves, birds and insects, having been the means of transport. This immigration must have commenced at an early date if the aboriginal flora is partly traceable, as is asserted, to the Miocene flora of Europe, which has been found to contain genera now represented by species only living in the Atlantic islands and in America.

In one of the northern ravines of Madeira some masses of hypersthenite are exposed to view, and these are believed to belong to a diabase formation (better displayed in some of the Canary Islands than in Madeira) of much older date than the beds of basalt, tuff, &c., constituting the rest of the island. It is therefore supposed that there existed at an ancient but unknown epoch an island or the foundation of an island composed of diabase rocks, which, after being subjected to denudation, were overlaid by the materials thrown out by volcanoes of Miocene or later times.

All the islands of the group are of volcanic origin, and recent soundings show that they are the summits of very lofty mountains which have their bases in an abyssal ocean. The greater part of what is now visible in Madeira is of subaerial formation, consisting of an accumulation of basaltic and trachytic lavas, beds of tuff and other ejectamenta, the result of a long and complicated series of eruptions from innumerable vents. Besides this operation of building up by the emission of matter from craters and clefts there is evidence that a certain amount of upheaval in mass has taken place, for at a spot about 1200 feet above the sea in the northern valley of St Vicente, and again at about the same height on Pico Juliana in Porto Santo, there have been found fragments of limestone accompanied by tuffs containing marine shells and echinoderms of the Miocene Tertiary epoch. We have here proof that during or since that epoch portions at least of these islands have been bodily uplifted more than 1000 feet. The fossils are sufficiently well preserved to admit of their genera and in many instances even their species being made out.

That there were pauses of considerable duration whilst the island of Madeira was being increased in height is proved by several facts. The leaf bed and the accompanying carbonaceous matter, frequently termed lignite, although it displays no trace of structure, which lie under 1200 feet of lavas in the valley of St Jorge, afford proof that there had been sufficient time for the growth of a vegetation of high order, many of the leaf impressions having been identified as belonging to species of trees and shrubs which still exist on the island. It is evident, moreover, that great alterations and dislocations had taken place in the rocks of various localities before other lavas and tuffs had been thrown upon them.

There are no data for determining when volcanic action commenced in this locality, but looking at the enormous depth of the surrounding sea it is clear that a vast period of time must have elapsed to allow of a great mountain reaching the surface and then rising several thousand feet into the air. Again, considering the comparatively feeble agents for effecting the work of denudation (neither glaciers nor thick accumulations of alpine snow being found here), and then the enormous erosion that has actually taken place, the inference is inevitable that a very great lapse of time was required to excavate the deep and wide ravines that everywhere intersect the island. Nor is anything known as to the period of the cessation of volcanic action. At the present day there are no live craters, or smoking crevices, as at the Canaries and Cape Verds, nor any hot springs, as at the Azores. On the slopes which descend from the central ridge to the sea, especially in the neigbourhood of Funchal, there are many hills with conical shapes of more or less regularity, which seem to have been formed at a comparatively modern epoch. Volcanic cinders and slag are lying upon several of them, which look as if they had been thrown out of a furnace yesterday. Yet round the base of others there may be traced streams of lava flowing from a higher source, and showing that, subsequent to the construction of these lateral cones, modern as they look, molten matter issued from higher vents, which assumed, on cooling, the character of ordinary compact basalt.

If we examine the general configuration of Madeira, we shall see a mountain chain, about 30 miles in length, running east and west, and throwing off lateral ridges, that give it an extreme breadth of about 12 miles. Peaks rise about the middle to a height of more than 6000 feet; and deep ravines, lying between the lateral ridges, strike for the most part north and south from the central ridge to the sea. In the sections afforded by the ravines, the nucleus of the island is seen to consist of a confused mass of more or less stratified rock, upon which rest beds of tuff, scoriæ, and lava, in the shape of basalt, trap, and trachyte, the whole traversed by dykes. These beds are thinnest near the central axis; as they approach the coast they become thicker and less intersected by dykes. At the centre of the island there are several summits of nearly the same altitude, and these are in some places connected by narrow walls and ridges, which are frequently quite impassable, whilst at others they are separated by ravines of great depth. On all sides are seen vertical dykes, projecting like turrets above the weathered surface of the softer beds.

In various parts of the island may be seen elevated tracts of comparatively level ground. These are supposed to have been formed by the meeting of numerous streams of lava flowing from cones and points of eruption in close proximity, various ejectamenta assisting at the same time to fill up inequalities. Deep down in some of the lateral ravines may be seen ancient cones of eruption which have been overwhelmed by streams of melted matter issuing from the central region, and afterwards exposed to view by the same causes that excavated the ravines. These ravines may be regarded as having been formed at first by subterranean movements, both gradual and violent, which dislocated the rocks, and cut clefts through which streams flowed to the sea. In course of time the waters, periodically swollen by melted snows and the copious rains of winter, would cut deeper and deeper into the heart of the mountains, and would undermine the lateral cliffs, until the valleys became as large as we now find them. Even the Curral, which, from its rounded shape and its position in the centre of the island, has been usually deemed the ruins of a crater, is thought to be nothing more than a valley scooped out in the way described. The rarity of crateriform cavities in Madeira is very remarkable. There exists, however, to the east of Funchal, on a tract 2000 feet high, the Lagoa, a small but perfect crater, 500 feet in diameter, and with a depth of 150 feet; and there is another, which is a double one, in the district known as Fanal, in the north-west of Madeira, nearly 5000 feet above the sea. The basalt of which much of the outer part of the island is composed is of a dark colour and a tough texture, with small disseminated crystals of olivine and augite. It is sometimes full of vesicular cavities, formed by the expansion of imprisoned gases. A rudely columnar structure is very often seen in the basalt, but there is nothing so perfect as the columns of Staffa or the Giant's Causeway. The trachytic rocks are small in quantity compared with those of the basaltic class. The tufa is soft and friable, and generally of a yellow colour; but where it has been overflowed by a hot stream of lava it has assumed a red colour. Black ashes and fragments of pumice are sometimes found in the tufaceous strata.

The mineral contents of the rocks of Madeira are unimportant. There are no metallic ores, nor has any sulphur been found; but a little iron pyrites and specular iron are occasionally met with. The basalt yields an excellent building-stone, various qualities of which are quarried near Cama dos Lobos, 5 or 6 miles west of Funchal.

At Porto Santo the trachytic rocks bear a much greater proportion to the basaltic than in Madeira. An adjacent islet is formed of tuffs and calcareous rock, indicating a submarine origin, upon which supramarine lavas have been poured. The older series contains corals and shells (also of the Miocene Tertiary epoch), with water-worn pebbles, cemented together by carbonate of lime, the whole appearing to have been a coral reef near an ancient beach. The calcareous rock is taken in large quantities to Funchal, to be burnt into lime for building purposes.

Porto Santo.—This forms a single concelho and parish, about 25 geographical miles north-east of Madeira. It has a length of 6½ geographical miles and a width of 3. A stationary population of about 1750 persons inhabits 435 houses, chiefly collected at one spot known as the Villa, where a lieutenant-governor resides. The island is very unproductive, water being scarce and wood wholly absent. Around the little town there is a considerable tract of pretty level ground covered by calcareous sand containing fossil land shells. At each end of the island there are hills, of which Pico do Facho, the highest, reaches the altitude of 1600 feet. Barley, but little else, is grown here, the limited requirements of the inhabitants being supplied from Funchal by means of small sailing vessels.

The Desertas.—These are three uninhabited rocks lying about 11 miles south-east of Madeira. They are not easily accessible, as they present lofty precipices to the sea on all sides. Rabbits and goats abound on them. The archil weed grows on the rocks, and is gathered for exportation. The largest islet is 6½ miles long, and attains the height of 2000 feet. These rocks are conspicuous objects in the sea-views from Funchal. (J. Y. J.)

MADISON, a city of the United States, the county seat of Jefferson county, Indiana, is situated on the north bank of the Ohio, 90 miles below Cincinnati, and 44 above Louisville, with which it has daily steamboat communication. As the terminus of one of the divisions of the Jeffersonville, Madison, and Indianapolis Railroad, Madison commands extensive means of traffic; and its provision trade especially has attained important dimensions. Pork-packing is also carried on, and brass and iron foundries, tanneries, and flour-mills appear among the industrial establishments. The population was 8012 in 1850, 8130 in 1860, 10,709 in 1870, and 8945 in 1880.

MADISON, a city of the United States, the capital of Wisconsin, and seat of justice of Dane county, lies towards the south of the State, in 43° 4′ N. lat. and 89° 21′ W. long., 75 miles west of Milwaukee. In the beauty of its situation it has few rivals, occupying as it does the undulating isthmus between Mendota and Menona, two of the lakes which give name to the Four Lake Region, connected with the Mississippi by Yahara or Catfish river and Rock river; and the cool summer climate, which it owes to the fact that it stands 788 feet above the level of the sea, and 210 feet above Lake Michigan, renders it a health resort of some value, especially for consumptive patients. The State capitol, situated in the midst of a finely wooded park of 13 acres, is a rather imposing but hybrid edifice of white limestone crowned by a central dome rising 200 feet above the level of the basement; it was originally built in room of an earlier capitol in 1860, at a cost of $400,000, and has since been greatly enlarged. About a mile to the west of the capitol stand, on the high grounds known as College hill, the buildings of the Wisconsin university, an institution dating from 1850, and attended by about eight hundred students. Other buildings of note are the United States post-office and court-house, the soldiers' orphans' home, and at some distance from the city the State lunatic asylum. The Wisconsin Historical Society has a library of 58,000 volumes. Various lines belonging to the Chicago and North-Western Railway and to the Chicago, Milwaukee, and St Paul Railway meet at Madison; and the city has not only a good general trade, but manufactures ploughs and other agricultural implements, waggons, woollen goods, and flour. The population, which was only 1525 in 1850, appears in the three later censuses as 6611, 9176, and 10,325. When the site was selected (1836) for the capital of the territory of Wisconsin it was altogether unoccupied.

MADISON, JAMES (1751–1836), fourth president of the United States, was born in King George county, Virginia, on the 16th of March 1751, during a temporary visit of his mother to her relatives. His father was the owner of large landed estates in Orange county, Virginia, and was a man of distinction in the county. In 1769 Madison entered Princeton College in New Jersey, and graduated as B.A. in 1771; but he remained another year at Princeton studying under the direction of President Witherspoon. His close application to study had seriously impaired his health, which continued delicate for many years. Returning to Virginia in 1772, he pursued his reading and studies, however, with the same zeal as before, the subjects chosen being particularly those of philosophy, theology, and law.

Madison had as yet taken no active part in the exciting politics of the time. In 1775, however, he was chairman of the committee of public safety for Orange county, and in the spring of 1776 he was chosen a delegate to the new Virginia convention, which formed a constitution for the State. Failing to be re-elected in 1777, he was chosen in that year a member of the council of State, in which he took a prominent part until the end of 1779, at which time he was elected a delegate to the Continental Congress, later the Congress of the Confederation. It was in this assembly that Madison first displayed those powers which ultimately made him the founder of the constitution of the United States. He was in Congress during the final stages of the revolutionary war, and one year after the establishment of peace, at a time when the confederation was in a chronic state of collapse, occasioned by the neglect or the refusal of the States to respond to the requisitions of Congress for supplies for the federal treasury, Madison was among the first to advocate the granting of additional powers to Congress. In 1781 he favoured the amendment of the articles of confederation, giving to Congress the power to enforce its requisitions; and in 1783 he zealously advocated the proposed plan by which the States should grant to Congress for a period of twenty-five years the authority to levy an impost duty. Accompanying this plan was an address to the States drawn up by Madison. This address is one of the ablest of his state papers, and with others of this period placed him in the front rank of American statesmen.

In November 1783, the constitutional limit of his term as deputy having expired, Madison returned to Virginia, and the next year he again took a seat in the legislature of that State. As chairman of the judiciary committee, he was particularly instrumental in revising the statute laws of the State. He opposed the further issue of paper money by the State, and tried to induce the legislature to repeal the law confiscating British debts.

As a member of the legislature of Virginia, Madison did not lose sight of the interests of the confederacy. He looked beyond mere local interests, believing that the highest good of the State would best be advanced through a respected central Government. Virginia and Maryland possessing a common jurisdiction over the waters of the Potomac river and the Chesapeak Bay, it became necessary to come to some agreement between them as to the commerce and navigation upon those waters. On Madison's proposal, commissioners of the two States met at Mount Vernon in March 1785. Maryland having proposed to invite the States of Pennsylvania and Delaware to join in the arrangement, Madison saw an opportunity for a more extended and general concert in regard to commerce and trade, and proposed that all the States should be invited to send commissioners to take into consideration the trade of the United States. This resolution was adopted by the legislature of Virginia; and thus was inaugurated the movement which led to the meeting at Annapolis in 1786, and later to the convention at Philadelphia in 1787. The palpable defects in the government of the confederation had led Madison to make an extended study of confederacies, ancient and modern. Among his papers was found one bearing the title *Notes on Confederacies*, but he gave the results of these researches more at length in Nos. 17, 18, and 19 of *The Federalist*. His conclusion was that no confederacy could be long successful which acted upon States only, and not directly upon individuals.

As the time for the meeting of the convention approached, he drew up an outline of a new system of government to take the place of the articles of confederation.

As expressed in a letter to General Washington of the 16th of April 1787, it was in substance that the individual sovereignty of the States is totally irreconcilable with the aggregate sovereignty, and that a consolidation of the whole into one simple republic would be as inexpedient as it was unattainable. He sought therefore some middle ground, which might at once support a due supremacy of the national authority and not exclude the local authorities whenever they might be subordinately useful. He proposed, to this end, to change the basis of representation in Congress from States to the population.

The national government should have authority in all cases requiring uniformity. In addition to this positive power, the national government should have a negative on all State laws "as heretofore exercised by the kingly prerogative." This negative, he thought, would best be vested in the senate, which should be a comparatively permanent body.

The national supremacy should extend to the judiciary department and to the militia. The legislature should be composed of two branches—one, the more numerous, elected for a short term, the other, few in number, for a longer term. A national executive should be provided for, and the States should be guaranteed against both internal and external dangers. The right of coercion should be expressly declared. "But the difficulty and awkwardness of operating by force on the collective will of a State rendered it desirable that the necessity of it should be precluded." He thought the negative on State laws might answer the purpose. This was a weak point in Madison's theory of government. He thought, with Jefferson, that there could be found some means of governing without resorting to force. Lastly, "to give the new system its proper validity and energy, a ratification must be obtained from the people, and not merely from the legislatures."

These ideas, somewhat modified and extended in details, formed the Virginia plan of government, presented in the convention by Edmund Randolph; and this plan, again, became the basis of the extended deliberations in the convention which resulted in the constitution adopted in that body on the 17th of September 1787. In the convention, as a delegate from Virginia, Madison took a leading part in the debates, of which he kept notes which were afterwards published by order of Congress. It was his influence which largely shaped the form of the final draft of the constitution. But the labour was not finished with this draft; the constitution was yet to be accepted by the people; that it was accepted was due in an eminent degree to the efforts of Madison. In order to place the new constitution before the people in its true light, and to meet objections brought against it, he joined Hamilton and Jay in the publication of a series of essays, which were published in a collected form in 1788 under the name of *The Federalist*, and which are still worthy of careful study.

In the Virginia convention for ratifying the constitution he was again called upon to defend that instrument, and against such staunch patriots as Patrick Henry and George Mason. Madison here appeared at his best. He answered every objection in detail, calmly, yet with an eloquence and zeal that carried conviction to his audience. The result was a victory against an adverse public opinion, as well as against the eloquence of his opponents.

Although he remained in the public service for nearly twenty-five years longer, his greatest work was finished with the adoption of the constitution. He had gained the well-earned title of "father of the constitution." The part he had taken, however, alienated from him the support of a majority of the people of his State. He was defeated as a candidate for United States senate, though he was chosen in his own district as representative to Congress. Taking his seat in the Lower House in April 1789, he assumed a leading part in the legislation necessary to the organization of the new government. To Hamilton's measures, however, for the funding of the debt, the assumption of the State debts, and the establishment of a national bank, he was opposed. On other questions, too, he sided with the Anti-Federalists, and gradually assumed the leadership of the opposition in the House of Representatives.

One would have expected to find him advocating with Washington, Hamilton, Marshall, Jay, and others those measures which would strengthen still more the federal government. On the contrary, we find him labouring to confine the powers of the national government within the narrowest possible limits.

Much has been said in regard to Madison's change of principles at this time. It has been intimated that he was influenced, perhaps unconsciously, by the decided attitude of his State, but especially by the dominating mind of his most intimate friend, Jefferson. Probably there is something of truth in this charge, yet it must be said that Madison had shown on many previous occasions an aversion to a liberal construction of granted powers. Timid by nature, he was frightened at the bold and comprehensive measures of the secretary of the treasury. He thought he saw in them a constructive latitude of interpretation and a centralization of interests dangerous to republican principles.

Madison opposed also the foreign policy of the administration in 1793–96, in its attempts to maintain a neutral position between Great Britain and France, then at war with each other. And under the signature of "Helvidius" he published in the public journals five papers of great power and acuteness, criticizing the "monarchical prerogative of the executive" as exercised in the proclamation of neutrality of 1793, and the right of the recognition by the president of foreign states. So far as the question of international law was concerned, Madison was essentially right, but in regard to the authority of the executive, and the question of the expediency of Washington's neutral policy, the subsequent practice of the Government and the general verdict of history condemn his view. In 1794 Madison introduced in the House of Representatives resolutions based upon Jefferson's report on commerce, advising retaliatory measures against Great Britain and a discrimination in commercial and navigation laws in favour of France. Again, in 1796 he strenuously opposed the appropriation of money for the purpose of carrying into effect the treaty of 1794 with Great Britain. He scouted the idea as visionary that Great Britain would go to war on a refusal to carry the treaty into effect. It was not conceivable, he thought, that she would "make war upon a country which was the best market she had for her manufactures." It had been a favourite theory with Madison, as with Jefferson, that foreign nations could be coerced through their commercial interests. The fallacy of this doctrine was well exemplified by its utter inefficiency when put in practice by them in 1807–12.

In 1797 Madison withdrew to private life, though not to a life of inactivity. In 1798 he was induced by Jefferson to join in a movement in opposition to the Alien and Sedition Laws passed by the Federalists in that year, and was himself the author of the Virginia resolutions, which declared—

"That the constitution of the United States was a compact, to which the States were parties, granting limited powers of government; that in case of a deliberate, palpable, and dangerous exercise of other powers, not granted by the compact, the States had the right, and were in duty bound, to *interpose* for arresting the progress of the evils and for maintaining within their respective limits, the authorities, rights, and liberties pertaining to them; that the Alien and Sedition Laws were such infractions of the compact; . . . . and finally that the State of Virginia declared those laws unconstitutional and not law, but utterly null, void, and of no effect, and invited the other States to join her in this action."

These resolutions, with those of Kentucky drawn by Jefferson, met with decided objections from the other States. Upon these objections Madison made a report to the legislature of Virginia, consisting of an elaborate and carefully considered argument sustaining in every point the resolutions of 1798. Thirty years later these arguments were freely made use of by Calhoun and his school of nullifiers as the basis of their doctrine. But Madison, in 1830, repudiated the idea that the resolutions of 1798 involved the principles of nullification. He wrote at that time many letters to public men, and especially one to Edward Everett, in August 1830, to prove this position. The nullifiers were not convinced, however, by this reasoning, and continued to use his arguments in favour of their doctrine, till it became a source of great annoyance to him.

With the rise of the republican party to power in 1801, Madison became secretary of state in Jefferson's cabinet,—a position for which he was well fitted both by his temperament and his training, well versed as he was in constitutional and international law, and practising a calmness and fairness in discussion which are essential qualities of the diplomatist. In defending the neutral rights of the United States against the encroachments of European belligerents (1801–9), there was almost constant need of the use of all those qualities. The most important of his papers during this period was *An Examination of the British Doctrine which subjects to capture a neutral trade not open in time of peace*, that is, the so-called "rule of the war of 1756," as extended by Great Britain in 1793 and 1803. This treatise, published in 1806, was an argument against the British doctrine, drawn from a careful investigation of authorities on international law, and was a valuable contribution to the discussion of a question which, for various reasons, has now lost its importance.

In 1809 Madison was elected president to succeed Jefferson, whose peace policy—a policy of commercial restrictions to coerce Great Britain and France—he continued to follow until, in 1812, he was forced by his party to change it for a policy of war. He had been, under the lead of Jefferson, a great lieutenant; he had for the most part furnished the arguments in support of the republican policy since 1790; but he did not possess the qualities of a leader. His cabinet was in part forced upon him in 1809 by a senatorial clique, and his administration lacked vigour, particularly during the war of 1812–15. He had never been a partisan in politics, and was averse to forcing his views upon others, except in so far as he could do so by impartial arguments. In argument, he was not satisfied with generalities; his reasoning went to the foundation of principles—to the minutest details, sometimes almost painfully so. His analysis of the arguments was powerful and searching. In this he resembled Hamilton; but his conclusions were reached through a laborious process of induction, whilst those of Hamilton seemed more the result of intuition. Madison, moreover, lacked Hamilton's boldness of conception and courage in assuming the responsibility of his theories. The difference between them was the difference between great talent and genius.

Madison served two terms as president, and in 1817 retired to Montpellier, his country seat in Virginia. For nearly twenty years thereafter he was engaged in agricultural pursuits, but was ever interested in literature and politics. To the time of his death he continued to be consulted by statesmen as an oracle on all constitutional questions.

In character he was mild and conciliatory; and, whether in power or in opposition, he never lost the friendship or confidence of his political opponents. His death occurred on the 28th of June 1836.

His *Letters and Writings*, in 4 vols., were published by order of Congress in 1865. *The Madison Papers*, a report of debates during the Congress of the Confederation, and reports of debates in the Federal Convention, were also published by order of Congress. *The History of the Life and Times of Madison*, by William C. Rives, in 3 vols., comes down only to 1794.

MADRAS, a presidency of British India, occupying, with its dependencies, the entire south of the Indian peninsula, and washed on the east by the Bay of Bengal and on the west by the Indian Ocean. The north boundary is extremely irregular. On the extreme north-east is the Bengal province of Orissa; then the wild highlands of the Central Provinces; next the dominions of the nizám of Hyderabad; and lastly, on the north-west, the Bombay districts of Dhárwár and North Kánara. The extreme length from north-east to south-west is about 950 miles, and the breadth 450 miles; the area of the British districts (1879) is 138,856 square miles, and the population in 1871 was 31,672,613. The five native states attached to Madras—Travancore, Cochin, Puducottah, Banganapalli, and Sandúr—have an additional area of 9818 square miles, and a population of 3,289,392, making a grand total area of 148,674 square miles, with a population of 34,962,005.

General Aspect.—From a physical point of view, the Madras presidency may be roughly divided into three tracts —(1) the long and broad east coast, (2) the shorter and narrower west coast, and (3) the high interior table-land. These divisions are determined by the great mountain ranges of the Eastern and Western Gháts. The Eastern Gháts form a continuation of the confused hill system of Chutiá Nágpur. They run in a south-west direction through almost the entire length of Madras until they lose themselves in the Nílgiris, and there join the Western Gháts. Their average height is only 1500 feet, and for the most part they leave a broad expanse of low land between their base and the sea; their line is pierced by three great rivers—the Godávari, Kistna, and Káveri (Cauvery). The Western Gháts stretch continuously along the shore of the Indian Ocean. Rising steeply at a distance of from 30 to 50 miles from the coast, they catch almost the whole rainfall of the monsoon; and within Madras territory not a single stream breaks through their barrier. Some of the peaks attain an elevation of more than 5000 feet. Between these two ranges lies the central table-land, with an elevation of from 1000 to 3000 feet, which includes the whole of Mysore, and extends over about half a dozen districts of Madras. The three principal rivers above-mentioned, each having a large tributary system, all rise in the Western Gháts, and run across the peninsula in a south-east direction into the Bay of Bengal. In the upper parts of their course they drain rather than water the country through which they flow, and are comparatively valueless either for navigation or for irrigation; but before reaching the sea they spread over alluvial deltas. Other but smaller rivers of the same character are the North and South Pennár or Ponniyár, Palar, Váigai, Vellar, and Tambraparni. The two main hill systems have been already described (see Gháts, vol. x. p. 559). The Nílgiris, which join these, culminate in Dodabetta (8640 feet), the loftiest peak in southern India. There are, besides, many outlying spurs and tangled masses of hills, of which the Shevaroys, Anamalais, and the Palnis are the most important. The principal lake in the presidency is that of Pulicat on the east coast, which is 33 miles from north to south, and forms an important means of communication between Madras city and the north districts. On the west coast are a remarkable series of backwaters or lagoons, fringing the seaboard of Kánara, Malabar, and Travancore. The largest is the backwater of Cochin, which extends for a distance of 120 miles from north to south.

The mineral wealth of the province is as yet undeveloped. Iron of excellent quality has been smelted by native smiths in many localities from time immemorial; but attempts to work the beds after European methods have hitherto proved unsuccessful. Carboniferous sandstone extends across the Godávari valley as far as Ellore, but the coal has been found to be of inferior quality. Scientific researches have proved the existence of gold in the Nílgiris, in sufficient quantity to render outlay on it profitable; and several companies, representing a large amount of capital, have been formed for working the mines. Among other minerals may be mentioned manganese in the Nílgiris and Bellary; copper and lead ores in many parts of the Eastern Gháts; antimony and silver; and corundum in the valley of the Káveri. Garnets are abundant in the sandstone of the Northern Circars, and diamonds of moderate value are found in the same region. Stone and gravel quarries are very numerous.

The Forest Department of Madras was first organized in 1856, and it is estimated that forests cover a total area of more than 5000 square miles, the whole of which is under conservancy rules. For supplying fuel to the railways an area of about 160,000 acres is strictly conserved. In the remaining forests, after supplying local wants, timber is either sold direct by the department, or licences are granted to wood-cutters. The more valuable timber-trees comprise teak, ebony, rosewood, sandal-wood, and redwood. The Government plantations cover an area of 9000 acres. The trees thus artificially reared are teak, sandal-wood, *Casuarina*, and *Eucalyptus*. The finest teak plantation (over 3000 acres) is near Beypur in Malabar. At Mudumalli there are plantations of both teak and sandal-wood; and the *Eucalyptus* or Australian gum-tree now grows on the Nílgiris in magnificent clumps. The total value of timber and wood exported was £95,801 in 1875–76, and £122,413 in 1880–81.

The wild animals are those for the most part common to the rest of India. Those deserving mention are the elephant, bison, sambur, and ibex of the Western Gháts and the Nílgiris. Bison are also found in the hill tracts of the Northern Circars. In Travancore state the black variety of leopard is not uncommon. In 1880–81 182 persons and 11,628 cattle were returned as killed by wild beasts. The number of persons killed by snake-bites in 1880 was 928. The elephant is now protected by law from indiscriminate destruction. The agricultural returns for 1880–81 report the number of buffaloes as

1,324,435, bullocks 3,228,907, cows 2,873,979, goats 2,803,407, sheep 4,082,411, horses 8986, and elephants 532. The cattle are small, but in Nellore and along the Mysore frontier a superior breed is carefully kept up by the wealthier farmers. The best buffaloes are imported from the Bombay district of Dhárwár. Experiments in sheep breeding have been made at the Saidápet model farm, with fair success.

Population.—The first census, in 1822, returned the population as 13,476,923, and an enumeration in 1866-67 gave 26,539,052. The census of November 1871, however, was the first conducted in regular form. The following table gives the results for the British districts of the presidency. According to the preliminary return the total population at the census in 1871 was 30,839,181 (15,242,122 males and 15,597,059 females). This would seem to show that the loss caused by the famine of 1876–78 has been nearly made up.

Area, Population, &c., of Madras Presidency in 1871.

Name of District.	Sq. Miles.	Villages.	Houses.	Population.	Inhab. per Sq. Mile.
Ganjám	8,313	4,562	341,404	1,520,088	182·9
Vizagapatam	18,344	8,581	489.419	2,159,199	117·7
Godávari	6,224	2,202	389,712	1,592,939	253·9
Kistna	8,036	2,140	282,358	1,452,374	180·7
Nellore	8,462	2,174	263,820	1,376,811	162·7
Cuddapah	8,367	1,337	339,063	1,351,194	161·5
Bellary	11,007	2,568	351,943	1,668,006	151·5
Karnúl	7,358	787	205,884	959,640	130·4
Chengalpat	2,753	2,362	141.434	938,184	340·7
North Arcot	7,139	5,292	329,844	2,015,278	282·3
South Arcot	4,873	3,198	228,761	1,755,817	360·3
Tanjore	3,654	3,935	369,984	1,973,731	540·1
Trichinopoli	3,515	1,641	210,690	1,200,408	311·5
Madura	9,502	5,459	443.513	2,266,615	238·5
Tinnevelli	5,176	1,824	403,803	1,693,959	327·3
Coimbatore	7,432	1,575	361,109	1,763,274	237·3
Nílgiris	749	17	13,922	49,501	66·0
Salem	7,483	4,021	391,519	1,966,995	262·9
South Kánara	3,902	1,288	184,569	918,362	235·4
Malabar	6,002	432	435,462	2,261,250	376·7
Madras city	27	23	51,741	397,552	14,724·1
Total	138,318	55,421	6,229,954	31,281,177	226·2

Hindus numbered 28,863,978 ; Mohammedans, 1,857,857; Christians, 533,760 ; Jains, 21,254 ; and "others," 4328. The Hindus (92·3 per cent. of the whole) are subdivided into 16,159,610 Sivaites, 11,657,311 Vishnuvites, 154,989 Lingáyats, and 892,068 "others," including hill tribes. The Sivaites are most numerous in the extreme south and on the west coast, while the Vishnuvites are chiefly found in the northern districts. The Lingáyats may be described as a sect of Sivaite puritans, who derive their name from their practice of carrying about on their persons the *lingá* or emblem of Siva. Of Hindu castes, Bráhmans number 1,094,455. They follow various pursuits, and many of them are said to be recent immigrants, who came south in the train of the Mahratta armies. A peculiar caste of Bráhmans, called Namburi, is found in Malabar, who are said to be descended from fishermen. The Kshattriyas, or warrior caste of the ancient Hindu organization, number only 190,415. The three trading castes of Chettis, Beri Chettis, and Komatis number 714,712, and except in Kánara district still retain in their hands nearly all the commerce of the country. Agricultural castes number 7,826,127 ; the highest classes among them do not cultivate with their own hands, and many of them formerly held their lands on a military tenure. The pastoral castes number 1,730,681, but a large proportion of them have now abandoned their hereditary occupation. Artisans number 785,085, of whom nearly one-half are workers in metal. Weavers number 1,017,781, but their industry is now decayed owing to Manchester competition. The labouring castes are returned at 3,944,463. Fishing and hunting castes number 971,837, but many have now betaken themselves to agriculture. The palm cultivators and toddy makers amount to 1,664,862. Out-castes (Pariahs) number 4,761,503 ; in the country round Madras they form about one-quarter of the total population. Up to the close of the last century they lived in a state of slavery to the superior castes ; and they are still compelled by custom to live in separate hovels outside the boundary of the village, and to perform all menial services. They are described as a laborious, frugal, pleasure-loving people, omnivorous in diet, and capable of performing much hard work. Unclassified Hindus (2,666,890) consist of aboriginal hill races and wandering tribes. Numerically the most important are the Kandhs and Sauras, two cognate races who inhabit the mountainous tracts of the Eastern Gháts attached to several of the large *zamindáris* of Ganjám and Vizagapatam. On the Nílgiris, the aboriginal tribe best known to Europeans is the Todas, a stalwart, haughty race, who domineer over the more timid jungle folk, and confine themselves to the pasturing of buffaloes. It is believed that the Todas are now dying out, for in 1871 they numbered only 693. The principal wandering tribes are the Brinjaris and Lambadis, who are to be found in all parts of the country as carriers of grain and salt.

The Mohammedans are thus subdivided:—Sunnis, 1,654,529 ; Shias, 69,302 ; Wahhábis, 3954 ; unspecified, 130,072. A more familiar division is a race one :—Labbay, Mopla, Arab, Shaikh, Sayyid, Pathán, and Mughal. The Labbays (312,088) are the descendants of Hindu converts, and are traders by hereditary occupation, although many now employ themselves as sailors and fishermen. The Moplas (612,789) are the descendants of Malayalam converts to Islám,—the head of the tribe, the rájá of Kananúr, being descended from a fisher family in Malabar. They are a hard-working, frugal people, but quite uneducated and very fanatical, and under the influence of religious excitement have often disturbed the public peace. The Shaikhs number 511,112, the Sayyids 89,219, the Patháns 70,943, and the Mughals 12,407.

Christians are more numerous in Madras than in any other part of India. They number in the British districts 533,760, of whom 40,879 are Europeans or Eurasians, and the remainder native converts ; Roman Catholics number 397,071, and Protestants 93,228. In Travancore and Cochin states the native Christians are still more numerous, constituting as much as one-fourth of the population. The Roman Catholics, whose number throughout southern India is estimated at upwards of 650,000, owe their origin to St Francis Xavier, and the famous Jesuit mission of Madura ; they are partly under the authority of the archbishop of Goa, and partly under twelve Jesuit vicariates. Protestant missions date from the beginning of the last century. The Danes were the pioneers ; but their work was taken up by the Society for Promoting Christian Knowledge, under whom laboured the great Lutherans of the last century—Schultz, Sartorius, Fabricius, and Schwartz. The Church Missionary Society entered the field in 1814 ; and subsequently an American mission joined in the work. The total number of Protestant native Christians in southern India (British and native) in 1878 was 296,408.

Urban life may be said to be more highly developed in Madras than in Bengal or Bombay. Populous cities, indeed, are not numerous, but there is an unusual proportion of towns with from 2000 to 20,000 inhabitants. The six cities with a population of more than 50,000 are—Madras city (1871), 397,552 ; Trichinopoli, 76,530 ; Tanjore, 52,175 ; Madura, 51,987 ; Bellary, 51,766; Salem, 50,012.

Agriculture.—Over the greater part of the area of Madras artificial irrigation is impossible, and cultivation is dependent upon the local rainfall, which rarely exceeds 40 inches a year, and is liable to fall irregularly. The Malabar coast is the only part where the rainfall brought by the south-west monsoon may be trusted both for its amount and regularity. Other districts, such as Bellary, are also dependent upon this monsoon, but in their case the rain clouds have spent themselves in passing over the Western Gháts, and cultivation becomes a matter of hazard. Over the greater part of the presidency the rainy season is caused by the south-east monsoon, which breaks about the end of September. The deltas of the Godávari, Kistna, and Káveri rivers are the only spots on the east coast which artificial irrigation is able to save from risk of occasional scarcity. Of the total cultivated area about 80 per cent. is returned as "dry" land, or that which is solely dependent upon local rainfall ; 15 per cent. as "wet" land, irrigated from river channels ; 2 per cent. as garden land irrigated from wells ; and about 3 per cent. fallow and pasture. The principal food staples are rice, *cholam*, *kambu*, *ragi*, and *varagu*. The most common oil-seed is gingelly. Garden crops comprise tobacco, sugar-cane, chillies, betel-leaf, and plantains. The fruit trees are cocoa-nut, areca-nut, date and palmyra palm, jack, tamarind, and mango. Special crops include cotton, indigo, coffee, tea, cinchona. The principal coffee tract stretches along the slopes of the Western Gháts from the north of Mysore almost down to Cape Comorin. The larger portion of this area lies within Mysore, Coorg, and Travancore states, but Wainád and the Nílgiri hills are within Madras. The first coffee plantation was opened in the Wainád in 1840. Many of the early clearings proved unprofitable, and the enterprise made little progress till about 1855, in which year the total exports were 32,000 cwts. Coffee, which is much cultivated on the Nílgiris, now covers in the whole presidency 131,348 acres. The tea plant was also introduced into the Nílgiri hills about 1840, but was not taken up as a commercial speculation till 1865. The area under tea is over 4000 acres, and the exports in 1880–81 were 263,940 lb. The cinchona plant was successfully introduced into the Nílgiri hills by Government in 1860. In 1880–81 847 acres were under cultivation ; 1,087,637 plants were raised ; and the receipts of sales were £39,618, the amount in 1875–76 being only £4989. Tobacco is extensively grown in Godávari and Kistna districts. The greater part of the soil in Madras is held by the cultivators direct from Government under the tenure known as *ráyatwari*. The average rate of Government assessment is about 2s. 3d. per acre on unirrigated and 9s. 6d. on irrigated land. In 1880–81 the total revenue from this source amounted to £4,170,052. Besides these lands in the hands of the Government, there are also proprietary or *zamindári* estates in all parts of the country. These estates are either the remains of ancient principalities, which the holder cannot sell or encumber beyond his own life interest, or they are creations of British rule and subject to the usual Hindu custom of partition. The total area of the *zamindári* estates is about 21 million acres, or one-fourth of the whole presidency. The *peshkash* or tribute payable to Government in perpetuity amounts to about £500,000 a year. *Ináms*, revenue-free or quit-rent grants of lands made for religious endowments or for services rendered to the state, occupy an aggregate area of a little over 1,500,000 acres.

Manufactures.—Madras possesses few staple manufactures. The preparation of the coffee berry for export constitutes the one great business carried on by means of European capital and under European supervision. Indigo is manufactured in considerable quantities, but of inferior quality. The more important of the large manufactories are three cotton mills in Madras, a weaving establishment maintained by the Basel mission in South Kánara, sugar works in Ganjám and South Arcot, and a jute factory at Vizagapatam. Up to the close of the last century cotton goods constituted the main article of export. Masulipatam, where the first English factory on the Coromandel coast was established in 1620, enjoyed a special reputation for its chintzes, which were valued for the freshness and permanency of their dyes. There is still a small demand for these articles in Burmah, the Straits, and the Persian Gulf; but Manchester goods have nearly beaten the Indian exporter out of the field. Native looms, however, still hold their own in the local market, in face of strenuous opposition. After weaving, working in metals appears to be the most widespread native industry. Among local specialities which have attracted European curiosity may be mentioned the jewellery of Trichinopoli, ornaments of ivory and horn worked at Vizagapatam, and sandal-wood carving at Kánara. The manufacture and sale of salt is a Government monopoly, carried on under close supervision. The process employed is solar evaporation, and the entire eastern coast-line from Orissa to Cape Comorin affords natural facilities for the industry. The preparation of arrack and toddy spirit is also a Government monopoly. On the Nílgiri hills and at Bellary country beer is manufactured by European firms subject to an excise duty of 6d. per gallon.

Railways.—Two guaranteed railway companies, the Madras and the South Indian, have their lines almost entirely within the presidency. The Madras Railway, which connects at Ráichur with the Great Indian Peninsular system, runs south-east to Madras, and then west across the peninsula to Beypur, with branches to Bellary and Bangalore. The total length open in 1881 was 858 miles; the capital expended, £10,441,699; the net profits £177,433, giving a dividend of 1·7 per cent. on the capital expended. The South Indian Railway (narrow guage) runs north from Tuticorin to Madras. In 1881 the total length was 658 miles; the capital expended, £4,291,311; and the net profits yielded a dividend of 2·9 per cent.

Commerce and Trade.—The continuous seaboard of the Madras presidency, without any natural harbours of the first rank, has tended to create a widely diffused trade. Madras city conducts nearly one-half of the total sea-borne commerce; next comes Malabar, containing the western railway terminus near Calicut; then Godávari, with its cluster of ports along the fringe of the delta; Tinnevelli, with the new harbour at Tuticorin, which has opened large dealings with Ceylon; Tanjore, South Kánara, Ganjám, and Vizagapatam in the order given. The total foreign trade in 1880–81 was as follows. The imports amounted to £6,518,783, of which cotton piece goods and twist made up £2,908,379, grain £158,144, and apparel £147,691. The exports amounted to £9,271,345, the chief items being—coffee, £1,393,090; raw cotton, £939,127; hides and skins, £1,261,182; rice, £996,314; seeds, £708,390; indigo, £693,103; spices, £379,282; oils, £372,119; sugar, £301,670. The total number of vessels engaged in foreign trade that cleared and entered Madras ports in 1880–81 was 6247, with a tonnage of 1,177,337; the coasting trade was conducted by 11,316 vessels, with 3,748,474 tons, for ports outside Madras presidency, and 24,057 vessels, with 3,092,286 tons, for ports within the presidency. The importance of this active coasting trade may be gathered from the fact that in 1876–77 (the first year of the late famine) the imports of grain suddenly rose to 652,850 tons, by far the greater part consisting of rice from Bengal.

Administration.—The supreme executive authority is vested in the governor, with a council of three members, of whom one is the commander-in-chief; the others belong to the covenanted civil service. For legislative purposes this council is increased by the presence of the advocate-general and from four to eight other members nominated by the governor, of whom not less than one-half must be non-officials. The local administration is organized with the district or *zilá* as its unit. Of these districts there are twenty-one in all, including the Nílgiris and Madras city, both of which occupy an exceptional position. Each of the remaining districts is under the jurisdiction of a collector-magistrate and a sessions judge. Beneath the collector-magistrate come deputy collectors, sub-collectors, and assistants. Each district is subdivided into *táluks*, numbering one hundred and fifty-six in all, under the charge of a *tahsildár*. Each *táluk* comprises from fifty to one hundred villages, which constitute the ultimate units for fiscal and administrative purposes. The hereditary village officials, to be found in almost every Hindu village, are employed to perform minor public offices, revenue and judicial, and are inadequately remunerated either by fees in grain and other cesses levied from the villagers, or by a reduction in their land assessment. The heads of villages and village accountants (*karnam*) collect and account for all revenue, rates, and taxes within their respective villages or townships.

Local and municipal administration, including roads and communications, schools and primary education, public health and local endowments, together with special taxation levied for any of these purposes, is provided for by special legislation passed in 1871. Entire districts or, where these are of unmanageable size, parts of districts have been constituted local fund circles, each under the management of a board of commissioners, of which the collector is *ex officio* president, and the district engineer, medical officer, and one or more civil officers are official members. With them are associated at least an equal number of native non-official gentlemen, appointed by Government. To these boards is entrusted the entire management of the local interests above named, subject to the submission of an annual budget for the sanction of Government, and of a report of the board's transactions at the close of each year. The twenty-one districts of the presidency comprise thirty-five such local fund circles. The sources of income at the disposal of these boards are a grant from provincial funds, a special land rate not exceeding one *anna* in the rupee of the Government assessment, tolls, school fees, local endowments, and other minor special funds. Municipal administration of the larger towns is provided for by boards of town commissioners, constituted similarly to the local boards as regards official and non-official members, except that, with the consent of Government, the latter may be elected by the ratepayers. Besides the above-named local interests, the commissioners manage the local sanitation and hospitals of the towns, registration of births and deaths, lighting, and police. About fifty towns, including Madras city, with an aggregate population of 1,500,000, are provided with municipal administration, and the number is steadily increasing. The funds at the disposal of the commissioners consist of rates on houses and lands, a tax on professions and trades, a wheel and animal tax, tolls and ferries, school and market fees, &c. Under the administration of these local and municipal boards great impulse has been given to the development of roads, education, and hospitals and dispensaries.

Revenue and Expenditure.—Down to 1871 every branch of revenue and expenditure throughout India was managed in all details by the Government of India. Under the decentralization scheme of that year the financial administration of the jail, police, and educational services, together with certain branches of the medical, sanitary, and other minor services, were transferred to the Government of Madras, and a grant of a single fixed sum from the imperial funds was assigned for their maintenance. The local fund boards, described above, were constituted in the same year, and the municipal administration improved. The provincial expenditure is almost entirely met by a grant from imperial funds; and the local receipts benefit in a similar way by a subsidy from the imperial budget. The following figures show the revenue and expenditure under each head of finance for the year 1880–81, exclusive of the charges under the heads of army, interest, and imperial public works. (1) Imperial: total revenue, £8,526,451, of which about one-half, £4,284,335, is derived from the land revenue, and £1,433,974 from salt; expenditure, £3,478,655. (2) Provincial: total revenue, £955,162, of which £781,990 forms the allotment from the imperial funds; expenditure, £971,011,—the main items being police, £376,356; law and justice, £105,962; public works, £142,187; education, £90,875. (3) Unfettered local funds: receipts, £24,768; charges, £19,628. (4) Fettered local funds: income, £748,315; expenditure, £729,746. (5) Municipal: total revenue, £137,364; expenditure, £129,525. The gross revenue of the presidency was £9,030,152, and the expenditure £6,893,960.

Army.—The Madras army garrisons, besides the whole of Madras proper, the adjoining state of Mysore, the Nizám's Dominions, the Central Provinces, and British Burmah; a regiment is also usually stationed at Dorunda in the Chutia Nágpur division of Bengal, and another at Cuttack in Orissa. The entire force consists of 1 regiment of European cavalry, 19 batteries of European artillery, and 8 regiments of European infantry, with 1 company of native sappers and miners, 4 regiments of native cavalry, and 40 regiments of native infantry. In 1880–81 the European force numbered 10,229, and the native army 30,958 of all ranks. The military expenditure charged against Madras in 1880–81 was £2,722,105. The principal cantonments are Kámpti, Secunderábád, Bangalore, Bellary, and Rangoon. St Thomas's Mount near Madras city is an important station for artillery. The two military sanatariums are Ramandrug near Bellary, and Jakatála or Wellington in the Nílgiri hills.

Administrative Statistics.—An early task of the English administration was the repression of the system of black mail levied by bands of Kavílgárs, which was not fully extinguished for many years. By a Government regulation in 1866 the village police was placed under the head of the village, and became practically the most useful (although a somewhat dishonest) agency of the magistrate in the police administration. The Madras police force was organized in its present form in 1860. In March 1881 it consisted of a total strength of 26,415 officers and men, maintained at a cost of £364,233. In 1880 the total number of prisoners passing through the jails in the presidency was 27,708,—considerably less than during and after the famine; the daily average number of prisoners was 12,202. Education was afforded in 1880–81 by 12,878 schools, attended by 327,808 pupils; the expenditure was £284,873, of which £86,641 was contributed by the state. The chief educational institutions are the Madras university, the provincial college of Combaconum, the Madras Christian college, the Doveton Protestant college, S. P. G. high school at Tanjore, medical college, civil engineering college, Lawrence asylum, school of agriculture, school of ordnance artificers and school of arts, and the military orphanage at Utakamand in memory of the late Sir Henry Lawrence.

Climate and Health.—The climate varies in different parts of the presidency, being determined by the very diverse geographical conditions. The Nílgiri hills enjoy the climate of the temperate zone, with a moderate rainfall, and a thermometer rarely exceeding 80° F., and sometimes falling to the freezing-point. On the Malabar coast the south-west monsoon brings an excessive rainfall, reaching 150 inches in the year at certain spots. The rain clouds hanging on the slope of the Western Gháts sometimes obscure the sun for month after month. Along the eastern coast and on the central table-lands the rainfall is comparatively low, but the heat of the summer months is excessive. At Masulipatam the thermometer frequently rises to above 110° F. in the shade. The whole coast of the Bay of Bengal is liable to disastrous cyclones, which not only wreck the shipping in the roads, but have repeatedly overwhelmed the low-lying ports. The most prevalent diseases are fevers, diarrhœa, dysentery, and other bowel complaints, cholera, and small-pox.

History.—Until the English conquest the whole of southern India had never acknowledged a single ruler. The difficult nature of the hill passes and the warlike character of the highland tribes forbade the growth of great empires, such as succeeded one another on the plains of Hindustán. The Tamil country in the extreme south is traditionally divided between the three kingdoms of Pandya, Chola, and Chera. The west coast supplied the nucleus of a monarchy which afterwards extended over the highlands of Mysore, and took its name from the Carnatic. On the north-east the kings of Kalinga at one time ruled over the entire line of seaboard from the Krishna to the Ganges. Hindu legend has preserved marvellous stories of these early dynasties, but our only authentic evidence consists in their inscriptions on stone and brass, and their noble architecture. The Mohammedan invader first established himself in the south in the beginning of the 14th century. Alá-ud-dín, the second monarch of the Khiljí dynasty at Delhi, and his general Malik Kafur conquered the Deccan, and overthrew the kingdoms of Karnataka and Telingána, which were then the most powerful in southern India. But after the withdrawal of the Musalmán armies the native monarchy of Vijayanagar arose out of the ruins. This dynasty gradually extended its dominions from sea to sea, and reached a pitch of prosperity before unknown. At last, in 1565, it was overwhelmed by a combination of the four Mohammedan principalities of the Deccan. At the close of the reign of Aurangzeb, although that emperor nominally extended his sovereignty as far as Cape Comorin, in reality South India had again fallen under a number of rulers who owned no regular allegiance. The nizám of the Deccan, himself an independent sovereign, represented the distant court of Delhi. The most powerful of his feudatories was the nawáb of the Carnatic, with his capital at Arcot. In Tanjore, a descendant of Sivají ruled; and on the central table-land a Hindu chieftain was gradually establishing his authority and founding the state of Mysore, destined soon to pass to a Mohammedan usurper.

Vasco da Gama cast anchor off Calicut on the 20th May 1498, and for a century the Portuguese retained in their control the commerce of India. The Dutch began to establish themselves on the ruin of the Portuguese at the beginning of the 17th century, and were quickly followed by the English, who established themselves at Calicut and Cranganore in 1616. Tellicherri became the principal British emporium on the west coast of Madras. The Portuguese eventually retired to Goa, and the Dutch to the Spice Islands. The first English settlement on the east coast was in 1620, at Masulipatam, even then celebrated for its fabrics. Farther south a factory, the nucleus of Madras city, was erected in 1639. Pondicherri was purchased by the French in 1762. For many years the English and French traders lived peacefully side by side, and with no ambition for territorial aggrandisement. The war of the Austrian succession in Europe lit the first flame of hostility on the Coromandel coast. In 1746 Madras was forced to surrender to Labourdonnais, and Fort St David remained the only British possession in southern India. By the peace of Aix-la-Chapelle Madras was restored to the English; but from this time the rivalry of the two nations was keen, and found its opportunities in the disputed successions which always fill a large place in Oriental politics. English influence was generally able to secure the favour of the rulers of the Carnatic and Tanjore, while the French succeeded in placing their own nominee on the throne at Hyderabad. At last Dupleix rose to be the temporary arbiter of the fate of southern India, but he was overthrown by Clive, whose defence of Arcot in 1751 forms the turning point in Indian history. In 1760 the crowning victory of Wandewash was won by Colonel (afterwards Sir Eyre) Coote, over Lally, and in the following year, despite help from Mysore, Pondicherri was captured.

Though the English had no longer any European rival, they had yet to deal with Mohammedan fanaticism and the warlike population of the highlands of Mysore. The dynasty founded by Hyder Ali, and terminating in his son Tipú Sultán, proved itself in four several wars, which terminated only in 1799, the most formidable antagonist which the English had ever encountered (see HYDER ALI and INDIA). Since the beginning of the present century Madras has known no regular war, but occasional disturbances have called for measures of repression. The *pálegárs* or local chieftains long clung to their independence after their country was ceded to the British. On the west coast, the feudal aristocracy of the Nairs, and the religious fanaticism of the Moplás, have more than once led to rebellion and bloodshed. In the extreme north, the wild tribes occupying the hills of Ganjám and Vizagapatam have only lately learned the habit of subordination. In 1836 the *zamíndári* of Gúmsúr in this remote tract was attached by Government for the rebellious conduct of its chief. An inquiry then instituted revealed the wide prevalence among the tribe of Kandhs of human sacrifice, under the name of *meriah*. The practice has since been suppressed by a special agency.

The different territories comprising the Madras presidency have been acquired by the British at various dates. In 1763 the tract encircling Madras city, now Chengalpat district, was ceded by the nawáb of Arcot. In 1765 the Northern Circars, out of which the French had recently been driven, were granted to the Company by the Mughal emperor, but at the price of an annual tribute of £90,000. Full rights of dominion were not acquired till 1823, when the tribute was commuted for a lump payment. In 1792 Tipú was compelled to cede the Baramahál (now part of Salem district), Malabar, and Dindigal subdivision of Madura. In 1799, on the reconstruction of Mysore state after Tipú's death, Coimbatore and Kánara were appropriated as the British share; and in the same year the Mahratta rájá of Tanjore resigned the administration of his territory, though his descendant retained titular rank till 1855. In 1800 Bellary and Cuddapah were made over by the nizám of Hyderabad to defray the expense of an increased subsidiary force. In the following year the dominions of the nawáb of the Carnatic, extending along the east coast almost continuously from Nellore to Tinnevelli, were resigned into the hands of the British by a puppet who had been put upon the throne for the purpose. The last titular nawáb of the Carnatic died in 1855; but his representative still bears the title of prince of Arcot, and is recognized as the first native nobleman in Madras. In 1838 the nawáb of Karnúl was deposed for misgovernment and suspicion of treason, and his territories annexed.

MADRAS, capital of Madras presidency, is situated on the sea-coast in 13° 4′ 8″ N. lat., 80° 14′ 51″ E. long. Although at first sight the city presents a disappointing appearance, and possesses not a single handsome street, it has several edifices of high architectural pretensions, and many spots of historical interest. Seen from the roadstead, the fort, a row of merchants' offices, a few spires and public buildings, are all that strike the eye. Roughly speaking, it consists of the following divisions. (1) Black Town, an ill-built, densely populated block, about a mile square, is the business part of the town, and contains the banks, custom house, high court, and all the mercantile offices. The last, for the most part handsome structures, lie along the beach. On the sea-face of Black Town are the pier and the new harbour. Immediately south of Black Town there is (2) an open space which contains the fort, esplanade, brigade parade ground, Government house, and several handsome public buildings on the sea-face. (3) West and south of this lung of the city come a series of crowded quarters known by

Plan of Madras.

various native names—Chintadrapet, Tiruvaleswarampet, Pudupák, Royapet, Kistnampet, and Mylapur, which bend to the sea again at the old town of Saint Thomé. (4) To the west of Black Town are the quarters of Veperi and Pudupet, chiefly inhabited by Eurasians, and the suburbs of Egmore, Nangambákam, and Perambúr, adorned with handsome European mansions and their spacious "compounds" or parks. (5) South-west and south lie the European quarters of Tanampet and aristocratic Adyar. Amongst the buildings most deserving of notice for their architectural features are the cathedral, Scotch church, Government house, Patcheappah's hall, senate house, Chepauk palace (now the Revenue Board), and the Central Railway station.

Nearly all the most important offices of the presidency, and the headquarters of every department, are located in Madras. Apart from the headquarters staff of the Madras army, that of the central division is also stationed here, with a garrison of 1 European and 3 native infantry regiments, 1 battery of artillery, and the bodyguard of the governor (100 sabres). At St Thomas's Mount are 3 batteries of artillery and a detachment of native infantry. Including these, the garrison of Madras is about 3500 strong, of whom 1200 are Europeans.

The population of Madras city, as ascertained by the census of 1871, was 397,552, including 330,062 Hindus, 50,964 Mohammedans, 12,013 Eurasians, and 3613 Europeans. The annual municipal income is about £53,000. Madras, notwithstanding its exposed situation, ranks third among the ports of India in respect of the number and tonnage of vessels calling and the value of its imports and exports. The port trades with every part of the world, exporting coffee, cotton, grain, hides, indigo, oilseeds, dyes, sugar, and horns, and importing piece goods, iron and other metals, and all kinds of European manufactures. The lighthouse, 125 feet high, is visible from a ship's deck 15 miles at sea. The Madras roadstead, like the whole line of the western coast of India, is liable to be swept by hurricanes of irresistible fury, which occur at irregular intervals of years, generally at the beginning of the monsoons in May and October. The first recorded cyclone was in October 1746, a few weeks after the fort had surrendered to Labourdonnais. A French fleet then lay at anchor in the roads. Five large ships foundered, with 1200 men on board; and scarcely a single vessel escaped with its masts standing. Perhaps the most destructive of these storms occurred in May 1872. On this occasion the registered wind pressure reached a maximum of 53 ℔ to the square foot. In the space of a few hours nine English vessels and twenty native craft were driven ashore. In May 1874 another cyclone broke on the Madras coast, but the ships were warned in time to put to sea and gain an offing. The most recent of these periodical hurricanes occurred in November 1881, when the new harbour works sustained serious damage.

The trade of the town does not depend on any special local manufactures or produce. Such industries as once flourished—weaving, for instance—have decayed, and no others have grown up to replace them. As elsewhere in India, spinning companies have recently been formed, but what effect they are likely to exercise on local trade remains to be seen. With the exception of banks, and enterprises connected with the preparation of produce for export, *e.g.*, cotton-pressing and coffee-cleaning, joint-stock undertakings have not prospered. As the capital of southern India, Madras is the centre on which all the great military roads converge. It is also the terminal station of two lines of railway, the Madras line and the Madras and Tanjore section of the South Indian Railway.

The Buckingham Canal, which passes through an outlying part of the city, connects South Arcot district with Nellore and the Krishna and Godávari system of canal navigation. This long delayed project was undertaken as a famine work.

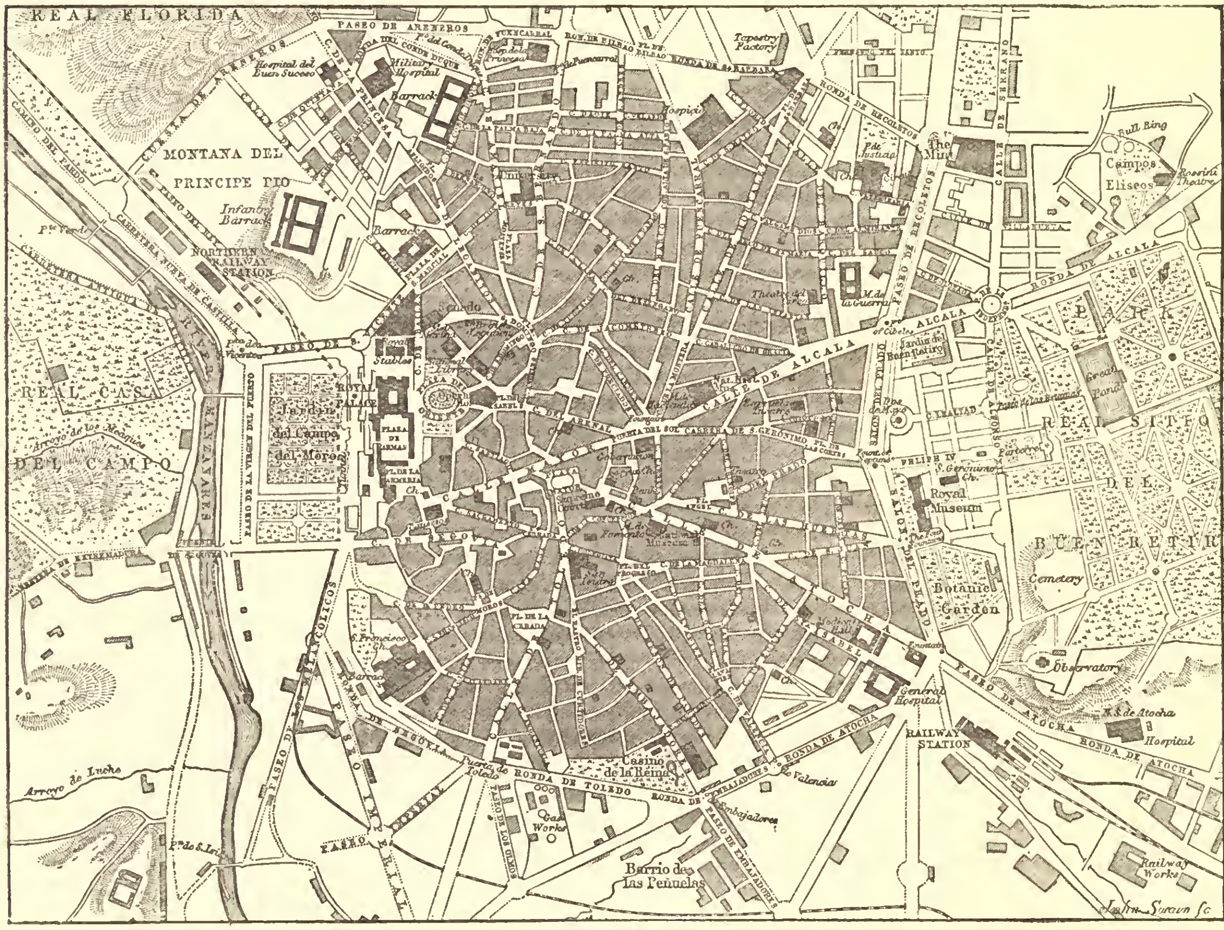
The town of Madras dates from 1639, when Francis Day, chief of the East India Company's settlement at Armagon, obtained a grant of the present site of the city from the rájá of Chandragiri. A factory, with some slight fortifications, was at once constructed, and a gradually increasing population settled around its walls. In 1653 Madras, which had previously been subordinate to the settlement of Bantam in Java, was raised to the rank of an independent presidency. In 1702 Dáúd Khán, Aurangzeb's general, blockaded the town for a few weeks, and in 1741 the Mahrattas unsuccessfully attacked the place. In 1746 Labourdonnais bombarded and captured the fort. The settlement was restored to the English two years later by the treaty of Aix-la-Chapelle, but the government of the presidency did not return to Madras till 1762. In 1758 the French under Lally occupied the Black Town, and invested the fort. The siege was conducted on both sides with great skill and vigour. After two months, the arrival of a British fleet relieved the garrison, and the besiegers retired with some precipitancy. With the exception of the threatening approach of Hyder Ali's horsemen in 1769, and again in 1780, Madras has since the French siege been free from external attack. The town of Saint Thomé, now part of Madras city, was founded and fortified by the Portuguese in 1504, and was held by the French from 1672 to 1674.

MADRID, a province of Spain, one of the five into which New Castile is divided, is bounded on the W., N.W., and N. by Avila and Segovia, on the E. by Guadalajara, on the S.E. by Cuenca, and on the S. by Toledo. The area is 2997 square miles, with a population in 1877 of 593,775, an increase of 104,443 since 1860. Madrid belongs to the basin of the Tagus, being separated from that of the Douro by the Sierra Guadarrama, which skirts the province on the north-west and north. The Tagus itself is the southern boundary for some distance, its chief tributary being the Jarama, which rises in the Somosierra in the north, and terminates at Aranjuez. The Jarama, in turn, is joined by the Henares and Tajuña on the left, and by the Lozoya and Manzanares on the right. The Guadarrama, another tributary of the Tagus, has its upper course within the province. Like the rest of Castile, Madrid is chiefly of Tertiary formation; the soil is mostly clayey, and there are sandy tracts. Agriculture is in a somewhat backward condition; the rainfall is deficient, and the rivers, poor though they are, are not utilized as they might be for irrigation. The chief products are wheat, barley, rye, oats, algarrobas (*Ervum tetraspermum*), pease, chick pease, and various other legumes, wine, oil, flax, hemp, wax, honey, and various fruits. Gardening is carried on to some extent near the capital, though the markets of Madrid receive their most liberal supply of fruits and vegetables from Valencia. Sheep, goats, and horned cattle are reared, and fish are found in the Jarama and other rivers. The province is on the whole treeless; but some wood is grown on the mountain slopes in the north. The Sierra Guadarrama has quarries of granite, lime, and gypsum, and is known to contain iron, copper, and argentiferous lead, but these resources are as yet undeveloped. The manufactures are trifling (coarse cloth, leather, paper, earthenware, porcelain, bricks and tiles, saltpetre, glass and crystal, chocolate, lace); and there is very little commerce beyond that for the supply of the capital with necessaries. The only towns with a population above 10,000 are Alcalá (Complutum) on the Henares, and Madrid; the famous university of the former was transferred to the latter in 1836. Aranjuez (8154), on the Tagus, is also of historical importance.

MADRID, capital of the above province and of Spain, is situated in 40° 24′ 35″ N. lat. and 3° 41′ 51″ W. long., on the left bank of the Manzanares, a subtributary of the Tagus, at a maximum elevation of 2372 feet above the sea-level. The population (397,816 in 1877) was over 400,000 in 1881. The town is nearly in the centre of the kingdom, almost equidistant from the Mediterranean, the Atlantic, and the Bay of Biscay. The site consists of some sandy hills of little elevation, in the midst of an extensive plain, bounded to the view on the north only by the Sierra Guadarrama. The basin in which it stands is of Tertiary formation, consisting of gypsum, marl, and limestone.

Owing to its elevated and exposed situation, the climate of Madrid has some marked peculiarities. In winter the mean temperature is 43° Fahr., and as many as sixteen degrees of frost have been observed; the mean in summer is 76° Fahr., but a temperature of 107° has been registered; and the daily oscillation sometimes amounts to as much as 57°. The readings in sun and shade at the same moment are also widely different. The tendency to inflammatory disorders in the population is, as might be expected from these circumstances, very pronounced; but against it must be set the advantages of a dry atmosphere and a cloudless sky, and in point of fact the city is not exceptionally unhealthy; its salubrity has been much enhanced by the recent introduction of a plentiful supply of pure water from the Lozoya (32 miles distant).

The form of Madrid proper is almost that of a square with the corners rounded off; from east to west it measures rather less than from north to south. It was formerly surrounded by a poor wall, partly of brick, partly of earth, some 20 feet in height, and pierced by five principal gates (*puertas*) and eleven "portillos." Of these gateways only three, the Puerta de Alcalá on the east, the Puerta de Toledo on the south, and the Portillo de San Vicente on the west, now actually exist; the first and the third were erected in the time of Charles III., and the second in honour of the restoration of Ferdinand VII.; all have some architectural pretensions. The Manzanares (or rather its bed, for the stream is at most seasons of the year quite insignificant) is spanned by six bridges, the Puente de Toledo and that of Segovia being the chief. The Puerta del Sol (formerly the east gate and tower of the city, having on its front a representation of the sun—



Plan of Madrid.

whence the name) is now the central plaza, and the favourite lounge and place of most traffic in the city; the animated scene it presents has been described with more or less fulness in almost every book of Spanish travel. On its south side stands the Palacio de la Gobernacion, or Home Office, a heavy square building, by a French architect, J. Marquet, and dating from 1768. From the Puerta del Sol diverge, immediately or mediately, almost all the principal streets of Madrid—eastward by north, the Calle de Alcalá, terminating in the Prado; eastward, the Carrera de San Geronimo, terminating by the Plaza de las Cortes also in the Prado; southward, the Calle de Carretas; westward, the Calle Mayor, which leads to the council chamber and to the palace, and the Calle del Arenal, terminating in the Plaza de Isabel II. and the opera-house; north-westward, the Calles de Preciados and Del Carmen; and northward, the Calle de la Montera, which afterwards divides into the Calle de Fuencarral to the left and the Calle de Hortaleza to the right. Of these the Calle de Alcalá is the finest; it is bordered on both sides with acacias, and contains some elegant buildings, including the museum of natural history, formerly the general custom-house, dating from 1769, and the offices of the Board of Trade (Ministerio de Hacienda) on the north side, and on the south the palace of the duke of Sesto (the site of which is about to be occupied by the new buildings of the Banco de España or Bank of Spain); its irregularity in point of width and level, however, detracts much from its appearance. The Plaza de las Cortes is so called from the Congreso de los Diputados, or House of Commons, on its north side, a building in the Corinthian style, but of little merit; the square contains a bronze statue of Cervantes, by Sola, erected in 1835. The Calle de Carretas ranks with the Carrera de San Geronimo and Calle de la Montera for the excellence of its shops. From the Calle Mayor is entered the Plaza Mayor, a rectangle of about 430 feet by 330, formerly the scene of tournaments, bull fights, autos-de-fe, and similar exhibitions, which used to be viewed by the royal family from the balcony of one of the houses called the Panaderia (belonging to the guild of bakers). The square, which was built under Philip III. in 1619, is surrounded by an arcade; the houses are uniform in height and decoration. In the centre stands a bronze equestrian statue of Philip III., designed by Pantoja, cast by Juan de Bologna, and finished by Pedro Tacca. From the south-east angle of the Plaza Mayor the Calle de Atocha, one of the principal thoroughfares of Madrid, leads to the outskirts of the city; at the south-west angle of the same square the Calle de Toledo begins, the chief mart for the various woollen and silken fabrics from which the picturesque costumes peculiar to the peninsula are made. In the Plaza de Isabel II., at the western extremity of the Calle del Arenal, stands the royal opera-house, the principal front of which faces the Plaza del Oriente and the royal palace. In the centre of the plaza is a fine bronze equestrian statue of Philip IV.; it was designed by Velazquez and cast by Tacca, while Galileo is said to have suggested the means by which the balance is preserved. The gift of the grand-duke of Tuscany in 1640, it stood in the Buen Retiro gardens until 1844.

As compared with other capitals, Madrid has very few buildings of much interest architecturally or otherwise. There is no cathedral. The Basilica de Nuestra Señora de Atocha, on the Paseo de Atocha, a continuation of the Calle de Atocha, originally founded in 1523, after being destroyed by the French was rebuilt by Ferdinand VII.; it contains one of those miraculous images attributed to St Luke with which Spain abounds, and is specially associated in history with the name of Queen Isabella II. The collegiate church of San Isidro el Real, in the Calle de Toledo, dates from 1651; it has no architectural merit, but contains one or two valuable pictures and other works of art. The modern Gothic church of San Geronimo el Real occupies a conspicuous site eastward of the town; it is not at present used as a place of worship. Of secular buildings unquestionably the most important is the royal palace (Palacio Real) on the west side of the town, on a rising ground overhanging the Manzanares. It occupies the site of the ancient Moorish alcazar, where a hunting seat was built by Henry IV.; this was enlarged and improved by Charles V. when he first made Madrid his residence in 1532, was further developed by Philip II., but ultimately was destroyed by fire in 1734. The present edifice was begun under Philip V. in 1737 by Sacchetti of Turin, and was finished in 1764. It is in the Tuscan style, and is 470 feet square and 100 feet in height, the material being white Colmenar granite, resembling marble. To the north of the palace are the royal stables and coach-houses, remarkable for their extent; to the south is the armoury (Museo de la Real Armería), containing what is probably the best collection of the kind anywhere to be met with. After the Palacio Real may be mentioned the royal picture gallery (Real Museo de Pinturas), adjoining the Salon del Prado; it was built about 1785 for Charles III. by Juan de Villanueva, as a museum of natural history and academy of sciences. It contains the collections of Charles V., Philip II., and Philip IV., and the pictures number upwards of two thousand. The specimens of Titian, Raphael, Veronese, Tintoretto, Velazquez, Vandyck, Rubens, and Teniers are numerous and remarkable, giving it a claim to be regarded as the finest picture gallery in the world. The palaces of the grandees are generally noteworthy only for their size. There are some seventeen theatres of all classes. The bull-ring (Plaza de Toros), to the east of the town, accommodates 12,000 spectators; the present building dates from 1874. Of the promenades and open places of public resort the most fashionable and most frequented is the Prado (Paseo del Prado, Salon del Prado) on the east side of the town, with its northward continuation the Paseo de Recoletos. To the south of the town is the Paseo de las Delicias, and on the west, below the royal palace, and skirting the Manzanares, is the Paseo de la Virgen del Puerto, used chiefly by the poorer classes. Eastward from the Prado are the Buen Retiro gardens, with the usual ponds and pavilions, and a poor menagerie. The gardens were formerly the grounds surrounding a royal hunting seat, on the site of which a palace was built for Philip IV. in 1633; it was destroyed during the French occupation.

Modern educational movements have not left Madrid unaffected, and considerable improvements in this respect have taken place within recent years. There are upwards of 100 official primary schools (attended by 4810 boys and 3958 girls), and a large number of private ones; among the other educational instrumentalities the numerous schools connected with various Protestant missions claim special mention. There are two normal schools. The university of Alcalá, founded by Cardinal Ximenes in 1508, was transferred in 1836 to Madrid, and has since that time undergone much reform and extension. In 1882 the teaching staff numbered 88, and the students 7000. Of these 2400 belonged to the faculty of law, 2500 to that of medicine, 400 to that of science, 1400 to that of pharmacy, and 250 to that of philosophy and literature. The faculty of theology was suppressed in 1868, and has not been re-established. Madrid also has schools of agriculture, architecture, civil and mining engineering, the fine arts, veterinary science, and music. The school of military engineering is at Guadalajara. Among the educational institutions may be reckoned the botanical garden, originated in 1781, the national library, with those of the palace, the university, and San Isidro, and the museum of natural science, exceedingly rich in the mineralogical department. The principal learned society is the Royal Spanish Academy, founded in 1713 for the cultivation and improvement of the Spanish tongue. The Academy of History possesses a good library, rich in MSS. and incunabula, as well as a fine collection of coins and medals. There are likewise academies of the fine arts, the exact sciences, moral and political science, medicine and surgery, and jurisprudence and legislation, all possessing libraries. There are also anthropological, economical, and geographical societies, and a scientific and literary athenæum. The charitable institutions include upwards of eighteen hospitals, the largest of which contains 1200 beds; there are three foundling hospitals and six for orphans. The military hospital is large and well conducted. There are very good schools for the blind and for deaf mutes, and a number of asylums of various kinds.

The manufactures of Madrid are inconsiderable; every article of food and clothing, almost without exception, is imported. The most important industries are the manufactures of tobacco and cigars, gold and silver wares, tapestry and carpets, porcelain, hats, mirrors, and beer. Little wine is grown near the capital, and not much fruit; but the markets are well supplied, and regularly, from all quarters of the kingdom. Madrid is still the principal, one might almost say the only, focus of the now largely developed railway system of the peninsula. The suburbs of the town are rapidly extending, especially towards the north and south. The immediate environs are uninteresting. About 6 miles to the north-west lies the fine hunting seat El Pardo, restored by Charles III.

Spanish archæologists have frequently claimed for Madrid a very high antiquity, but the earliest authentic historical mention of the town (Majrít, Majoritum) occurs in an Arab chronicle, and does not take us farther back than to the first half of the 10th century. The place was finally taken from the Moors by Alphonso VI. (1083), and was made a hunting-seat by Henry IV., but first rose into importance when Charles V., benefiting by its keen air, made it his occasional residence. Philip II. created it his capital and "only court" (*única corte*) in 1560. To this day it only ranks, however, as "villa," not as "ciudad." Fruitless attempts were made by Philip III. and Charles III. respectively to transfer the seat of government to Valladolid and to Seville.

MADRIGAL. The notice of this branch of musical art which will be included in the general article MUSIC may here be anticipated by an approximately chronological list, according to nationalities, of the masters who have been chiefly distinguished for their compositions of the class:—*Flanders*: Egide Binchois, Brusnois, Jean Okeghem or Ockenheim, Jean Tinctor, Adrian Willaert, Cyprian di Rore, Jacques Hobrecht, Firmin Caron, Josquin des Près, Alexander Agricola, Antoine Brumel, Pierre de la Rue, Jacques Arcadelt, Claude Goudimel, Philippe Verdelot, Jacques de Wert, Hubert Waelrent, and Orlando di Lasso; *Rome*: Costanzo Festa, Giovanni Pierluigi da Palestrina, Felice and Francesco Anerio, Giovanni Maria, Bernardino Nanini, and Luca Marenzio (styled in his own time "Il più dolce Cigno d'Italia"); *Venice*: Giovanni Croce, Andrea and Giovanni Gabrielli, Costanzo Porta, Orazio Vecchi, and Giovanni Giacomo Gastoldi; *England*: William Cornyshe (father and son), Richard Taverner, Robert Fayrefax, Thomas Phelyppes, Richard Edwards, William Byrd, Thomas Morley, Giles Farnaby, Edward Johnson, Thomas Weelkes, George Kirbye, John Dowland, Michael Este, Thomas Tomkins, John Benet, John Hilton, John Wilbye, Thomas Ford, Thomas Bateson, Richard Allison, John Ward, and Orlando Gibbons, also John Cooper and Peter Philips, who dwelt long in Rome, and published their works under the names respectively of Giovanni Coperario and Pietro Filippi. Many of all these wrote strictly madrigals, that is, continuous compositions abounding in ingenious artifices of imitation of one part by another; others wrote rhythmical songs of four or more parts, or ballets, or fal-las, all of which, being for unaccompanied voices, or for viols instead of voices, are often erroneously ranked as madrigals, though differing entirely in structure from them. The English composers, to Byrd inclusive, produced pieces distinctly of the madrigal class, but described them by other definitions; it was in the year 1588, when Byrd published *Psalms, Sonets, and Songs of Sadness and Pietie*, that the word madrigal was first introduced into England by Nicholas Yonge, a merchant, a lover of music who, having received copies of some foreign compositions in his chests of merchandise, adapted English words to these, and printed a collection under the title *Musica Transalpina*, the success of which stimulated the powers of English writers that had already been proved, and excited others to emulate their example. The art of madrigal composition was never practised in Germany, and it died out in other countries early in the 17th century. The knowledge of the works that endear the madrigal writers to lovers of a high and most pure form of music was revived, and has since been kept alive, by the Madrigal Society. This was founded in 1741 by John Immyns, an attorney, and its original members were mechanics or small tradesmen; it held its first meeting at the Twelve Bells Tavern in Bride Lane, made many migrations to other houses of entertainment, and has its present home at the Freemasons' Tavern, where its members are of a far higher social caste than the men who associated themselves for the practice of contrapuntal vocal music when the rank and fashion of the land went to worship Farinelli at the Italian opera, and to take part with the followers of the king or the prince of Wales in supporting one or other of the opposition establishments for its performance. In 1811 the society offered a prize for the composition of a madrigal, which was won by William Beale. The same incentive has occasionally been repeated. This encouragement, and still more the love for the class of music engendered by the public performance of madrigals by large choral societies during the last fifty years, have incited later composers to more or less successful imitations of the style, especially distinguished among whom was Robert Lucas Pearsall (1795–1856).

MADURA, a district in the south of the Madras presidency, India, lying between 9° 4′ and 10° 44′ N. lat., and 77° 14′ and 79° 20′ E. long., is bounded on the N. by Coimbatore, Trichinopoli, and Tanjore districts, E. and S.E. by the sea, S.W. by Tinnevelli district, and W. by Travancore state. Broadly speaking, it consists of a section of the plain stretching from the mountains east to the sea, coinciding with the basin of the Vaigái river, and gradually sloping to the south-east. The plain is broken in the west by the outlying spurs of the Gháts, and by a few isolated hills and masses of rock scattered over the country. The most important spur of the Gháts is that known as the Palni hills, which project east-north-east across the district for a distance of about 54 miles. Their highest peaks are more than 8000 feet above sea-level, and they enclose a plateau of about 100 square miles in area, with an average height of 7000 feet. A sanatarium has been recently established on this plateau, at Kodáikanal, and coffee planting is here successfully carried on. Farther east a confused group of hills, known as the Sirumalais, the highest of which has an elevation of nearly 4000 feet, clusters round the village of Nattam. Among isolated rocks may be mentioned the precipitous fortress of Dindigal, and the "Elephant Rock," the "Cow Hill," and the sacred Skandamalia—all in the immediate vicinity of Madura town. The chief river is the Vaigái, which divides the district into two almost equal portions. Very little forest is found in any part of the district. The cultivated plain is absolutely barren of trees, except where a newly-planted avenue marks a line of road. Groves of palmyra and cocoa-nut palms flourish along the sea-coast and river banks. Among the wild products of the Palni hills are nutmeg, cinnamon, and pepper. The predominant geological formation is granite. Syenite occurs in large boulders. A gravelly bed of laterite, which runs across the district, is quarried for building purposes; and sandstone is said to extend along the whole length of the sea-coast. Mineral products include saltpetre, salt, lime, chalk, and graphite. Iron in various forms is found, but it is nowhere worked profitably, even by the rude native processes. Gold is washed in some of the streams. Several kinds of opal, chalcedony, jasper, garnet, and rock-crystal are found.

The census of 1871 showed a total population of 2,266,615 persons (1,112,066 males and 1,154,549 females), spread over an area of 9502 square miles, and inhabiting 5459 villages and 443,513 houses. Hindus numbered 2,062,768, and Mohammedans 132,833; and the Catholics at the present day number about 60,000, under the charge of the missions of the Jesuits and of the Church of Goa. The Protestant population are under the charge of an American mission, first established in 1834. The principal towns are Madura city (51,987), Dindigal (12,818), Palni (12,801), Rámnád (15,442), Tirumangalam (5772), Parambakudi (6284), Sivagangá (7392), Killakarai, Aruppukotai, and Periyakulam. The only municipalities are Madura and Dindigal.

Of a total area of 9502 square miles, 6507 belong to *zamíndári* or permanently assessed estates. The total area of Government lands in occupation in 1875–76 was 1,013,000 acres, of which 806,630 were under cultivation. The chief food crops are rice, *cholam* (*Holcus saccharatus*), *kambu* (*Holcus spicatus*), *ragí* (*Eleusine coracana*), *varagu* (*Paspalum frumentaceum*), *samái* (*Panicum miliaceum*), and several kinds of pulses. Other crops include oil-seed, tobacco of excellent quality, and a little indigo and cotton. The rainfall is small and variable in its seasons. Every possible means of storing up surplus water has been resorted to from time immemorial. An important engineering project, known as the Periyár scheme, has long been under consideration, by which the abundant rainfall on the farther slope of the Travancore hills might be diverted into the drainage basin of the Vaigái. Salt is manufactured at certain stations on the coast as a Government monopoly. Handsome turbans fringed with gold cloth, and a peculiar kind of red cloth, are specialities of Madura town. Considerable sea-borne trade is carried on by native craft, chiefly with Ceylon. Rice and other food grains, gingelly oil, spices, cloth, salt fish, tobacco, red ochre, and earthenware are the principal exports. The district is traversed by the South Indian railway from Tinnevelli to Trichinopoli. The total imperial revenue in 1875–76 amounted to £393,448, of which £280,067 was derived from the land. Education in 1876–77 was afforded by 424 schools, attended by 12,509 pupils. Besides ordinary diseases, Madura possesses three special scourges:—endemic fever, which sometimes rages with exceptional severity; cholera, disseminated by pilgrims to the sacred temple at Rámeswaram; and the well-known "Madura foot." This last complaint, known to science as *morbus pedis entophyticus*, is a species of fungus which spreads over the whole foot in a mass of tubercles. Its primary cause seems to be unknown.

History.—Madura was the seat of the Pandian monarchy, which ruled over this part of India from the 5th century B.C. to the end of the 11th century of our era. The last of the Pandiá kings is said to have exterminated the Jains, and conquered the neighbouring kingdom of Chola; but he was in his turn overthrown by an invader from the north, conjectured to have been a Mohammedan. In 1324 a Moslem army under Malik Kafur occupied Madura, and the Hindus were held in subjection for a period of fifty years. Subsequently Madura became a province of the Hindu empire of Vijáyanagar. In the middle of the 16th century the governor Viswanáth established an hereditary rule which lasted for a century. The greatest of the line was Tirumala Náyak (1623–1659), whose magnificence and military exploits are recorded in the contemporary letters of the Jesuit missionaries. He adorned Madura with many public buildings, and extended his empire over the adjoining districts of Tinnevelli, Travancore, Coimbatore, Salem, and Trichinopoli. His repudiation of the nominal allegiance paid to the rájá of Vijáyanagar brought him into collision with the sultán of Bijápur, and Mohammedans, after the lapse of three centuries, again invaded Madura, and compelled him to pay them tribute. After the death of Tirumala the kingdom of Madura gradually fell to pieces. In 1740 the district fell into the hands of the nawáb of the Carnatic, and the line of the Náyaks was extinguished. In 1762 British officers took charge of Madura, in trust for Wallah Jah, the last independent nawáb of the Carnatic, who finally ceded his rights of sovereignty to the East India Company in 1801.

MADURA, the chief town and headquarters of Madura district, is situated on the south bank of the Vaigái river in 9° 55′ 16″ N. lat., and 78° 9′ 44″ E. long., with a population (1871) of 51,987, being the fourth largest town in the Madras presidency. Its principal architectural feature is the great temple, forming a parallelogram 847 feet by 744 feet, surrounded by nine gopuras, one of which is 152 feet high. The principal structure is the "Hall of a Thousand Pillars" (the actual number being 997). The other buildings comprise the celebrated palace of Tirumala Náyak, the most perfect relic of secular architecture in Madras. Its ruins cover a large area of ground, and a considerable sum of money has been recently assigned by Government for the restoration of the building. Only second in importance to the palace is the Vasanta or Puthu *mantapam*, which still exists in complete preservation, and is said to have been built as a summer retreat for the god Sundareshwara, a form of Siva. On the opposite bank of the river is the Tamakam, a two-storied building of quaint architecture, said to have been erected as a stand from which to view sports and combats. Last is the Teppukulam or great tank, situated 1½ miles to the east of the town, and measuring 1200 yards each way. Once a year its banks are illuminated by (it is said) 100,000 lamps, while the idols from the pagoda are drawn round it on a *teppam* or raft.

MADURA, in High Javanese *Madunten*, an island of the East Indian Archipelago, separated by the shallow Strait of Madura from the east end of Java. It extends from about 112° 32′ to 114° 7′ E. long., and is divided into two nearly equal portions by the parallel of 7° S. lat.; the area is estimated at 2100 square miles. As the few travellers who have visited Madura have been for the most part content to follow the highways which, though running the whole length of the island, never strike very far inland either from the north or the south coast, a considerable part of the country is but vaguely known to Europeans. It may be safely asserted, however, that the general configuration is fairly simple,—the island being a plateau-like prolongation of the limestone range of northern Java, with frequent interchange of hill and dale, culminating towards the east in Gunong Pedjudan or Tambuko at a height of 1542 feet. Hot springs are not unfrequent; and in the valley between Gunong Geger and Bandjar lies the mud volcano of Banju Ening. "Round the coast runs a girdle of tropical vegetation, broken only here and there by small white peaks with steep perpendicular cliffs;" but, except in a few alluvial tracts in the lower courses of the streams, the soil is thin and poor, and better fitted for pastoral than agricultural purposes. Maize is by far the most important of the crops; it is planted after rice in the non-irrigable sawahs, and often before it in the irrigable; in the tagal fields it is sometimes sown thrice in a single year, frequently along with *katjang* (various kinds of native beans). European enterprise has not yet invaded the island; there is only one sugar plantation, Tedjeh, near Pamakasan, established in 1835. Much attention is paid to the rearing of cattle,—the small Madura oxen being greatly prized in Java, and consequently forming a regular article of export. Petroleum is found in small quantities in all the departments, but the most valuable product of the island is its salt (hence perhaps the name Madura; Sansk. *Mandura*, salt). The manufacture, a Dutch Government monopoly, was formerly carried on in several places, as at Brantah and Bunder (where the salt pans now serve as fish ponds), but in 1870 Sumenep was made the sole establishment for Java and Madura, and it still remains by far the most important, though its annual production of 875,000 cwts. has since 1875 to be supplemented by Ragung and Pangaringan. The population of Madura was in 1879 returned as 768,992,—472 Europeans (mostly at Maringan near Sumenep), 3702 Chinese, 1445 Arabs and other Orientals, and 763,373 natives. These last constitute one of the three great races of Java and Madura, and speak a distinct language, for which compare JAVA, vol. xiii.

The following are the places of chief note in the island. Kamal at the south-west corner is the point where people usually cross from Java. Bangkalang is the large and flourishing chief town of Madura proper, with the old palace of the sultan and the residences of the princes of the blood; the mosque is adorned with the first three suras of the Koran, thus differing from nearly all the mosques in Java and Madura, though resembling those of western Islam. In the vicinity once stood the Erfprins fort. Arisbaya (less correctly Arosbaya) is the place where the first mosque was built in Madura, and where the Dutch sailors first made acquaintance with the natives. The once excellent harbour is now silted up. Ajermata, so called from its salt-springs, is the burial-place of the princes of Bangkalang. Pamakasan, though a town of considerable extent, presents nothing worthy of notice apart from the regent's residence. Sampang, the seat of an important market, seems hardly so flourishing as in Valentyn's days. The town or *kota* of Sumenep had 15,000 inhabitants in 1846; and there are populous Malay, Arab, and Chinese villages between the town and the European settlement of Maringan. On a hill in the neighbourhood, with a fine outlook over the Bay of Sumenep, lies Asta, the burial-place of the Sumenep princes; and Nâta Kusuma's mausoleum excels everything of the kind in Java.

Madura formerly consisted of three native states—Madura or Bangkalang, Pamakasan, and Sumenep. Dutch authority was represented by an assistant resident, and the whole island considered part of the Java residency of Surabaya. The separate residency of Madura was constituted in 1857. On the death of the second sultan of Bangkalang (1847) the title had been reduced to that of panembahan;

and in 1872 the new ruler was deprived of the right of collecting taxes, and made a Government pensioner, while his territory was split into the two Dutch "departments" of Madura and Sampang. The sultan of Sumenep was in like manner succeeded by a panembahan in 1853; and the death of the panembahan in 1879 afforded an opportunity of enlarging the Government control. There are thus four "departments" in Madura,—Pamakasan, Madura, Sumenep, and Sampang. The first three are also regencies, and the fourth a subregency of Bangkalang; but Pamakasan alone has the full regency organization. The number of village communities is 1271.

The best systematic account of Madura will be found in Professor Veth's *Java*, vol. iii., the proof sheets of which have, by the author's courtesy, been consulted for this article. See also Bleeker, in *Indisch. Archief.*, i., and *Tijds. van Ned. Ind.*, ix.; C. de Groot in *Nat. Tijds. van Ned. Ind.*, iv.; Hoevell, *Reis over Java*, ii.; Zollinger, "Jets over de Nat. geschied. van Madura," in *N. Tijds. van Ned. Ind.*, xvii.; Jukes, *Voyage of the "Fly"*; and Hageman in *Tijds. van Ned. Ind.*, 1858.

MÆCENAS, C. CILNIUS, is, from two different points of view, a prominent representative man of the ancient world. He was the first, and one of the most capable and successful, of those who filled the office of a great minister under the Roman empire. He was also, if not the first, certainly the most fortunate and influential among the patrons of Roman literature. It is in the latter capacity that he is best known. Among all the names, royal, noble, or otherwise eminent, associated with the patronage of letters, none either in ancient or modern times is so familiarly known as that of Mæcenas. Yet, if we had any contemporary history of the establishment of the empire, possessing the same permanent interest which the poetry of Virgil and Horace possesses, it is probable that his influence in shaping the political destinies of the world would have been as amply recognized as his influence on its literature.

The date and place of his birth are unknown. He first appears in history in the year 40 B.C., when he is employed by Octavianus in arranging his marriage with Scribonia, and afterwards in negotiating, along with Pollio and Cocceius Nerva ("aversos soliti componere amicos," Hor., *Sat.*, i. 5, 28), the peace of Brundisium, and the reconciliation with Antony, which was confirmed by the marriage of the latter with Octavia. From the fact that he was then the most trusted friend and agent of the future emperor it is likely that he had been associated with his fortunes from the time when he came forward to claim his inheritance after the death of Julius Cæsar; and expressions in Propertius (ii. 1, 25–30) seem to imply that he had borne some share in the campaigns of Mutina, Philippi, and Perusia. He may have been a few years older than Octavianus, who began to play the foremost part in Roman politics before he was twenty years of age. The men of the Augustan age great in action and literature were all born within a few years of one another. Agrippa, the right hand of Augustus in war as Mæcenas was in peace, was born in the same year as his master; and there is no indication in the relations of Mæcenas to Augustus or to his friend Horace that he stood towards either of them in the relation of an older to a younger man. Although the place of his birth is unknown, we learn from Horace and Propertius that he prided himself on his ancient Etruscan lineage, and claimed descent from the princely house of the Cilnii, who, as is recorded by Livy (x. 3), excited the jealousy of their townsmen by their preponderating wealth and influence at Arretium in the 4th century before our era. He probably prized the glories of his paternal and maternal ancestry (Hor., *Sat.*, i. 6, 3) as compensating him for his original social inferiority to the members of the great Roman houses; and the fact dwelt on so prominently by his panegyrists, that, through all his life, he preferred the position of a great commoner to the new honours of the senate and of the Roman magistracies, may have been the result as much of pride in his provincial ancestry as of a politic desire to disarm the jealousy of his master or of the Roman aristocracy. Cicero, in his defence of Cluentius, speaks of a C. Mæcenas as one of the most substantial members of the equestrian order during the tribunate of Drusus (91 B.C.), and as one of those who preferred the position their fathers had enjoyed before them to the higher rank obtainable through office (Cic., *Cluent.*, 56, 153). From the identity of the *prænomen* and the rarity of the *cognomen* it is not unlikely that he may have been the grandfather, or perhaps the father, of the future minister. It was in accordance with the policy of Julius Cæsar to choose his confidential friends from men of this order, as he chose his tools from a less reputable class; and the two most trusted friends and ministers of his successor would both have been regarded as "novi homines" by the representatives of the great senatorian families. The testimony of Horace (*Odes*, iii. 8, 5) and his own literary tastes imply that he had profited by the highest education of his time. His great wealth may have been in part hereditary, as there was no district of Italy in which the inequalities of wealth and station were greater than in Etruria;[1] but he owed his position and influence in the state to his early adherence to and close connexion with Augustus. Among the charges brought against him by Seneca, one of the most prominent is that he had been spoiled by his excessive good fortune.

From the year 40 B.C. his influence as the confidential adviser of Octavianus seems to have been thoroughly established. It was in the following year that Horace was introduced to him, and he had before this received Varius and Virgil into his intimacy. In the "Journey to Brundisium," which took place in the year 37 B.C., Mæcenas and Cocceius Nerva are described as "missi magnis de rebus uterque Legati," and were again successful in patching up, by the treaty of Tarentum, a reconciliation between the two claimants for supreme power. During the Sicilian war against Sextus Pompeius in 36 B.C., he was sent back to Rome, and was entrusted with supreme administrative control in the city and in Italy. He is again found acting as vicegerent of Octavianus during the campaign of Actium, when with great promptness and secrecy he crushed the conspiracy of the younger Lepidus; and during the subsequent absences of his chief in the provinces he held the same position. During the latter years of his life he fell somewhat out of favour with his master, or his services were less needed. Perhaps the freedom with which, in the earlier stages of his career, he had offered advice and told unpleasant truths had become distasteful. One cause for a comparative coolness between the old friends was said to be the emperor's relations with Terentia, the wife of Mæcenas, to whom he was uxoriously attached. Perhaps the ennui resulting from the cessation of a life of constant vigilance and activity may account for the state of sleepless restlessness and fever in which he passed the last three years of his life. He died in the year 8 B.C., leaving the emperor heir to his wealth, and affectionately commending his friend Horace, who only survived him a few days, to his protection.

Opinions were much divided in ancient times as to the personal character of Mæcenas; but the testimony as to his administrative and diplomatic ability was unanimous. He enjoyed the credit—or discredit, as the adherents of the republic must have regarded it—of sharing largely in the establishment of the new order of things,[2] of reconciling parties, and of carrying the new empire safely through many dangers. To his influence especially was attributed

[1] The lines of Propertius (iv. 8, 27–8)—

> Et tibi ad effectum vires det Cæsar et *omni*
> *Tempore tam faciles insinuentur opes*—

show that his position under the empire also brought very substantial additions to his original fortune.

[2] This is implied by the long speech which Dion Cassius puts into his mouth, recommending the establishment and prompting the policy of the new empire (Dion Cass., lii. 14–40).

the humaner policy of Octavianus after his first alliance with Antony and Lepidus. Even Seneca, who shows a very bitter animus against him, admits that he deserved the credit of clemency,—although he attributes it to effeminacy rather than to true humanity. The highest tribute paid to him in his capacity of minister is to be found in the least eminent of the poets whose genius he fostered. "The true trophies of Mæcenas," says Propertius, "will be his loyalty."[1] And in another elegy he addresses him as "fidele caput." One great testimony both to his loyalty and to his tact is the saying of Augustus, when he had made public the scandal concerning his daughter Julia, "that all this would never have happened if Agrippa or Mæcenas had lived" (Sen., *De Ben.*, vi. 32). The only instance in which he is said to have acted with indiscretion as a minister was in his betrayal to his wife Terentia of his knowledge of the conspiracy in which her brother Licinius Muræna was involved.

The best summary of his character as a man and a statesman is that of Velleius (ii. 88), who describes him as "in critical emergencies of sleepless vigilance far-seeing and knowing how to act, but in his relaxation from business more luxurious and effeminate than a woman." The latter is the aspect of his character on which Seneca chiefly dwells. He draws attention to the enervating effect which his good fortune had even on his literary style. We need not ask how far "the stately mansion on the Esquiline" outdid in luxury the "gardens of Seneca the millionaire" ("Senecæ prædivitis hortos").[2] Mæcenas was certainly a man who combined an epicurean love of pleasure with a thorough devotion to business; and verses of his own are quoted against him indicative of an unmanly clinging to life after the loss of all that makes life valuable. These may have been written in the feverish unrest of his last years, when he was no longer himself; but expressions in the *Odes* of Horace (ii. 17, 1), written at a much earlier period, seem to imply that he was deficient in the robustness of fibre characteristic of the average Roman. His style of dress and his indolent lounging walk exposed him to animadversion; and the Maltinus of Horace's *Satires* (i. 2, 25) was supposed by some ancient commentators to be a sketch of the great man, drawn before the poet was admitted to his intimacy. Probably there may have been some affectation or politic dissimulation in this assumption of a character so alien to the standard of the aspirants to public honours at Rome. It was an exaggerated form of that indifference to appearances and conventionalities which made him satisfied with the position of an eques, and induced him to choose his intimate associates from poets of obscure and provincial origin. His ambition was to be the second man in the empire, and to enjoy the reality without the show of power. A similar character is attributed by Tacitus to Sallustius Crispus, who, after the death of Mæcenas, most enjoyed the favour of Augustus.

His character as a munificent patron of literature is not only acknowledged gratefully by the recipients of it in his own time, but is attested by the regrets of the men of letters of a later age, expressed through the mouths of Martial and Juvenal. His patronage was exercised, not from vanity or a mere dilettante love of letters, but with a view to the higher interest of the state. He recognized in the genius of the poets of that time, not only the truest ornament of the court, but a power of reconciling men's minds to the new order of things, and of investing the actual state of affairs with an ideal glory and majesty. The change in seriousness of purpose between the *Eclogues* and the *Georgics* of Virgil was, in a great measure, the result of the direction given by the statesman to the poet's genius. A similar change between the earlier odes of Horace, in which he declares his epicurean indifference to affairs of state, and the great national odes of the third book is to be ascribed to the same guidance. He endeavoured also to divert the less masculine genius of Propertius from harping continually on his love to themes of public interest.

But, if the motive of his patronage had been merely politic, it never could have inspired the affection which it did in its recipients. The great charm of Mæcenas in his relation to the men of genius who formed his circle was his simplicity, cordiality, and sincerity. Although not particular in the choice of some of the associates of his pleasures, he admitted none but men of worth to his intimacy, and when once admitted they were treated like equals. That loyalty which was his own distinction in his public life was, if we may trust the evidence of Horace, the characteristic of his own relations to his intimates, and of their relations to one another. But, while loyal to all, to Horace he was bound by a closer tie. Among the great friendships of history, none is more certainly attested, or more honourable to both parties, than that between the poet and the statesman. Much of the wisdom of Mæcenas probably lives in the *Satires* and *Epistles* of Horace. It has fallen to the lot of no other patron of literature to have his name associated with works of such lasting interest as the *Georgics* of Virgil, the first three books of Horace's *Odes*, and the first book of his *Epistles.* Such a fortune can scarcely have been altogether undeserved. Accepting as literally true the disparaging statements of Seneca, admitting the weakness, and perhaps the vanity, which were the blots in his character, and considering at the same time the difficulties of an unprecedented position, we must allow that few ministers of an irresponsible monarch have accomplished so much with such immunity from the baser and more violent passions, for the gratification of which that position holds out unlimited opportunities. As a minister and friend of the emperor he compared favourably, both as regards capacity and character, not with men of the stamp of Sejanus and Tigellinus, but with Seneca. Few men have used the influence of a grand seigneur with such enlightened beneficence, with such lasting results on human culture and civilization, with such genuine simplicity and cordial loyalty. (W. Y. S.)

MAESTRICHT, or MAASTRICHT, the chief town of the province of Limburg, in the Netherlands, lies, as the name expresses, at the *trecht* or crossing of the Maas (Meuse), where the Romans erected a military post on the road between Bagacum (Bavay) and Colonia Agrippina (Cologne). Aix-la-Chapelle is 18 miles east-south-east, and Liége 18 miles south by west. The baths discovered in 1840 in the Groote Stokstraat show that the settlement at Trajectum ad Mosam became a place of some considerable importance. The town is divided by the river into two parts—the larger portion, or Maestricht proper, on the left bank, and the smaller portion, distinguished as Wijk, on the right. A stone bridge of eight arches connecting the two took the place of a wooden structure as early as 1280, and was greatly improved in 1828 and 1836. Formerly a fortress, Maestricht is still a considerable garrison town, but its ramparts were dismantled 1871–78; formerly the seat of a bishop, it still bears a strongly Roman Catholic impress; and, in modern times more especially, it has developed into a great centre of commerce and industry. The churches and religious foundations are almost the only buildings of note, the chief exceptions being the town-house, completed in 1683, and the solitary Protestant church, Janskerk (13th century). The church of St Servatius was, according to one account, rebuilt and enlarged as early as the time of Charles the Great. It is now 260 feet in length, and

[1] Propert., *El.* iv. 9, 34; ii. 1, 36. [2] Juv. x. 16.

in the varied character of its Gothic architecture bears evidence of the frequency with which it has been restored and altered. The high altar has a Descent from the Cross by Anthony Vandyck. The saint whose name it preserves obtained great reputation in Maestricht by transferring his bishopric thither from Tongres, and his miracle-working relics became the occasion of a great septennial fair which was formerly of great service to the city. The Church of Our Lady (Lieve-Vrouwe-kerk), possibly founded in the 6th century, has two very ancient crypts and an 11th century choir of exceptional beauty, but in the nave has suffered severely from a restoration in 1764. St Matthyskerk was founded by the cloth-weavers' guild in the 13th century; and, though the present Gothic building of St Martin's (in Wijk) was erected so late as 1859, the original church was one of the oldest in the city, and is said by tradition to have occupied the site of one of the old heathen temples. The twelve hospitals, the poor-house, the orphanage, and most of the other charitable foundations are Roman Catholic institutions, and neither the administrative bodies nor the educational establishments are free from ecclesiastical influence. Though Maestricht is no doubt mainly indebted for its commercial prosperity to its position on the river, it did not begin to reap the full advantages of the situation till the removal of the fortifications and the opening of the railways (Aix-la-Chapelle, 1853; Hasselt, 1856; Liége, 1861; Vanlo, 1865, &c.). At first a trade was carried on in wine, colonial wares, alcoholic liquors, and salt; but now, besides Regout's well-known earthenware, glass, and crystal factory, there are establishments for the making of arms, tools, lead, copper, and zinc work, &c., as well as tobacco and cigar factories. The Maestricht beer also is highly esteemed. The population, which was 18,000 in the beginning of the century, was 28,917 on January 1, 1882.

Maestricht was taken and plundered by the Normans (881 and 884), by Bishop Henry of Guelders (1267), by Adolph de la Marck (1334), and by the people of Liége (1407 and 1408). In the war with Spain it was successively besieged by the Spaniards, the prince of Orange, Prince Maurice, and Frederick Henry (1579, 1580, 1594, 1632); and in the struggle between Louis XIV. of France and William III., and again during the French Revolution and the Napoleonic period, it paid the penalty of its frontier position—witness the sieges of 1673, 1676, 1701, and 1793. During the revolution of 1830 it was invested by the Belgians. Among the more peaceful memories of the place is the marriage of Otto IV. with Mary of Brabant. The people of Maestricht have a special dialect of their own;[1] but French and Dutch are in use among the upper classes. In the neighbourhood of the town are the great sandstone quarries of Petersberg, one of the most extraordinary labyrinths of subterranean excavation in the world.

MAFFEI, Francesco Scipione, Marchese di (1675–1755), Italian archæologist and man of letters, was born at Verona on June 1, 1675. He studied for five years in Parma at the Jesuit college, and afterwards from 1698 at Rome; and in 1703-4 he took part as a volunteer in the war of succession, fighting on the Bavarian side at Donauwerth. In 1709 he began at Padua along with Apostolo Zeno and Valisnieri the *Giornale dei letterati d'Italia*, a literary periodical which had but a short career; and subsequently an acquaintance with the actor Riccoboni led him to exert himself for the improvement of dramatic art in Italy. His *Merope*, a tragedy, appeared in 1713; *Teatro Italiano*, a small collection of works for presentation on the stage, in 1723–25; and *Le Ceremonie*, an original comedy, in 1728. From 1718 he became specially interested in the archæology of his native town, and his investigations resulted in the valuable *Verona Illustrata* (1731–32). Maffei afterwards devoted four years to travel in France, England, Holland, and Germany. He died at Verona on February 11, 1755. A list of his very numerous works will be found in the *Biographie Générale*. A complete edition of them appeared at Venice (28 vols. 8vo) in 1790.

[1] While the North Limburg dialects, says Professor Gallée of Utrecht, are largely corrupted with Dutch forms and words, the Maestricht or South Limburg dialect (to which those of Hasselt, St Fruiden, and Sittand are nearly akin) has remained comparatively free from such admixture. Its phonology is peculiarly interesting both in itself and because its history can be traced to an early date by authentic documents. The Old Frankish psalms and the Limburg sermons are written in it; and it was also the original dialect of the St Servatius Legend (ed. by Bormanns) now transcribed in the Belgian Limburg dialect, and of Veldeke's *Æneid* (ed. by Behoghel), now in Middle High German. About these works consult Cosyn, *Taal en letterbode* iii., v., vi.; and in regard to the modern dialect Mone's *Anz. für Kunde der teutschen Vorzeit*, 1836; *Belgisch. Museum*, iii.; Franquinet in Jager's *Archief*, iii.; and Winkler's *Nederduitsch en Friesch dialecticon* i. Specimens will be found in Firmenich's *Völkerstimmen* and Leopold's *Van de Schelde tot de Weichsel*.

MAFRA, a town of Portugal, in the province of Estremadura and district of Lisbon, lies near the Atlantic coast, about 20 miles to the north-west of Lisbon, and had a population in 1878 of 3231. It is remarkable for its cloister-palace, built by John V. in 1717–32, in consequence of a vow made during a dangerous illness to build a convent for the poorest friary of the kingdom,—which proved to be a small Franciscan settlement here. The architect, Ludovici, took the Escorial for his model; but the imitation is still less successful than the original. The building, which is in the form of a parallelogram measuring upwards of 800 feet from north to south and 700 feet from east to west, is said to contain 866 rooms, and to be lighted by no fewer than 5200 windows. The centre is occupied by the domed church, sumptuously built of marble, and richly adorned with statues and other objects of art. The conventual buildings (which are no longer used as such) contain 300 cells; and the library numbers 30,000 volumes. Adjoining the palace are fine gardens and pleasure grounds.

MAGDALA (more correctly *Makdala*), a natural stronghold in the country to the south of Abyssinia, situated about 200 miles inland from the Gulf of Aden, in 11° 22′ N. lat. and 39° 25′ E. long. The basaltic plateau of which it consists rises 9110 feet above the level of the sea, and forms along with the neighbouring height of Salassye (9160 feet), with which it is connected by the ridge of Salamgye (8650 feet), a comparatively small and narrow outrunner of the Amara Seint plateau. It is about three quarters of a mile in length by less than half a mile in breadth, and lies more than a thousand feet higher than the neighbouring plain of Arogye. To the south runs the Kukullo Ravine and to the north and the west the Bashilo and the Wark Waha Ravines, all of which ultimately drain into the Abai, and thus belong to the basin of the Nile. Chosen by King Theodore of Abyssinia as his principal stronghold in the south, Magdala owes its celebrity to the fact that, as the place of imprisonment of the English captives, it became the goal of the great English expedition of 1868. At the time of its capture it contained huts for a permanent population of about three thousand, a royal residence of the most meagre pretensions, a still more insignificant church, and a large treasure-house stored with arms, ecclesiastical furniture, and vast quantities of Abyssinian manuscripts. The whole rock was burned bare by order of Sir Robert Napier, and on the departure of the English it was seized by Mastwat, queen of the Wollo Gallas, in whose country it is situated.

See Markham, *History of the Abyssinian Expedition*, 1869; and Rassam, *British Mission to Theodore*, 1869. Both contain plans and views of Magdala.

MAGDEBURG, the capital of the Prussian province of Saxony, and one of the strongest fortresses in Germany, is situated in 52° 8′ N. lat. and 11° 40′ E. long., mainly on the left bank of the Elbe, which here divides into three branches. It consists of the town proper and of the four suburbs of Friedrichstadt, Neustadt, Sudenburg, and

Buckau; the last three of these are separated from the town by the ramparts and glacis, but are all included within the new line of advanced bastions. In the Elbe, between the old town and the Friedrichstadt, lies an island called the Werder, occupied by the citadel, and united with both banks by bridges. With the exception of the Breiter Weg, a handsome thoroughfare running from north to south, the streets of the town proper are narrow and crooked. Along the Elbe, however, extends a fine promenade named the Fürstenwall, at one end of which stands a monument in commemoration of the Franco-German war. To the south of the inner town is the Friedrich-Wilhelm's Garten, a beautiful park laid out on the site of the celebrated convent of Bergen, which was founded in 937 and suppressed in 1810. By far the most important building in Magdeburg is the cathedral, a handsome and massive structure of the 13th and 14th centuries, exhibiting an

interesting blending of Romanesque and Gothic architecture. The two fine towers were completed about 1520. The interior contains the tombs of the emperor Otho the Great and his wife Editha, an English princess, and the fine monument of Archbishop Ernest, executed in 1497 by Peter Vischer of Nuremberg. The Liebfrauenkirche, the oldest church in Magdeburg, is an interesting Romanesque edifice of the 12th and 13th centuries. The chief secular buildings are the town hall, built in 1691 and enlarged in 1866, the theatre, the governor's house, the central railway station, and the exchange. The Breiter Weg and the old market contain numerous fine private houses in the style of the Renaissance. In front of the town-hall stands an equestrian statue of the emperor Otho the Great, erected towards the close of the 13th century. The favourable situation of Magdeburg, in the very heart of Germany, and on the Elbe below all its principal affluents, has made it one of the most important commercial towns in the empire, and it is also the focus of several important railways. The chief articles of commerce are agricultural and colonial products, manufactured goods, and wine. The town and its suburbs contain numerous manufactories of woollen, cotton, and silk goods, sugar, spirits, tobacco, organs and pianos, chocolate, and chicory. Magdeburg is the head-quarters of the 4th corps of the German army, and the seat of the provincial court of appeal and administrative offices, of a Lutheran consistory, and of a superintendent general of the Evangelical (Reformed) Church. It also contains two gymnasia, two "Realschulen," schools of art, medicine, surgery, and mining, and numerous scientific and charitable institutions. The population of Magdeburg in 1880 was 97,539, or, including Neustadt and Buckau, 137,109.

Magdeburg, which was in existence as a small trading settlement at the beginning of the 9th century, owes its early prosperity chiefly to the emperor Otho I., who established a Benedictine convent here in 937 (see above). In 968 it became the seat of an archbishop, who was also primate of Germany, and exercised sway over an extensive territory. By the 13th century Magdeburg had become a flourishing commercial town and an important member of the Hanseatic League. Its bench of sheriffs (*Schöppenstuhl*) became celebrated, and "Magdeburg law," securing the administrative independence of municipalities, was adopted in many parts of Germany, Poland, and Bohemia. During the Middle Ages the citizens were almost constantly at variance with the archbishops, and by the end of the 15th century had become nearly independent of them. It should, however, be noted that Magdeburg never became a free city of the empire. The town embraced the Reformation in 1524, and was thenceforth governed by Protestant administrators or archbishops. On the refusal of the citizens to accept the "Interim," Magdeburg was besieged by Maurice of Saxony in 1550, and capitulated in 1551 on favourable terms. During the Thirty Years' War the city was twice besieged, and suffered terribly. It successfully resisted Wallenstein for seven months in 1629, but was stormed and sacked by Tilly in 1631. The whole town, with the exception of the cathedral, the Frauenkirche, and about 140 houses, was burned to the ground, and 30,000 of its 36,000 inhabitants were butchered without regard to age or sex. The town recovered from this deadly blow with wonderful rapidity. In 1648 the archbishopric was converted into a secular duchy, to fall to Brandenburg on the death of the last administrator, which happened in 1680. In 1806 Magdeburg was taken by the French and annexed to the kingdom of Westphalia, but it was restored to Prussia in 1814, on the downfall of Napoleon. Otto von Guericke, the inventor of the air-pump, was burgomaster of Magdeburg at the time of Tilly's siege. Carnot died here in exile, and is buried in the cemetery, and Luther was at school here and sang in the streets for bread with other poor choristers.

See Rathmann, *Geschichte der Stadt Magdeburg*, 1800–17; Hoffmann, *Chronik der Stadt Magdeburg*, 1843–50; Barthold, *Geschichte der deutschen Städte*, 1850.

MAGELLAN, Ferdinand, in Portuguese Fernão de Magalhães (*c.* 1470-1521), who, though he did not survive to return home with his ship, well deserves the title of the "first circumnavigator," was born about 1470, and (according to the somewhat questionable authority of his will, dating from 1504) at Villa de Sabroza in the district of Villa Real, Traz os Montes. His family was "hidalgo," and he seems to have spent his boyhood in the household of Queen Leonora, consort of John II. of Portugal. For several years he was in active service in the East Indies. It was he who, in 1510, gave Siqueira timely warning of the plot of the people of Malacca, thus probably saving his countrymen from annihilation; and, along with Serrano, he commanded the ships sent out under Abreu for the discovery of the Spice Islands. On his return from the East, Magellan was sent to Azamor in Morocco; and this brief episode in his career is memorable for the wound which left him lame for the rest of his life, and for the beginning of the troubles which determined his future course. Contrary to what he had a right to expect, the king (Manuel) refused Magellan's application for an increase of the pay assigned to him as a member of the royal household; and the manner of the refusal added insult to what he considered injury. In company with another malcontent of note, Ruy Faleiro the astronomer, he formally renounced his nationality, and went to offer his services to the court of Spain. Word was no sooner brought to Manuel of the schemes proposed to the Spaniards than he felt the mistake he had committed; but all the efforts put forth by special agents to allure his alienated subjects back to their allegiance, or to thwart their negotiations, proved of no avail. The bishop of Burgos, Juan Rodriguez de Fonseca, had taken the matter up, and things had gone too far for Magellan to retrace his steps. On August 10, 1519, the expedition set sail; to find his way by a western route to the Spice Islands of the East was the task which its commander had undertaken. When more than three years afterwards, on September 6, 1522, the "Victoria" cast anchor in a Spanish port, the captain, Sebastian del Cano, had a strange tale to tell of mingled triumph and tragedy. While the squadron lay in Port St Julian, on the Patagonian coast, three of Magellan's Spanish captains had defied him and conspired against him, and it was only by a rapid execution of summary vengeance that he had maintained his authority. At a later date the "Antonio," at the instigation of Gomez, the Portuguese pilot, his personal enemy, sailed home to Spain with evil reports, at the very moment of success, when the Strait of the Eleven Thousand Virgins, or of the Patagonians, now known as the Strait of Magellan, had been explored almost to the Pacific. The strait was passed on November 28, 1520; and, though Magellan had not quite reached the Spice Islands when he fell in conflict with the people of Zebu, 27th April 1521, his task was virtually accomplished. The name Magellan's Land—long given to Patagonia and that hypothetical continent of which Tierra del Fuego was considered only a portion—had disappeared from our maps, but has again been bestowed by Chili on the territory she claims in the extreme south.

No record of his exploits has been left by Magellan himself; and contemporary accounts are less detailed and consistent than could be wished. The best is that of Antonio Pigafetta, a volunteer in the fleet. It is printed in Ramusio, and exists in four early MS. copies, three in French and one in Italian. The Italian was printed in 1801 by Amoretti. Along with five minor narratives an English version appears in Lord Stanley of Alderley's *First Voyage round the World by Magellan*, 1874 (Hakluyt Society's Publications, vol. lii.). See also J. G. Kohl, *Gesch. der Entdeckungsreise . . . zur Magellan's Strasse* (Berlin, 1877), and Ramon Guerrero Vergara, *Los descubridores del Estrecho de Magellanes*, Santiago de Chile, 1880.

MAGGIORE, Lago (French, *Lac Majeur*; in Italian also frequently *Lago Verbano*; Latin, *Verbanus*), is the westmost of the great lakes of northern Italy. In accordance with its popular name it has long been reputed the largest of them all; but though in length it somewhat surpasses Lago di Garda, it does not cover so extensive an area. Of the total surface of 82 square miles, 65 belong to Italy, and the remaining 17 to the Swiss canton of Tessin or Ticino. The length from north to south, between 45° 43′ and 46° 10′ N. lat., is 38 miles; the breadth, generally between 2 and 4 miles, is increased to 6 or 7 at the junction of the Toce valley on the west. The Ticino, the leading tributary of the Po, enters at the one end of the lake and escapes at the other. The very interesting geological problems which Lago Maggiore suggests are not yet fully cleared up. (See Taramelli, *Il cantone Ticino meridionale ed i paesi finitimi*, Bern, 1880, forming vol. xvii. of the materials for the geological map of Switzerland.) The whole of the west side and the east side as far south as Val Travaglia are shut in by a region of gneiss and schists, while the remaining portion presents dolomites, calcareous rocks, and conglomerates, mingled with strongly developed moraines. On Dufour's great map of Switzerland the greatest depth is given as 2801 feet, opposite Pino; but this is probably much in excess, as in G. B. Maggi's topographical map of the lake (Turin, 1857) the highest figure registered along the medial line is only 1233 feet between Barbe and Lavello, and at the laying of a telegraph line in 1860 Salis found no more than 337 between Vira and Locarno. The ordinary height of the surface above the sea is about 640 feet. Between the lowest and highest water-mark, however, there is a difference in ordinary years of nearly 12 feet, and in very exceptional cases of twice as much. For not only is the Ticino subject to floods, but the lake receives a number of considerable streams (the Toce, the Maggia, the Verzasca, the Tresa, &c.), and some of these bring down the surplus waters of other lakes—Lugano, Varese, and Orta. The flood of 1868, which exceeded by about 6 feet the greatest that had been known for centuries, so deepened and enlarged the outlet of the river that the level of the lake was permanently reduced by about a foot and a half, and alterations had to be made at the various ports to suit the new condition of things. (See Paolo Gallizia in *Atti del Coll. degli Ingegn. ed Archit. in Milano*, 1879.) At least twenty-three species of fish are caught in Lago Maggiore; and the fisheries are of value enough to be closely preserved by the proprietors.

Lago Maggiore.

The principal towns and villages round the lake are the following,—the first being in Switzerland, and the others in Italy:—Locarno (population in 1880, 2645), at the mouth of the Maggia, one of the alternate capitals of the canton of Ticino; Cannobio (2000), famous from the 15th century for its tanneries, and with paper-mills and silk-works; Luino (2000), the original home of the Luini family, and the scene of one of Garibaldi's exploits in 1867, commemorated on the spot by a statue of the victor; Laveno (1500), formerly an Austrian naval harbour; Intra (4500), a busy manufacturing town—cotton, glass, silk, &c.; and Pallanza (4200), a flourishing little city with a large cathedral, a penitentiary, &c., and altogether the most important place on the lake. The celebrated Borromean Islands, lying off Pallanza, have been already described, vol. iv. p. 64; compare Medone, *Le isole Borromee*, with views by Falkenstein (Novara, 1840). As the St Gotthard and St Bernardino routes meet at Bellinzona, much of the trade between Italy and the north used to pass by way of the lake and the high roads that skirt its banks; and the opening of the St Gotthard railway, which joins the Italian system at Pino on the east side, and goes as far as Locarno on the west side, will bring back some of the traffic which the earlier railways diverted into other channels. The first steamboat was launched on the lake in 1826.

See P. Morriggia, *Ist. della Nobiltà del Lago Maggiore*; Amoretti, *Viaggio ai tre laghi*; Vagliano, *Rive del Verbano*.

MAGHIÁNA, the chief town and headquarters of Jhang district, Punjab, India, is situated in 31° 17′ N. lat. and 72° 21′ E. long., and had a population in 1868 of 10,525 (Hindus, 5192; Mohammedans, 4698; Sikhs, 306; and "others," 329). It has a considerable trade with Kandahar, large exports of country cloth, and a fluctuating business in grain from the fertile lowlands of the Rávi. The civil station lies to the east of the town, and consists only of a court-house and treasury, sessions bungalow, jail, church, and three or four residences of officials. Maghiána forms a single municipality with Jhang town, which lies 3 miles to the north. The united population is 19,649.

Origin of term. MAGIC[1] has its name from the *magi*, Greek *μάγοι*, the hereditary caste of priests among the ancient Persians, thought to be of Median origin (Spiegel, *Avesta*, vol. ii. p. vi.). Among the magi the interpretation of dreams was practised, as appears from the story of the birth of Cyrus (Herodotus, i. 107); later writers describe them in both a sacerdotal and magical capacity, Lucian (*Makrob.*, 4) calling them a prophetic class and devoted to the gods, while Cicero (*De Divinatione*, i. 23, 41) writes of them as wise men, augurs, and diviners. In such supernatural crafts the magi seem to have much influenced the Western nations, to judge by their name having passed into a set of classical terms (*μαγεία*, *μαγεύω*, *magia*, *magice*, &c.) applied to sorcery, enchantment, and occult science in general. In the New Testament soothsaying and sorcery are so designated (Acts viii. 9, xiii. 6); while the astrologers who divine the birth of the King of the Jews by the appearance of a star in the east are called magi (Matt. ii.).

Magical beliefs and practices. The word magic is still used, as in the ancient world, to include a confused mass of beliefs and practices, hardly agreeing except in being beyond those ordinary actions of cause and effect which men accustomed to their regularity have come to regard as merely natural. Thus magical rites are difficult even to arrange in systematic order. A large proportion of them belong properly to the general theory of religion, inasmuch as their efficacy is ascribed to the intervention of spiritual beings. Thus the ghosts of the dead are called up by the necromancer to give oracles or discover hidden treasures, or sent to enter men's bodies and afflict them with diseases or to cure them, or in a score of ways to do the behests of the magician, whose spells or incantations are thought powerful enough to control the will even of such divine beings as can drive the winds and give or withhold the rain. It must be noticed, on the other hand, that many magical arts show no connexion with spirits at all, or, even if ghosts or demons or gods have to do with them, the nature of these beings does not of itself account for the processes employed or the effects believed to result. This non-spiritual element in magic depends on imagined powers and correspondences in nature, of which the adepts avail themselves in order to discover hidden knowledge, and to act on the world around them by means beyond the ordinary capabilities of men. Thus by mere effort of will, by traditional formulas and rites, or by working on symbolic fancies, the sorcerer believes he can bewitch others to sickness or death, the astrologer reads the future in the aspects of the stars, the augur attends to omens from the cries of birds and beasts, the haruspex prophesies by the heart or liver of a slaughtered animal, and other classes of diviners judge of the hidden past and the yet more hidden future by the falling of lots or dice, the twitching of their own fingers or the tingling of their ears, and a host of other facts of nature which, as the educated world has now found out, have no practical connexion with the magical meanings or effects assigned to them. The great characteristic of magic is its unreality. Its methods have often an ideal coherence which may be plainly traced, but practical effect they have none, and so they may be altered or transposed without being made worse or better. One remarkable consequence of this is the fixity with which some magical formulas framed thousands of years ago hold on almost unchanged to this day. To understand this, it must be borne in mind that, if there were any practical use in such rules as those for divining by the cries of animals, the old rules would have been improved by experience into new shapes. But, they being worthless and incapable of improvement, this motive of change is absent, and the old precepts have held their ground, handed on by faithful but stupid tradition, from age to age. When the test of practical efficacy comes in upon the magic art, it is apt either to destroy it utterly or to transform it into something more rational, which passes from supernatural into natural science.

Magic of lower races. Magic is to be reckoned among the earliest growths of human thought. The evidence for its remote antiquity lies partly in its presence among all races of mankind, the ruder tribes especially showing it in such intelligible shapes that the beginnings of magical crafts may be fairly supposed to have arisen in the oldest and lowest periods of culture. An example may be taken from the wild natives of Australia, whose whole life is pervaded by the belief, and embittered by the terror, of sorcery. They imagine the sorcerers, armed with their mysterious power called *boyl-ya*, to come moving along in the sky, invisible except to other sorcerers; they enter the bodies of men, and feed stealthily on them, not eating the bones, but consuming the flesh; the native feels the pain as the boyl-ya enters him like a bit of pointed quartz, and in this shape of quartz crystal the evil can be extracted by another sorcerer. The sorcerer has other means of attacking his victim: he can creep near to him when asleep, and bewitch him to death by merely pointing at him a leg bone of a kangaroo; or he can steal away his kidney fat, where, as the natives believe, a man's power dwells; or he can call in the aid of a malignant demon to strike the poor wretch with his club behind the neck; or he can get a lock of hair, and roast it with fat over the fire till its former owner pines away too, and dies. The Australians, like other low tribes in the world whose minds are thus set on imaginary causes of death, hardly believe a man can die unless by being slain or bewitched. When a native dies what we call a natural death, they ascribe it to magic. Then other magic must reveal the hostile sorcerer who has done him to death: either the corpse itself will seem to push its bearers in the direction of the murderer, or the flames of the grave-fire are seen to flicker towards where he is, or some insect will be seen creeping towards his home; and, when the next of kin thus discover the magic enemy, they set off to take vengeance with earthly weapons. The sorcerer has kindlier duties when he sits by a sick man and charms and charms till he recovers, or sucks out the disease from his body in the shape of a stone spear-head or a fish bone, or brings out the ailment along a string, the other end of which he draws between his own lips till it is covered with blood, telling the bystanders (who believe it) that this blood came along the string out of the sick man. Not disease and cure only, but other events of life, come within the scope of native magic. Storm and thunder are the work of the sorcerers; they can bring rain and make the rivers swell, or burn up the land with drought. Shooting stars and comets are to the natives omens of disaster; the great hawk's cry in the night portends the death of a child, whose soul the bird is carrying off; but when a man's finger-joints crack he stretches out his arm, for in that direction some one is doing him a kindness.[2]

[1] The etymology of the word is seen in the terms "art magic," or the "magic art"; French, *art magique*; Latin, *magica ars*.

[2] For these and other details see Grey, *Journals of Expeditions*; Waitz, *Anthropologie der Naturvölker*, vol. vi.; Brough Smyth, *Aborigines of Victoria*; Fison and Howitt, *Kamilaroi and Kurnai*, &c.

Taken together, such a repertory of the demonology and witchcraft of a special group of savage tribes shows remarkable correspondence in principle with the magic which once flourished in the civilized world, and which still lingers in peasant folklore. The very details often agree so much as to raise the question whether the magic of savages may sometimes have been borrowed from the lower class of colonists. The superstitions of the peasant are in fact what the savage would readily assimilate, as belonging to a state of mind like his own, and there is even evidence of European charms and omens having been sometimes borrowed by native tribes of Australia or America. It was necessary to mention this, if merely to point out that such borrowing has been only slight and superficial. It in no way upsets the general principle that the magic of the lower races was developed among them, fitting as it does with their low level of knowledge. Every book of travels in savage and barbaric countries shows the influence of the native magician, who, often at once sorcerer and established priest, and sometimes even chief of his tribe, by the aid of spirits and other supernatural means interferes in every act of life. Thus in the Pacific islands the Europeans found a whole class of sorcerers living by making diseases, their method being the familiar one of burning or otherwise practising on some morsel of hair or remnant of food, so as to send disease into its owner, by a malignant spirit tying knots in his inside till he writhed with agony. Every sick man was a source of profit to the sorcerer who was believed to have brought on the disease by burning his rubbish, and of course had to be bought off by liberal presents. In these Pacific islands a fact most important in the theory of magic everywhere comes into view with particular distinctness—that such magical arts prove effective through the patient's own imagination; when he knows or fancies that he has been bewitched he will fall ill, and he will actually die unless he can be persuaded that he has been cured. Thus, wherever sorcery is practised with the belief of its victims, some system of exorcism or some protective magical art becomes, not only necessary, but actually effective, a mental disease being met by a mental remedy to match it.[1] At the discovery of America, the Spaniards found the native sorcerers throwing themselves into delirious ecstasy by snuffing a narcotic powder, their ravings in this state being held to be conversation with departed souls, through whose help they were able to cure the sick by expelling the disease. The class to which these sorcerers belong extends over South America, and is generally known under the name of *payé* (or allied terms). The sorcerer is described as being initiated by living in some wild spot till by fasting and self-torture he attains his supernatural craft, becoming able to see spirits, to consecrate bits of bone or stone into powerful amulets, to make good or bad weather, to gain mystic powers over familiar birds and beasts, to take omens from their cries or from the itching of his own skin, which latter symptom an Abipone diviner declared to portend an attack from a tribe of enemies, in spite of the missionary, who irreverently set it down to fleas. The old arts of the payés, their malicious witchcraft with herbs and hair, the use of narcotics to produce ecstasy, and their mental excitement by drumming, rattling, and dancing are still to be met with in the wild districts of Guiana and Brazil. In North America practitioners of the same kind are generally known as "medicine-men," from the French colonists calling them *médecins*, as being the native doctors; the term is really appropriate to barbaric magicians in all parts of the world, whose arts of causing and curing disease generally include considerable knowledge of herbs powerful as poisons and remedies, of simple stopping of wounds and bandaging hurt limbs, in fact of medicine in its elementary state, as yet not separated from the magic with which it was at first inextricably mixed up. The medicine-man's apparatus includes the sorcerer's usual music, the rattle and the drum, simple and primitive instruments whose constant association with the lower magic bears witness to the beginnings of music and magic having been associated together when civilization was yet in its low stages of development. The American sorcerer carries a "medicine-bag" made with the skin of his guardian animal, which protects him in fight, cures the bites of serpents, and strikes at a distance as a spiritual weapon. He knows magic chants of power over the elements; he can by sucking and blowing extract disease-animals from the sick; he can make pictures and images and pierce them with thorns so as to kill the men or animals they represent; and he can compel love by practising on the heart of the picture of the beloved one.[2] In Africa the native sorcerer bears the name of *mganga* among the west and central negro tribes, *nyanya* among the Zulus of the south. He is the rain-maker, an office of the utmost importance among tribes who may perish of famine and disease after a long drought. In his craft a principal part is played by what the English in Africa (using the Portuguese word *feitiço*, charm or amulet) call "fetiches," which are claws, fangs, roots, stones, and any other odds and ends fancied to be inhabited by spirits or invested with superhuman power. These fetiches the negroes trust in for good and against evil fortune, with a confidence which no failure can shake further than to cause the unlucky bearer to discard a particular fetich which has failed, and to replace it by a more successful one. The African mganga has intercourse with demons; and, being called on every day to predict the fortune of a fight or a bargain, or to discover lost or stolen cattle, he professes to gain information from the spirits, or uses his various modes of divination, such as taking omens from the cries of the eagle or the owl, the swimming of berries, or the moving of sticks in his own hands as they twitch spasmodically in nervous excitement. As with magicians everywhere, his trade is profitable but dangerous, for if his arts of killing have been successful beyond bearing, or still worse if public opinion decides that he has wilfully withheld the rain, he may be drowned or burned as miserably as one of the many victims he has done to death.[3] These instances are selected to give an idea of the sorcerers of the lower races and their modes of working, which are remarkable for their uniformity in the most distant regions, among tribes who can have had no communication or connexion since remote ages. Where, however, such races as the African negroes come in contact with such foreigners as the Arabs, who though more civilized than themselves have not outgrown the magical stage, they borrow their more cultured magical arts, such as divination by lots. In this way the natives of Madagascar appear to have borrowed from the Arabs a system of lucky and unlucky days of birth, which, carried out with stupid ferocity, has cost the lives of thousands of children, born truly in an evil hour, for when the magician declares their birth ill-omened their fate is settled at once by putting them to death.[4]

Turning now to the cultured nations of antiquity, among

Egyptian magic. whom the art of writing consolidated and developed false as well as true science, we find magic in full vogue, hardly differing in principle from that of the illiterate barbarians, but worked into more elaborate system and ritual. Of ancient Egyptian magic various original documents have been preserved, containing formulas, mostly of religious magic,—that is, acting through the aid of deities invoked. For instance, there are hymns against dangerous animals in the water, and spells for remaining in the country; and the power ascribed to such formulas appears from passages like the following:—"I confide in the efficacy of that excellent written book given to-day into my hand, which repels lions through fascination, disables men, ... which muzzles the mouths of lions, hyænas, wolves, ... the mouth of all men who have bad faces, so as to paralyse their limbs," &c. Ancient as Egyptian magic is, it has evidently grown up from still earlier forms, as is shown by that plainest symptom of old traditional lore, the relying on ancient or foreign epithets as words of power over the gods. This practice appears in the ancient papyri, and goes on to later ages, when the god Set is invoked by other mystically powerful names which he must obey, such as "Joerbeth." The medical art in ancient Egypt shows an interesting combination of practical and magical remedies. The practical recipe might contain nitre or cedar chips, or deer horn, or various other ingredients administered in ointment or drunk in beer, but with this the magical formula was also required to deal with the demon-cause of the ailment. Thus an emetic was given with the following formula, "O demon who art lodged in the stomach of M., son of N., thou whose father is called Head-smiter, whose name is Death, whose name is cursed for ever!" &c. It must be remembered that such formulas, foolish as they seem to modern education, had and still have great efficacy in relieving the mind of the superstitious patient, and giving a fair chance to diet and medicaments. Their appearance in medicine so ancient as that of Egypt is good historical evidence how the old magical treatment was encroached upon by natural remedies, though then and for many ages afterwards the physicians, wise in their generation, thought it best not to discard the supernatural charm. The Egyptians divided out the limbs and organs of the human body, putting each under the special care of a god, a system which, like many other details of their magic, has lasted on into the modern world. From the astrological point of view they made a calendar of lucky and unlucky days, according to which for instance on the 19th of the month Athor one must not embark on the Nile, while a child born on the 5th of the month Paopi will be killed by a bull; traces of this set of precepts may be discerned still in the modern Egyptian almanac. Another point deserving attention is the appearance in early Egypt of the distinction between good and bad magic. Magical curative arts were practised by learned scribes or priests, and were doubtless in high esteem, but when it came to attracting love by charms or philtres, or paralysing men by secret arts, this was held to be a crime. As long ago as the time of Rameses III. it is recorded that one Hai was accused of making images and paralysing a man's hand, for which he was condemned to death; this was doubtless the ordinary bewitching by an image or picture, here already mentioned among the lower races, and to be mentioned again as not forgotten among ourselves.[1]

Babylonian-Assyrian magic. Still more prominent among the ancient nations who brought magic into its pseudo-scientific stage were the Babylonians, whose supernatural arts were adopted and continued among the Assyrians. No savage tribe ever filled their world with more swarming hosts of nature-spirits and demons; only these more cultured nations dealt systematically with them by set formulas of propitiation and expulsion. The cuneiform writings preserve numerous documents of this kind, such as "From the burning spirit of the entrails which devours the man, from the spirit of the entrails which works evil, may the king of heaven preserve, may the king of earth preserve!"—"The god . . . . shall stand by his bedside. Those seven evil spirits he shall root out, and shall expel them from his body; and those seven shall never return to the sick man again." The magic power believed to reside in the secret names of the gods was recognized by the Babylonians, one of whose famous myths relates how by the utterance of these mystic names the goddess Ishtar was delivered from Hades. In the rites of the magician priests, this kind of supernatural power resided in sacred texts, whether chanted or tied on as phylacteries. In divinatory magic the Babylonians had elaborate codes of rules, of which many have been preserved. Thus omens were drawn from prodigies, such as "when a woman bears a child and at the time of birth its teeth are cut, the days of the prince will be long." So with omens from animals: "if a dog goes to the palace and lies down on a throne, that palace will be burned." A remarkable passage, Ezekiel xxi. 21, mentions three modes of divination practised by the king of Babylon as he stood at the head of the two ways: "he shuffled arrows, he consulted teraphim, he looked in the liver." The arrow-divination or belomancy here mentioned was done with pointless arrows marked and drawn as lots. They are often represented on Babylonian and Assyrian cylinders, and their use was kept up among the Arabs till the time of Mohammed. The Babylonian rules of haruspication, or examining the entrails of animals, were most minute, to judge from the omens of prosperity or misfortune to be drawn from the twisting and colour of the intestines of an ass. Diodorus Siculus (ii. 29, &c.), in his account of the Chaldæan priests, mentions with evidently good information their hereditary skill in various branches of magic, their use of purifications, sacrifices, and chants, to avert evil and obtain good, their foretelling by omens, dreams, prodigies, &c. But it is on their astrology that he deservedly lays the greatest stress. The five planets, which they called "interpreters," they held to portend events by their rising and setting and their colour, foretelling the wind or rain or heat, comets also, and eclipses of the sun and moon, and earthquakes, and atmospheric changes, beneficial or harmful, both to nations and kings and common men. The Babylonian calendars still remain to show how eclipses were brought into connexion with floods, invasions, good and bad harvests,—such ideas being worked out, not by mere arbitrary fancy, but from such fancied regularities as that the same weather and the same famines and pestilences tended to recur in a cycle of twelve years. To the Babylonian astrological system belong the stars of men's nativities, the planetary houses, the twelve signs of the zodiac (probably invented in observatories in Babylon), while the fixed stars are associated with the planets and gods in a system which is seen at a glance to be the astrology which later nations of Asia and Europe have followed since with servile faithfulness.[2]

Egypt and Babylon, as these brief notices show, were the chief sources whence the world learnt what may be called the higher branches of occult science, and from the historical point of view the magical rites and beliefs of other ancient Eastern nations, such as Asia Minor and India, are of little importance. It was mainly through Greece and Rome that magic was consolidated and

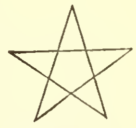
Greek and Roman magic.

developed in Western civilization. In these classic nations there may be traced the rude old magic inherited from barbaric ancestors, to which in later times were added ceremonies and calculations imported as Oriental wisdom. Ancient literature shows the Greeks as a people whose religion ran much into the consultation of oracle-gods at many temples, of which the shrine of Apollo at Delphi was the chief. No rite could keep up more perfectly the habit of savage religion than their necromancy (νεκρομαντεία, νεκυομαντεία) or consulting ghosts for prophecy; there was a famous oracle of the dead near the river Acheron in Thesprotia, where the departing souls crossed on their way to Hades (Herod., v. 92). The myth of Circe turning the companions of Odysseus into swine shows the barbaric belief in magical transformation of men into beasts, and the classic sorcerer was believed to turn himself into a wolf by spells like the medicine-man of some modern savage tribe. Not less clearly does the story of Medea and her caldron typify the witch-doctress with her pharmacy (φαρμακεία) powerful both to kill and bring to life. The worship of Hecate, the moon, sender of midnight phantoms, lent itself especially to the magician's rites, as may be seen from this formula to evoke her: "O friend and companion of night, thou who rejoicest in the baying of dogs and spilt blood, who wanderest in the midst of shades among the tombs, who longest for blood and bringest terror to mortals, Gorgo, Mormo, thousand-faced moon, look favourably on our sacrifices!" This magical record, preserved by an early Christian writer, may be compared with the poetic picture in Theocritus's idyll of the sorceress (*Idyll.*, ii.), where the passionate witch cries in similar words to Hecate, the moon, to shine clear while she compels by sacrifice her faithless lover, and goes through her magic ritual of love and hate, striving to force her beloved home to her by whirling the brazen rhomb, scattering his bones with the scattered barley, melting him to love by the melting wax, casting into the fierce flames a torn shred of his cloak and laurels to crackle and blaze and be consumed that his flesh shall be consumed likewise. This ancient witchcraft ascribed magic power to such filth as pounded lizards and the blood of creatures untimely dead, revolting messes made familiar to moderns by Shakespeare, who introduces real magic recipes in the witches' caldron in *Macbeth.* The early Greeks lived in the same fear as southern nations still do of the arts of "fascination" (βασκανία, Lat. *fascinatio*) worked by envious praise, or ill-wishing, or the evil eye; and they sought to avert these bad influences by the means still in use, spitting and symbolic gestures, and the use of charms and amulets. As to ancient Rome, much of the magic in the Latin poets, such as Virgil and Horace, is only Greek sorcery in a Latin dress. But severe Roman laws against those who practised such malefic arts as making hail and spoiling the crops show that here also the sorcerer was at his usual work. What is more remarkable is the high official place given to divination in old Rome, where every public act was done under magical sanction. The *auspex*, or bird-viewer, and the *augur*, whose similar name seems to refer also to omens from the flight and cries of birds, in fact carried on supernatural divination not by omens from birds only, but by a variety of magical processes forming a complex traditional system, partly adopted from the Etruscans, as to which some curious remarks have come down to us in the treatise *On Divination* by Cicero, himself an augur, though living in the days when the ancient lore was falling into contempt. The Roman divination was, as its name implies, a religious system of consulting the gods, who sent the signs to guide mankind. Jupiter, the Heaven-father himself, was heard and seen in thunder and lightning; wherefore these heavenly manifestations were of the highest import, observed by the augur in the *templum* or division of the sky marked out with his *lituus* or curved wand; there was no better omen than when Jove lightened on the left. Among birds, the fierce eagle, Jove's messenger, gave the highest presage of victory, while the owl with its dismal cry was unluckiest. The good or ill signs given by many birds depended on whether they were on the right or left hand, and the sacred chickens gave their omens according as they were eager or not to feed, and dropped crumbs on the ground. All prodigies were recorded as portents in Roman affairs; and those which Livy mentions year by year, whether they were real or fictitious, in either case had their effect on the minds of men who saw national signs in a heavy hailstorm, a calf born with two heads, or a bullock found when sacrificed to have no heart. It was in quest of such portents that the haruspex made his professional examination of the entrails of the victims, and reported the aspects of the head of the liver or cleft of the lungs, as a sacred guide to warriors and statesmen in the conduct of national affairs. Public divination being on this footing, it is not to be wondered at that, in the time of the empire, foreign soothsayers thronged to Rome to practise their craft among rich and credulous dupes. It appears that the magic of Egypt and Babylon still held a prominent place, for Juvenal refers to both in his sixth satire, where he rails at the superstitious women of his time for putting their trust in Chaldæan astrologers, all the more if under the laws against magicians they had been put in prison or banished, while ladies would not go out for a drive or take a meal without consulting their book of lucky and unlucky hours, which bore the Egyptian name of *Petosiris.*

In the classic world, however, the growth of knowledge and accurate reasoning began to have their effect in bringing magic to the test of facts, and proving its failure. Greek philosophy, with its physical theories of the universe, had shaken the old religion, and with it the old magic. Though the Romans kept it up as a matter of statecraft, the judgment of statesmen and philosophers revolted from it, holding rather with Ennius, who pointed out the absurdity of the hungry fortune-teller promising others wealth and begging a drachma for himself, or with Cato, who wondered that one diviner could meet another and not burst out laughing. These are both quoted by Cicero, with other passages argued quite in the modern spirit, as where he asks on what principle a raven's croak should be propitious on the right but a crow's on the left, or how a chicken eating a cake could help dropping crumbs. Historically attacks of this kind have a particular value, as recording many magical details which we do not know from the believers themselves. Of such details Pliny's *Natural History* is full, though he hates magic as the most fraudulent of arts; and among the most instructive accounts of classic astrology must be reckoned the treatise written against it by Sextus Empiricus. Had sceptical philosophy had its way, magic would have perished ages earlier out of the civilized world. But there were other influences already at work, not only to preserve it, but even to give it another great expansion before its final decay.

Philosophic and theurgic magic.

The Pythagorean philosophy, while on the one hand bringing in the science of Egypt and Babylon, and developing it into Greek mathematics and physics, on the other hand favoured the growth of magic by mystical speculations, such as those on numbers. Not that the Pythagoreans began this delusive science, which had long been at home in Babylon, where the occult powers of the planetary 7 and the zodiacal 12 were recognized, and spiritual arithmetic was carried so far as to indicate good deities by whole numbers and evil demons by fractions. But the Pythagoreans developed it further in their mystic symbolism of the active 1 and the passive 2, the sacred 4 of space proceeding from the 1, the 7 of intelligence, the 8 of love, and the 10 of the universe. Whatever rational thought may at first have been veiled under all this, its literal nonsense suited the magical mind, and its effects may be traced in magical literature ever since. With such speculations was combined an animistic system of spirits pervading the world, ranging from gods and demons down to the souls of beasts and plants. Both in mystic symbolism and in the doctrine of demons the mind of Plato followed the Pythagorean track, and at a later period the tendency towards magical speculation came out strongly among the Neo-Platonists, when enthusiasts, not content with speculating about the dæmonic powers of the universe, sought to establish personal relations with them, and use them for their own ends. The treatise on the Egyptian mysteries ascribed to Iamblichus is an interesting record of this phase of thought. Alexandria became the especial home of systems of theurgic magic, in which invocations, sacrifices, diagrams, talismans, were employed with rule and method, as though they were really effective. Much of this delusive craft has perished or become unintelligible, but its once considerable hold on men's minds may be traced in such relics as the gem-talismans of the Gnostics, still objects of curiosity to archæologists; among their formulas is the celebrated *Abraxas*, the Greek letters of which (Αβραξας, Αβρασαξ) stand with astronomical significance for the number 365. The theurgy which came down into mediæval and modern Europe is strongly marked with Jewish magical speculation. After the captivity, the Jews worked out a classification and nomenclature of angels and demons. On the one side are ranged such celestial powers as Gabriel and Raphael, while against them stand such beings as BEELZEBUB (*q.v.*) and Ashmodai or Asmodæus (Tobit, chap. iii., &c.), who is clearly the great evil demon Aeshma-daeva of the Persian religion. Many centuries afterwards, in European magic books of the Middle Ages we find the remains of these theurgic systems still handed on. Their elaborate folly may be best realized by looking into such books as Francis Barrett's *Magus*, or Horst's *Zauber-Bibliothek*, where the actual rites and formulas for raising demons are given. The evocations, with their uncouth jumbles of sacred names, have some historical interest from their strangely mixed traces of ancient religions, preserved by charlatans whose blunders show how little they understood the words they copied. We can fancy the magician in his black robe embroidered with mystic characters, waving his wand as he invokes at one breath the great demons "Acheront," "Ashtaroth," "Asmodi," names which the modern student recognizes as borrowed from the ancient religions of three different countries—Greece, Phœnicia, Persia. Of all the sources of this branch of magic, the Jewish tradition is the chief. The magician relies on the power of divine Hebrew names, such as the *shem hammephorash* or the name Jehovah in its true pronunciation, with which Solomon and other wonder-workers of old did marvellous things. He draws powerful spells from the KABBALAH (*q.v.*) of the later Jews, with its transposed letters and artificial words,—using for instance the name *Agla*, formed from the initials of the Hebrew sentence—"Thou art a mighty God for ever." But in compelling the spirits he can use Hebrew and Greek in admired confusion, as in the following formula (copied with its mistakes as an illustration of magical scholarship in its lowest stage)—"Hel Heloym Sother Emmanuel Sabaoth Agla Tetragrammaton Agyros Otheos Ischyros Athanatos Jehova Va Adonai Saday Homousion Messias Eschereheye!" One of the most curious features of the demon-evocation is the use of the pentagram, an essential adjunct of the magic circle, whose effect in barring the passage of Mephistopheles is described in a well-known scene in Goethe's *Faust*. This symbol is an interesting proof of tradition from the Pythagoreans. It is a geometrical figure for the construction of the regular pentagon (Euclid, iv. prop. 11), now familiar to school-boys, but which to the school of Pythagoras was so wondrous a novelty that they used it as a sign of fellowship (see Bretschneider, *Geometrie vor Euklides*, p. 85), and it afterwards became a magical symbol, still to be seen in use in every country from Ireland to China.



Pentagram.

The magic of the Moslem world is in part adopted from Jewish angelology and demonology, and in part carries on Babylonian-Greek astrology, as systematized by such writers as Paul of Alexandria and Claudius Ptolemy. Thus the proceedings of the Moslem magician, as met with in the *Thousand and One Nights*, mostly run parallel with those familiar in Europe, in their fumigations and incantations, talismans (τετελεσμένα), horoscopes, and almanacs or calendars of lucky and unlucky days. In fact a modern Zadkiel in England would find himself on common ground with his brother practitioner in Baghdad or Delhi.[1] In other districts of Asia, more peculiar developments of magic have been preserved. To mention a few of the most noteworthy, the Sanskrit literature in India is rich in ancient magical precepts and hymn-charms.[2] The ancient Hindu magic is religious, turning on the actions of demons (*bhûta*) in causing disease by possession, and their exorcism and compulsion, as well as power obtained over higher spirits by sacrifices, austerities, and formulas or charms (*mantra*). From their connexion with early Aryan customs, these rites sometimes throw light on European practices derived from the same stock. Thus the magical practice of going round "with the sun," well known as *deisil* in Highland superstition, and kept up in England in the rule of passing the decanter "through the button-hole," appears to be a rite of Aryan sun-worship belonging to remote antiquity, for (under the name of *pradaxina*) it forms part of the Hindu marriage ceremony handed down from Vedic times.[3] Buddhism as well as Brahmanism had its magical side, and its literature of magic formulas (*tantra*). The "red-cap" lamas of Tibet, with their pretended miracles of breathing fire, swallowing knives, and ripping themselves up, are curious as reminding us of the time when these tricks, now come down among us to jugglers' feats, were regarded as supernatural. In the low Buddhism of the Mongols, mixed with native barbarism, the *shamans* or sorcerer-priests, with their rude sacrifices and demon-dances, are among the most remarkable types of their ancient class. In this part of Asia, and farther east, a somewhat remarkable system of divinatory magic has grown out of the reckoning of days, months, and years by a zodiac-calendar, whose signs *ape*, *horse*, *dog*, &c., are combined in series with the elements, male and female, so that a year may be called that of the "female fire-dog." It was inevitable that such a system should lead the magicians to draw omens from its signs. They do so in a most elaborate way, interfering with their presages on every occasion of life, beginning when the child undergoes its ceremonial washing, and has its fate defined by the signs it is born under, as "in the element fire, under the red sign in the year of the tiger, in the month of the sheep and day of the hog, in the fortieth division of the day under the influence of the ninth star," &c. This quaint science seems, however, not altogether native, for the influence of

Babylonian and Greek scientific and magical ideas has extended across Asia, even into China. The magic of this latter country is remarkable for its various and elaborate modes of divination. These may be obtained from mediums possessed by spirits, and giving oracles by speech or writing with the "descending pencil," as has lately been done by "spiritualists" in Europe. But higher authority is given to divination by throwing sacred lots, as the two wooden *ka pwe*, which fall with the flat or rounded side up. The results of such processes of divination, in themselves meagre, may be brought to any required elaborateness by the use of the "eight diagrams" obtained by combinations of the whole line (—) and the broken line (--). These, primarily interpreted as representing the male and the female principle (*yang*, *yn*), perfect and imperfect, heavenly and earthly, are referred by systematic fancy to elements, qualities, tempers, &c., and interpreted in the celebrated Chinese classic book called the *Y-king* into a collection of oracular responses.[1] The *feng-shui*, or "wind-and-water" magic, is a system the practitioners of which regulate the building of houses and tombs by their local aspects; it has of late come under the notice of Europeans from the unexpected impediments it has placed in their way when desirous of building or constructing railways on Chinese soil.[2]

Magic in Christendom.

In the lower stages of civilization the distinction between religion and magic hardly appears, the functions of priest and sorcerer being still blended, as was long since pointed out by Meiners (*Geschichte der Religionen*, book xii.). As established religions were formed among nations of a higher grade, the separation became more distinct between the official rites of the priesthood and those practised by castes of magicians, rivalry often becoming serious between them. Thus in ancient Egypt there appear, on the one hand, the miracles worked by divinities under official sanction of the priesthood, and, on the other hand, the unlicensed proceedings of sorcerers, who indeed doubtless deserved ill of society by practices done by detestable means or for detestable ends, such as bewitching by hurtful demons, or administering love-potions. Here we come into view of the distinction still expressed by the terms "white magic" and "black magic." Laws were made against magic in these ancient times, but it must be remembered that then and for thousands of years later, the opposition to magic had seldom anything to do with the sceptical doubts of its reality which arose among the classic philosophers. Magic was none the less believed in for being hated and proscribed; and when a soothsayer was looked upon as a false prophet the inference was, not that magic was unreal, but that this particular magician was pretending to supernatural power he did not possess. The Levitical law prohibits sorcery under penalty of death (Levit. xx. 27). Among the early Christians sorcery was recognized as illegal miracle; and magic acts, such as turning men into beasts, calling up familiar demons, raising storms, &c., are mentioned, not in a sceptical spirit, but with reprobation. In the changed relations of the state to the church under Constantine, the laws against magic served the new purpose of proscribing the rites of the Greek and Roman religion, whose oracles, sacrifices, and auguries, once carried on under the highest public sanction, were put under the same ban with the low arts of the necromancer and the witch.[3] As Christianity extended its sway over Europe, the same antagonism continued, the church striving with considerable success to put down at once the old local religions, and the even older practices of witchcraft; condemning Thor and Woden as demons, they punished their rites in common with those of the sorcerers who bewitched their neighbours, and turned themselves into wolves or cats. Thus gradually arose the legal persecution of witches, which went on through the Middle Ages under ecclesiastical sanction both Catholic and Protestant. The literature of the Middle Ages does not contribute many new elements to the study of magic, which was carried on under the old traditional systems. But it shows on the one hand how unbroken the faith of even the educated classes remained in the reality of magic, and on the other hand that its more respectable branches, such as astrology and alchemy, were largely followed, and indeed included in their scope much of the real science of the period (see the works of Thomas Aquinas, Gerbert, Roger Bacon, Cornelius Agrippa, &c.). The final fall of magic began with the revival of science in the 16th and 17th centuries, when the question whether the supposed effects of magic really take place or not was raised, and decided against it. In our day the occult sciences are rapidly dying out in the educated classes of the civilized world, though astrology still has its votaries, and the communications in "spirit circles" by possessed mediums and spirit-writing are what would in old times have been classed as necromancy. The magic which holds its place most firmly in Europe has come down by tradition in popular folk-lore, which is full of precepts for bewitching and averting witchcraft, and divining by omens. Among the practices which occur to everyone's mind are foretelling changes of the weather by the moon's quarters, taking omens from seeing magpies and hearing a dog howl at night, the fear of spilling salt, observation of the shroud in the candle and the stranger in the tea-cup, the girls' listening to the cuckoo to tell how soon they will be married, pulling off the row of leaves to settle what the lover's calling will be, and perhaps even compelling him to come by a pin stuck through the rushlight. Nor has the wizard forgotten how to cure inflammation with a "thunderbolt," generally an ancient stone or bronze hatchet dug up in the fields, nor how to punish an enemy by means of a heart stuck full of pins and hung in the chimney. These are but a few out of hundreds to be found in Brand's *Popular Antiquities* and the volumes published by the Folklore Society, or in the similar collections from every country of Europe. If any one wonders that popular magic still enjoys much credit in the peasant class, it should be remembered that even the educated world still shows a remarkable unreasonableness in connecting causes and effects. Thus the old magical belief survives that a loadstone, because it draws steel, will also draw out pain. Peasants may well carry a magnet in their trousers' pocket against rheumatism when better-informed people will wear with as great confidence a "galvanic belt," though any electrician will tell them it has not the power to hurt or cure a fly. One of the most favourable proofs of the changed public opinion in England is seen in the laws, where the penalties of the old statute against those who keep familiar demons are abolished, and the time-honoured charge has disappeared from the commission of the peace to inquire of all "inchantments, sorceries, art magic, trespasses, forestallings, regratings, &c." But persons pretending to exercise witchcraft, sorcery, enchantment, or conjuration, or undertaking to tell fortunes or pretending by occult or crafty science to discover lost or stolen goods, may be imprisoned under 9 Geo. II. c. 5, or fortune-tellers dealt with as rogues and vagabonds under 5 Geo. IV. c. 83, or they may be prosecuted for obtaining money under false pretences.

Origin of magic.

Looked at as a series of delusions, magic is distasteful to the modern mind, which, once satisfied of its practical futility, is apt to discard it as folly unworthy of further notice.

---

[1] See Mohl, *Y-king*; Pauthier, *Livres Sacrés de l'Orient*.

[2] See Eitel, *Handbook of Chinese Buddhism*; Edkins, *Folklore of China*, p. 65.

[3] For an excellent account of the classical and mediæval history of magic see Maury, *La Magie et l'Astrologie*.

This, however, is hardly doing it justice, for in the early developments of the human mind both religion and science were intimately connected with magic, whose various branches, unfruitful as they may be, are nevertheless growths from the tree of knowledge. The universal diffusion of magical ideas among mankind, excepting only the limited class who have abandoned them through higher education, shows that we are here in presence of a deep-seated intellectual process, while the strong likeness in the principles of magic among the rudest tribes points to its having sprung up under most ancient and primitive conditions. The connexion between magic and religion in its lower stages is obvious from the impossibility of separating them, inasmuch as in every country sorcerers and diviners, savage or civilized, are found invoking the aid of ghosts, demons, or gods, to give them information or execute their will. So far as magic is ascribed to the influence of spirits, its theory belongs to the animistic philosophy developed in the lower levels of civilization, where all the powers of life and nature are set down to spiritual beings (see Animism). A chief part of the magician's business being to converse with spirits and gain their help, he sets about this in various ways. More often than not the spirit is considered to be a human ghost, which behaves much as it did while it was still a living man's soul; or if it is called a demon or deity, still these are beings modelled on the human soul. Thus their manner of hearing prayers and receiving offerings is like human intercourse, especially in the frequent cases where the sorcerer is a "medium" possessed by the spirit, who is considered to inhabit his body like his ordinary soul, and to give oracles speaking by his human voice. In such supposed interviews with spirits there is plenty of delusion and fraud, but nothing specially magical; and, in fact, were the whole craft of the sorcerer of this spiritualistic kind, there would be no practical distinction between the sorcerer and the priest, and magic would fall into its place as an inferior branch of religion. It is because magical practices are by no means accounted for altogether by the doctrine of spirits, but involve other special explanations of their own, that it is found convenient to make magic a department by itself. Such explanation is needed in ordinary magical practices, like that of the American medicine-man, who draws a deer on a piece of bark and shoots at it, expecting thereby to kill a real deer next day, or of the Tongan soothsayer, who spins a cocoa-nut as a teetotum, in order to discover a thief by noticing towards whom the monkey-face of the nut is looking when it stops. The magical train of thought which leads men to resort to such devices is childishly simple. It is merely imperfect reasoning, the mistaking of an ideal connexion for a real one, the confusion of ineffective analogy with effective cause. Our minds go with those of the barbaric magicians so far as to recognize the analogy between shooting an animal and its picture; we see as plainly as they that the cocoa-nut as it were looks in a particular direction. The difference is that, in the magical stage of thought, these are taken to be real connexions, while more advanced knowledge discards them as ideal. As Wilhelm von Humboldt well remarks, "Man begins by seeking the connexion even of external phenomena in the region of thought; . . . . pure observation, still more experiment, follow at a wide distance after ideal or phantastic systems. Man's first attempt is to govern nature through its idea."

So much of the intellect of mankind has been spent since remote antiquity on magic that it may seem hard to believe the chief secret of the occult sciences to be after all nothing but bad reasoning. This at any rate is very unlike the theories propounded by those who have condemned magic as a real craft made known to man by diabolical influence, or by those who have thought to find in its mystic precepts relics of antique wisdom. The question is not, however, an abstruse one, for every reader has the means of satisfying himself by inspection of a few magical processes, as to what amount of reason really goes to making them. In a large proportion of cases there may be perceived, not absolute nonsense, but a kind of half-formed sense stopping short of practical value. There being an evident relation between an object and the thought of it, it becomes one of the chief practices of the sorcerer to try to make things happen by thinking about them. Thus he so "takes the will for the deed" that when he "ill-wishes" his enemies, and looks upon them with the "evil eye," he believes that he does them direct harm. On the other hand, those who know or suspect that such influence has been used against them suffer in reality from fear, often even dying of it. The belief in this mysterious power furnishes an explanation which is resorted to when any one falls ill or has any misfortune, and thus the belief in witchcraft among savages leads to constant enmity and revenge. Nor is this state of things to be traced only in what is called the uncivilized world, for those who have much intercourse with English country folks may still meet with instances of some cow or child firmly believed to have been "overlooked," the death of which may possibly be revenged on a neighbouring cottager, supposed to be the witch. Whenever a good or evil wish is uttered in words, it becomes a blessing or curse. When these are addressed to some deity or demon, they are in fact prayers, but when they are merely expressed wishes, without reference to any spiritual being, then their supposed effects are purely magical. Thus, in an ancient Hindu love-charm, the girl expects to bring back an offended lover by repeating the formula, "May thy heart devour itself for me, may thy dry mouth water for me!" &c. Still more does this kind of magic explain itself in the various rites where some object is used as a symbol, and the association of ideas transfers whatever is done to it to the person it represents. Thus Ovid's sorceress (*Heroid.*, vi. 91)—

> "simulacraque cerea fingit,
> Et miserum tenuis in jecur urget acus."

King James in his *Dæmonology* says that "the devil teacheth how to make pictures of wax or clay, that by roasting thereof the persons that they bear the name of may be continually melted or dried away by continual sickness." By a similar association of ideas, any object which has belonged to a person may be thus practised on, as has been already here mentioned among the South Sea islanders, or, to take a case nearer home, when in 1618 two women were executed at Lincoln for burying the glove of Henry Lord Rosse, so that, "as that glove did rot and waste, so did the liver of the said lord rot and waste." By like reasoning, when internal disease is ascribed to knots within the patient's body, it becomes a branch of witchcraft to tie magic knots, which produce their corresponding effect within the victim. Kindlier though not less delusive operations of misunderstood analogy are found in attempted cures by sympathetic magic, on the same principle which malignant sorcerers would have used in giving the disease itself. Thus knots are untied in order to untie internal complications in the sick beast, and weapons treated to cure by sympathy the wounds they made:—

> "But she has ta'en the broken lance,
> And washed it from the clotted gore,
> And salved the splinter o'er and o'er.
> William of Deloraine in trance,
> Whene'er she turned it round and round,
> Twisted, as if she galled his wound.
> Then to her maidens she did say
> That he should be whole man and sound
> Within the course of a night and day."
> —*Lay of the Last Minstrel*, iii. 23.

The herbs used as medicaments in the infancy of medicine appear to have been chosen for magical rather than medical motives, by a kind of reasoning which comes out very plainly among Chinese physicians, who administer the heads, middles, and roots of plants to cure their patients' heads, bodies, and legs respectively. In like manner European doctors long followed the "doctrine of signatures," which was in fact mere magic,—prescribing euphrasy or "eye-bright" for complaints of the eyes, because of the likeness of an eye in the flower, and treating small-pox with mulberries because their colour made them proper to diseases of the blood (see Pettigrew, *Superstitions of Medicine and Surgery*). The same easily-understood though practically absurd principle may be seen to have guided the processes of divination, many of which show plainly the association of ideas that suggested them. Thus, in the Roman augury already mentioned, there is no difficulty in following the fancy which made the war-eagle give an omen of victory, but attached a doleful foreboding to the melancholy owl. The same half-rational meaning explains the reversal of omens accordingly as they come on the right or left, that is, the good or bad hand. Any one who glances through one of the cheap dream-books still bought by servant-maids, which fairly represent the ancient books on *oneiromancy*, such as that of Artemidorus, will find many of the analogies still intelligible on which they are founded, as that to dream of washing one's hands presages relief from anxiety, while he who dreams of losing a tooth will lose a friend. The ancient art of *chiromancy*, or telling fortunes by the hand, goes on the evident analogy between the lines of the palm and the diverging courses of human life; closely allied to this is *scapulimancy* or divining by the cracks of a shoulder-blade put into the fire. Of divination by lots, so common that the term for throwing lots (*sortes*) has passed into *sorcery*, there are many varieties. Some are quite pictorial, such as the Maori diviner's sticks set up in the ground to show by their standing or falling the fate of the warriors they represent. But this strong analogy is not necessary, for it only requires a particular lot to be mentally associated with a particular idea to make the diviner believe that the fall of that lot makes that idea true. It would be tedious to go at length through other details of magic where the same key of imperfect analogy applies. But it may be pointed out that this explanation is nowhere more conclusive than in astrology. The very foundation of the science of the horoscope lies in the mere analogy between the rising of a star above the horizon and the birth of a man. Such circumstances as whether a planet is in conjunction or opposition alter their effect on the "native" in corresponding ways. The names of gods, happening to be given also to certain planets, are taken as omens, so that because a planet bears the name of Mercury it is brought into fanciful connexion with wisdom, and in like manner the planet Venus with love. Each planet having a colour assigned to it, the aspect of Mars or Saturn is believed to tell one, when in quest of a thief, whether he will have on red or black clothes. So the arbitrary names of the signs of the zodiac are made into presages, a just person being found under the sign of Libra, and charms against bugs being effective in the sign of Cancer. For convenience some of these examples are taken from modern handbooks of astrology, but in principle the old starcraft has changed little in the course of ages. In the study of magic it is necessary further to notice that precepts which seem quite arbitrary, not showing even fanciful half-reason, are often explained on further examination, which gives the key to the symbolic process by which they are formed. For instance, it would hardly be guessed why Cancer should be a sign involving movableness, but Scorpio firmness, were it not known that this result is obtained by arranging the twelve signs in order as they stand, as successively movable, fixed, and double (see Proclus, *Paraphrasis*, i. 15). Considering the antiquity of magic, the wonder is not that so much of its sense should be lost, but that so much is still intelligible.[1] Various other causes may be traced in the occult sciences, among which can only be mentioned here *rhabdomancy* or the use of the divining rod, by which the cunning man professes to discover water springs, murderers, or hidden treasure. Here it is evident that the decision is really arrived at by the diviner himself, not by the twig, and the same is true of various similar arts. From the earliest times also tricks of sleight-of-hand, &c., have been passed off by magicians as miracles to deceive their dupes; our language still testifies to this in the use of the word *conjuror*, the wonder-worker carrying on the old juggling, although no longer evoking demons to give him his mysterious power.

Hitherto magic has been dealt with on its delusive and harmful side, this being what most practically manifests itself in history. Yet it must be borne in mind that in its early stages it has been a source of real knowledge. True as it is that misunderstood facts and misleading analogies have produced its delusions, its imperfect arguments have been steps towards more perfect reasoning. Analogy has always been the forerunner of scientific thought, and, as experience corrected and restricted it into real effectiveness, from age to age whole branches of what was magic passed into the realm of science. The vague and misleading parts which could not be thus transformed were left behind as occult science, and thus the very reason why magic is almost all bad is because when any of it becomes good it ceases to be magic. From this point of view the intellectual position of magic is well expressed by Adolf Bastian (*Rechtsalterthümer*, p. 242):—"Sorcery, or, in its higher expression, magic, marks the first dawning consciousness of mutual connexion throughout nature, in which man, feeling himself part of the whole, thinks himself able to interfere for his own wishes or needs. So long as religion fills the whole horizon of culture, the vague groping of magic contains the first experiments which lead to the results of exact science. Magic is the physics of mankind in the state of nature. It rests on the beginning of induction, which remains without result only because in its imperfect judgments by analogy it raises the *post hoc* to the *propter hoc*, &c." The nature-spirits and demons with which the magician has so much to do represent indeed the notion of physical cause in the rudimentary science of the lower races, while the association of ideas on which his sorcery and divination is based has much the same relation to the scientific induction which succeeds it. That this view is sound is best shown by noticing the great departments of science whose early development is known to have taken place through magic. Astronomy grew up in Babylon, not through quest of mechanical laws of the universe, but through observation of the heavens to obtain presages of wars and harvest; while even in modern times Kepler's discoveries in physical astronomy were led up to through mystic magical speculations. In alchemy appears the early history of chemistry, which only emancipated itself in modern ages from its magical surroundings. The astrological connexion of the metals each with its planet was one of its fundamental ideas, of which the traces are still to be found in the name of the metal "mercury," and that of "*lunar* caustic" for silver nitrate. Lastly, the history of medicine goes back to the times when primitive science accepted demoniacal possession as the rational means of accounting for disease, and magical operations with herbs originated their more practical use in materia medica. (E. B. T.)

[1] For details of the association of ideas in magic see Tylor, *Early Hist. of Mankind*, chap. vi., and *Primitive Culture*, chap. iv.

MAGIC, White. Under this head is included the art of performing tricks and exhibiting illusions by aid of apparatus, excluding feats of dexterity in which there is no deception, together with the performances of such automaton figures as are actuated in a secret and mysterious manner. Conjuring by prestidigitation, or sleight of hand, independently of mechanical apparatus, is referred to under Legerdemain.

Whether or not the book of Exodus makes the earliest historical reference to this natural magic when it records how the magicians of Egypt imitated certain miracles of Moses "by their enchantments," it is known that the Egyptian hierophants, as well as the magicians of ancient Greece and Rome, were accustomed to astonish their dupes with optical illusions, visible representations of the divinities and subdivinities passing before the spectators in dark subterranean chambers. From the descriptions of ancient authors we may conjecture that the principal optical illusion employed in these effects was the throwing of spectral images of living persons and other objects upon the smoke of burning incense by means of concave metal mirrors. But, according to the detailed exposure of the tricks of the magicians given by Hippolytus (*Ref. Om. Hær.*, iv. 35), it appears that the desired effect was often produced in a simpler way, by causing the dupe to look into a cellar through a basin of water with a glass bottom standing under a sky-blue ceiling, or by figures on a dark wall drawn in inflammable material and suddenly ignited. The flashes of lightning and the rolling thunders which sometimes accompanied these manifestations were easy tricks, now familiar to everybody as the ignition of lycopodium and the shaking of a sheet of metal. The ancient methods described by Hippolytus (iv. 32) were very similar.

Spectral pictures or reflexions of moving objects, similar to those of the camera or magic lantern, were described in the 14th and 16th centuries. Thus, in the *House of Fame*, bk. iii., Chaucer speaks of "appearances such as the subtil tregetours perform at feasts"—pictorial representations of hunting, falconry, and knights jousting, with the persons and objects instantaneously disappearing; exhibitions of the same kind are mentioned by Sir John Mandeville, as seen by him at the court of "the Great Chan" in Asia; and in the middle of the 16th century Benvenuto Cellini saw phantasmagoric spectres projected upon smoke at a nocturnal exhibition in the Colosseum at Rome. The existence of a camera at this latter date is a fact; for the instrument is described by Baptista Porta, the Neapolitan philosopher, in his *Magia Naturalis* (1558). And the doubt how magic lantern effects could have been produced in the 14th century, when the lantern itself is alleged to have been invented by Athanasius Kircher in the middle of the 17th century, is set at rest by the fact that glass lenses were constructed at the earlier of these dates,—Roger Bacon, in his *Discovery of the Miracles of Art, Nature, and Magic* (about 1260), writing of glass lenses and perspectives so well made as to give good telescopic and microscopic effects, and to be useful to old men and those who have weak eyes. Towards the end of last century Comus, a French conjuror (the second of the name), included in his entertainment a figure which suddenly appeared and disappeared about 3 feet above a table,—a trick explained by the circumstance that a concave mirror was among his properties; and a contemporary performer, Robert, exhibited the raising of the dead by the same agency. Early in the present century Philipstal gave a sensation to his magic lantern entertainment by lowering unperceived between the audience and the stage a sheet of gauze upon which fell the vivid moving shadows of phantasmagoria.

A new era in optical tricks began in 1863 when John Nevil Maskelyne, a Cheltenham artist in jewellery, invented a wood cabinet in which persons vanished and were made to reappear, although it was placed upon high feet, with no passage through which a person could pass from the cabinet to the stage floor, the scenes, or the ceiling; and this cabinet was examined and measured for concealed space, and watched round by persons from the audience during the whole of the transformations. The general principle undoubtedly was this:—if a looking-glass be set upright in the corner of a room, bisecting the right angle formed by the walls, the side wall reflected will appear as if it were the back, and hence an object may be hidden behind the glass, yet the space seem to remain unoccupied. This principle, however, was so carried out that no sign of the existence of any mirror was discernible under the closest inspection. Two years later the same simple principle appeared in "The Cabinet of Proteus," patented by Tobin and Pepper of the Polytechnic Institution, in which two mirrors were employed, meeting in the middle, where an upright pillar concealed their edges. In the same year Stodare exhibited the illusion in an extended form, by placing the pair of mirrors in the centre of the stage, supported between the legs of a three-legged table having the apex towards the audience; and as the side walls of his stage were draped exactly like the back, reflexion showed an apparently clear space below the table top, where in reality a man in a sitting position was hidden behind the glasses and exhibited his head ("The Sphinx") above the table. The plane mirror illusion is so effective that it has been reproduced with modifications by various performers. In one case a living bust was shown through an aperture in a looking-glass sloping upward from the front toward the back of a curtained cabinet; in another a person stood half-hidden by a vertical mirror, and imitation limbs placed in front of it were sundered and removed; and in another case a large vertical mirror was pushed forward from a back corner of the stage at an angle of 45 degrees, to cover the entrance of a living "phantom," and then withdrawn. Maskelyne improved upon his original cabinet by taking out a shelf which, in conjunction with a mirror, could enclose a space, and thus left no apparent place in which a person could possibly be hidden. He introduced a further mystification by secretly conveying a person behind a curtain screen, notwithstanding that, during the whole time, the existence of a clear space under the stool upon which the screen is placed is proved by performers continually walking round. And the illusion reached its height when he revealed or "vanished" a succession of persons out of a light shell obelisk or "Cleopatra's Needle," with a sheet of paper interposed between this cover and the stool it stood upon, thus intercepting the apparently only available avenue of approach. The principle of reflecting by means of transparent plate-glass the images of highly-illuminated objects placed in front, so that they appear as if among less brilliantly lighted objects behind the glass, was employed in the "ghost" illusions of Sylvester, of Dircks and Pepper, of Robin, and of some other inventors,—the transparent plate-glass being, in some cases, inclined forwards so as to reflect a lime-lighted object placed below the front of the stage, and in other arrangements set vertically at an angle so as to reflect the object from a lateral position.

Among the acoustic wonders of antiquity, fabled or real, were the speaking head of Orpheus, the golden virgins, whose voices resounded through the temple of Delphi, and the like. Hippolytus (iv. 4) explains the trick of the speaking head as practised in his day: the voice was really that of a concealed assistant who spoke through the flexible gullet of a crane. Towards the close of the 10th century Gerbert (Pope Sylvester II.) constructed (says

William of Malmesbury) a brazen head which answered questions; and similar inventions are ascribed to Roger Bacon, Albertus Magnus, and others. In the first half of the 17th century the philosopher Descartes made a speaking figure which he called his daughter Franchina; and the superstitious captain of a vessel had it thrown overboard. In the latter part of the same century Thomas Irson, an Englishman, exhibited at the court of Charles II. a wooden figure with a speaking-trumpet in its mouth; and questions whispered in its ear were answered through a pipe secretly communicating with an apartment wherein was a learned priest able to converse in various languages. Beckmann, in his *History of Inventions* (about 1770), relates his inspection of a speaking figure, in which the words really came through a tube from a confederate who held a card of signs by which he received intelligence from the exhibitor. Somewhat later was shown in England the figure of an infant suspended by a ribbon, having a speaking-trumpet in its mouth,—an illusion in which two concave mirrors were employed, one of them concentrating the rays of sound into a focus within the head of the figure; and the mirror nearest the figure was hidden by a portion of the wall-paper which was perforated with pin-holes. In 1783 Giuseppe Pinetti de Wildalle, an Italian conjuror of great originality, exhibited among his many wonders a toy bird perched upon a bottle, which fluttered, blew out a candle, and warbled any melody proposed or improvised by the audience,—doing this also when removed from the bottle to a table, or when held in the performer's hand upon any part of the stage. The sounds were produced by a confederate who imitated song-birds after Rossignol's method by aid of the inner skin of an onion in the mouth; and speaking-trumpets directed the sounds to whatever position was occupied by the bird. About the year 1825 Charles, a Frenchman, exhibited a copper globe, carrying four speaking-trumpets, which was suspended in a light frame in the centre of a room. Whispers uttered near to this apparatus were heard by a confederate in an adjoining room by means of a tube passing through the frame and the floor, and answers issued from the trumpets in a loud tone. And of late years have appeared more than one illusion of a similar order, in which the talking and singing of a distant person issue from an isolated head or figure by aid of ear-trumpets secretly contained within parts in which, from their outside form, the presence of such instruments would not be suspected. It is probable that the automaton trumpeters of Kaufmann and of Maelzel were clever deceptions of the same kind. As described in the *Journal de Mode*, 1809, Maelzel's life-size figure had the musical instrument fixed in its mouth; the mechanism was wound up, and a set series of marches, army calls, and other compositions was performed, accompaniments being played by a real band. Mechanical counterparts of the human lips, tongue, and breath, both in speech and in playing certain musical instruments, have, however, been constructed,—as in Vaucanson's celebrated automaton flute-player, which was completed in 1736; the same mechanician's tambourine and flageolet player, which was still more ingenious, as, the flageolet having only three holes, some of the notes were produced by half-stopping; Abbé Mical's heads which articulated syllables, and his automata playing upon instruments; Kempelen's and Kratzenstein's speaking-machines, in the latter part of last century; the speaking-machine made by Fabermann of Vienna, closely imitating the human voice, with a fairly good pronunciation of various words; the automaton clarionet-player constructed by Van Oeckelen, a Dutchman, and exhibited in New York in 1860, which played airs from a barrel like that of a crank-organ, and could take the clarionet from its mouth and replace it; and, lastly, Maskelyne's two automata, "Fanfare" (1878) playing a cornet, and "Labial" (1879) playing a euphonium, both operated by mechanism inside the figures and supplied with wind from a bellows placed separately upon the stage.

Lucian tells of the magician Alexander in the 2d century that he received written questions enclosed in sealed envelopes, and a few days afterwards delivered written responses in the same envelopes, with the seals apparently unbroken; and both he and Hippolytus explain several methods by which this could be effected. In this deception we have the germ of "spirit-reading" and "spirit-writing," which, introduced in 1840 by Anderson, "The Wizard of the North," became common in the *répertoire* of modern conjurors,—embracing a variety of effects from an instantaneous substitution which allows the performer or his confederate to see what has been secretly written by the audience. The so-called "second-sight" trick depends upon a system of signalling between the exhibitor, who moves among the audience collecting questions to be answered and articles to be described, and the performer, who is blindfolded on the stage. As already stated, the speaking figure which Stock showed to Professor Beckmann, at Göttingen, about 1770, was instructed by a code of signals. In 1783 Pinetti had an automaton figure about 18 inches in height, named the Grand Sultan or Wise Little Turk, which answered questions as to chosen cards and many other things by striking upon a bell, intelligence being communicated to a confederate by an ingenious ordering of the words, syllables, or vowels in the questions put. The teaching of Mesmer and feats of alleged clairvoyance suggested to Pinetti a more remarkable performance in 1785, when Signora Pinetti, sitting blindfold in a front box of a theatre, replied to questions and displayed her knowledge of articles in the possession of the audience. Half a century later this was developed with greater elaboration, and the system of telegraphing cloaked by intermixing signals on other methods, first by Robert-Houdin in 1846, then by Hermann in 1848, and by Anderson at a later period. Details of the system of indicating a very large number of answers by slight and unperceived variations in the form of question are given by F. A. Gandon, *La Seconde Vue Dévoilée*, Paris, 1849.

Fire tricks, such as walking on burning coals, breathing flame and smoke from a gall-nut filled with an inflammable composition and wrapped in tow, or dipping the hands in boiling pitch, were known in early times, and are explained by Hippolytus (iv. 33). At the close of the 17th century Richardson astonished the English public by chewing ignited coals, pouring melted lead (really quicksilver) upon his tongue, and swallowing melted glass. Strutt, in *Sports and Pastimes of the People of England*, relates how he saw Powel the fire-eater, in 1762, broil a piece of beefsteak laid upon his tongue,—a piece of lighted charcoal being placed under his tongue which a spectator blew upon with a bellows till the meat was sufficiently done. This man also drank a melted mixture of pitch, brimstone, and lead out of an iron spoon, the stuff blazing furiously. These performers anointed their mouths and tongues with a protective composition.

Galen speaks of a person in the 2d century who relighted a blown-out candle by holding it against a wall or a stone which had been rubbed with sulphur and naphtha; and the instantaneous lighting of candles became a famous feat of later times. Baptista Porta gave directions for performing a trick entitled "many candles shall be lighted presently." Thread is boiled in oil with brimstone and orpiment, and when dry bound to the wicks of candles; and, one being lighted, the flame runs to them all. He says that on festival days they are wont to do this among the Turks. "Some call it Hermes his ointment." In 1783

Pinetti showed two figures sketched upon a wall, one of which put out a candle, and the other relighted the hot wick, when the candle was held to their mouths. By wafers he had applied a few grains of gunpowder to the mouth of the first, and a bit of phosphorus to that of the other. A striking trick of this conjuror was to extinguish two wax candles and simultaneously light two others at a distance of 3 feet, by firing a pistol. The candles were placed in a row, and the pistol fired from the end where the lighted candles were placed; the sudden blast of hot gas from the pistol blew out the flames and lighted the more distant candles, because in the wick of each was placed a millet-grain of phosphorus. A more recent conjuror showed a pretty illusion by appearing to carry a flame invisibly between his hands from a lighted to an unlighted candle. What he did was to hold a piece of wire for a second or two in the flame of the first candle, and then touch with the heated wire a bit of phosphorus which had been inserted in the turpentine-wetted wick of the other. But in 1842 Louis Döbler, a German conjuror of much originality, surprised his audience by lighting two hundred candles instantaneously upon the firing of a pistol. This was the earliest application of electricity to stage illusions. The candles were so arranged that each wick, black from previous burning, stood a few inches in front of a fine nozzle gas-burner projecting horizontally from a pipe of hydrogen gas, and the two hundred jets of gas passed through the same number of gaps in a conducting-wire. An electric current leaping in a spark through each jet of gas ignited all simultaneously, and the gas flames fired the candle wicks.

Robert-Houdin, who opened his "Temple of Magic" at Paris in 1845, originated the application of electromagnetism for secretly working or controlling mechanical apparatus in stage illusions. He first exhibited in 1845 his light and heavy chest, which, when placed upon the broad plank or "rake" among the spectators, and exactly over a powerful electromagnet hidden under the cloth covering of the plank, was held fast at pleasure. In order to divert suspicion Houdin showed a second experiment with the same box, suspending it by a rope which passed over a single small pulley attached to the ceiling; but any person in the audience who took hold of the rope to feel the sudden increase in the weight of the box was unaware that the rope, while appearing to pass simply over the pulley, really passed upward over a winding-barrel worked as required by an assistant. Remarkable ingenuity was displayed in concealing a small electromagnet in the handle of his glass bell, as well as in his drum, the electric current passing through wires hidden within the cord by which these articles were suspended. In one of Houdin's illusions—throwing eight half-crowns into a crystal cash-box previously set swinging—electricity was employed in a different manner. Top, bottom, sides, and ends of an oblong casket were of transparent glass, held together at all the edges by a light metal frame. The coins were concealed under an opaque design on the lid, and supported by a false lid of glass, which was tied by cotton thread to a piece of platinum wire. Upon connecting the electric circuit, the platinum, becoming red-hot, severed the thread, letting fall the glass flap, and dropping the coins into the box.

Down to the latter part of last century no means of secretly communicating *ad libitum* motions to apparently isolated pieces of mechanism had superseded the clumsy device of packing a confederate into a box on legs draped to look like an unsophisticated table. Pinetti placed three horizontal levers close beside each other in the top of a thin table, covered by a cloth, these levers being actuated by wires passing through the legs and feet of the table and to the confederate behind a scene or partition. In the pedestal of each piece of apparatus which was to be operated upon when set loosely upon the table were three corresponding levers hidden by cloth; and, after being examined by the audience, the piece of mechanism was placed upon a table in such a position that the two sets of levers exactly coincided, one being superimposed upon the other. In one "effect" the confederate worked a small bellows in the base of a lamp, to blow out the flame; in another he let go a trigger, causing an arrow to fly by a spring from the bow of a doll sportsman; he actuated a double-bellows inside a bottle, which caused flowers and fruit to protrude from among the foliage of an artificial shrub, by distending with air a number of small bladders shaped and painted to represent them; he opened or shut valves which allowed balls to issue out of various doors in a model house as directed by the audience; and he moved the tiny bellows in the body of a toy bird by which it blew out a candle. Other conjurors added more complicated pieces of apparatus,—one being a clock with small hand moving upon a glass disk as required by the audience. The glass disk carrying the numbers or letters was in reality two, the back one being isolated by ratchet teeth on its periphery hidden by the ring frame which supported it, and, though the pillar-pedestal was separated into three pieces and shown to the spectators, movable rods, worked by the table levers, were in each section duly covered by cloth faces. Another mechanical trick, popular with Torrini, Houdin, Philippe, and Robin, and worked in a similar way, was a little harlequin figure which rose out of a box set upon the table, put his legs over the front of the box and sat on the edge, nodded his head, smoked a pipe, blew out a candle, and whistled a one-note obbligato to an orchestra. Robert-Houdin employed, instead of the table levers, vertical rods each arranged to rise and fall in a tube, according as it was drawn down by a spiral spring or pulled up by whip-cord which passed over a pulley at the top of the tube and so down the table leg to the hiding-place of the confederate. In his centre table he had ten of these "pistons," and the ten cords passing under the floor of the stage terminated at a keyboard. Various ingenious automata were actuated by this means of transmitting motion; but the most elaborate piece of mechanical apparatus constructed by Houdin was his orange tree. The oranges, with one exception, were real, stuck upon small spikes, and concealed by hemispherical screens which were covered with foliage; and the screens, when released by the upward pressure of a piston, made half a turn, and disclosed the fruit. The flowers were hidden behind foliage until raised above the leaves by the action of another piston. Near the top of the tree an artificial orange opened into four portions; while two butterflies attached to two light arms of brass rose up behind the tree, appeared on each side by the spreading of the arms, and drew out of the opened orange a handkerchief which had been borrowed and vanished away.

It is remarkable how many of the illusions regarded as the original inventions of eminent conjurors have been really improvements of older tricks. *Hocus Pocus Junior, The Anatomy of Legerdemain* (4th edition, 1654), gives an explanatory cut of a method of drawing different liquors out of a single tap in a barrel, the barrel being divided into compartments, each having an air-hole at the top, by means of which the liquid in any of the compartments was withheld or permitted to flow. Robert-Houdin applied the principle to a wine-bottle held in his hand from which he could pour four different liquids regulated by the unstopping of any of the four tiny air-holes which were covered by his fingers. A large number of very small liqueur glasses being provided on trays, and containing drops of certain flavouring essences, enabled him to supply imitations of various wines and liquors, according to the glasses into which he poured syrup from the bottle; while by a skilful substitution of a full bottle for an emptied one, or by secretly refilling in the act of wiping the bottle with a cloth, he produced the impression that the bottle was "inexhaustible." In 1835 was first exhibited in England a trick which a Brahman had been seen to perform at Madras several years before. Ching Lau Lauro sat cross-legged upon nothing,—one of his hands only just touching some beads hung upon a genuine hollow bamboo which was set upright in a hole on the top of a wooden stool. The placing of the performer in position was done behind a screen; and the explanation of the mysterious suspension is that he passed through the bamboo a strong iron bar, to which he connected a support which, concealed by the beads, his hand, and his dress, upheld his body. In 1849 Robert-Houdin reproduced the idea under the title of ethereal suspension,—professedly rendering his son's body devoid of weight by administering vapour of ether to his nose, and then, in sight of the audience, laying him in a horizontal position in the air with one elbow resting upon a staff resembling a long walking-stick. The support was a jointed iron frame under the boy's dress, with cushions and belts passing round and under the body. Subsequently the trick was improved upon by Sylvester—the suspended person being shown in several changes of position, while the sole supporting upright was finally removed. For the latter deception the steel upright was made with polished angular faces, apex toward the spectators, and acted in a dim light on the same principle as the mirrors of a Sphinx table. Before lowering the light, the reflector bar is covered by the wood staff set up before it.

The mysterious vanishing or appearing of a person under a large extinguisher upon the top of a table, and without the use of mirrors, was first performed by Comus, a French conjuror very expert in the cups-and-balls sleight-of-hand, who, appearing in London in 1789, announced that he would convey his wife under a cup in the same manner as he would balls. The feat was accomplished by means of a trap in a box table. Early in the present century Chalons, a Swiss conjuror, transformed a bird into a young lady, on the same principle. In 1836 Sutton varied the feat by causing the vanished body to reappear under the crust of a great pie. Houdin "vanished" a person standing upon a table top which was shown to be only a few inches thick; but there was a false top which was let down like the side of a bellows, this distension being hidden by a table-cloth hanging sufficiently low for the purpose, and the person, when covered by the extinguisher, entered the table though a trap-door opening upwards. Robin, in 1851, added to the wonder of the trick by vanishing two persons in succession, without any possibility of either escaping from the table,—the two persons really packing themselves into a space which, without clever arrangement and practice, could not hold more than one. The sword-and-basket trick was common in India many years ago. In one form it consisted in inverting an empty basket over a child upon the ground; after the child had secreted himself between the basket-bottom and a belt concealed by a curtain painted to look like the actual wicker bottom, a sword was thrust through both sides of the basket, the child screaming, and squeezing upon the sword and upon the ground a blood-coloured liquid from a sponge. When the performer upset the basket, the child could not be seen; but another child similarly costumed suddenly appeared among the spectators, having been up to that time supported by a pair of stirrups under the cloak of a confederate among the bystanders. In another form an oblong basket is used large at the bottom and tapering to the top, with the lid occupying only the central portion of the top, and the child is so disposed round the basket that the sword plunged downward avoids him, and the performer can step inside and stamp upon the bottom to prove that the basket is empty. In 1865 Stodare introduced the trick into England, but in a new manner. Upon light tressels he placed a large oblong basket; and after a lady attired in a profuse muslin dress had composed herself and her abundance of skirt within, after the lid had been shut and the sword plunged through the sides, the basket was tilted towards the audience to show that it was empty, and the lady reappeared in a gallery of the hall. The basket was formed with an outer shell to turn down, leaving the lady with her dress packed together lying upon the basket bottom and behind what had formed a false front side,—the principle being the same as in the clown's box, which, when containing a man, is rolled over to display the inside empty. The reappearing lady was a double, or twin sister.

Among the most meritorious and celebrated mechanical illusions have been automaton figures secretly influenced in their movements by concealed operators. In the 17th century M. Raisin, organist of Troyes, took to the French court a harpsichord which played airs as directed by the audience; but, upon opening the instrument, Louis XIV. discovered a youthful performer inside. In 1769 Baron Kempelen, of Pressburg, in Hungary, completed his chess-player, which for a long time remained the puzzle of Europe. It was an illusion,—the merit consisting in the devices by which the confederate player was hidden in the cabinet and body of the figure, while the interior was opened in successive instalments to the scrutiny of the spectators. The first player was a Polish patriot, Worousky, who had lost both legs in a campaign; as he was furnished with artificial limbs when in public, his appearance, together with the fact that no dwarf or child travelled in Kempelen's company, dispelled the suspicion that any person could be employed inside the machine. This automaton, which made more than one tour to the capitals and courts of Europe, and was owned for a short time by Napoleon I., was exhibited by Maelzel after the death of Kempelen in 1819, and ultimately perished in a fire at Philadelphia in 1854. A revival of the trick appeared in Hooper's "Ajeeb," shown a few years ago at the Sydenham Crystal Palace and elsewhere. Still more recently a chess-playing figure, "Mephisto," designed by Gumpel, has been on view. No space exists for the accommodation of a living player within; but, as there is no attempt at isolating the apparatus from mechanical communication through the carpet or the floor, there is nothing to preclude the moving arm and gripping finger and thumb of the figure from being worked by any convenient connexion of threads, wires, rods, and levers. In 1875 Maskelyne and Cooke produced at the Egyptian Hall, in London, an automaton whist-player, "Psycho," which, from the manner in which it is placed upon the stage, appears to be perfectly isolated from any mechanical communication from without; there is no room within for the concealment of a living player by aid of any optical or other illusion, and yet the free motions of both arms, especially of the right arm and hand in finding any card, taking hold of it, and raising it or lowering it to any position and at any speed as demanded by the audience, prove that the actions are directed from without. The arm has all the complicated movements necessary for chess or draught playing; and Psycho calculates any sum up to a total of 99,000,000. What the mysterious means of connexion are has not been discovered; or, at any rate, down to the time of writing this article there has appeared no correct imitation of this joint invention of John Nevil Maskelyne and John Algernon Clarke. Perhaps a still more original automaton is Maskelyne's figure "Zoe," constructed in 1877, which writes and draws at dictation of the audience, yet cannot have a living person within, and could not be more completely severed from all conceivable means of control without. "Zoe," a nearly life-size but very light doll, sits loose upon a cushioned skeleton-stand, of which the solid feet of the plinth rest upon a thick plate of clear glass laid upon the floor-cloth or carpet of the stage. "Psycho," a smaller Oriental figure, sitting cross-legged on a box, is supported by a single large cylinder of clear glass, which, as originally exhibited, stood upon the carpet of the stage, but was afterwards set loose upon a small stool, having solid wood feet; moreover, this automaton may be placed in almost any number of different ways. Thus, from the precautions observed in the isolation of Maskelyne's automata, no current of electricity, no magnetic attraction, no hydraulic or pneumatic force can reach them, or, if it could, would not account for the many and delicate movements which they execute; and there can be no wires, threads, or hairs, passing in any direction away from the figures, seeing that persons from the audience admitted close around the figures while they are in operation could not fail to observe them. It may be mentioned that, in the same year in which "Psycho" appeared, the joint inventors patented a method of controlling the speed of clock-work mechanism by compressed air or gas stored in the pedestal of an automaton, this compressed fluid acting upon a piston in a cylinder and also upon a rotating fan when a valve is opened by "an electrical or other connexion worked by the foot of the performer or an assistant." But it is not known whether the principle obscurely described in the specification was applicable in any way to the invisible agency employed in "Psycho" or in "Zoe," or whether it had reference to some other invention which has never been realized. The whist-playing automaton is affirmed to be the only one of Maskelyne's many subtle inventions in which he received suggestions from another person.

That a mysterious and apparently elaborate mechanical movement may, after all, possess the utmost simplicity is illustrated by the familiar conjuring trick known as "rising cards." Four cards having been chosen by the audience and returned to the pack, this is placed end upwards in a glass goblet, or in a thin case not deep enough to hide the pack, upon the top of a decanter or upon a stick. At command, the cards rise, one at a time, out of the pack; one rises part of the way and sinks back again; one rises quickly or slowly as directed; one comes out feet first, and, on being put back, rises head upwards like the others; and one dances in time to music, and finally jumps out of the pack. At the conclusion there remain only the goblet or the case and the cards, subject to the minutest examination of any one from the audience, without a trace of moving mechanism visible. This was one of the chief *jeux* of Comte, the French conjuror and ventriloquist, at the end of last century, and in varied forms has been popular to the present day. Probably it was suggested by the earlier device of the golden head dancing in a glass tumbler, which is described in *The Conjuror Unmasked*, 1790. Several crown pieces were put in the glass, a small gilded head above them, and a plate or other flat cover laid upon the mouth of the glass; yet the head thus isolated jumped inside the glass so as to count numbers and answer questions. The secret communicator of motion was a fine silk thread attached to the head and passing through a tiny notch cut in the lip of the glass, and so to a confederate who pulls it. In the case of the rising cards the whole of the movements are effected by arranging a single silk thread in the previously prepared pack, passing over some cards and under others, and led behind the decanter or other support to the stage and thence to the confederate. As this infinitely simple mechanical agent is drawn altogether out of the pack after the last card has risen, literally no trace remains of any means of communicating motion to the cards.

Oriental ingenuity, which furnished the original idea of the ethereal suspension trick, contributed the Chinese rings introduced into England in 1834; also the Chinese feat of producing a bowl of water with gold-fish out of a shawl, first seen in England in 1845, and the Indian rope-tying and sack feats upon which the American brothers Davenport founded a distinct order of performances in 1859. Their quick escape from rope bonds in which they were tied by representatives of the audience, the instantaneous removal of their coats in a dark séance, leaving themselves still bound, and their various other so-called "phenomena" were exposed and imitated by Maskelyne, who, in 1860, greatly surpassed any feats which they had accomplished. He proceeded to exhibit himself floating in the air, to show "materialized spirit forms," and to present a succession of wonders of the spirit mediums in novel performances down to the present time. One of Maskelyne's cleverest inventions was the box which he constructed in 1860; it closely fitted when he packed himself in a cramped position within; it was enclosed in a canvass wrapper, corded with any length and complicated meshing of rope, and the knot sealed, yet his escape was effected in the brief space of seven seconds. Taking more time, he performed the converse of these operations except the sealing. Provided with the wrapper and the open box, himself standing outside, he drew a curtain before him to conceal the *modus operandi*, and in a few minutes was found in the box, which, though so small as to permit no limb to be moved more than a few inches, he nevertheless wrapped and corded as exactly as if he had operated from the outside. Partially imitated with trick boxes of larger size, this feat has never been executed under the same conditions by any other conjuror; and the process of escape and repacking has never been fully elucidated. (J. A. CL.)

MAGIC LANTERN is the name given to an optical instrument for projecting on a white wall or screen largely magnified representations of transparent pictures painted or photographed on glass.

The invention of the magic lantern is usually attributed to Athanasius Kircher, who died in 1680, although, according to some, it was known four centuries earlier to Roger Bacon (see p. 207). For long after its discovery the magic lantern was used chiefly to exhibit comic pictures, or in the hands of so-called wizards to summon up ghosts and perform other tricks astonishing to those who were ignorant of the simple optical principles employed. Within the last twenty or thirty years, however, and mainly on account of the invention of photography, the magic lantern has been greatly improved in construction, and its use widely extended. By its means finely executed photographs on glass can be shown greatly magnified to large audiences. The scientific lecturer is thus saved the trouble and expense of preparing large diagrams, besides having his subject better illustrated. When suitably constructed, the magic lantern can be used in the form of a microscope to exhibit on a screen the forms and movements of minute living organisms, or to show to an audience delicate physical and chemical experiments which could otherwise be seen only by a few at a time.

The magic lantern in its simplest form is represented in fig. 1. A is a dark box surmounted by a suitable chimney for carrying off the products of combustion from the source of light L, which is placed in the focus of a spherical reflector. On the side opposite the reflector the box is pierced by a round hole, into which is fitted the metal tube D, which may either be cylindrical or slightly tapered. To the inner end of the tube D is fitted a lens or combination of lenses C called the "condenser." Immediately in front of the condenser, and at right angles to the axis of the tube, is a vertical slit S for receiving the transparent pictures usually called "slides." To the outer end of D is fitted a lens or combination of lenses O called the "objective" or "projecting lens." At a suitable distance from O is placed the screen for receiving the magnified picture —the screen and slit being in the conjugate foci of the lens O. Since the objective reverses, the picture must be inserted in the slit upside down. The objective can be moved backwards and forwards in the tube D by means of a rack and pinion. Since the screen and slide are in the conjugate foci of O the diameter of the picture on the screen has the same ratio to the screen's distance from O that the diameter of the picture on the slide has to the slide's distance from O. The ratio adopted is generally 1 to 3 or 4.

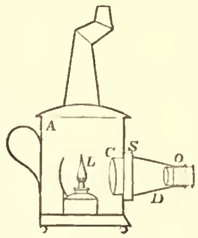

Fig. 1.

Source of Light.—Almost any good source of light can be used in the magic lantern. In the earlier forms a simple oil light was used; and in the toy forms either an oil light or simple gas-flame is still employed. Better effects are obtained from the Argand fountain lamp (fig. 2) or from the common Argand gas burner with a glass chimney. In the sciopticon (fig. 3)—a handy and excellent form recently introduced—a specially constructed paraffin lamp is employed with three parallel flat wicks set edgeways to the condenser. With this lamp a clear, well-defined picture varying from 6 to 10 feet in diameter can be readily thrown on the screen. For the best effects, however, recourse must be had to the oxy-calcium light (fig. 4), in which a small cylinder of lime is heated to intense luminosity in the flame of a spirit lamp through which a jet of oxygen plays; the Oxy-hydrogen Light

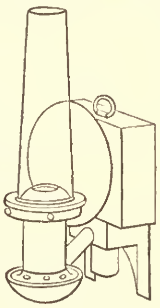

Fig. 2.—Argand Fountain Lamp.

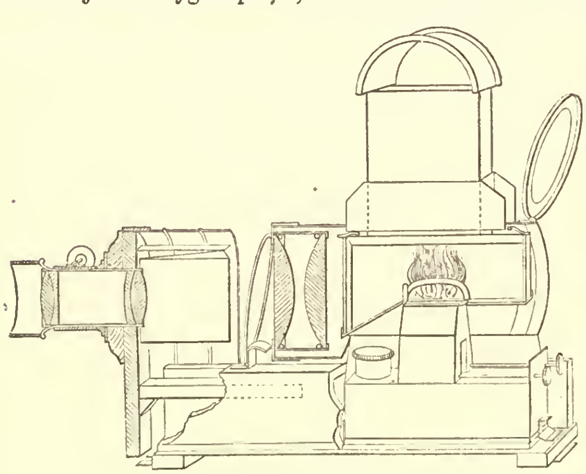

Fig. 3.—Sciopticon.

(*q.v.*); the magnesium light, in which two narrow ribands of magnesium are put through slits by a clock-work arrangement and burn as they advance; or, best of all,—unless when sunlight can be used with the aid of a heliostat (see Heliography),—the electric light.

Condenser and Objective.—The object of the condenser (fig. 5, C) is to collect as much light as possible from the source, and pass it through the transparent picture in the slit. For this purpose the condenser should subtend as large an angle as possible at the source of light. To secure this, the condenser should be tolerably large, and its distance from the light, that is, its focal length, small. Since effective single lenses of large diameter are necessarily of long focus, a really good condenser of considerable diameter and yet of short focus must be a combination of two or more lenses.

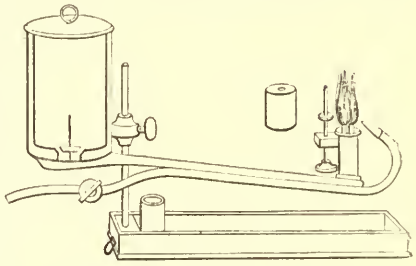

Fig. 4.—Oxy-calcium Lamp.

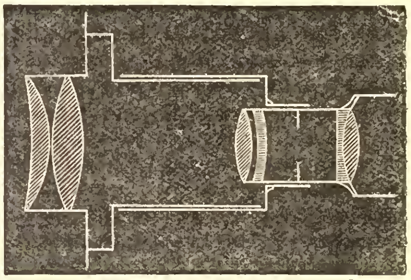

C O
Fig. 5.—Condenser and Objective.

Let f_1 and f_2 be the focal lengths of two lenses, and f the focal length of their combination. Then, neglecting the thickness of the lenses, we have when the two are close toegther

$$\frac{1}{f}=\frac{1}{f_1}+\frac{1}{f_2}.$$

From which we get $f=\frac{f_1 f_2}{f_1+f_2}$, a fraction which is always less than either f_1 or f_2 provided these are not zero. Suppose, for example, two lenses of 6 and 10 inches focal length respectively; the focal length of their combination will be $\frac{6\times 10}{6+10}=3\frac{3}{4}$ inches.

In the earlier lanterns, as still in the cheaper forms, only a single plano-convex lens or bull's-eye was employed as a condenser. Better effects are produced by two such lenses. Perhaps the best condenser for ordinary work is that proposed by Herschel and represented in fig. 5, C, consisting of a biconvex lens and a meniscus mounted together with the concave side of the meniscus next the light. The diameter of such a condenser is about 6 inches, and its focal length a little over 3 inches. The focus must not be so short as to bring the lens too near the light, and render it liable to crack from the intense heat. In some lanterns this is guarded against by placing a plate of thin glass between the condenser and the light. In the sciopticon (fig. 3) the condenser consists of two plane-convex lenses, each about 4 inches in diameter. Condensers of large diameter are not so essential now as formerly, seeing that small pictures can easily be produced by photography.

The function of the objective (fig. 5, O) is to produce a magnified inverted image of the picture on the screen. In toy lanterns it is a simple double-convex lens of short focus. This, however, can only produce a small picture, and that not very distinct at the edges. The best objective is the portrait combination lens used in ordinary photographic cameras. These are carefully corrected both for spherical and chromatic aberration, which is absolutely essential in the objective, although not so necessary in the condenser. It is essential, however, that the condenser be free from cracks or flaws, as these would appear and mar the picture.

Slides.—These are pictures, painted with transparent water or oil colours, or photographed on pieces of glass. The pieces of glass are usually fixed in small wooden frames for insertion in the slit. If parts of the picture are to be movable, two disks of glass are employed, the one movable in front of the other, the fixed part of the picture being painted on the fixed disk and the movable part on the other. By means of a lever the latter disk is moved in its own plane; and in this way a cow for instance can be represented drinking, or a donkey cutting amusing capers. A lever slide is represented in fig. 6. In the chromatrope

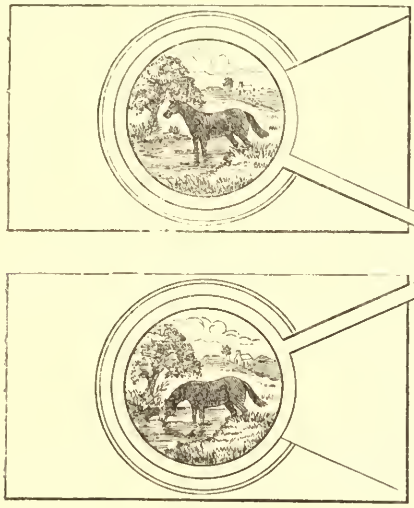

Fig. 6.—Lever Slide.

slide (fig. 7) two circular disks of glass are placed face to face, each containing a design radiating from the centre, and painted with brilliant transparent colours. By a small pinion gearing in toothed wheels or endless bands the disks are made to move in opposite directions in their own plane.

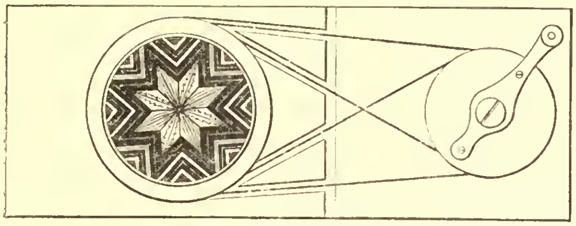

Fig. 7.—Chromatrope.

The effect produced is a singularly beautiful change of design and colour. In astronomical slides the motions of the heavenly bodies, eclipses, the phases of the moon, or the like are similarly represented by mechanical means. Slides can also be made from narrow glass tanks with parallel sides. When these are filled with water containing delicate living organisms the forms and movements of the latter are beautifully seen. Such tanks can also be employed to show such phenomena as the gradual growth of crystals, the electrolysis of water between platinum electrodes, &c. A great variety of physical and chemical experiments can be shown in this way.

Dissolving Views.—For this purpose two magic lanterns are necessary, arranged either side by side or the one on the top of the other. The fronts of the lanterns are slightly inclined to each other so as to make the illuminated disks on the screen due to each lantern coincide. By means of a pair of thin metallic shutters terminating in comb-like teeth, and movable by a rack or lever, the light from either lantern can be gradually cut off at the same time that the light from the other is allowed gradually to fall on the screen. In this way one view appears to melt or dissolve into another. This arrangement was first adopted by Childe in 1811.

Phantasmagoria.—In this arrangement the pictures on the screen appear gradually to increase or diminish in size and brightness. To effect this a semi-transparent screen of cotton or other material is used, the lantern being behind and the audience in front. The lantern is mounted on wheels so that it can be rapidly moved up to or withdrawn from the screen; and an automatic arrangement is provided whereby simultaneously with this the objective is made to approach or recede from the slide so as to focus the picture on the screen in any position of the lantern. In this way a very small picture appears gradually to grow to enormous dimensions.

Lantern Polariscope.—This, perhaps the most beautiful modification of the magic lantern for scientific purposes, consists of an elbow-shaped tube, containing mirrors, lenses, &c., and attached to the front of the lantern in place of the tube containing the objective. It is represented in section in fig. 8. C′ is the usual condenser belonging to the lantern. G is a set of thin glass plates inclined at the polarizing angle 56° 45′ to the axis of the tube. The beam of polarized light from L reflected from G passes through the lenses

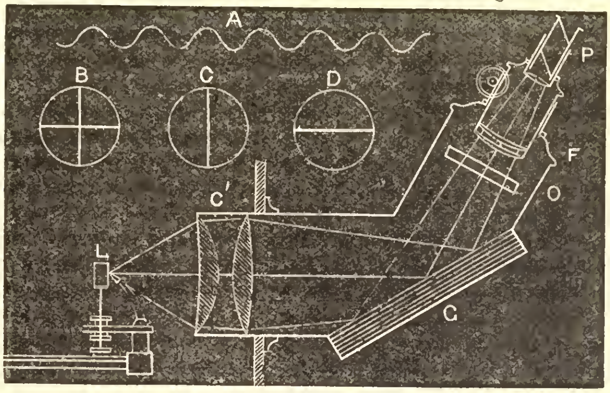

Fig. 8.—Lantern Polariscope.

F and the analysing Nicol's prism P, and falls on the screen. The objects to be examined by the polarized light are placed in the transverse slit O. When thin plates of selenite or other doubly refracting crystals are placed in O, a most beautiful display of complementary colours is produced on the screen by rotating the Nicol's prism. Almost all the experiments on polarized light can be well shown by this arrangement.

The *sciopticon* (fig. 3) is an excellent and convenient lantern, very suitable for all the requirements of the lecturer, as well as for school use in teaching geography, &c.

See Brewster's *Optics*; Ganot's *Physics*; and Chadwick's *Manual of the Magic Lantern*. (J. BL.)

MAGIC SQUARE. A magic square is one divided into any number of equal squares, like a chess-board, in each of which is placed one of a series of consecutive numbers from 1 up to the square of the number of cells in a side, in such a manner that the sum of those in the same row or column and in each of the two diagonals is constant.

From a very early period these squares engaged the attention of mathematicians, especially such as possessed a love of the marvellous, or sought to win for themselves a superstitious regard. They were then supposed to possess magical properties, and were worn, as in India at the present day, engraven in metal or stone, as amulets or talismans. According to the mystic imaginings of the old astrologers relations subsisted between these squares and the planets: a square with only one cell, containing 1, symbolized the unity of the deity; a square of two, containing the four elements, was the symbol of matter; while those of 3, 4, 5, 6, 7, 8 were consecrated respectively to Saturn, Jupiter, Mars, the Sun, Venus, and Mercury. In later times such squares ranked only as mathematical curiosities; till at last their mode of construction was systematically investigated. These squares were at first mere triumphs of the same dogged perseverance as was in later times exhibited by the Dutchman, Ludolph van Ceulen, who, after calculating π to 35 places of decimals, directed, like Archimedes, that it should be engraven on his tomb, though his industry was surpassed by M. de Lagry, who continued the decimal to 127 places. The earliest known writer on the subject was Emanuel Moscopulus, a Greek, who lived in the 4th or 5th century, and whose manuscript is preserved in the National Library at Paris. After him Frenicle constructed magic squares, such that if one or more of the encircling bands of numbers be taken away the remaining central squares are still magical. Subsequently M. Poignard constructed squares with numbers in arithmetical progression, having the magical summations. The later researches of M. de la Hire, recorded in the *Mémoires de l'Académie Royale* in 1705, are interesting as giving general methods of construction. He has there collected the results of the labours of earlier pioneers; but the subject has now been fully systematized, and extended to cubes.

In order to understand the rest of this article diagram A should be carefully examined. A square of 5 has adjoining it one of the eight equal squares by which any square may be conceived to be surrounded, each of which has two sides resting on adjoining ones, while four have sides resting on the surrounded square, and four meet it only at its four angles. 1, 2, 3 are placed along the path of a knight in chess; 4, along the same path, would fall in a cell of the outer square, and is placed instead in the corresponding cell of the original square; 5 then falls within the square. *a*, *b*, *c*, *d* are placed diagonally in the square; but *e* enters the outer square, and is removed thence to the same cell of the square it had left. α, β, γ, δ, ε pursue another, but regular, course; and the diagram shows how that course is recorded in the square they have twice left. Whichever of the eight surrounding squares may be entered, the corresponding cell of the central square is taken instead. The 1, 2, 3, ... , *a*, *b*, *c*, ... , α, β, γ, ... are said to lie in *paths*.

the squares E, F, being combined as above, give the magic square G. M. Bachet arranged the numbers as in H, where there are three numbers in each of four surrounding squares; these being placed in the corresponding cells of the central square, the square I is formed. He also constructed squares such that if one or more outer bands of numbers are removed the remaining central squares are magical. His method of forming them may be understood from a square of 5. Here each summation is 5×13; if therefore 13 is subtracted from each number, the summa-

in the rows and columns, we must assign such values to the p's and q's as satisfy the equations $p_1 + p_2 + a_1 + a_2 = 0$, $p_3 + p_4 + a_3 + a_4 = 0$, $p_1 + p_3 - a_1 - a_3 = 0$, and $p_2 + p_4$

$-\alpha_2-\alpha_4=0$,—a solution of which is readily obtained by inspection, as in diagram P; this leads to the square, diagram Q. When the root is 8, the upper four subsidiary rows may at once be written, as in diagram R; then, if the square be completed, 65 added to each, and the sums halved, the square is completed. In such squares as these, the two opposite squares about the same diagonal (except that of 4) may be turned through any number of right angles, in the same direction, without altering the summations.

Nasik Squares.—Squares that have many more summations than in rows, columns, and diagonals have been investigated by the Rev. A. H. Frost (*Cambridge Math. Jour.*, 1857), and called Nasik squares, from the town in India where he resided; and he has extended the method to cubes, various sections of which have the same singular properties. In order to understand their construction it will be necessary to consider carefully diagram S, which shows that, when the root is a prime, and not composite, number, as 7, eight letters $a, b, \ldots h$ may proceed from any, the same, cell, suppose that marked 0, each letter being repeated in the cells along different paths. These eight paths are called *normal paths*, their number being one more than the root. Observe here that, excepting the cells from which any two letters start, they do not occupy again the same cell, and that two letters, starting from any two different cells along different paths, will appear together in one and only one cell. Hence, if p_1 be placed in the cells of one of the $n+1$ normal paths, each of the remaining n normal paths will contain one, and only one, of these p_1's. If now we fill each row with $p_2, p_3, \ldots p_n$ in the same order, commencing from the p_1 in that row, the p_2's, p_3's, and p_n's will lie each in a path similar to that of p_1, and each of the n normal paths will contain one, and only one, of the letters $p_1, p_2, \ldots p_n$, whose sum will be Σp. Similarly, if q_1 be placed along any of the normal paths, different from that of the p's, and each row filled as above with the letters $q_2, q_3, \ldots q_n$, the sum of the q's along any normal path different from that of the q_1 will be Σq. The n^2 cells of the square will now be found to contain all the combinations of the p's and q's; and, if the q's be multiplied by n, the p's made equal to $1, 2, \ldots n$, and the q's to $0, 1, 2, \ldots \overline{n-1}$ in any order, the Nasik square of n will be obtained, and the summations along all the normal paths, except those traversed by the p's and q's, will be the constant $\Sigma nq+\Sigma p$. When the root is an odd composite number, as 9, 15, &c., it will be found that in some paths, different from the two along which the p_1 and q_1 were placed, instead of having each of the p's and q's, some will be wanting, while some are repeated. Thus, in the case of 9, the triplets $p_1p_4p_7$, $p_2p_5p_8$, $p_3p_6p_9$, and $q_1q_4q_7$, $q_2q_5q_8$, $q_3q_6q_9$ occur, each triplet thrice, along paths whose summation should be—Σp, 45, and Σr, 36. But if we make $p_1, p_2, \ldots p_9 = 1, 3, 6, 5, 4, 7, 9, 8, 2$, and the $r_1, r_2, \ldots r_9 = 0, 2, 5, 4, 3, 6, 8, 7, 1$, thrice each of the above sets of triplets will equal Σp and Σq respectively. If now the q's are multiplied by 9, and added to the p's in their several cells, we shall have a Nasik square, with a constant summation along eight of its ten normal paths. In diagram T, the numbers are in the nonary scale; that in the centre is the middle one of 1 to 9^2, and the sum of pairs of numbers equidistant from and opposite to the central 45 is twice 45; and the sum of any number and the 8 numbers 3 from it, diagonally, and in its row and column, is the constant Nasical summation, *e.g.*, 72 and 32, 22, 76, 77, 26, 37, 36, 27. The numbers in T being kept in the nonary scale, it is not necessary to add any nine of them together in order to test the Nasical summation; for, taking the first column, the figures in the place of units are seen at once to form the series, $1, 2, 3, \ldots 9$, and those in the other place three triplets of 6, 1, 5. For the squares of 15 the p's and q's may be respectively 1, 2, 10, 8, 6, 14, 15, 11, 4, 13, 9, 7, 3, 12, 5, and 0, 1, 9, 7, 5, 13, 14, 10, 3, 12, 8, 6, 2, 11, 4, where five times the sum of every third number and three times the sum of every fifth number makes Σp and Σq; then, if the q's are multiplied by 15, and added to the p's, the Nasik square of 15 is obtained. When the root is a multiple of 4, the same process gives us, for the square of 4, the diagram U. Here the columns give Σp, but alternately $2q_1$, $2q_3$, and $2q_2$, $2q_4$; and the rows give Σq, but alternately $2p_1$, $2p_3$, and $2p_2$, $2p_4$; the diagonals giving Σp and Σq. If p_1, p_2, p_3, p_4 and q_1, q_2, q_3, q_4 be 1, 2, 4, 3, and 0, 1, 3, 2, we have the Nasik square of diagram V. A square like this is engraven in the Sanskrit character on the gate of the fort of Gwalior, in India. The squares of higher multiples of 4 are readily obtained by a similar adjustment.

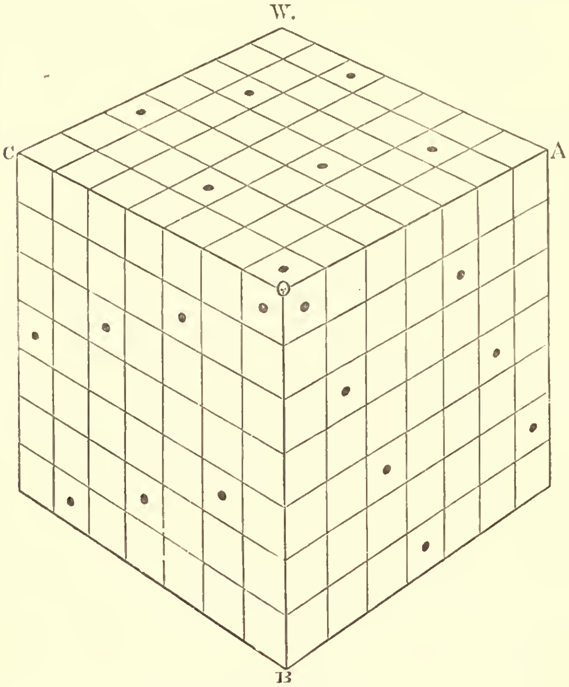
A *Nasik cube* is composed of n^3 small equal cubes, here called cubelets, in the centres of which the natural numbers from 1 to n^3 are so placed that every section of the cube by planes perpendicular to an edge has the properties of a Nasik square; also sections by planes perpendicular to a face, and passing through the cubelet centres of any path of Nasical summation in that face. Diagram W shows by dots the way in which these cubes are constructed. A dot is here placed on three faces of a cubelet at the corner, showing that this cubelet belongs to each of the faces AOB, BOC, COA, of the cube. Dots are placed on the cubelets of some path of AOB (here the knight's path), beginning from O, also on the cubelets of a knight's path in BOC. Dots are now placed in the cubelets of similar paths to that on BOC in the other six sections parallel to BOC, starting from their dots in AOB. Forty-nine of the three hundred and forty-three cubelets will now contain a dot; and it will be observed that the dots in sections perpendicular to BO have arranged themselves in similar paths. In this manner, p_1, q_1, r_1 being placed in the corner cubelet O, these letters are severally placed in the cubelets of three different paths of AOB, and again along any similar paths in the seven sections perpendicular to AO, starting from the letters' position in AOB. Next, $p_2q_2r_2$, $p_3q_3r_3$, $\ldots$ $p_7q_7r_7$ are placed in the other cubelets of the edge AO, and dispersed in the same manner as $p_1q_1r_1$. Every cubelet will then be found to contain a different combination of the p's, q's, and r's. If therefore the p's are made equal to $1, 2, \ldots 7$, and the q's and r's to $0, 1, 2, \ldots 6$, in any order, and the q's multiplied by 7, and the r's by 7^2, then, as in the case of the squares, the 7^3 cubelets will contain the numbers from 1 to 7^3, and the Nasical summations will be $\Sigma 7^2 r+\Sigma 7q+p$. If 2, 4, 5 be values of r, p, q, the number for that cubelet is written 245 in the septenary scale, and if all the cubelet numbers are kept thus, the paths along which summations are found can be seen without adding, as the seven numbers would contain $1, 2, 3, \ldots 7$ in the unit place, and $0, 1, 2, \ldots 6$ in each of the other places. In all Nasik cubes, if such values are given to the letters on the central cubelet that the number is the middle one of the series 1 to n^3, the sum of all the pairs of numbers opposite to and equidistant from the middle number is the double of it. Also, if around a Nasik cube the twenty-six surrounding equal cubes be placed with their cells filled with the same numbers, and their corresponding faces looking the same way,—and if the surrounding space be conceived thus filled with similar cubes, and a straight line of unlimited length be drawn through any two cubelet centres, one in each of any two cubes,—the numbers along that line will be found to recur in groups of seven, which (except in the three cases where the same p, q, or r recur in the group) together make the Nasical summation of the cube. Further, if we take n similarly filled Nasik cubes of n, n new letters, $s_1, s_2, \ldots s_n$, can be so placed, one in each of the n^4 cubelets of this



Nasik Cube.

group of n cubes, that each shall contain a different combination of the p's, q's, r's, and s's. This is done by placing s_1 on each of the n^2 cubelets of the first cube that contain p_1, and on the n^2 cubelets of the 2d, 3d, . . . and nth cube that contain $p_2, p_3, \ldots p_n$ respectively. This process is repeated with s_2, beginning with the cube at which we ended, and so on with the other s's ; the n^4 cubelets, after multiplying the q's, r's, and s's by n, n^2, and n^3 respectively,

will now be filled with the numbers from 1 to n^4, and the constant summation will be $\Sigma n^3 s + \Sigma n^2 r + \Sigma nq + \Sigma p$. This process may be carried on without limit ; for, if the n cubes are placed in a row with their faces resting on each other, and the corresponding faces looking the same way, n such parallelepipeds might be put side by side, and the n^5 cubelets of this solid square be Nasically filled by the introduction of a new letter t ; while, by introducing another letter, the n^6 cubelets of the compound cube of n^3 Nasik cubes

might be filled by the numbers from 1 to n^6, and so ad infinitum. When the root is an odd composite number the values of the three groups of letters have to be adjusted as in squares, also in cubes of an even root. A similar process enables us to place successive numbers in the cells of several equal squares in which the Nasical summations are the same in each, as in diagrams X.

Among the many ingenious squares given by various writers, this article may justly close with two by Euler, in the *Histoire de l'Académie Royale des Sciences*, Berlin, 1759. In diagram Y the natural numbers show the path of a knight that moves within an odd square in such a manner that the sum of pairs of numbers opposite to and equidistant from the middle figure is its double. In diagram Z the knight returns to its starting cell in a square of 6, and the difference between the pairs of numbers opposite to and equidistant from the middle point is 18.

A model consisting of seven Nasik cubes, constructed by Mr Frost, can be seen in the South Kensington Museum. The centres of the cubes are placed at equal distances in a straight line, the similar faces looking the same way in a plane parallel to that line. Each of the cubes has seven parallel glass plates, to which, on one side, the seven numbers in the septenary scale are fixed, and behind each, on the other side, its value in the common scale. 1201, the middle number from 1 to 7^4, occupies the central cubelet of the middle cube. Besides each cube having separately the same Nasical summation, this is also obtained by adding the numbers in any seven similarly situated cubelets, one in each cube. Also, the sum of all pairs of numbers, in a straight line through the central cube of the system, equidistant from it, in whatever cubes they are, is twice 1201.

A very complete bibliographical index of writers on this subject is given in Professor Lucas's *Récréations Mathématiques*, Paris, 1882. (A. H. F.)

MAGISTRATE. The term magistrate, derived from the Latin *magistratus*, is one of more general and comprehensive meaning than JUSTICE OF THE PEACE, which has already been treated of (vol. xiii. p. 789), and is of far higher antiquity. In its full significance it indicates one side of the universal public relation by which men are connected together as governors and governed—in other words, as magistrates and people. Of magistrates some are supreme, in whom the sovereign power and executive government of the state reside, as the king or queen regnant, or the president of a republic, as of the United States; and such a functionary would formally be designated the first magistrate of the realm or state. Speaking generally, a magistrate may be described as a public civil officer invested with legal or other authority; but the term is more particularly applied to subordinate officers, as justices of the peace and the like, deriving their authority solely from the chief of the state or in virtue of legislative enactment. During the Roman republic the offices of magistrate and judge were distinct and separate. A magistrate was appointed *cum jurisdictione et imperio* ; to a judge belonged only *nuda notio sine jurisdictione et imperio*. The office of the magistrate was to inquire into matters of law ; and whatever business was transacted before him was said to be done *in jure*. The office of the judge was to inquire into matters of fact ; and whatever was transacted before him was said to be done *in judicio*. This distinction is thus clearly defined by Cicero in his well-known oration for Cluentius :—" Legum ministri, magistratus ; legum interpretes, judices." When the magistrate took cognizance both of the law and the fact he was said to administer justice *extra ordinem* ; and the judgment so administered was called extraordinary. The magistrate, when he decided on matters of law, was assisted by a council of ten, called *decemviri litibus judicandis*. To these was added in important cases another council of one hundred and five persons, selected from each tribe, whose judgment was final; this was called *judicium centumvirale*. After the decline of the Roman republic the offices of magistrate and judge were united, by which means all judgments became extraordinary, and the distinction of what was done *in jure* and *in judicio* was abolished. The magistrates were chosen only from the patricians in the early republic, but in the course of time the plebeians shared in these honours. The chief magistrates of Athens were designated archons. They were nine in number, and none were chosen but such as were descended from ancestors who had been free citizens of the republic for three generations. They took an oath that they would observe the laws, administer justice with impartiality, and never suffer themselves to be corrupted. They all had the power of punishing malefactors with death. The chief among them was called archon, and the year took its designation from him,—the *archon eponymus*, who was also constituted a sort of state protector of those who were unable to defend themselves. The Franks, Lombards, and Saxons appear to have been jealous of judicial authority, and averse to removing what concerned a man's private right out of the hands of his neighbours and equals; every ten families are supposed to have had a magistrate of their own election, the tything man of England, the decanus of France and Lombardy. The decanus was the lowest species of judge.

MAGLIABECHI, ANTONIO (1633–1714), one of the most remarkable bibliophiles of his time, was born at Florence, October 28, 1633, and followed the trade of a goldsmith until 1673, when he received the appointment of librarian to the grand-duke of Tuscany, a post for which he had qualified himself by his vast stores of self-acquired learning. He died on July 4, 1714, bequeathing his large private library to the grand-duke, who in turn handed it over to the city. See LIBRARIES, vol. xiv. pp. 530, 548.

MAGNA GRÆCIA. See GRÆCIA.

MAGNESIA, in ancient geography, was the name of two cities in Asia Minor, both of considerable interest and importance.

(1) A city of Ionia, situated on a small stream flowing into the valley of the Mæander, whence it was commonly called Magnesia ad Mæandrum. It was distant 120 stadia or 15 Roman miles from Miletus, and rather less from Ephesus. According to tradition, as well as the similarity of names, it was founded by a body of colonists from the Thessalian tribe of the Magnetes, with whom were associated, according to Strabo, some Cretan settlers. It was thus not properly an Ionic city, and for this reason apparently was not included among the cities of the Ionic league, though superior in wealth and prosperity to most of them, except Ephesus and Miletus. It was indeed taken and destroyed by the Cimmerians in their irruption into Asia Minor (about 660 B.C.), but was soon after rebuilt, and gradually recovered its former prosperity. It was one of the towns assigned by Artaxerxes to Themistocles for his support in his exile, and there the latter ended his days (449 B.C.). In later times it was chiefly noted for its temple of Artemis Leucophryne, which, according to Strabo, surpassed that at Ephesus in the beauty of its architecture, though inferior to it in size and wealth. The remains of this temple, as well as of the ancient city adjoining it, are still extant, and have been laid open by recent excavations. They are described by M. Texier (*Asie Mineure*, vol. iii.). Magnesia continued under the kings of Pergamum to be one of the most flourishing cities in this part of Asia, but appears to have gradually declined under the Roman empire, and its name disappears from history, though its continued existence is attested by coins as late as the time of Gallienus.

(2) A city of Lydia, about 40 miles north-east of Smyrna, which stood on the southern bank of the river Hermus, at the foot of Mount Sipylus, from which circumstance it was often called for distinction's sake Magnesia ad Sipylum. It is probable from its name that it was founded, like the city of the same name in the valley of the Mæander, by Magnesian colonists from Thessaly; but we have no authority for the fact. Nor is any mention of the town found in history till 190 B.C., when the Syrian king, Antiochus the Great, was defeated under its walls by the Roman consul L. Scipio, who derived from his success in this campaign the surname of Asiaticus. Magnesia became a city of importance under the Roman dominion, and, though nearly destroyed by an earthquake in the reign of Tiberius, was restored by that emperor, and continued to flourish throughout the period of the Roman empire. It was one of the few towns in this part of Asia Minor that retained its prosperity under the Turkish rule; and MANISA (*q.v.*) is at the present day a large and flourishing town with considerable trade.

MAGNESIUM, a metallic element (symbol Mg) forming a basic oxide "magnesia," MgO, which in some form or other is universally disseminated throughout the whole of the earth's crust, apart from the large masses of mineral consisting essentially of magnesia compounds. This accounts for the presence of at least traces of magnesia in the ashes of all plants and animals, and for its presence in almost all natural waters. In these, however, it in general is present only as a quasi-contamination of the lime; in certain mineral waters, on the other hand, known as bitter waters (as those of Epsom, Sedlitz, Püllna), sulphate of magnesia forms the principal solid component. All native chloride of sodium is accompanied by magnesia salts, including the cases of salt-springs and of ocean-water, the latter containing about 0·21 per cent. of magnesia as sulphate and chloride.

Of magnesium minerals we may name the following:—

A. *Silicates.*—(1) Olivine, $SiO_2.2MgO$, occasionally met with in transparent crystals ("chrysolite"), but more frequently embedded as an admixture in lava, basalt, and other rocks; also in meteorites. (2) Augite and (3) hornblende, both $MgO.SiO_2$. The latter more frequently than the former forms independent rocks; both occur abundantly as components of more ordinary mixed rocks, all basalts containing augite as a principal component. (4) Serpentine, $SiO_2 2H_2O.3(SiO_2.2MgO) + 2Aq$ (meaning $2H_2O$ loosely combined),—a very common mineral; there are mountain masses consisting almost of it alone. In all these silicates, and more especially in (2) and (3), the MgO is partly replaced by FeO, CaO, MnO, and other isomorphous oxides, these latter not unfrequently even predominating over the MgO itself. Their names, in fact, represent genera of minerals comprising each numerous species. Asbestos (so remarkable on account of its exceptional structure, which lends itself for the production of fire-proof textile fabrics, paper, pasteboard, &c.) must be mentioned here, as some varieties fall under hornblende, others under chrysotil (included in serpentine). More purely magnesian are—(5) talc, $4SiO_2.3MgO.H_2O$ (Rammelsberg), and (6) meerschaum, $3SiO_2.2MgO + 4(?)H_2O$ (same authority).

B. *Carbonates.*—Of these the most abundant are the dolomites, all compounds of the carbonates of lime and magnesia, $x\text{Ca}.(1-x)\text{Mg.O.CO}_2$, where x may assume almost any value down to zero, which it actually has in "magnesite," $MgOCO_2$. Bitter spar, $MgOCO_2$, is very similar to and isomorphous with Iceland spar, $CaOCO_2$.

C. *Soluble Salts,* known chiefly as occurring in the famous salt-deposits of Stassfurth in Germany:—kieserite, $MgOSO_3.H_2O$ (Epsom salt minus $6H_2O$); carnallite, $MgCl_2.KCl + 6H_2O$; kainite, a hydrated compound of chlorides and sulphates of magnesium and potassium.

Any of these minerals may be used, and A (4), B, and C are actually used for the preparation of magnesium compounds. Starting from magnesite, we need only subject it to gentle ignition to obtain the oxide MgO; treatment with dilute sulphuric or muriatic acid produces the sulphate (EPSOM SALT, *q.v.*) or the chloride, as a solution, contaminated in general,—chiefly with iron, also with alumina, and perhaps lime. The two former, after peroxidation of the iron by chlorine, may be eliminated by digestion with powdered magnesite, and filtered off. The acidified muriate solution, on evaporation and cooling, deposits transparent crystals, $MgCl_2.6H_2O$, very hygroscopic, very readily soluble in water, and (like the anhydrous salt) soluble also in alcohol. When dehydrated by heat it loses acid (HCl), so that the residue is largely contaminated with oxychlorides, $MgCl_2.xMgO$. Certain of these are industrially important as cements, used by dentists and otherwise. A concentrated solution of the chloride, made into a paste with the ignited (CO_2-free) oxide, in a few hours hardens into a stone susceptible of polishing (Sorel). To prepare the anhydrous chloride, the crystallized or dissolved hydrated salt is evaporated with sal-ammonia to dryness, and the residue (a stable double salt) is ignited in platinum. Pure chloride, $MgCl_2$, remains as a clear liquid, solidifying on cooling into a compact aggregate of flexible crystal-leaves of a mother-of-pearl lustre. From the chloride the metal can be produced, either by electrolysing the fused substance, or (more conveniently) by Caron and Deville's method: 600 grammes of the chloride, 480 grammes of powdered fluor-spar, and 230 grammes of finely cut-up sodium are mixed, and thrown, small portions at a time, into a red-hot crucible, which is then well covered. When the reaction, which is violent, is over, the contents are well stirred with an iron rod to cause the small metal-beads to unite into bigger lumps, which, after cooling, are picked from the broken-up mass. Sonstadt (who, along with Mellor, was the first to prepare magnesium industrially) substitutes for plain $MgCl_2$ the double chloride of potassium and magnesium, obtainable synthetically from the hydrated components without the use of sal-ammoniac, or simply by ignition of pure carnallite. To purify the crude metal Sonstadt and Mellor distil it "per descensum" out of an iron crucible provided with a pipe piercing the bottom and reaching up to almost the lid; an atmosphere of coal-gas is established to prevent oxidation of the metal in this operation, as also in the subsequent casting of the ingot.

The metal magnesium has the colour of silver, and remains unchanged in *dry* air; in ordinary air it tarnishes a little more readily than zinc does. It is malleable and ductile, but has little tenacity. The specific gravity is 1·75; thus it is considerably lighter than even aluminium, whose specific gravity is 2·6. It fuses and distils at about the same temperatures as zinc. It is generally sold in the form of thin ribbon, being used for the easy production of highly intense light. The ribbon kindles readily in a candle flame, and then continues burning most intensely by itself, the solid oxide produced radiating out abundant light. A wire 0·3 millimetre (= ·012 inch) thick gives out the light of 74 stearine candles weighing 100 grammes ($\frac{2}{9}$ ℔ avoirdupois) a piece (Bunsen and Roscoe). It used to be employed for photographing at night, but is now superseded by the electric light. Magnesium has the exceptional property of combining (at a bright red heat) directly with nitrogen gas into Mg_3N_2 (Briegleb and Geuther), a greenish-yellow powder, which, when heated in steam, yields magnesia and ammonia, NH_3.

Of magnesium salts the most important is the sulphate, EPSOM SALT (*q.v.*). This salt serves as a raw material for the preparation of two or three medicinally important substances, especially magnesia alba. When epsom salt solution is precipitated by carbonate of soda, the salt $MgOCO_2$, first formed, loses carbonic acid and takes up water, forming a precipitate of the approximate composition $3MgCO_3.Mg(OH)_2 + 2$ to 3 times H_2O. When prepared by cold precipitation it forms a very light, when in the heat a somewhat denser, white powder (magnesia alba levis and ponderosa). This substance holds an important position in the history of chemistry, having served, in the hands of Black, to prove finally the individual existence of magnesia as something distinct from lime, and helped him in establishing the true relation between "caustic" and "mild" alkalies. Before his time the "causticity" was supposed to go into the "mild" substance from the fire; Black showed that it is owing to the loss of a ponderable substance, which he called "fixed air," that is, carbonic acid. It was in this memorable research that for the first time in chemistry the balance was used for the precise determination of quantitative relations.

Magnesia, the oxide MgO, is produced by the gentle ignition of magnesia alba. It is a white powder, absolutely infusible and non-volatile, and not reducible by charcoal, and is used medicinally. The gently ignited oxide combines very slowly with water into the practically insoluble hydrate $MgO.H_2O$. Magnesia when boiled with sugar-water dissolves into a solution of saccharate, and in this form is sometimes administered medicinally in lieu of plain magnesia. Magnesia alba (also the normal carbonate) dissolves rather largely in carbonic acid water. According to R. Wagner, one part of $MgOCO_2$ dissolves in 760 parts of water saturated by carbonic acid under 1 atmosphere pressure. Under 6 atmospheres pressure it requires only 76 parts of carbonic acid water for its solution. Dinneford's "fluid magnesia" is a solution of such bicarbonate of magnesia. The bicarbonate solution, when allowed to stand in air, deposits crystals of hydrated normal carbonate, $MgCO_3 + 3$ or $5H_2O$.

Magnesia preparations play a great part in therapeutics. The oxide and basic carbonate (also the dissolved forms of saccharate and bicarbonate) are used in small doses as anti-acids, in larger ones as very mild purgatives, for children more especially. For the latter purpose, however, the sulphate is generally preferred as acting far more energetically. The nauseous bitter taste of the salt can be concealed, to some extent, by acidification of its solution with dilute sulphuric acid. Citrate of magnesia, being exceptionally free of the "*Bittererde*" taste, was introduced some thirty years ago by the French as a pleasant substitute for Epsom salt, and it has since come much into fashion everywhere, although, weight for weight, it is far less efficient than the sulphate. The preparation of dry soluble citrate offering difficulties, the French originally dispensed it exclusively in the dissolved form of "Limonade au citrate de magnésie," a flavoured, decidedly acid solution of the salt, rendered effervescent by addition of some bicarbonate of soda immediately before corking up. In England it is generally preferred to offer the dry ingredients of the "limonade" in the form of "granular effervescent citrate of magnesia." Magnesia alba is pounded up with an excess of citric acid crystals and a few drops of water to produce a paste of amorphous acid citrate, which is dried at a temperature below 30° C. At higher temperatures the salt would pass into a crystalline, insoluble, and consequently therapeutically valueless modification. The citrate is mixed with bicarbonate of soda, citric acid, and sugar, made into a "dough" with alcohol, granulated, and dried. The granules, when thrown into water, dissolve with effervescence. We must not omit to state here that much of what is sold under the name is a mere concoction in which Epsom salt figures as "citrate."

To test a solution for magnesia, remove whatever can be precipitated by means of sulphuretted hydrogen or sulphide of ammonium; then eliminate lime, baryta, and strontia by precipitation with carbonate of ammonia in the presence of sal ammoniac. The magnesia remains dissolved, and can be precipitated (and detected) by addition of phosphate of ammonia (or soda) and free ammonia; the salt $PO_4MgNH_4.6H_2O$ gradually separates out as a crystalline precipitate. This method of course fails when the magnesia is present from the first as phosphate; but we cannot here enter into a consideration of this or any other exceptionally difficult case. (W. D.)

MAGNETISM

Deriva-tion of the word magnet.

THE word magnetism is derived from the Greek word *μάγνης*, which was applied to an ore of iron possessing a remarkable attractive power for iron, and supposed to have been originally found near the town of Magnesia, in Lydia.[1] Thus Lucretius writes:—

> Quem Magneta vocant patrio de nomine Graii,
> Magnetum quia fit patriis in finibus ortus.

This name is said by Plato[2] to have been given to it by Euripides, and he adds that most call it the Heraclean stone. It is needless here to criticize the above or other derivations that have been given for the word; we merely remark that it is now applied to all the phenomena kindred to that which first drew attention to the magnetic iron ore, viz., a selective attraction for iron.

Plan of the article.

In the following article we shall give, in the first place, a sketch of the leading phenomena of strongly magnetic bodies. We shall then describe a provisional theory sufficient to render a general account of these phenomena, and shall afterwards proceed to render this theory more precise, to develop it to its necessary conclusions, and to compare these with experiment, indicating where the theory is either incorrect or incomplete. Then we shall discuss the paramagnetic and diamagnetic properties of all bodies, as expounded by Faraday; an account will be given of the connexion between the magnetic and the other physical properties of bodies; and, lastly, we shall endeavour to give some idea of the different physical theories that have been proposed in order to give something more than a mere shorthand record of the facts of observation.

LEADING PHENOMENA.

Magnetic knowledge of the ancients.

It appears, from what Lucretius says in the passage above quoted,[3] that the Greeks and Romans were aware, not only that the loadstone, or magnetic iron ore, attracted iron, but also that it endued iron in contact with it with its own peculiar property. Thus an iron ring will hang suspended by the attraction of a loadstone, and from that ring another, and so on, up to a certain number, depending on the power of the stone and the weight, &c., of the rings. They were also aware that the attraction was confined to iron, or at all events was not indiscriminate, and that it was not destroyed by the intervention of other bodies, such as brass, between the magnet and the iron. It appears, too, from the passage—

> Fit quoque ut a lapide hoc ferri natura recedat
> Interdum, fugere atque sequi consueta vicissim, &c.—

that they had an idea that, under certain circumstances, the attraction might be replaced by a repulsion. If, however, we understand aright the latter part of Lucretius's somewhat obscure description of what seems to have been an actual experiment of his own, this notion was in reality a hasty generalization, not justified by the observed facts.[4] In any case there seems no warrant for assuming, as some have done, that the ancients had any definite conception of magnetic polarity.

What they wanted in definite experimental knowledge they supplied by an abundant use of the imagination. We are told, for instance, that the magnet attracts wood and flesh, which was certainly beyond their powers of observation; that it is effective in the cure of disease; that it affects the brain, causing melancholy; that it acts as a love philtre; that it may be used in testing the chastity of a woman; that it loses its power when rubbed with garlic, but recovers it when treated with goat's blood; that it will not attract iron in the presence of a diamond, and much else that was eagerly copied by the wonder-loving writers of the Middle Ages.

Beginning of magnetic science. Mariner's compass.

The science of magnetism made no real progress till the invention of the mariner's compass. The early history of this instrument is very obscure. According to some authorities it was invented in China, and found its way into Europe probably through Arabian sources. The light thrown by recent researches on the literature of the Chinese has apparently thrown doubt upon their claim to this invention,[5] although the knowledge of the loadstone and its attractive property may have been older among them than even among the Greeks. The first accounts of the compass in Europe go back to the 12th century, and, although the instrument described is very rough, it is not spoken of as a new invention. In its earliest form it seems to have consisted simply of an iron needle which was touched with the loadstone and placed upon a pivot, or floated on water, so that it could turn more or less freely. It was found that such a needle came to rest in a position pointing approximately north and south (some accounts say east and west, in which case there must have been a cross piece on the needle to indicate what was probably the important direction for the mariner). As these compasses were made of iron (steel was not used till much later), and were probably ill-pivoted, they must have been very inaccurate; and the difficulty of using them must have been much increased by the want of a card, which was a later addition made apparently by the Dutch.

It is unnecessary to enter into more detail here respecting the early history of the compass, as the matter has been very fully treated in the article COMPASS.[6] We proceed therefore to show the bearing of the invention upon the science of magnetism. It will at once be seen that it involves two scientific discoveries of capital importance:—first, that the loadstone can transmit to iron with which it comes in contact a permanent property like its own; and, secondly, that a loadstone or magnet if suspended freely will turn so that a certain direction in it assumes a fixed position relative to the geographical meridian, a certain part of the magnet turning always towards the north, and the part opposite towards the south. These opposite parts of the magnet are called its "poles."

Axis of a magnet experimentally defined.

To fix our ideas we shall describe a process by which we might definitely determine this direction in the magnet. Following the example of Gilbert, let us consider a spherical magnet. Our reason for dealing with this form in the first instance is to make it perfectly clear that the phenomena depend essentially on something apart from the form of the body. We shall suppose that the magnet is homogeneous as to its mass, so that its centre of gravity

---

[1] Gilbert, *De Magnete*, lib. i. chap. ii., says, "Magnesia ad Mæandrum"; but it is uncertain whether this or Magnesia ad Sipylum is meant.

[3] Bk. vi. line 906 *sq.*, and 1042 *sq.*; comp. Plato, *Ion*, *ut supra*, whom there is reason to think he is quoting.

[4] See below, p. 225.

[5] See Möllendorff, *Z. D. M. G.*, xxxv. 76.

[6] It may be mentioned that the statement that Peter Adsiger, in a letter written in 1296, mentions the magnetic declination, appears to be a mistake, arising from the mistranscription of a title. See Wenckebach, quoted by Lamont, *Handbuch des Magnetismus*, p. 449. The passage from Are Frode, quoted by Hansteen, and alluded to in last edition of this encyclopædia, appears also to be of doubtful antiquity. See Poggendorff, *Geschichte der Physik*, p. 99.

coincides with its centre of figure. Suspend this spherical magnet by a fine thread of untwisted silk, attached to any point of its surface, say P. After the magnet has come to rest, mark the vertical plane through the centre which falls in the geographical meridian; this may be done by tracing a great circle on the surface of the magnet. Next find the point P′ in which the vertical through P cuts the surface again, and suspend the magnet by P′, again marking the plane which falls in the meridian. Now, find the plane which bisects the acute angle between the two former planes, mark it by a great circle, and call it the axial plane of P. If we thus find the axial planes of any number of points, we shall find that they all intersect in one common line passing through the centre of the sphere. We may call this line the "axis" of the magnet. Let us mark the points where it cuts the surface; we may call these the "poles" of the magnet. We shall then observe that, however we suspend it, the magnet will always come to rest so that the vertical plane through the axis makes a definite angle with the meridian. This angle (δ) is called the "declination" (also, by sailors, the "variation"); it varies from place to place, and from time to time, but very slowly, so that throughout a limited area of the earth's surface, and for a limited time, it may be regarded as constant.[1]

Poles, north and south.

One end of the axis always turns northwards, and the other always southwards; we shall call the former the "north" and the latter the "south pole," although, for reasons to be afterwards explained, it would be more appropriate to invert the order of these names. Henceforth the vertical plane in which the axis of the magnet comes to rest will be called the magnetic meridian, and the two horizontal directions in this plane magnetic north and magnetic south respectively.

Magnetic meridian.

It must be carefully noticed that there is a certain amount of arbitrariness in our definition of the axis and poles of a magnet. In reality it is only the direction of the axis that is fixed in the body, and not its absolute position. This will be made plain if we repeat all our experiments with the spherical magnet after fastening to it a piece of wax or other non-magnetic body, so as to leave its magnetic properties unchanged, but to throw its centre of gravity out of the centre of figure. Everything will fall out as before, only the axial planes of the different points of suspension will now meet in a line, parallel, it is true, to the axis determined before, but passing through the new centre of gravity. In point of fact, therefore, we might choose any point in the body, draw a line through it in the proper direction, and call this the axis. Hereafter we shall, unless the contrary is stated, draw the axis through the centre of gravity of the body, or through its centre of figure if it has one; and we define the poles, for the present, as the points in which the axis cuts the surface of the magnet, supposing, as will be generally the case, that the line cuts the surface in two points and no more.

Magnetic needle.

Having now obtained a definite idea of the axis of a magnet, and seen that it has, in the first instance at least, nothing to do with the external form of the body, let us proceed to make an artificial magnet of the particular kind usually called a "magnetic needle," and briefly examine its properties. Take a tolerably thin flat piece of pretty hard-tempered steel, of the elongated symmetrical form NS shown in fig. 1. We suppose it, in the first place, in an unmagnetic condition. Let it be pierced by a well-turned axis *ab*, passing accurately through its centre of gravity, and perpendicular to its plane, so that, when the axis is placed on two horizontal knife edges, the needle will rest in any position indifferently. Further, let four very small hooks, *c*, *d*, *e*, *f*, be attached, two (*c*, *d*) to the ends of the axis, and other two (*e*, *f*) to the edges of the needle in a line perpendicular to NS. Now rub the half of the needle

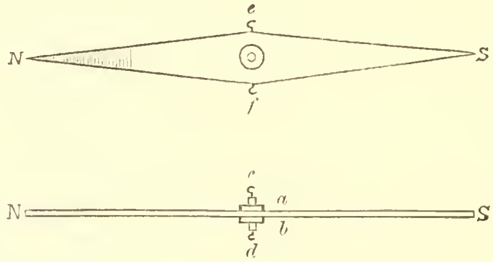

Fig. 1.

towards N with the south pole of the spherical magnet whose properties we have just discussed, beginning the stroke at the middle and ending it at the point of the needle, and for symmetry's sake let us do the same to the other side of the needle, and then repeat this process with the north pole of the sphere on the other half towards S. Let us examine the properties of the needle thus "magnetized." If we suspend it first by the hook *c* and then by the hook *d*, we shall find that in both cases the line joining NS[2] makes very nearly the same angle with the geographical meridian. Hence the magnetic axis must lie in a plane through NS perpendicular to the plane of the needle. A similar experiment with the two hooks *e*, *f* will show that the magnetic axis lies approximately in the plane of the strip, which we may suppose for the present to be infinitely thin. Hence the magnetic axis may be taken to be coincident with the line NS joining the points of the needle. This coincidence is, however, in general only approximate, and in delicate measurements corrections have to be made on that account, of which more hereafter. If we now mount our magnetized needle on a piece of cork or two straws, and float it in a basin of water, or replace its axle by a small cap and set it on a pivot, we have the mariner's compass in its early form. We shall call it a magnetic needle, to distinguish it from the more elaborate compass of the present day. A favourite way of showing the directive property of a magnet, described by Gilbert, is to magnetize a sewing-needle, and lay it very gently, by means of a fork of wire, on the surface of water; it will float and turn until it takes up its position in the magnetic meridian.

A needle mounted in this way, so as to have great freedom to move in a horizontal plane, is of great use in magnetic experiments. Gilbert calls it a "versorium." When very delicate applications are in view, the point of the pivot on which it is mounted must be very hard (say of hard tempered steel or iridium), and the cap should be fitted with an agate or other hard stone having a polished cavity of the form of a blunted cone to receive the pivot. A still better arrangement, also used by Gilbert, is to suspend a short and very light piece of steel wire—a fine sewing needle may be used—by means of a single fibre of silk. The most delicate arrangement of all is to use one of Sir W. Thomson's light galvanometer mirrors with the magnets attached, and follow its movements by means of the lamp and scale as usual. See GALVANOMETER.

Such, with as much of modern accuracy imported into them as was necessary for clearness of exposition, were the facts of magnetism as known up to the beginning of the 16th century.

Discovery of the dip.

Another experiment with our magnetized needle will enable us to describe the next important magnetic discovery. In its unmagnetized condition the needle rested indifferently in any position when its axis was placed on

[1] For the early observations on the declination the reader is referred to the treatment of the subject of terrestrial magnetism in the article METEOROLOGY. At the present time the declination at Greenwich is a little over 18°; at Edinburgh it would be about 4° more.

[2] Or the vertical plane through it, should it happen to be not quite horizontal.

two horizontal knife edges. In the magnetized state this is no longer the case. The axis of the needle now takes up a fixed position, with its north end pointing downwards (fig. 2), and if disturbed will oscillate about that position, and finally settle into it again. The angle which the axis NS makes with the horizon is least when the plane of rotation of the needle is in the magnetic meridian: the angle (ι) in this case is called the "dip," or (by Continental writers) the "inclination." It is greatest, viz., 90°, when the plane of rotation of the needle is vertical and perpendicular to the magnetic meridian. At Greenwich the dip is about 67° 30′ at the present time. If we place the needle with its plane of rotation perpendicular to the line of dip, the equilibrium will be indifferent, as it was in all positions before magnetization; but there is no other position of the magnetized needle for which this is true.

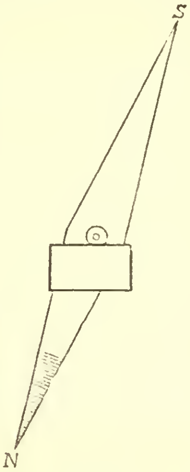

Fig. 2.

The remarks which we made as to variation in space and time of the declination apply also to the dip. The variation from place to place differs, however, in nature from that of the declination. Along a line running in the neighbourhood of the geographical equator, partly north and partly south of it, the dip is zero. North of this line, which is called the magnetic equator, the north end of the needle dips below the horizon; and the angle of dip increases as we go northwards, until, at a point in the Hudson's Bay Territory, the needle dips with its north pole vertically downwards. South of the magnetic equator the south end dips below the horizon; and there is again a point in the southern hemisphere where the south end dips vertically downwards. These points are called the "magnetic poles" of the earth. For further details on this subject we refer the reader to the discussion of terrestrial magnetism in the article METEOROLOGY.

It was in the accurate observation of the declination and dip of the magnetic needle that the science of magnetism arose. The dip appears to have been first observed by Georg Hartmann, vicar of the church of St Sebaldus at Nuremberg (1489–1564), who seems to have been in advance of his age in magnetical matters. In a letter[1] to Duke Albrecht of Prussia, dated 4th March 1544, he writes:— art-ann.

"Besides, I find this also in the magnet, that it not only turns from the north and deflects to the east about 9° more or less, as I have reported, but it points downwards. This may be proved as follows. I make a needle, a finger long, which stands horizontally on a pointed pivot, so that it nowhere inclines towards the earth, but stands horizontal on both sides. But as soon as I stroke one of the ends (with the loadstone), it matters not which end it be, then the needle no longer stands horizontal, but points downwards (*fällt unter sich*) some 9° more or less. The reason why this happens was I not able to indicate to his Royal Majesty."

From this it will be seen that Hartmann had unquestionably observed the tendency of the magnetized needle to dip. His method of observing is of course unsuited for *measurement*, and it is not surprising that he got a result of 9° instead of somewhere about 70°.

In 1576 the dip was independently discovered by Robert Norman, a skilful seaman and an ingenious artificer, according to Gilbert. He was in the habit of making compass needles, and carefully balancing them so as to play horizontally on their pivots before magnetization. He found that, after they were magnetized, they constantly dipped with the north end downwards, so that a counterpoise had to be added to bring them back to the horizon. This led him to construct a special instrument, the prototype of the modern dipping needle, to show this new phenomenon. With this instrument he made the first accurate measurement of the dip, and found it to be 71° 50′ at London.[2] Norman.

The early English magnetic observers, of whom Norman and Burroughs (who wrote an able supplement to Norman's work) were admirable examples, must have done much for the introduction of precise ideas into magnetism. But their fame was speedily eclipsed by William Gilbert of Colchester[3] (1540–1603), whom Poggendorff has justly called the Galileo of magnetism, and whom Galileo himself thought enviably great. In his great work entitled *De Magnete Magneticisque Corporibus et de Magno Magnete Tellure Physiologia Nova*, first published in 1600, we find a complete account of what was known of magnetic phenomena up to his time, with a large number of new ideas and new experimental facts added by himself. We find in Gilbert's work, in a more or less accurate form, nearly all that we shall lay before the reader in the first section of this article, described very much in the language that we shall use. "How far he was ahead of his time is best proved by the works of those who wrote on magnetism during the first few decades after his death. They contributed in reality nothing to the extension of this branch of physical science."[4] Gilbert.

Mutual Action of Like and Unlike Poles.—If we take a magnet whose poles N′, S′ have been determined and marked as above explained, and bring its north pole N′ near the north pole N of a magnetic needle, N will move in a direction indicating repulsion between N and N′. The same result will follow if the south pole S′ of the magnet be brought near the south pole S of the needle. But if S′ be brought near N, or N′ near S, attraction will be indicated. Hence the following fundamental law of the action between two magnets:—*Like poles repel each other; unlike poles attract each other.* It would appear, therefore, that the whole action of one magnet upon another is of a somewhat complicated character, even if we take the simplest view of it that the experimental facts will allow, viz., that the action may be represented by forces acting between the two pairs of points in each magnet which we have defined as north and south poles. On this assumption, the action of N′S′ upon NS would consist of the four forces represented in fig. 3, for all these must exist in accordance with the law just established. Whether this is a sufficient Like magnetic poles repel; unlike attract.

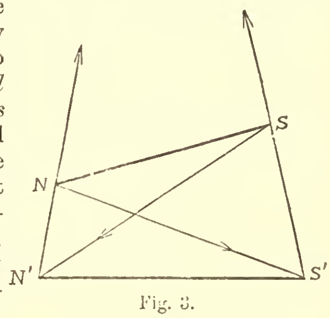

Fig. 3.

[1] Brought to light by Moser. See Dove's *Repertorium der Physik*, ii., 1838. It does not appear that Hartmann's letter was ever before published. Moser is therefore scarcely justified in attacking Norman's priority in this matter, still less in attempting to deny him the credit of first observing the dip by a sound method. Had he read the *Newe Attractive* he could scarcely have fallen into such an error; for in respect of clearness and scientific precision Hartmann's letter, interesting as it is, cannot for a moment be compared with Norman's little work.

[2] He published a work, of which the following description is given in the *Ronalds' Catalogue*:—"The *Newe Attractive*, containing a short discourse of the Magnes or Lodestone, and amongst other his vertues, of a new discovered secret and subtill propertie concernyng the Declyning of the Needle, touched therewith, under the plaine of the Horizon. Now first found out by Robert Norman, Hydrographer. 4to (black letter, scarce), London, 1581."

[3] For details as to his life, see art. GILBERT.

[4] Poggendorff, *Geschichte der Physik*, p. 286.

representation of the most general case, and what the exact law of the forces ought to be, we are not yet in a position to decide. One thing, however, is clear, that the action between two poles must diminish when the distance between them increases; otherwise we should not have been able to make the action of N or S upon N′ prevail, by bringing the one or the other nearer.

It was perhaps the complexity of this analysis (along with the fact that the action of the magnet upon soft iron, which was the earliest discovered magnetic phenomenon, is not a pure case of this action, but involves also another phenomenon, viz., magnetic induction) that prevented for so long the discovery of the elementary law we are now discussing. At all events, it seems to have been a new discovery in the 16th century, if we may judge from a passage in the letter of Hartmann above alluded to. He was certainly aware of the existence of magnetic repulsion in some form or other. It is somewhat difficult to gather from his description what it was exactly that he observed, and he nowhere states the law fully and explicitly. In Norman's *Newe Attractive* [1] we find it clearly stated, and demonstrated by means of a needle floating on water or suspended by a thread;[2] yet he does not appear to claim the fact as his discovery. If, therefore, Hartmann was not the actual discoverer, we may at least conclude that the law became familiar to magnetic philosophers during the thirty years that separated him from Norman.

Mapping out the magnetic field.

Lines of magnetic force.

The Magnetic Field.—We next introduce a method of conceiving and describing magnetic actions which was invented and much used by Faraday. Since a magnet acts upon a magnetic needle placed anywhere in the surrounding space,[3] we call that space the magnetic field of the magnet. Neglecting the earth's magnetism, we may map out this field as follows. Conceive any plane drawn through the axis of the magnet, and place it so that this plane shall be horizontal. Then at any point in this plane place a very small magnetic needle, and note the direction which its axis assumes under the action of the magnet; then proceed to move the centre of the needle in the direction in which its north pole points, and continue the motion so that at each point the centre is following the direction indicated by the north pole. The line thus traced will at last cut the surface of the magnet at some point lying towards its south pole; and if we continue the line backwards, by following the direction continually indicated by the south pole of the needle, it will cut the surface of the magnet at some point lying towards the north pole. Such a line is called a line of magnetic force; and, since one such line can be drawn through every point of the plane, and any number of planes can be taken through the axis of the magnet, we can conceive the whole magnetic field filled with such lines. Fig. 4, taken from Faraday, gives an idea of the distribution of the lines of force in the field of a bar magnet; fig. 5 represents the lines in the field due to two neighbouring like poles.

These diagrams were not obtained by the method we have just described, but by a much simpler process which we shall describe by and by. Their use, so far as we have gone, is to tell us how a small needle, free to move about its centre in any direction, will place itself at any part of the field, viz., it will place its axis along the tangent to the line of force which passes through its centre, its north pole pointing in that direction which ultimately leads to the south pole of the magnet producing the field.

Terella or ideal earth.

Suppose we apply these ideas to a spherical magnet (a terella, or earthkin, as Gilbert calls it). The lines of force in any plane through its axis would be found to run something like the curves in fig. 6. If, therefore, we carried a small needle (suspended from a silk fibre so as to be perfectly free to move in all directions) round the magnet

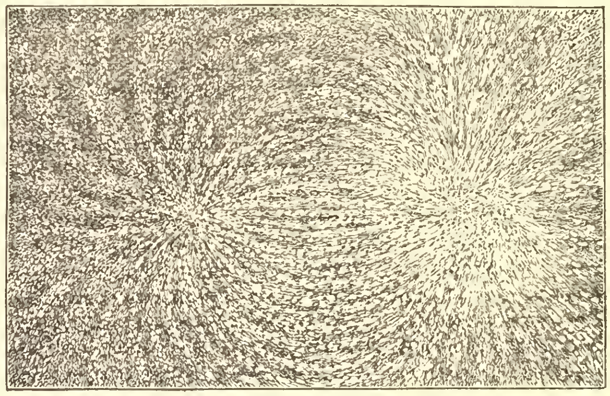

Fig. 4.

in a meridian plane, its axis would constantly remain in the meridian plane, its north pole always point towards the south pole of the spherical magnet, but dip more and more

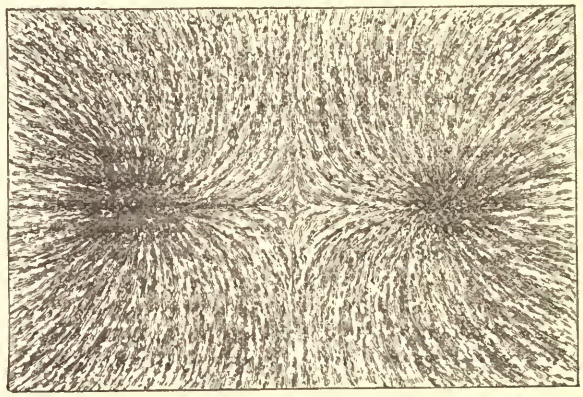

Fig. 5.

below the tangent plane to the sphere as the centre recedes from the equator, and end by pointing straight towards the south pole when the centre reaches the magnetic axis (see fig. 6).

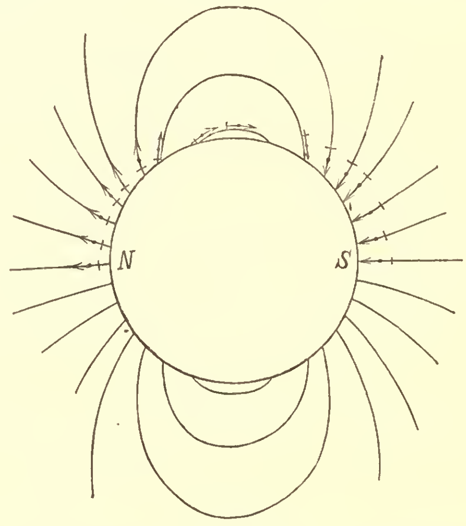

Fig. 6.

When we reflect that in all our experiments the properties of magnets, whether native, such as the loadstone, or artificial, such as the needles magnetized by rubbing with the loadstone, have proved alike, and that every

[1] Chap. i.

[2] See also Gilbert, *De Magnete*, lib. i. cap. v.

[3] Gilbert uses the phrase *orbis virtutis* in a somewhat similar sense.

purely magnetic action on a magnet has its source in some other magnetic body, we are naturally led to the conclusion that the reason why at every point of the earth's surface the axis of a freely suspended magnet assumes a definite position is simply that the earth itself is a great magnet, and that in observing the declination and dip we are simply exploring the magnetic field of the earth. It is true that, according to the experiment above described, the declination would every where be zero, and the magnetic equator would coincide with the geographical, but that arises merely because we assumed our earthkin, for simplicity of explanation, to be symmetrically magnetized, so that its lines of force ran in planes passing through its axis. It remains to be discussed whether the most general assumption, viz., that the earth is a magnetic body, will not account for the facts of terrestrial magnetism. The answer to this question has been given, as we shall see, by Gauss.

This idea, whose simplicity is the truest measure of its greatness, is due to Gilbert, and was by him made the foundation of his work on magnetism. The boldness of his theory will be appreciated when we remind the reader that in his day the dip was but newly discovered, and had been measured only at London, so that Gilbert's very full and clear exposition of this phenomenon, which we have given above, was in fact a scientific prediction, which was not fully verified till long afterwards.[1] Before Gilbert a variety of wild conjectures had been made as to the cause of the directive property of the magnet.[2] Many, like Columbus, Cardan, and Paracelsus, believed that the magnet was attracted by a point in the heavens, possibly some magnetic star. Others supposed that the attracting point was situated in the earth; Fracastorius imagined hyperborean mountains of loadstone situated near but not quite at the north pole; and to this theory others contributed the detail that the magnetism of these mountains was so powerful that ships in these regions have to be built with wooden nails instead of iron ones, which would be instantly drawn out by the magnetic attraction.

It is clear that, if we call that magnetic pole of the earth which lies in the northern hemisphere its north pole, we ought, in accordance with our fundamental law of magnetic action, to call the north-seeking pole of an ordinary magnet a *south* pole. When it is necessary to speak of magnets from this point of view, the difficulty is got over by calling the north-seeking pole the austral pole, and the south-seeking pole the boreal pole. In reality the danger of confusion is more imaginary than real. The reader should be warned, however, that in some French works the ordinary nomenclature is reversed, and that Faraday uses "marked" and "unmarked," and Airy "red" and "blue," in the sense in which north and south are commonly used.

ırth's rce of ansla- on nil.

The Earth's Action on a Magnet is a Couple.—Norman in his *Newe Attractive* (chapters v. and vi.) discusses very acutely the question whether there is any force of translation exerted upon a magnet. He advances three conclusive experiments to prove the negative. First, he weighed several small pieces of steel in a delicate gold balance, and then magnetized them, but could not detect the slightest alteration in their weight, "though every one of them had received vertue sufficient to lift up his fellow." Secondly, he pushed a steel wire through a spherical piece of cork, and carefully pared the latter so that the whole sank to a certain depth in a vessel of water and remained there, taking up any position about the centre indifferently. After the wire was magnetized very carefully, without disturbing its position in the cork, it sank to the same depth as before, neither more nor less, the only difference being that now the wire set itself persistently in a definite fixed direction parallel to the magnetic meridian, the north end dipping about 71° or 72° below the horizon. Thirdly, he arranged a magnetized needle on a cork so as to float on the surface of water, and found that, although it set in the magnetic meridian, there was not the slightest tendency to translation in any direction.[3] He concludes that there is no force of translation on the magnet, either vertical or horizontal. He was evidently somewhat puzzled how to put this result into a positive form, and his "point respective," as he calls it, is not a very clear explanation of the earth's action. What he wanted was the modern idea of a "couple," *i.e.*, a pair of equal but oppositely directed parallel forces acting on the two ends of the needle; but such an idea was not conceived in Norman's day. Gilbert adopts Norman's result in this matter, adding nothing essential, reproducing even Norman's diagram of the spherical cork with the wire through it. It is clear therefore that Gilbert had a forerunner in the practice, as Bacon had in the theory, of inductive science; for Norman says, speaking of the mass of fables that had passed for truth in geography, hydrography, and navigation before his time, "I wish experience to bee the leader of Writers in those Artes, and reason their rule in setting it downe, that the followers bee not led by them into errors, as oftentimes have beene seene."

Magnetism a molecular property.

The Magnetic Property is Molecular.—Apart altogether from the question as to how we are to represent the action of a magnet upon other magnets, there arises another quite distinct question, as to where the cause of this action resides. That these two questions are really distinct, although there has always been a tendency in the more superficial treatises on the subject to confuse them, will be obvious from the fact that we shall afterwards obtain more than one perfectly general way of representing the action of a magnet at external points, whereas there must be one and only one cause of this action. A very old experiment[4] at once throws considerable light on this point. If we break a bar magnet into two pieces, it will be found that each of these is itself a magnet, its axis being in much the same direction as that of the original magnet, and its poles in corresponding positions, see fig. 7.

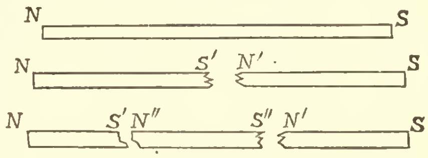

Fig. 7.

The same holds if we break the bar into any number of pieces; and, quite generally, if we remove any piece, however small, from a magnet, this piece will be found to be magnetic, the direction of its axis usually bearing a distinct and easily recognizable relation to the direction of the axis of the whole magnet. We are therefore driven to the conclusion that the magnetic quality of a body is related to its ultimate structure, and not simply to its mass as a whole, or to its surface alone; and this conclusion is not to be invalidated by the fact that we can in general, as will afterwards appear, represent the action of the magnet at external points by means of a proper distribution of centres of attractive and repulsive forces upon its surface merely.

Temporary Magnetism of Soft Iron and Steel in the Magnetic Field.—Bodies which possess permanent magnetic

[1] The first verification was by Hudson, who, in 1608, found the dip in 75° 22′ N. lat. to be 89° 30′. Gilbert found 72° at London in 1600. The place of vertical dip in the northern hemisphere was first reached by Sir James Ross in 1831. It was found about 70° 5′ 17″ N. lat. and 96° 45′ 48″ W. long.

[2] See Gilbert, *De Magnete*, lib. i. cap. i.

[3] Hartmann (see his letter above cited) was in error on this subject. He describes a somewhat similar experiment, and distinctly states that the needle has a motion of translation. "Schwimmt mit dem Ort welcher ist mitternächtlich am Stein, bis er kam an den Port der Schüssel, da das Wasser in war."

[4] *Cf.* Gilbert, *De Magnete*, lib. i. cap. v.

Magnetic induction.

properties, not depending on the circumstances in which they are placed, we shall henceforth call "permanent magnets." The law of the action of one permanent magnet upon another, as we have seen, is that like poles repel and unlike poles attract each other. The action of a permanent magnet on pieces of soft iron is, at first sight, different, for either pole attracts them alike.

Experiments illustrating induction.

To fix our ideas let us take a small thin bar of soft iron or of steel, and test it with a delicate magnetic needle. It will usually be found, more particularly if a steel bar is taken, that one end of the bar will *repel* one or other of the poles of the needle. This is a sure sign of permanent magnetism. If, however, we heat the bar to whiteness and allow it to cool in a position perpendicular to the earth's magnetic force, all permanent magnetism will be found to have disappeared. If we now place the bar in a horizontal plane (fig. 8) with its axis perpendicular to the axis of the needle, and one of its ends A, B near either pole of the needle, that pole will be attracted, no matter whether it be the north pole or the south pole of the needle, or which end of the bar be used.

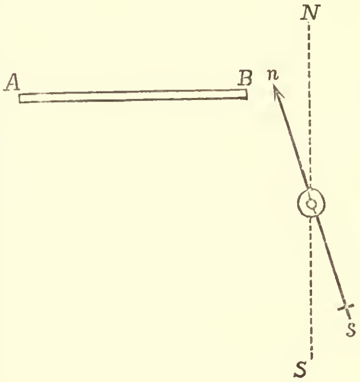

Fig. 8.

Care must be taken in this experiment to avoid using a too strongly magnetized needle, and to keep the needle from touching the bar, otherwise the bar may receive traces of permanent magnetism which will disturb the result. It is very easy, by repeating the above experiment with an unmagnetized needle, to show that the power that the bar acquires of attracting the poles of the needle is temporary and depends on the presence of a magnetized body.

Keeping to our principle that a magnetic cause is to be sought for every magnetic action, we are led to explain the above experiment by saying that in the magnetic field a bar of soft iron or of unmagnetized steel becomes magnetic in such a way that its north pole points as nearly as may be in the positive direction of the lines of force passing in its neighbourhood (or, in other words, in the direction, as nearly as may be, in which a magnetic needle would point if placed in its neighbourhood). A body which becomes magnetic in this way by the magnetic action of another body is said to be "magnetized" by "induction." We shall suppose, in the meantime, that it loses all the magnetism thus acquired when the inducing action is withdrawn; although this is not necessarily, and in fact not generally, the case, as we shall see by and by. The reason why soft iron is attracted by a permanent magnet is therefore now said to be that the iron becomes magnetic by induction, and is then acted upon by the magnet like any other magnet similarly placed. The accuracy of this analysis of the phenomenon may be confirmed by many simple but striking experiments, such as the following.

In the experiment above described, instead of placing the non-magnetic bar in a horizontal plane, place it in the plane of the magnetic meridian with its axis in the direction of the earth's force (*i.e.*, parallel to the line of dip). The lower end of the bar will then be found to repel and the upper end to attract the north pole of the needle (figs. 9, 10). This is at once explained on the above hypothesis; for the bar will be magnetized inductively by the earth's force, so that its lower end becomes a north pole, and its upper end a south pole.

Let NS (fig. 11) be a bar magnet placed horizontally so that its axis produced passes through O, the centre of suspension of the needle *sn*, then the needle will be deflected

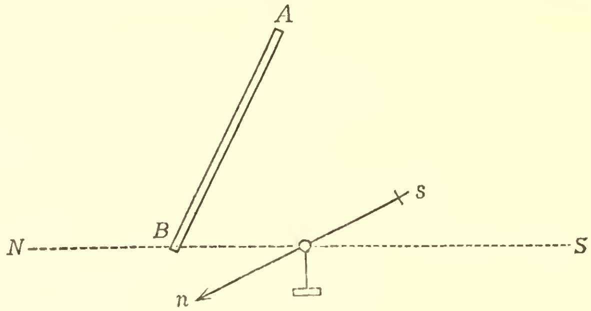

Fig. 9.

in the direction of the arrow. If now we place between S and O a small sphere of soft iron, this deflexion will be

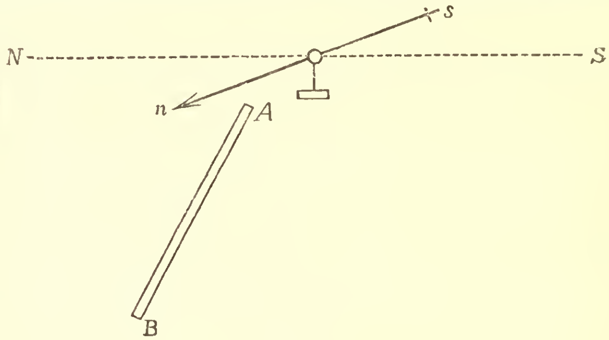

Fig. 10.

increased, the reason being that the sphere is magnetized by induction, having a south pole towards O and a north pole

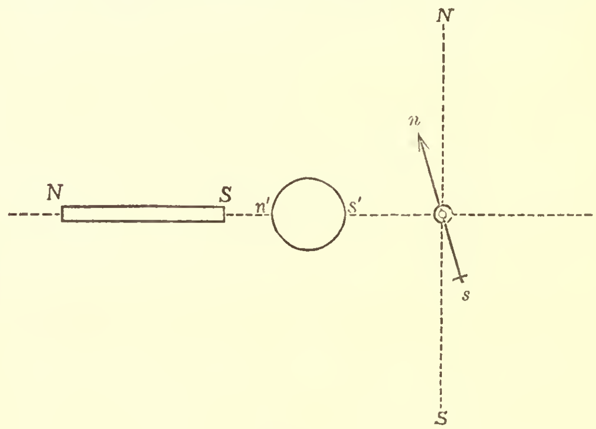

Fig. 11.

towards S, and the action of these is added to that of NS.

Let NS (fig. 12) be a magnet placed in the magnetic meridian, *n's'* a small magnetic needle in the same horizontal plane, with its centre in the line bisecting NS at right angles. When acted on by NS alone, *n's'* will place itself parallel to NS, with its north pole pointing in the direction NS

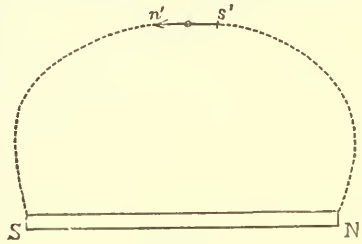

Fig. 12.

Let the dotted line represent a line of force. If we move a small piece of soft iron *ns* along this line in the direction from N towards S, it will first deflect the needle as in fig. 13, and finally as in fig. 14, and in each position reversing it end for end will not alter the effect. All this is at once explained by the above hypothesis.

A variation of the last experiment may be made thus. Place a magnet vertically, in the neighbourhood of a magnetic needle; by moving it up and down a position will be found in which the action of the magnet on the needle is wholly vertical, so that the needle is not deflected from the magnetic meridian. Now take a small piece of soft iron and move it along a line of force passing near the needle, proceeding from the north to the south pole of the vertical magnet. It will then be found, in accordance with our hypothesis, that the north pole of the needle is first repelled, and finally attracted by the soft iron.

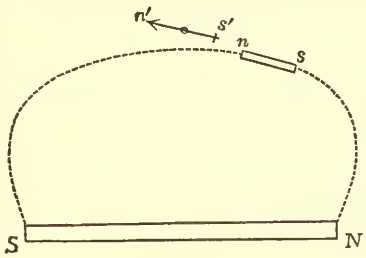

Fig. 13.

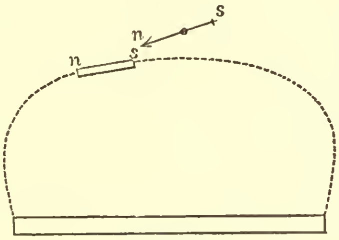

Fig. 14.

[Gilbert's experiment.] If we hang two short pieces of iron wire alongside of each other by parallel threads, they will be found to repel one another, and to hang separated by a considerable interval when a magnet is brought under them (see figs. 15 and 16). This experiment is due to Gilbert, who rightly explains it by saying that the two ends nearer the magnetic pole S become like poles of opposite kind to S, while the two farther ends are like poles of the same kind as S. The experiment may be varied by placing some little distance below the pole of a magnet S a piece of mica or thin cardboard M, and placing below that a short piece of soft iron wire; it will remain adhering to the mica, and so long as it is alone will hang more or less nearly vertical, but when another is placed alongside of it the two will diverge as in fig. 17.

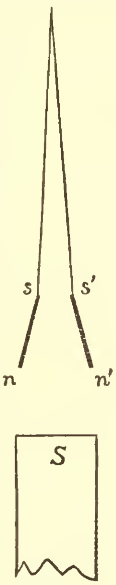

Fig. 15.

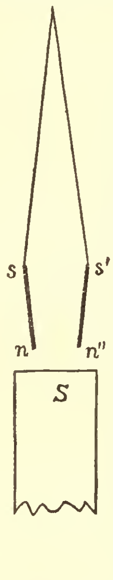

Fig. 16.

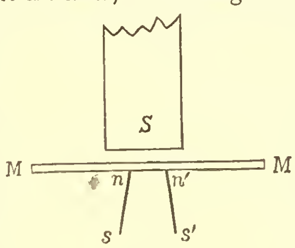

Fig. 17.

[Experiments with iron filings.] One of the most interesting examples of magnetic induction is furnished by the action of a magnet on iron filings. If we plunge a magnet into a quantity of iron filings and then remove it, we find it thickly fringed around the poles, where the filings adhere to the magnet and to one another so as to form short bushy filaments; the thickness of the fringe diminishes very rapidly towards the middle of the magnet, where very few adhere at all. These filaments are composed of magnetized particles of iron adhering by their unlike poles.

If we place a small bar magnet under a piece of moderately rough drawing paper, strewn as uniformly as possible with fine iron filings, and then tap the paper very gently so as to relieve the friction, and allow each filing to follow the magnetic action, then the filings will be seen to arrange themselves in a series of lines, passing, roughly speaking, from pole to pole, as in fig. 4 (p. 222). The explanation of this phenomenon is simply that each filing becomes magnetized by induction, and, if it were quite free to move about its centre, it would not be in equilibrium until it set its longest dimension along the line of force through its centre. The roughness of the paper effectually prevents translation, but does not hinder rotation, especially when the friction is relieved by tapping; hence every filing does actually set as if it were a little magnetic needle, subject of course to some slight disturbance from the neighbouring filings. The whole therefore assumes a grained structure, and the graining runs in the direction of the lines of force. We have thus an extremely convenient way of representing these lines to the eye, which lends itself in a variety of ways to the illustration of magnetic phenomena. In fig. 5 are shown the lines formed in the field near two like magnetic poles. These magnetic figures may be fixed in a great variety of ways, and projected on a screen so as to be visible to a large audience, but it is scarcely necessary to dwell here upon details of this kind.

These magnetic curves seem to have fixed the attention of natural philosophers at a very early period. They were originally called the magnetic currents, from an idea that they represented the stream lines of magnetic matter, which explained the magnetic action according to the theory then in vogue. La Hire mentions them, *Mém. de l'Acad.*, 1717. Bazin gives an elaborate account of them in his *Description des Courans Magnétiques dessinés d'après Nature*, Strasburg, 1753. Musschenbroek seems to have been the first to give the correct explanation depending on magnetic induction, *Diss. de Magnete*, 1729.

Lucretius's experiment. If the filings be laid very thickly on the paper, and one pole of the magnet be brought under them at a short distance off, they will arrange themselves in a pattern, and at the same time bristle up so as to stand more or less erect, according as they are nearer or farther from the magnet. They have thus the appearance of being *repelled* from the magnet. It was, in all probability, this phenomenon that was observed by Lucretius when he says (vi. 1042):—

> "Exultare etiam Samothracia ferrea vidi,
> Ac ramenta simul ferri furere intus ahenis
> In scaphiis, lapis hic Magnes cum subditus esset."

His conclusion, therefore, that iron sometimes flies and sometimes follows the magnet, was scarcely justified by his experimental facts, and it is a mistake to suppose, as some have done, that he was aware of the polarity of *permanent* magnets.

Magnetic paradox. If we tap the card in the last experiment a curious result may sometimes be observed.[1] The lines of filings will be seen to *recede* from the point of the card immediately over the pole of the magnet. If, however, the magnet be held over, instead of under, the card, tapping will cause the filings to approach the point under the pole of the magnet. The most probable explanation[2] of this is to be found in the fact that the erected filings stand in the

[1] Æpinus, *Tentamen Theoriæ Electricitatis et Magnetismi*, 1759; Cavallo, *Treatise on Magnetism*, 1787.
[2] Roget, *Library of Useful Knowledge*, 1832.

former case as shown in fig. 18, and in the latter as shown in fig. 19; that is, in both cases, owing to the action of gravity, they are more acutely inclined to the card than

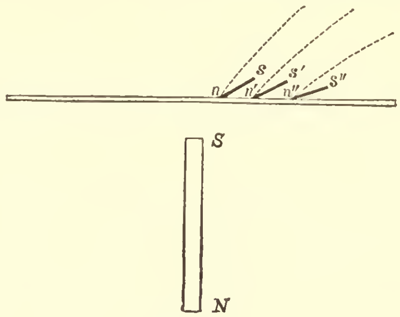

Fig. 18.

the lines of force (represented by dotted lines in the figure). Consequently, when the filing springs up into the air, and is thus free to follow the magnetic couple, it turns more

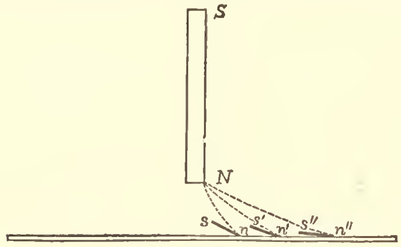

Fig. 19.

into the direction of the line of force; the effect of this is to carry its lower end each time a little farther from the axis of the magnet in the one case, and a little nearer to it in the other.

Electro-magnets.

By far the most important case of magnetic induction is the electromagnet. Whenever an electric current flows in a closed circuit, the surrounding space becomes a field of magnetic force, and any piece of iron in it will be inductively magnetized. Such an arrangement of an electric circuit and iron is called an electromagnet. The variety of form and of application of such instruments in modern science is endless. A few of the more important modifications will be considered below.

Induced and permanent magnetism in the same body.

Co-existence of Induced and Permanent Magnetism.—The fact that a body is already a permanent magnet does not prevent its being susceptible to magnetic induction. If we take any piece of iron at random, the chances are that one end or other of it will repel the north pole of a magnetic needle,—in other words, it will be to some extent permanently magnetic; but if we bring it slowly nearer and nearer to the pole of the needle, provided its magnetism be not *too* strong, it will by and by attract the pole which it at first repelled. Again, if we take two steel magnets, which may be as powerful as we please, provided at all events that they are unequally powerful, and bring two *like* poles together, these poles will at first repel each other in accordance with the fundamental law of permanent magnets; but, when the distance is less than a certain amount, the repulsion passes into an attraction, and when the poles are in contact this attraction may be very considerable. These phenomena are at once explained by the law of induction. The induced or temporary magnetism is superposed on the permanent magnetism, and, when the poles are near enough, the opposite magnetism induced by the pole attracts it more than the permanent like magnetism repels it; and this happens even with steel, whose susceptibility for magnetic induction is considerably less than that of iron. This phenomenon was observed pretty early in the history of magnetism, but was not fully explained until the idea of magnetic induction was fully developed. Michell, in his *Treatise of Artificial Magnets*,[1] gives a tolerably clear account of it. Musschenbroek mentions it,[2] along with the fact that a magnet attracts iron more than it does another magnet, but offers no explanation of either fact. The latter result, so far as it is true, can of course be explained by the smaller susceptibility of steel, particularly of hard steel, to magnetic induction, which is the main factor in attraction at small distances. Poggendorff[3] and others have experimented on the subject in later times. The reader should notice the close analogy between these phenomena and the repulsion and attraction at different distances between two similarly electrified conductors. See article ELECTRICITY, vol. viii. p. 33.

Induction of Permanent Magnetism.—The case above supposed, in which the induced magnetism is wholly temporary, although it can be easily realized with small magnetizing forces, is not the general one, but in fact the exception. Usually a certain proportion of the magnetism remains after the inducing force is removed. This happens even with the softest iron, when the inducing force is very great. Just as bodies differ very much in their susceptibility for induced magnetism, so they differ greatly in their power of retaining this magnetism when the inducing force ceases, or, as the phrase is, in "coercive force." Thus, while the inductive susceptibility of steel is less than that of iron, it retains much more of the magnetism imparted to it, and is therefore said to have much greater coercive force; and the coercive force is greater the harder the steel is tempered.

Coercive force.

It is obvious, therefore, that the principle of "induction," along with the idea of "retaining power" or "coercive force," furnishes us with the key to the explanation of the communication of permanent magnetism, whether by means of natural magnets or of artificial magnets, or of the electric current. In particular, we see at once the reason why the end of a needle which has been touched by the north pole of another magnet becomes a south pole, and *vice versa*,—a fact which greatly puzzled the earlier magnetic experimenters, and indeed all who were inclined to think that, in the process of magnetization, something was communicated from the one magnet to the other.

Mathematical Theory of the Action of Permanently Magnetized Bodies.

In this section we shall suppose the bodies considered to be rigidly magnetized; *i.e.*, we shall suppose that magnetic action exerted on any body produces no change in its magnetization. It is further to be observed that we are merely establishing a compendious representation of observed facts, and foreclosing nothing as to their physical theory or ultimate cause. Our method is therefore to some extent tentative, and its success is to be judged by the agreement of the results with experiment.

There are two main facts to be borne in mind:—(1) that a magnet is polarized, and (2) that the properties of its smallest parts are similar to those of the whole. Adopting the mathematical fiction of action at a distance, we may represent the action of such a body by a proper distribution of imaginary *positive* and *negative* attracting matter throughout its mass. This imaginary matter, following Sir W. Thomson, we shall call "magnetism," as we thus avoid suggesting other properties of matter than attraction, of which in the present case experience has given no evidence. We assume that *magnetism of any sign repels magnetism*

Positive and negative magnetism.

[1] Cambridge, 1750.

[2] *Philosophia Naturalis*, §§ 953, 954, 1762.

[3] *Pogg. Ann.*, xlv. p. 375, 1838.

of the same sign and attracts magnetism of the opposite sign. Magnetism is supposed to be so associated with the matter of the body that magnetic force exerted on the magnetism is ponderomotive force exerted on the matter. On the other hand, magnetic force is always supposed to be exerted by magnetism upon magnetism, and never directly by or upon matter. Into the nature of this association of magnetism with matter there is no pretence, indeed no need, to enter.

Elementary law of action at a distance.

The elementary law of action assumed is that *the attraction or repulsion (as the case may be) between two quantities m and m′ of magnetism supposed concentrated in two points at a distance r apart is* $\frac{mm'}{r^2}$, *and is in the line joining the two points.*

Unit of magnetism.

This supposes that the unit quantity of magnetism is so chosen that two units of positive magnetism at unit distance apart repel each other with unit force. This definition, which is fundamental in the electromagnetic system of units, gives for the dimensions of a quantity of magnetism $[L^{\frac{3}{2}}M^{\frac{1}{2}}T^{-1}]$. If the electrostatic system be adopted the result would of course be different.

Strength of magnetic field. Resultant magnetic force.

An accurate meaning can now be given to the phrase "strength of a magnetic field," or its equivalent "resultant magnetic force at a point in the field;" it is defined to be *the force exerted upon a unit of positive magnetism supposed concentrated at the point.* The force exerted on a unit of negative magnetism would of course be equal in magnitude, but oppositely directed; and in general, if R denote the resultant magnetic force at the point, the magnetic force exerted on a quantity κ of magnetism concentrated there is κR.

Volume and surface density of magnetism.

We may, as in the corresponding theory of electricity, introduce the ideas of volume density (ρ) and surface density (σ),—so that ρdv and σdS denote the quantities of magnetism in an element of volume and on an element of surface respectively; ρ and σ may of course be positive or negative according to circumstances.

It will now be seen that, mathematically speaking, the theories of action at a distance for electricity and magnetism are identical, and every conclusion drawn will have, so far as the physical diversity of the two cases may allow, a double application.[1] In particular it will be found that the theory of magnetism, when properly interpreted, gives the theory of dielectrics polarized in the way imagined by Faraday.

Total magnetism zero.

The fact of magnetic polarity requires the conception of negative as well as positive magnetism; the fact that the properties of the smallest parts of a magnet are similar to those of the whole requires that in every element of the body there shall be both negative and positive magnetism. From the fact that in a *uniform field, i.e.,* one in which the resultant magnetic force has at every point the same magnitude and direction, the force of translation upon a magnet is nil, it follows that the algebraic sum of all the magnetism in any magnet must be zero; for, if R denote the strength of the field, by the theory of parallel forces the whole force on the magnet will be $\Sigma(\kappa R), = R\Sigma\kappa$; hence $\Sigma\kappa = 0$. In other words, *in every magnet there must be as much negative as positive magnetism*; and this conclusion also must be extended to the smallest parts of every magnet, so long as we do not go behind the mere facts of observation. The positive and negative magnetism cannot be coincident throughout, otherwise there would be no external magnetic action, but the separation is in the elements of the body. Thus, although there is no force of translation in a uniform field, there will in general be a couple. Consider the positive and negative magnetism separately, and let κ denote any element of the former and κ' any element of the latter. Let N be the centre of mass of the positive, S the centre of mass of the negative magnetism; so that, if the magnet be referred to a set of rectangular axes, the coordinates of N and S are

$$\left.\begin{array}{c} \frac{\Sigma\kappa x}{\Sigma\kappa}, \quad \frac{\Sigma\kappa y}{\Sigma\kappa}, \quad \frac{\Sigma\kappa z}{\Sigma\kappa} \\ \text{and} \\ \frac{\Sigma\kappa' x'}{\Sigma\kappa'}, \quad \frac{\Sigma\kappa' y'}{\Sigma\kappa'}, \quad \frac{\Sigma\kappa' z'}{\Sigma\kappa'} \end{array}\right\} \quad . \quad . \quad . \quad . \quad . \quad (1).$$

Magnetic moment.

Let the distance NS $= l$, and let $K = l\Sigma\kappa, = -l\Sigma\kappa'$; this quantity K is called the "magnetic moment." By the theory of parallel forces, if we suspend the magnet in a uniform field of strength R, the action upon it reduces to two forces $R\Sigma\kappa$ and $-R\Sigma\kappa$, each parallel to the direction of the field, acting respectively at N and S, in other words to a couple whose moment is $R\Sigma\kappa l \sin\chi$ or $KR\sin\chi$, where χ is the angle between $\overrightarrow{SN}$ and the direction of the field.

Magnetic couple in uniform field.

Hence, if the magnet be perfectly free to follow the magnetic action of the field, it will set so that the line $\overrightarrow{SN}$ or the line $\overrightarrow{NS}$ is parallel to the direction of the field, the equilibrium being stable in the former case, but unstable in the latter. The line NS is therefore parallel to what we have already defined on experimental grounds as the axial direction in the magnet. N, S, and NS are sometimes called *par excellence* the poles and the axis of the magnet; we have adopted the looser definition given above because it is more convenient and nearer the popular usage.

Theory of dipping needle.

The above results may be applied to some cases very important in practice. Let the magnet whose centres of positive and negative magnetism are N and S be suspended by the middle point of NS, which, for simplicity, may be assumed to be also its centre of gravity. Let OX (fig. 20) be a horizontal line drawn northwards, OZ

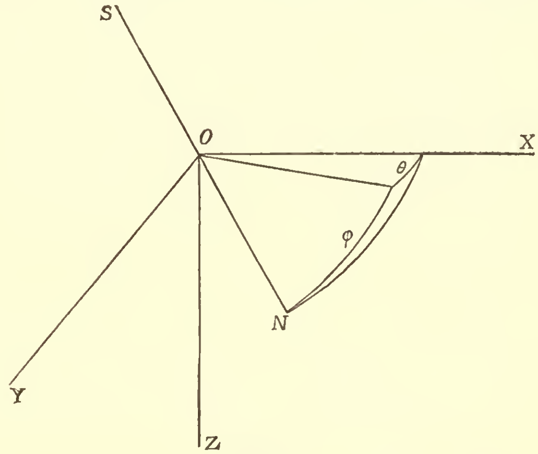

Fig. 20.

a vertical drawn downwards, both in the magnetic meridian. Let the vertical plane through NS make an angle θ with the magnetic meridian, and let ON make an angle ϕ with the horizon. If R be the strength of the earth's magnetic field, and ι the angle of dip, then the horizontal and vertical components of the earth's force are $H = R\cos\iota$ and $Z = R\sin\iota$.

First, suppose the angle ϕ fixed, and the magnet free to rotate about OZ only; then the couple tending to diminish the angle θ is

$$2 \cdot \Sigma\kappa \cdot R\cos\iota\frac{l}{2}\cos\phi\sin\theta, \text{ or } KR\cos\iota\cos\phi\sin\theta.$$

In other words the directive couple varies as the sine of the angle of deviation from the magnetic meridian. This conclusion was verified experimentally by Lambert, and also by Coulomb[2] by means of his torsion balance. It will be seen that, *cæteris paribus*, the directive couple is greatest when the magnetic axis is horizontal.

[1] To prevent needless repetition, we shall adopt henceforth, without further explanation, the definitions, terminology, and results given in the article ELECTRICITY, vol. viii. p. 24 *sq.*

[2] *Mém. de l'Acad.*, 1785.

Next suppose the angle θ fixed, and the magnet free to rotate about a horizontal axis inclined at an angle $90^\circ - \theta$ to OX. The couple tending to diminish the angle ϕ is $\mathrm{KR}(\cos\iota\cos\theta\sin\phi - \sin\iota\cos\phi)$. The position of equilibrium is given by the equation $\tan\phi = \sec\theta\tan\iota$.

The angle at which the axis is depressed below the horizon is therefore least when $\theta = 0$, and greatest when $\theta = 90^\circ$, its value being ι in the former case, and 90° in the latter, as stated above, p. 221.

In general, if λ', μ', ν' and λ, μ, ν be the direction cosines of the direction of the field and of the axis of the magnet respectively, then, resolving the forces acting at N and S, we see at once that the three components of the magnetic couple are

$$\mathrm{KR}(\nu'\mu - \mu'\nu),\ \mathrm{KR}(\lambda'\nu - \nu'\lambda),\ \mathrm{KR}(\mu'\lambda - \lambda'\mu) \quad . \quad . \quad . \quad (2).$$

Magnetic moment resolved as a vector.

These are clearly the same as the components of the couple on a system of three magnets whose axes are parallel to OX, OY, OZ, and whose magnetic moments are $\mathrm{K}\lambda$, $\mathrm{K}\mu$, $\mathrm{K}\nu$. Hence, so far as the action of a uniform field is concerned, we may resolve the magnetic moment like a vector, and replace a given magnet by others the resultant of whose moments is the moment of the given magnet.

It appears therefore that in a uniform field every magnet behaves as if it were made up of a certain quantity of positive magnetism and an equal quantity of negative magnetism placed at such a distance apart on a line parallel to the magnetic axis that the product of the quantity of magnetism into that distance has a value equal to the magnetic moment of the magnet. It is very important to observe that the magnetic moment alone appears in the above formulæ for the magnetic action. We cannot therefore separately determine from observations in a uniform field either the quantity of positive or negative magnetism in a magnet or the distance between the magnetic centres of mass.

Finite magnet replaced by an infinite number of infinitely small magnets.

Let M be any magnet, and P a point whose distance from any point of M is infinitely great compared with the linear dimensions of M. Then, since all the lines drawn from P to different points of M are sensibly parallel and equal in length, we may suppose the positive and negative magnetism of M to be collected at their mass centres, *i.e.*, M to be replaced by an ideal magnet. It is also obvious that, throughout a region around P whose linear dimensions are of the same order as those of M, the field due to M may be regarded as uniform. Hence we conclude that in calculating the mutual action of two magnets M and M′ we may replace each of them by an ideal magnet, provided the distance between them be infinitely great compared with the linear dimensions of either. This condition may be satisfied either by making the distance between the magnets very great if their dimensions be finite, or by making their dimensions infinitely small if the distance between them be finite. The second alternative suggests at once a method for representing the magnetic action of magnetized bodies at finite distances. We may divide up the body into portions whose linear dimensions are infinitely small compared with their distance from any point at which their action is to be considered; each of these portions is itself a magnet, and may be replaced by an ideal magnet having the same axis and moment. The whole magnetic action is obtained by integrating the action of all the ideal magnets of which the body is thus supposed to be composed.

Intensity of magnetization.

Let λ, μ, ν be the direction cosines of the magnetic axis of any element dv of a magnet, and I such that $\mathrm{I}dv$ is the magnetic moment of the element, and let $\mathrm{I}\lambda = \mathrm{A}$, $\mathrm{I}\mu = \mathrm{B}$, $\mathrm{I}\nu = \mathrm{C}$; then I is called the "intensity of magnetization" at the point where the element is taken. I may be regarded as a vector which specifies the magnetization of the body; in general it varies continuously from point to point; if it has the same value and direction at every point, the body is said to be uniformly magnetized. A line drawn so that the direction of I at every point of it is tangential to it is called a "line of magnetization." It is clear from what has already been shown that we may if we choose replace the element dv by three ideal magnets whose axes are parallel to the coordinate axes, and whose moments are $\mathrm{A}dv$, $\mathrm{B}dv$, $\mathrm{C}dv$ respectively.

Line of magnetization.

Resultant magnetic moment and axis.

If then K be the magnetic moment of the whole magnet, $\delta\mathrm{K}$ the moment of any element δv, and p, q, r the direction cosines of the axis of the whole magnet, we have $\mathrm{K} = l\Sigma\kappa, = -l\Sigma\kappa'$; and, remembering that $\kappa' = -\kappa$ for every element,

$$p = \left(\frac{\Sigma\kappa x}{\Sigma\kappa} - \frac{\Sigma\kappa' x'}{\Sigma\kappa'}\right)\frac{1}{l} = \frac{\Sigma\left(l\kappa\,.\,\frac{x - x'}{l}\right)}{l\Sigma\kappa} = \frac{\Sigma(\delta\mathrm{K}\lambda)}{\mathrm{K}} = \frac{\Sigma\mathrm{I}\lambda\delta v}{\mathrm{K}} = \frac{\Sigma\mathrm{A}\delta v}{\mathrm{K}}.$$

We may therefore write, replacing summation by integration,

$$\mathrm{K}p = \iiint \mathrm{A}dv,\quad \mathrm{K}q = \iiint \mathrm{B}dv \quad \mathrm{K}q = \iiint \mathrm{C}dv \quad . \quad . \quad (3).$$

Potential of infinitely small magnet.

Let SN be an ideal magnet of infinitely small length l, let m be its magnetic moment, and $m = \kappa l$. Let Q be its middle point, and the angle $\mathrm{PQN} = \theta$, N being the positive or north-seeking pole; and let $\mathrm{QP} = \mathrm{D}$. Then the potential at P due to this magnet is

$$\kappa\left\{\mathrm{D}^2 - \mathrm{D}l\cos\theta + \tfrac{1}{4}l^2\right\}^{-\frac{1}{2}} - \kappa\left\{\mathrm{D}^2 + \mathrm{D}l\cos\theta + \tfrac{1}{4}l^2\right\}^{-\frac{1}{2}}.$$

Expanding and neglecting powers of $\frac{l}{\mathrm{D}}$ above the first, we get for the potential

$$\frac{m\cos\theta}{\mathrm{D}^2} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4).$$

Potential of finite magnet.

Hence the potential at P (ξ, η, ζ) of an infinitely small magnet $\mathrm{A}dv$ at (x, y, z), having its axis parallel to the axis of x, is $\mathrm{A}(\xi - x)/\mathrm{D}^3$, and similarly for the other two. We therefore obtain for the potential of the whole magnet

$$\left.\begin{aligned} \mathrm{V} &= \iiint\left\{\mathrm{A}(\xi - x) + \mathrm{B}(\eta - y) + \mathrm{C}(\zeta - z)\right\}\frac{1}{\mathrm{D}^3}dv \\ &= \iiint\left\{\mathrm{A}\frac{d\left(\frac{1}{\mathrm{D}}\right)}{dx} + \mathrm{B}\frac{d\left(\frac{1}{\mathrm{D}}\right)}{dy} + \mathrm{C}\frac{d\left(\frac{1}{\mathrm{D}}\right)}{dz}\right\}dv \\ &= \iiint \mathrm{I}\left\{\lambda\frac{d}{dx} + \mu\frac{d}{dy} + \nu\frac{d}{dz}\right\}\frac{1}{\mathrm{D}}dv \end{aligned}\right\} \quad . \quad (5).$$

Taking the second of these expressions and integrating by parts in the usual way, we get

$$\left.\begin{aligned} \mathrm{V} &= \iint\frac{\sigma}{\mathrm{D}}d\mathrm{S} + \iiint\frac{\rho}{\mathrm{D}}dv\,; \\ \text{where}\quad \sigma &= l\mathrm{A} + m\mathrm{B} + n\mathrm{C} = \mathrm{I}\cos\theta \\ \rho &= -\left(\frac{d\mathrm{A}}{dx} + \frac{d\mathrm{B}}{dy} + \frac{d\mathrm{C}}{dz}\right) \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad (6),$$

l, m, n being the direction cosines of the outward normal to any element $d\mathrm{S}$ of the surface of the magnet, and θ the angle between the normal and the direction of magnetization at $d\mathrm{S}$.

Poisson's distribution.

Hence the action of any magnet may be represented by means of a certain volume distribution (ρ) and a certain surface distribution (σ) of free magnetism. This important proposition is due to Poisson.[1]

The fact, in itself obvious, that the sum of all the magnetism of Poisson's distribution must be zero, gives the theorem

$$\left.\begin{aligned} \iiint\left(\frac{d\mathrm{A}}{dx} + \frac{d\mathrm{B}}{dy} + \frac{d\mathrm{C}}{dz}\right)dv &= \iint(l\mathrm{A} + m\mathrm{B} + n\mathrm{C})d\mathrm{S} \\ &= \iint \mathrm{I}\cos\theta d\mathrm{S} \end{aligned}\right\} \quad . \quad (7),$$

which admits of course of direct analytical proof.

Gaussian distribution.

The magnet may also be replaced, so far as its external action is concerned, by a distribution wholly on its surface, as was shown by Gauss.[2] This will be seen at once if we replace the positive and negative magnetism throughout the body by positive and negative electricity, and suppose the surface of the magnet covered with a conducting layer in connexion with the earth. The surface will thus become charged with a distribution of positive and negative electricity whose total sum is zero, such that the potential of the surface is zero, and hence the potential at every external point zero. The potential of this surface layer

[1] *Mém. de l'Institut*, tom. v., 1821.

[2] *Intensitas Vis*, § 2 (1832), and *Allgemeine Lehrsätze*, § 36 (1839).

at every point external to the body is therefore equal and opposite to that of the internal electricity. If, therefore, we change the sign of the surface density at every point, we obtain a surface distribution whose potential at every external point is the same as that of the body. There is of course only one such distribution: we may call it Gauss's distribution.

Case of solenoidal magnetization.

Poisson's distribution will coincide with that of Gauss provided the magnetization be such that

$$\frac{dA}{dx}+\frac{dB}{dy}+\frac{dC}{dz}=0 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (8);$$

when this condition is satisfied at every point of the body, A is said to be "solenoidally" magnetized; a particular case is that of uniform magnetization.

Resultant force inside a magnetized body.

So long as the point considered is external to the magnet there is no difficulty in attaching a definite meaning to the resultant magnetic force ($\mathfrak{H}$) at a point; its components are given by

$$\alpha=-\frac{dV}{dx}, \quad \beta=-\frac{dV}{dy}, \quad \gamma=-\frac{dV}{dz} \quad . \quad . \quad . \quad (9);$$

and the values obtained will be the same whether V be calculated by means of Poisson's or of Gauss's distribution. Inside the body the result is otherwise, for reasons that are not difficult to understand, when we examine the nature of our fundamental assumptions. It is therefore necessary to be careful to define what we mean by resultant magnetic force in the interior of a magnet. It is defined by the above equation (9) on the understanding that V is calculated from Poisson's distribution. We can show that $\mathfrak{H}$ thus defined is the resultant force in an infinitely small cylindrical cavity within the magnet, whose axis is parallel to the line of magnetization, and whose radius a is infinitely small compared with its axis $2b$.

The removal of the matter filling such a cavity will affect Poisson's volume distribution to an infinitely small extent; the alteration of the force if any, will therefore arise simply from the surface distribution which we must place on the walls of the cavity in order to make up the complete representation of the action of the magnet in the cavity. This distribution reduces to two circular disks of radius a at the two ends, the densities of the magnetism on which are $-I$ and $+I$ respectively. The action due to these is a force $4\pi I(1-b/\sqrt{a^2+b^2})$ in the direction of magnetization. If a be infinitely small compared with b, this force becomes zero, which proves our proposition.

Magnetic induction.

If, on the other hand, the cavity in the magnet be disk-shaped—say a narrow crevasse perpendicular to the line of magnetization—then the force due to the distribution on its walls becomes $4\pi I$, and the resultant force in the cavity is no longer $\mathfrak{H}$, but a force $\mathfrak{B}$, whose components are

$$a=\alpha+4\pi A, \quad b=\beta+4\pi B, \quad c=\gamma+4\pi C \quad . \quad . \quad (10).$$

$\mathfrak{B}$ is called the "magnetic induction" at the point (x, y, z).

From the definition of $\mathfrak{H}$ it follows that outside the magnet

$$\frac{d\alpha}{dx}+\frac{d\beta}{dy}+\frac{d\gamma}{dz}=0 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (11).$$

Inside

$$\left.\begin{aligned}\frac{d\alpha}{dx}+\frac{d\beta}{dy}+\frac{d\gamma}{dz}&=4\pi\rho\\ &=-4\pi\left(\frac{dA}{dx}+\frac{dB}{dy}+\frac{dC}{dz}\right)\end{aligned}\right\} \quad . \quad . \quad (12).$$

Continuity and discontinuity of $\mathfrak{H}$ and $\mathfrak{B}$.

At the surface of a magnetized body the tangential component of $\mathfrak{H}$ is continuous, but the normal component increases abruptly by $4\pi I\cos\theta$ in passing from the inside to the outside of the surface.

Outside magnetized matter the magnetic force and the magnetic induction are coincident. Inside we have

$$\frac{da}{dx}+\frac{db}{dy}+\frac{dc}{dz}=\frac{d\alpha}{dx}+\frac{d\beta}{dy}+\frac{d\gamma}{dz}+4\pi\left(\frac{dA}{dx}+\frac{dB}{dy}+\frac{dC}{dz}\right)=0. \quad (13).$$

Hence the magnetic induction satisfies the solenoidal condition both inside and outside magnetized matter. It has normal continuity, and, in general, tangential discontinuity, at the surface of a magnetized body.

For if ν, τ and n, t be the normal and tangential components of $\mathfrak{H}$ and $\mathfrak{B}$ just inside, and ν', τ' and n', t' the corresponding components just outside the surface near any point, we have $n=\nu+4\pi I\cos\theta$, and $n'=\nu'$; but $\nu'=\nu+4\pi I\cos\theta$, therefore $n=n'$. On the other hand $\tau'=t'$, whereas τ is the resultant of t and $4\pi I\sin\theta$, which is parallel to the surface, but otherwise may have any direction according to circumstances; hence, since $t'=t$, in general τ' is not equal to τ.

In fact there will be tangential discontinuity of the magnetic induction unless the line of magnetization be perpendicular to the surface of the magnet; in this case there is complete continuity of the magnetic induction. When the magnetization at the surface is tangential, there is, on the other hand, complete continuity of the magnetic force.

Surface integral of magnetic induction is zero.

It follows from the above that the surface integral of the magnetic induction taken over any closed surface S vanishes.

First, let the surface be wholly within or wholly without continuously magnetized matter. We have, integrating all over S and all over the space enclosed by S, the analytical theorem

$$\iint(la+mb+nc)dS=\iiint\left(\frac{da}{dx}+\frac{db}{dy}+\frac{dc}{dz}\right)dv \quad . \quad . \quad (14);$$

hence the result follows, for every element of the right-hand integral vanishes. Next, suppose S to be partly within and partly without a magnetized body. Divide it into two parts by a double partition one of whose walls runs outside the surface of the body and infinitely near it, the other inside and infinitely near it; then, on account of the normal continuity of $\mathfrak{B}$, the surface integral will be the same in absolute value over each of these walls. Hence the integral over the whole of S differs infinitely little from the sum of the integrals over the two surfaces into which it is broken up by the double partition, each of which vanishes by the former case. Hence the theorem holds in this case also.

We may therefore apply to lines and tubes of magnetic induction without restriction all the theorems proved for lines and tubes of electric force in space free from electrified bodies. We may speak of the number of lines of magnetic induction instead of the surface integral if we choose. And we have this important theorem:—

The number of lines of magnetic induction that pass through an unclosed surface depends merely on its boundary.

Vector potential.

There must therefore be a vector $\mathfrak{A}$, whose line integral round the boundary is equal to the surface integral of $\mathfrak{B}$ over the surface.

The components F, G, H of $\mathfrak{A}$ are connected with those of $\mathfrak{B}$ by the equations

$$a=\frac{dH}{dy}-\frac{dG}{dz}, \quad b=\frac{dF}{dz}-\frac{dH}{dx}, \quad c=\frac{dG}{dx}-\frac{dF}{dy} \quad . \quad . \quad (15),$$

as has been shown in the article ELECTRICITY, vol. viii. p. 69.

Mutual potential energy of two magnets.

Mutual potential energy and mutual action of two magnetic systems.—The potential energy of a small magnet is $\kappa(V_2-V_1)$, where V_1 and V_2 are the values of V at its negative and positive poles. If the magnet be infinitely small, of length ds say, the direction cosines of ds being λ, μ, ν, this may be written $\kappa ds dV/ds$, *i.e.*, $m dV/ds$, or, if we are considering a magnetized element of volume dv,

$$I\left(\lambda\frac{dV}{dx}+\mu\frac{dV}{dy}+\nu\frac{dV}{dz}\right)dv \quad . \quad . \quad . \quad . \quad . \quad (16).$$

Hence the potential energy of the whole magnetic system in a field whose potential is given by V is

$$\left.\begin{aligned}W&=\iiint\left(A\frac{dV}{dx}+B\frac{dV}{dy}+C\frac{dV}{dz}\right)dv\\ &=-\iiint(A\alpha+B\beta+C\gamma)dv\end{aligned}\right\} \quad . \quad . \quad . \quad (17),$$

the integration being extended all over the magnetized masses supposed to be acted upon. Integrating by parts, we get at once

$$W=\iint V\sigma dS+\iiint V\rho dv \quad . \quad . \quad . \quad . \quad . \quad (18),$$

σ and ρ being the surface and volume densities of Poisson's distribution, a result that might have been expected. W may also be expressed as a sextuple integral; for, if I', λ', μ', ν', x', y', z' refer to the acting system, then

$$V=\iiint I'\left(\lambda'\frac{d}{dx'}+\mu'\frac{d}{dy'}+\nu'\frac{d}{dz'}\right)\frac{1}{D}dx'dy'dz'.$$

Whence

$$W = \iiiiiint dx\,dy\,dz\,dx'\,dy'\,dz'\,\Pi'\left(\lambda\frac{d}{dx}+\mu\frac{d}{dy}+\nu\frac{d}{dz}\right) \times\left(\lambda'\frac{d}{dx'}+\mu'\frac{d}{dy'}+\nu'\frac{d}{dz'}\right)\frac{1}{D} \quad (19).$$

A remarkable expression for W may be obtained by supposing the integration in (17) extended throughout the whole of space, on the understanding that A, B, C are zero where there is no magnetized matter, and then integrating by parts. We get, since the surface integral at infinity may be shown to vanish,

$$\begin{aligned} W &= \iiint_{-\infty}^{\infty}\left(A\frac{dV}{dx}+B\frac{dV}{dy}+C\frac{dV}{dz}\right)dv \\ &= -\iiint_{-\infty}^{\infty}V\left(\frac{dA}{dx}+\frac{dB}{dy}+\frac{dC}{dz}\right)dv \end{aligned} \quad . \quad . \quad (20),$$

where it must be understood that A, B, C vary continuously, however rapidly. In point of fact, where, as at the surface of a magnetized body, there is discontinuity, a finite portion of the integral will arise from an infinitely thin stratum near the surface. The proper representation of this part will be a surface integral, as may be seen by referring to (18), from which we might have started.

If now V′ be the potential of the magnet acted upon, then

$$\frac{d^2V'}{dx^2}+\frac{d^2V'}{dy^2}+\frac{d^2V'}{dz^2}=4\pi\left(\frac{dA}{dx}+\frac{dB}{dy}+\frac{dC}{dz}\right);$$

whence

$$\begin{aligned} W &= -\frac{1}{4\pi}\iiint_{-\infty}^{\infty}V\left(\frac{d^2V'}{dx^2}+\frac{d^2V'}{dy^2}+\frac{d^2V'}{dz^2}\right)dv \\ &= +\frac{1}{4\pi}\iiint_{-\infty}^{\infty}\left(\frac{dV}{dx}\frac{dV'}{dx}+\frac{dV}{dy}\frac{dV'}{dy}+\frac{dV}{dz}\frac{dV'}{dz}\right)dv \\ &= +\frac{1}{4\pi}\iiint_{-\infty}^{\infty}RR'\cos\theta\,dv \text{ [1]} \end{aligned} \quad (21),$$

where R and R′ are the resultant forces at any point of space due to the acting and acted-upon systems respectively, and θ the angle between their directions.

Force and couple on a magnet in given field.

In practice W is expressed as a function of the variables (equal in number to the degrees of freedom) that determine the relative position of the two systems; differentiation with respect to any one of these then gives the generalized force component tending to decrease that variable.

We may also calculate the forces directly. For, the components of force on the element dv, being the differences of the forces acting on the two poles of the element, are

$$\left(A\frac{d\alpha}{dx}+B\frac{d\alpha}{dy}+C\frac{d\alpha}{dz}\right)dv, \text{ \&c.};$$

and the components of couple, in calculating which the field may be supposed uniform, are (see above, p. 228)

$$(\gamma B - \beta C)dv, \text{ \&c.}$$

Hence, integrating, we get, with the chosen origin, for the components of the whole force and couple,

$$\begin{aligned} \mathfrak{X} &= \iiint\left(A\frac{d\alpha}{dx}+B\frac{d\alpha}{dy}+C\frac{d\alpha}{dz}\right)dv, \\ &\text{and similarly for } \mathfrak{Y} \text{ and } \mathfrak{Z}. \\ \mathfrak{L} &= \iiint\left\{\gamma B-\beta C+y\left(A\frac{d\gamma}{dx}+B\frac{d\gamma}{dy}+C\frac{d\gamma}{dz}\right)\right. \\ &\quad \left.-z\left(A\frac{d\beta}{dx}+B\frac{d\beta}{dy}+C\frac{d\beta}{dz}\right)\right\}dv, \\ &\text{and similarly for } \mathfrak{M} \text{ and } \mathfrak{N}. \end{aligned} \quad . \quad (22).$$

In the important case of a uniform field whose components are α, β, γ, we have

$$W = -K(l\alpha+m\beta+n\gamma) \quad . \quad . \quad . \quad . \quad . \quad (23),$$

K being the moment of the magnet, and l, m, n the direction cosines of its axis. From this formula the results given above (p. 227) can be deduced with great ease.

Examples.—Some examples of the application of the foregoing theory are here given, partly on account of their intrinsic value as types enabling us to conceive the different varieties of magnetic action, partly for the sake of the light they throw on the theory itself. The reader who desires more such should consult Maxwell's *Electricity and Magnetism*, or Mascart and Joubert, *Leçons sur l'Électricité et le Magnétisme.*

Solenoidal magnetization.

Solenoidal Magnets have already been defined as such that the vector I satisfies the solenoidal condition

$$\frac{dA}{dx}+\frac{dB}{dy}+\frac{dC}{dz}=0.$$

The lines of magnetization, therefore, have all the properties of lines of magnetic induction or electric force. In particular, if we consider a portion of the magnet enclosed by a tube of the lines of magnetization, the product of the intensity of magnetization by the section at each point is the same. Such a portion of magnetized matter taken by itself is called a "magnetic solenoid," and the product mentioned is called its "strength." It is clear (from the general definition, or it may be proved directly from the secondary property just mentioned) that the action of the solenoid may be represented by the distribution of a certain quantity ωI of positive magnetism on the one end and an equal quantity of negative magnetism on the other, I being the intensity of magnetization, ω the normal section at the end. The action therefore depends merely on the strength of the solenoid and on the position of its ends. The shape

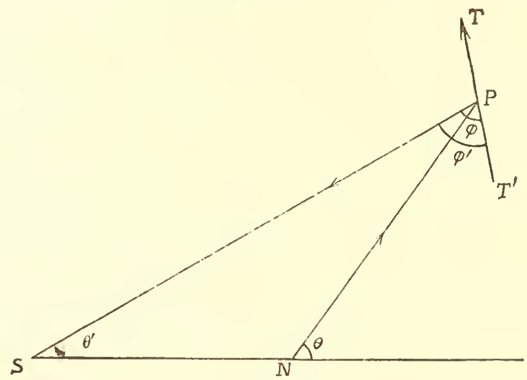

Fig. 21.

of the intervening portion is immaterial. If we suppose it straight, and if the section be infinitely small so that the magnetism at the ends may be regarded as condensed at two points, we have an ideal magnet of finite length. The equipotential lines of such a magnet in any plane through its axis are of course given by the equation

Equipotential lines and lines of force.

$$\frac{1}{r}-\frac{1}{r'}=\text{const.} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (24),$$

where r and r' are the distances of any point P on the line from the poles.

Ideal bar magnet.

The equation to the lines of force is easily obtained;[2] for, if NP and SP (fig. 21) make angles θ and θ' with the axis of the magnet, and ϕ and ϕ' with the line of force, we must have

$$\sin\phi/r^2 - \sin\phi'/r'^2 = 0;$$

hence, since

$$\sin\phi = r\,d\theta/ds, \quad \sin\phi' = r'd\theta'/ds,$$

we get

$$d\theta/r - d\theta'/r' = 0; \quad i.e., \sin\theta\,d\theta - \sin\theta'd\theta' = 0;$$

which gives for the equation to a line of force

$$\cos\theta - \cos\theta' = \text{const.} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (25).$$

Two like poles.

We may imagine a magnet of this kind so long that the action of one of its poles may be altogether neglected at points which are at a finite distance from the other. We thus *effectively* realize what never occurs in nature, viz., a magnet with one pole only. If we place the like poles of two such magnets near each other, we get a field the equipotential lines and lines of force in any axial plane of which are given by the equations

$$\frac{1}{r}+\frac{1}{r'}=\text{const.} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (26).$$

$$\cos\theta + \cos\theta' = \text{const.} \quad . \quad . \quad . \quad . \quad . \quad . \quad (27).$$

The lines of force given by equations (25) and (27) may be traced in a diagram by means of the following simple and elegant construction[3] Draw two circles A and B, having equal radii and N and S respectively for centres; produce the line NS both ways, and, starting from the centre, divide it into any number of equal parts; through these draw perpendiculars to meet the circles A and B;

[1] See Thomson, *Reprint of Papers on Electricity and Magnetism*, p. 433.

[2] The first mathematical investigations of the equation to the lines of force of an ideal magnet appear to have been made by Playfair at the request of Robison, and by Leslie, *Geom. Analysis*, 1821. They had previously been very carefully considered from an experimental point of view by Lambert, *Mém. de l'Acad. de Berlin*, 1766.

[3] Roget, *Jour. Roy. Inst.*, 1831.

from N draw a series of lines to the points of division on B, and from S a similar series to the points of division on A. These lines will form a network of lozenges the loci of the vertices of which will be lines of force, corresponding to (25) or (27) according as we

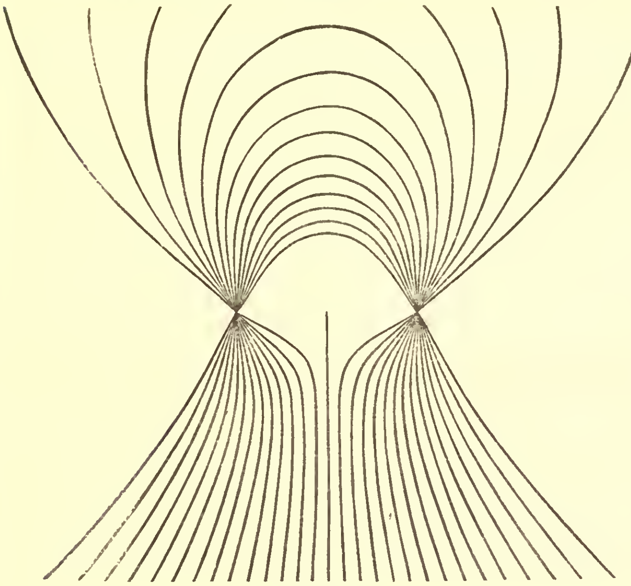

Fig. 22.

pass from point to point along one set of lozenge diagonals or along the other. Fig. 22 will give the reader an idea of the general appearance of the two sets of lines. He may compare the ideal with the actual cases by referring to figs. 4 and 5, p. 222.

Infinitely small magnet.

In the case of an infinitely small magnet, the equipotential lines are of course given by the polar equation $r^2 = c^2 \cos\theta$, c being a variable parameter. It is easily shown that the lines of force, which are necessarily orthogonal to these, have for their equation $r = c \sin^2\theta$.[1] If ϕ be the angle between r and the tangent of the line of force, we have $\tan\phi = rd\theta/dr = \frac{1}{2}\tan\theta$; hence the following construction for the direction of the line of force at P due to a small magnet at O:—let K be the point of trisection of OP nearest O, and let KT, perpendicular to OP, cut the axis of the magnet in T; then TP is the tangent to the line of force at P. This construction in a slightly different form was given by Hansteen[2] and by Gauss[3]; the latter adds that the resultant force at P is given by $M.PT/OT.OP^3$ where M is the magnetic moment of the magnet, a proposition which the reader will easily verify. These propositions are of considerable use in rough magnetic calculations. As this is an important case we give a diagram of the equipotential lines and lines of force in fig. 23.

We may, if we choose, consider a filament of matter magnetized longitudinally at every point, but so that the strength ωI ($=J$, say) is variable. Such a filament is called a complex solenoid. It may clearly be supposed made up of a bundle of simple solenoids whose ends are not all coincident with the ends of the filament. If ds be an element of such a filament, the potential is given by

$$V = \int dsJ \frac{d\left(\frac{1}{D}\right)}{ds} = \frac{J_1}{D_1} - \frac{J_2}{D_2} - \int ds \frac{1}{D}\frac{dJ}{ds} \quad . \quad . \quad . \quad (28).$$

That is, its action may be represented by two particles of magnetism J_1 and J_2 at its two ends, and by a continuous distribution of free magnetism along its length whose density is $-dJ/ds$. This is of course merely a particular case of Poisson's distribution.

When a body is solenoidally magnetized, the magnetic force 𝔜 both external and internal depends solely on the surface distribution, *i.e.*, merely on the ends of the solenoids of which the body is composed. We may therefore suppose the two ends of any solenoid joined by a solenoid of equal strength lying in the surface of the body. Proceeding thus, we may in an infinite number of ways construct a surface layer of *tangentially* magnetized matter which will represent the magnetic action of a solenoidally magnetized body. Thomson has shown by means of a highly interesting piece of analysis how to find the components of this tangential magnetization. See *Reprint of Papers on Electricity and Magnetism*, p. 401.

The magnetic theorems just stated will suggest at once to the mind of the reader acquainted with the analysis employed in hydro kinetical problems the close analogy that subsists between the two methods. In fact, by proper arrangement, every problem in the one subject can be converted into a problem in the other. For details we refer the reader to Thomson, who was, so far as we know, the first to work out this matter fully; in the present connexion he should consult more particularly §§ 573 *sq.* of the *Reprint*.

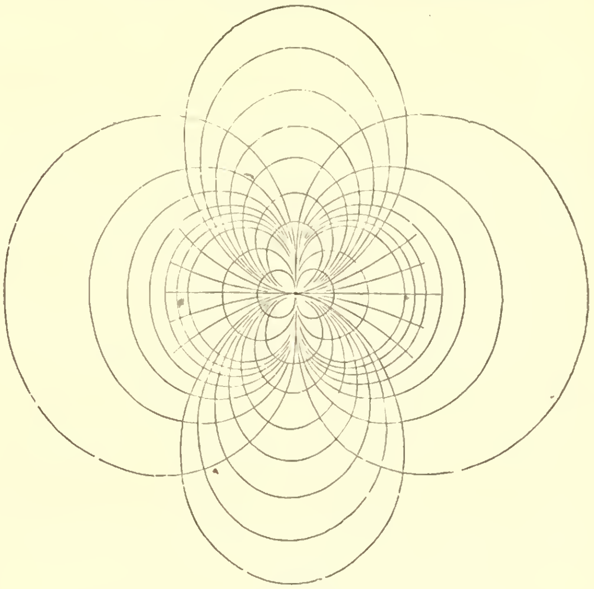

Fig. 23.

Potential of uniformly magnetized bodies.

Uniformly Magnetized Bodies constitute in practice the most important case of solenoidal magnets. In the first place it is obvious that the whole magnetic moment of such a body is simply its volume multiplied by the intensity of magnetization, and that the axis of the whole is parallel to the axis of each of its infinitely small parts. The method usually applied to calculate the potential in this case may be presented in two ways. The potential is calculated according to Poisson's method in this case merely from a surface distribution of varying density $I\cos\theta$. We may replace this by a layer of uniform density ρ and varying normal thickness. Let the thickness at any point measured parallel to the magnetic axis be t; then the normal thickness is $t\cos\theta$; hence $\rho t\cos\theta = I\cos\theta$, and $\rho t = I$; *i.e.*, t is constant. We may therefore suppose the magnet replaced by itself (fig. 24) with a uniform volume distribution ρ of positive magnetism, and itself displaced through a distance t in a direction opposite to that of magnetization with a uniform volume distribution $-\rho$; or, which comes to the same thing, the potential of the magnet at P is $\rho(U - U')$, where U is the potential at P of a uniform volume distribution of density $+1$ throughout the magnet, and U′ the potential of the same at a point P′ displaced through a distance t in the direction of magnetization.

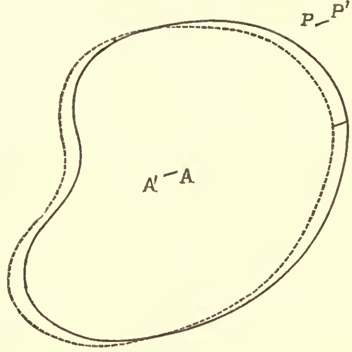

Fig. 24.

If l, m, n be the direction cosines of the magnetic axis, this gives at once

$$\left.\begin{aligned} V &= -\rho\left(\frac{dU}{dx}tl + \frac{dU}{dy}tm + \frac{dU}{dz}tn\right) \\ &= -I\left(l\frac{dU}{dx} + m\frac{dU}{dy} + n\frac{dU}{dz}\right) \\ &= AX + BY + CZ \end{aligned}\right\} \quad . \quad . \quad . \quad (29);$$

where X, Y, Z are the components of the resultant force due to volume distribution $\rho = +1$ throughout the body, and A, B, C the components of the magnetization.

The same result may also be arrived at thus. The part of the potential due to the element dv is $Idv\cos\theta/r^2$, but this is the component parallel to the direction of I of the resultant force at P of a volume distribution whose density in dv is I; hence, since the

[1] Hansteen, *Magnetismus der Erde*, p. 208 (1819).
[2] *Magnetismus der Erde*, p. 209.
[3] *Resultate d. Mag. Vereins*, 1837 and 1840.

direction of I is everywhere the same, the whole potential is the component parallel to the magnetic axis of the body of the resultant force at P of a volume distribution $\rho = 1$ throughout its whole extent. This gives at once the expression of (29) for V.

Sphere.

In the case of a uniformly magnetized sphere of radius a, the axis being parallel to the axis of x, and the centre at the origin, we get, if r be the distance of P from the origin, for external points,

$$V = \tfrac{4}{3}\pi I a^3 x / r^3 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (30);$$

in other words, the external action is that of a magnet of infinitely small dimensions, having the same moment and axis, placed at the centre.

For internal points

$$V = \tfrac{4}{3}\pi I x \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (31);$$

whence it appears that the magnetic force inside the sphere is constant in magnitude and in direction, being opposite to the uniform magnetization, and equal to $-\tfrac{4}{3}\pi I$.

Ellipsoid.

The potential of a uniformly magnetized ellipsoid may be similarly treated. Let the origin be at the centre, and the axes along the principal diameters of the ellipsoid, whose lengths are $2a$, $2b$, $2c$, and let l, m, n be the direction cosines of its magnetic axis. Consider first an external point. Then,[1] if

$$L = 2\pi abc \int_\alpha^\infty \frac{d\phi}{\sqrt{(a^2+\phi)^3(b^2+\phi)(c^2+\phi)}}, \quad M = \&c., \quad N = \&c. \quad (32),$$

where α is the positive root of

$$\frac{x^2}{a^2+\phi} + \frac{y^2}{b^2+\phi} + \frac{z^2}{c^2+\phi} = 1,$$

we have

$$X = Lx, \quad Y = My, \quad Z = Nz,$$

and

$$V = ALx + BMy + CNz \quad . \quad . \quad . \quad . \quad . \quad (33),$$

where it must be remembered that L, M, N are functions of x, y, z, inasmuch as α is so.

If (x, y, z) be an internal point, X, Y, Z are the components of the force due to a similar and similarly situated ellipsoid through (x, y, z). Let its axes be pa, pb, pc; we now have

$$X = Lx, \quad Y = My, \quad Z = Nz,$$

where

$$L = 2\pi papbpc \int_0^\infty \frac{d\phi}{\sqrt{(p^2a^2+\phi)^3(p^2b^2+\phi)(p^2c^2+\phi)}};$$

or, writing $\phi = p^2\psi$,

$$L = 2\pi abc \int_0^\infty \frac{d\psi}{\sqrt{(a^2+\psi)^3(b^2+\psi)(c^2+\psi)}}, \quad M = \&c., \quad N = \&c. \quad (34).$$

We thus obtain for V,

$$V = ALx + BMy + CNz, \quad . \quad . \quad . \quad . \quad . \quad . \quad (35),$$

where L, M, N are now constants, which remain the same so long as the ratios of the axes remain unaltered. The components of the force inside the ellipsoid are

$$\alpha = -AL, \quad \beta = -BM, \quad \gamma = -CN \quad . \quad . \quad . \quad (36).$$

The force is therefore uniform; but its direction does not coincide with that of the magnetization, unless the latter be parallel to one of the principal diameters, and then the force is opposite in direction to the magnetization. It will be observed that the force inside similar ellipsoids similarly magnetized to the same intensity is always the same.

For an oblate ellipsoid of revolution, in which $b = c = a/\sqrt{1-e^2}$,

$$L = 4\pi\left(\frac{1}{e^2} - \frac{\sqrt{1-e^2}}{e^3}\sin^{-1}e\right), \quad M = N = 2\pi\left(\frac{\sqrt{1-e^2}}{e^3}\sin^{-1}e - \frac{1-e^2}{e^2}\right).$$

For a very flat oblate ellipsoid of revolution $L = 4\pi$, $M = N = \pi^2 a/c$. For a prolate or ovary ellipsoid of revolution, in which

$$a = b = c\sqrt{1-e^2},$$

$$L = M = 2\pi\left(\frac{1}{e^2} - \frac{1-e^2}{2e^3}\log\frac{1+e}{1-e}\right),$$

$$N = 4\pi\left(\frac{1}{e^2} - 1\right)\left(\frac{1}{2e}\log\frac{1+e}{1-e} - 1\right).$$

From the formulæ for an ellipsoid we could easily deduce those for an infinitely long elliptic or circular cylinder; we have merely to make one of the axes infinite. We find in this way, for instance, that the force inside a circular cylinder of infinite length magnetized transversely is $-2\pi I$.

The reader will find it interesting to examine the values of the magnetic induction in the foregoing cases, and to verify its normal continuity at the surface of the magnet.

Lamellar Magnets form another very important class. In them the components of magnetization are derivable by differentiation

Lamellar magnetization.

from a function $\phi(x, y, z)$, which is sometimes called the "potential of magnetization,"[2] so that

$$A = \frac{d\phi}{dx}, \quad B = \frac{d\phi}{dy}, \quad C = \frac{d\phi}{dz} \quad . \quad . \quad . \quad . \quad . \quad (37).$$

It is obvious at once that the family of surfaces $\phi(x, y, z) = \text{const.}$ cut the lines of magnetization at right angles; for, if dx, dy, dz be the projections of the element of any line on the surface, we have by differentiation

$$\frac{d\phi}{dx}dx + \frac{d\phi}{dy}dy + \frac{d\phi}{dz}dz = 0,$$

$$i.e., \quad A\,dx + B\,dy + C\,dz = 0,$$

which is the analytical expression of the property in question.

Magnetic shells.

We may therefore suppose a lamellar magnet divided up by these surfaces of magnetization into an infinite number of infinitely thin normally magnetized shells or lamellæ. It can be shown that the product of the intensity of magnetization by the thickness at each point of any such shell is the same; for, if $\phi(x, y, z) = c$ and $\phi(x, y, z) = c + \delta c$ be the equations to the two surfaces bounding the shell, $\delta\nu$ the normal distance between them at any point, we have

$$\frac{d\phi}{dx}\delta x + \frac{d\phi}{dy}\delta y + \frac{d\phi}{dz}\delta z = \delta c,$$

hence

$$\left(\frac{d\phi}{dx}\frac{dx}{d\nu} + \frac{d\phi}{dy}\frac{dy}{d\nu} + \frac{d\phi}{dz}\frac{dz}{d\nu}\right)\delta\nu = \delta c,$$

i.e., $I\delta\nu = \delta c = \text{constant}$ for the same shell, which was to be proved. This product is called the strength of the shell.

A shell, which is everywhere normally magnetized, but whose strength is not constant, is called a "complex shell"; a magnet made up of such shells is called a "complex lamellar magnet." The condition to be satisfied by A, B, C in this case is simply that the lines of magnetization must be orthogonal to a family of surfaces, *i.e.*, $A\,dx + B\,dy + C\,dz$ must be convertible into a perfect differential by multiplication by a factor; otherwise that

$$A\left(\frac{dB}{dz} - \frac{dC}{dy}\right) + B\left(\frac{dC}{dx} - \frac{dA}{dz}\right) + C\left(\frac{dA}{dy} - \frac{dB}{dx}\right) = 0.$$

The potential at P of a simple magnetic shell of strength i is given by the formula

$$V = \iint \frac{i\cos\theta\, dS}{D^2} = i\iint \frac{dS\cos\theta}{D^2} = i\omega \quad . \quad . \quad . \quad (38),$$

where ω is the solid angle subtended at the point P.[3] There is a convention here as to sign, viz., that side of the shell is positive towards which the lines of magnetization pass, and the solid angle subtended at points infinitely near that side is positive, while that subtended at points infinitely near the other side is negative. If we cause P to move from the positive side away to infinity, then back from infinity to the negative side, or to move anyhow from infinitely near the positive side to a point infinitely near the negative side without cutting through the shell, it will decrease continuously by $4\pi i$; if we pass *through* the shell from a point infinitely near on the negative side to a point infinitely near on the positive side, there will be a sudden increase of $4\pi i$; tangentially to the shell there is continuity. The potential of a closed shell is evidently zero for any external point, $\pm 4\pi i$ for an internal point according as the positive or negative side is innermost. It appears also that the potential of a simple magnetic shell depends merely on its strength and on its boundary, just as that of a magnetic solenoid depends merely on its strength and the position of its ends.

Potential of lamellar magnet.

A lamellar magnet will in general be made up partly of closed shells, and partly of shells whose boundaries lie on the surface; only the latter of course can influence the potential at external points. The general expression for the potential at any point $P(\xi, \eta, \zeta)$ is

$$\left.\begin{aligned} V &= \iiint\left(\frac{d\phi}{dx}\frac{d\left(\frac{1}{D}\right)}{dx} + \frac{d\phi}{dy}\frac{d\left(\frac{1}{D}\right)}{dy} + \frac{d\phi}{dz}\frac{d\left(\frac{1}{D}\right)}{dz}\right)dv \\ &= \iint\phi\left(l\frac{d\left(\frac{1}{D}\right)}{dx} + m\frac{d\left(\frac{1}{D}\right)}{dy} + n\frac{d\left(\frac{1}{D}\right)}{dz}\right)dS - \iiint\phi\nabla^2\left(\frac{1}{D}\right)dv \\ &= \iint\frac{\phi\cos\theta}{D^2}dS + 4\pi\phi' \end{aligned}\right\} (39),$$

where θ is the angle between D and the outward normal to dS, and ϕ' the value of ϕ at the point ξ, η, ζ (zero of course if ξ, η, ζ be outside the magnet). The value of V thus found is not discontinuous at the surface as might be supposed, for both the surface integral and

[1] See Thomson and Tait, *Natural Philosophy*, vol. i. § 522.

[2] To be distinguished of course from the magnetic potential.

[3] Gauss, *Allgemeine Theorie des Erdmagnetismus*, § 38.

$4\pi\phi'$ have discontinuities there, and they are equal in amount and of opposite sign.

For an external point the potential is

$$\iint \frac{\phi\cos\theta}{D^2}dS\,.$$

The immediate interpretation of this is that the potential is the same as that due to a normally magnetized layer on the surface of the body whose strength at dS is ϕ; in other words, *qua* external action, every lamellar magnet may be replaced by a complex shell on its surface.

There is, however, another way of looking at the result. Since A, B, C are derivable from a potential ϕ, the difference between the values of ϕ at any two points is simply the value of the line integral $\int(Adx+Bdy+Cdz)$ along any path between those points. Hence if the tangential component of magnetization be given in direction and magnitude all over any surface, the value of ϕ, *à constant près*, is given all over that surface. We conclude therefore that, if a body be lamellarly magnetized, and we know the tangential component of its magnetization all over its surface, its external action is determined;[1] for a constant c added to ϕ will simply add to the surface integral

$$c\iint\frac{\cos\theta\,dS}{D^2}\,,$$

which, being c times the whole solid angle subtended by the surface at any external point, vanishes. For another very interesting proof of this result, see Thomson, *Reprint*, p. 398 *sq.*

Vector potential of lamellar magnet.

The vector potential of a lamellar magnet may be expressed by means of the formulæ

$$\left.\begin{aligned} F&=\iiint\left(\frac{d\phi}{dy}\frac{d\left(\frac{1}{D}\right)}{dz}-\frac{d\phi}{dz}\frac{d\left(\frac{1}{D}\right)}{dy}\right)dv\\ &=\iint\phi\left(m\frac{d\left(\frac{1}{D}\right)}{dz}-n\frac{d\left(\frac{1}{D}\right)}{dy}\right)dS'\\ &=-\iint\frac{1}{D}\left(m\frac{d\phi}{dz}-n\frac{d\phi}{dy}\right)dS'\,;\ G=\&c.\,;\ H=\&c. \end{aligned}\right\}\quad(40).$$

These formulæ furnish an immediate proof of the theorems of Thomson above stated.

Potential energy of magnetic shell, &c.

By means of the last of them, it has been shown in the article ELECTRICITY[2] that the vector potential of a simple magnetic shell can, as might be expected, be expressed by means of a line integral taken round its boundary; in the same place it has also been shown that the potential energy of such a shell in a magnetic field reduces to a similar line integral; and that the mutual potential energy of two such shells reduces to a double line integral taken round their boundaries.

Approximate expression for magnetic potential.

An important approximate expression for the potential of a magnet at a point P, whose distance r from some chosen point in the magnet is great compared with the greatest linear dimension of the magnet, may be obtained as follows. Let the coordinates of P with respect to the chosen point and any axes through it be $\xi,\ \eta,\ \zeta$; and let the coordinates of any point in the body referred to the same axes be $x,\ y,\ z$. Also let $D=\left\{(\xi-x)^2+(\eta-y)^2+(\zeta-z)^2\right\}^{\frac{1}{2}}$, and let $r=(\xi^2+\eta^2+\zeta^2)^{\frac{1}{2}}$, $s=(x^2+y^2+z^2)^{\frac{1}{2}}$, $t=\xi x+\eta y+\zeta z$. Then the potential U at $(x,\ y,\ z)$ of a unit pole placed at $(\xi,\ \eta,\ \zeta)$ is given by

$$\begin{aligned} U=\frac{1}{D}&=\frac{1}{r}+\frac{t}{r^3}+\frac{3t^2-r^2s^2}{2r^5}+\frac{5t^3-3tr^2s^2}{2r^7}+\&c.\\ &=\frac{1}{r}+U_1+U_2+U_3+\&c., \end{aligned}$$

by a well-known theorem, where $U_1,\ U_2,\ U_3$, &c., are spherical harmonics of degrees 1, 2, 3, &c., in $x,\ y,\ z$, and $-2,\ -3,\ -4$, &c., in $\xi,\ \eta,\ \zeta$. Now, by the theorem of mutual potential energy, the potential V of the magnet at $(\xi,\ \eta,\ \zeta)$ is the potential energy of the magnet in the field due to a unit pole at $(\xi,\ \eta,\ \zeta)$; hence by (17)

$$\left.\begin{aligned} V&=\iiint\left(A\frac{dU}{dx}+B\frac{dU}{dy}+C\frac{dU}{dz}\right)dv\\ &=V_1+V_2+V_3+\&c. \end{aligned}\right\}\quad .\ .\ .\quad(41),$$

where V_1 arises from U_1, V_2 from U_2, and so on. $V_1,\ V_2,\ V_3$, &c., will be spherical harmonics in $\xi,\ \eta,\ \zeta$ of the most general kind, involving essentially 3, 5, 7, . . . $2i+1$ constants respectively, their degrees being $-2,\ -3,\ .\ .\ .\ -i$ respectively. These constants will, however, depend in each case on a larger number of integrals taken throughout the magnetized body, thus the constants in V_i will depend upon $\frac{3}{2}(i+1)(i+2)$ integrals.[3] There is no difficulty in writing down these terms except the length of the formulæ. Putting

$$\left.\begin{aligned} &\iiint A\,dv=Kl,\quad \iiint B\,dv=Km,\quad \iiint C\,dv=Kn\\ &L=\iiint Ax\,dv,\quad M=\iiint By\,dv,\quad N=\iiint Cz\,dv\\ &P=\iiint(Bz+Cy)dv,\quad Q=\&c.,\quad R=\&c. \end{aligned}\right\}\ .\quad(42),$$

we get

$$V=K\frac{l\xi+m\eta+n\zeta}{r^3}+\frac{(2L-M-N)\xi^2+\&c.+3P\eta\zeta+\&c.}{r^5}+\&c.\qquad(43).$$

It may be shown[4] that, in the most general case, if we take the axis of x parallel to the magnetic axis, and the origin at the point

$$\left\{(2L-M-N)/2K,\ \ R/K,\ \ Q/K\right\},^5$$

and turn the axes about an angle $\tan^{-1}P/(M-N)$, the above reduces to

$$V=\frac{K\xi}{r^3}+\frac{3}{2}\frac{(M-N)(\eta^2-\zeta^2)}{r^5}+\&c.\quad .\ .\ .\quad(44).$$

An interesting particular case is that in which the magnet is symmetrical with respect to the three coordinate planes. If we take its axis to be in the axis of x, then, since all the integrals L, M, N, P, Q, R vanish, V_2 disappears, of the next set only

$$A_1=\iiint Ax^2dv,\quad A_2=\iiint Ay^2dv,\quad A_3=\iiint Az^2dv\quad .\quad(45)$$

remain, and we get

$$V=\frac{K\xi}{r^3}+\frac{3\left\{A_1(2\xi^2-3\eta^2-3\zeta^2)+A_2(4\eta^2-\zeta^2-\xi^2)+A_3(4\zeta^2-\xi^2-\eta^2)\right\}\xi}{2r^7}\quad(46).$$

The potential to the same degree of approximation of a positive and negative pole of strength μ, placed on the magnetic axis at distances $+L$ and $-L$ from the origin (centre of symmetry), is

$$V'=\frac{2\mu L\xi}{r^3}+\frac{2\mu L^3\xi(2\xi^2-3\eta^2-3\zeta^2)}{2r^7}.$$

Ideal representative magnet.

If we attempt now to find μ and L, so that the two magnetic systems may be equivalent, we find different values for L for different positions of the external point. If, however, the magnet be symmetrical *about its axis*, so that $A_2=A_3$, then the expression for V reduces to

$$V=\frac{K\xi}{r^3}+\frac{3(A_1-A_2)\xi(2\xi^2-3\eta^2-3\zeta^2)}{2r^7}\quad .\ .\ .\quad(47),$$

we then get $2\mu L=K$, and $2\mu L^3=3(A_1-A_2)$, whence $L^2=3(A_1-A_2)/K$. In other words, in the case of a magnet which is symmetrical about its axis and also about an equatorial plane, we can represent the external action by means of a fixed ideal magnet, provided higher powers of the ratio of the greatest linear dimension of the magnet to the distance of the point considered than the fourth can be neglected. It is to be observed, however, that if $A_1<A_2$ the length of the ideal representative magnet will be imaginary.[6]

Series for potential energy.

A convergent series for the mutual potential energy of two magnets M and M′ may be obtained from the sextuple integral of mutual (19). Let the origin be a fixed point O in M, and let the coordinates of a fixed point O′ in M′ with reference to a set of axes fixed in O be $\xi,\ \eta,\ \zeta$; further, let $x,\ y,\ z$ and $x',\ y',\ z'$ be the coordinates of any elements dv and dv' in M and M′, the axes being in the former case the system already indicated, in the latter a parallel system through O′; then, if r denote $(\xi^2+\eta^2+\zeta^2)^{\frac{1}{2}}$, and $\delta_1,\ \delta_2,\ \delta_3$ stand for $\frac{d}{d\xi},\ \frac{d}{d\eta},\ \frac{d}{d\zeta}$, we have

$$W=-\int dv\int dv'(A\delta_1+B\delta_2+C\delta_3)(A'\delta_1+B'\delta_2+C'\delta_3)\left(\frac{1}{r}+\Sigma u_n\right),$$

where $$u_n=\frac{1}{n!}\left\{(x'-x)\delta_1+(y'-y)\delta_2+(z'-z)\delta_3\right\}^n\frac{1}{r}\,;$$

or

$$W=W_1+W_2+W_3+\quad .\ .\ .\ .\ .\ .\ .\ .\ .\ .\quad(48),$$

where $W_1,\ W_2,\ W_3$, are spherical harmonics in $\xi,\ \eta,\ \zeta$ of degrees $-2,\ -3,\ -4$, &c.

If we neglect all the terms except those of the first order, which amounts to supposing M and M′ infinitely small, we get

$$W=-KK'\left\{ll'\delta_1^2+\ .\ .\ .\ +(mn'+m'n)\delta_2\delta_3+\ .\ .\ .\right\}\frac{1}{r}\,.$$

If $\theta_1,\ \theta_2$ be the angles between the axes of M and M′ and the line

[1] Sir W. Thomson, *Reprint of Papers on Electricity and Magnetism*, p. 392.

[2] Vol. viii. p. 60.

[3] This fact is a further proof, if that were wanted, that the magnetization of a body cannot be determined from its external action.

[4] See Sir W. Thomson, *Reprint*, p. 368.

[5] This point is sometimes called the centre of the magnet, and the new axes of Y and Z its secondary axes. It should be observed, however, that this "centre" is not necessarily the middle point of the line joining the mass centres of the positive and negative magnetism. On this subject see a paper by Beltrami, "Sul Potenziale Magnetico," *Ann. d. Matem.*, 1882.

[6] *Cf.* Riecke in *Pogg. Ann.*, p. 149, 1873; and *Wied. Ann.*, p. 8, 1879.

from the centre of M to the centre of M′, and θ_{12} the angle between the axes, this reduces to

$$W=\frac{KK'}{r^3}(\cos\theta_{12}-3\cos\theta_1\cos\theta_2)\quad . \quad . \quad . \quad . \quad . \quad (49).$$

Action between two infinitely small magnets.

From this formula we can derive at once by differentiation the force of translation and the couple about the centre of M′, which represent the action of M upon it. An elegant synthesis of this action has been given for the most general case by Tait.[1] It will be sufficient to confine ourselves here to the case where the magnetic axes are in one plane. In this case $\theta_{12}=\theta_1-\theta_2$, and W becomes $KK'(\sin\theta_1\sin\theta_2-2\cos\theta_1\cos\theta_2)/r^3$. Denoting by X, Y, L the forces of translation parallel to $\overrightarrow{MM'}$ and perpendicular to MM′ (so as to decrease θ_1) and the couple tending to decrease θ_2, we have

$$\left.\begin{aligned}X&=-\frac{dW}{dr}=\frac{3KK'}{r^4}(\sin\theta_1\sin\theta_2-2\cos\theta_1\cos\theta_2)\\ Y&=\frac{dW}{rd\theta_1}+\frac{dW}{rd\theta_2}=\frac{3KK'}{r^4}\sin(\theta_1+\theta_2)\\ L&=\frac{dW}{d\theta_2}=\frac{KK'}{r^3}(\sin\theta_1\cos\theta_2+2\cos\theta_1\sin\theta_2)\end{aligned}\right\}\quad . \quad (50).$$

Force of translation ∝ (dist)$^{-4}$. Couple ∝ (dist)$^{-3}$.

One most important conclusion follows at once from these formulæ, viz., that the translatory forces vary inversely as the fourth power of the distance, whereas the directive couple varies only inversely as the third power. Hence the couple may be quite sensible at distances for which the force of translation is inappreciably small. These conclusions apply of course equally to any pair of magnetized bodies, provided the distance between them be sufficiently great as compared with their linear dimensions. This, applied to the case of the earth, at once explains the phenomena that puzzled Norman and the earlier magnetic philosophers so greatly. The following particular cases are important (fig. 25):—

(A) $\theta_1=\theta_2=0,\ X=-\frac{6KK'}{r^4},\ Y=0,\ L=0.$

(B) $\theta_1=\theta_2=\frac{\pi}{2},\ X=\frac{3KK'}{r^4},\ Y=0,\ L=0.$

(C) $\theta_1=0,\ \theta_2=\frac{\pi}{2},\ X=0,\ Y=\frac{3KK'}{r^4},\ L=\frac{2KK'}{r^3}.$

(D) $\theta_1=\frac{\pi}{2},\ \theta_2=0,\ X=0,\ Y=\frac{3KK'}{r^4},\ L=\frac{KK'}{r^3}.$

Deflecting magnet "end on" and "broadside on."

The last two cases are especially important: the position of the deflecting magnet in (C) is described as "end on" (erster Hauptlage), in (D) as "broadside on" (zweiter Hauptlage); it will be noticed that the couple in the former case is double that in the latter.

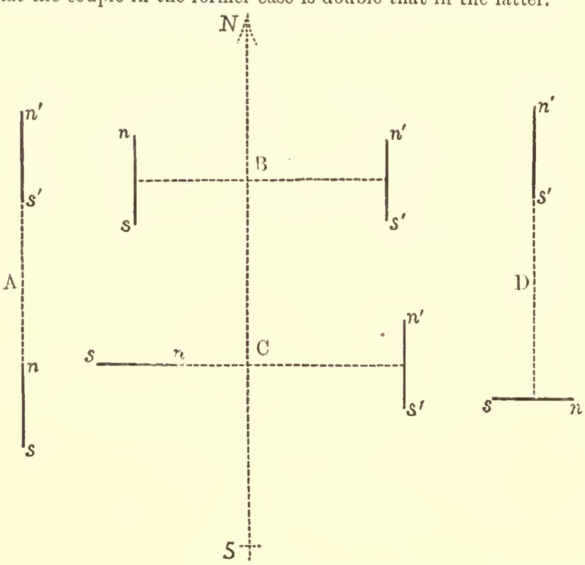

Fig. 25.

Closer approximation for deflecting couple end on and broadside on.

If the terms of the second and third order be taken into account, and the magnet $n's'$ be deflected through an angle ϕ from its original position by a deflecting magnet (I.) originally end on and (II.) originally broadside on, we get for the couples

$$\left.\begin{aligned}&\text{I.}\quad \cos\phi\left[\frac{2KK'}{r^3}-\frac{T_1}{r^4}+\frac{T_2}{r^5}+\ .\ .\ .\ \right]\\ &\text{II.}\quad \cos\phi\left[\frac{KK'}{r^3}+\frac{T'_1}{r^4}+\frac{T'_2}{r^5}+\ .\ .\ .\ \right]\end{aligned}\right\}\quad . \quad . \quad (51),$$

where T_1 and T'_1 are odd functions of the relative position of M and M′, but T_2 and T'_2 are even. In the case where M and M′ are symmetrical about three orthogonal planes, O and O′ being the centres of symmetry, T_1 and T'_1 vanish, and the writer has obtained for the values of T_2 and T'_2

$$\left.\begin{aligned}T_2&=-6\{K(3A'_1-4A'_2+A'_3)-K'(2A_1-A_2-A_3)\}\\ T'_2&=-\tfrac{3}{2}\{K(12A'_1-11A'_2-A'_3)-K'(3A_1-4A_2+A_3)\}\end{aligned}\right\}\quad (52),$$

where A_1, A_2, &c., have the meanings above assigned in (45).[2]

Gauss's theory of terrestrial magnetism.

Sphere Magnetized in any Manner.—This is the most interesting of all the cases that fall under the present section, both from its being amenable to mathematical treatment and on account of its historical interest. It was first discussed in the beautiful memoir, entitled *Allgemeine Theorie des Erdmagnetismus*,[3] in which Gauss laid the foundation of the rational theory of terrestrial magnetism. The following is a brief account of the theory, which has not been greatly added to since he left it.

Let X, Y, Z be the components of the earth's resultant magnetic force at any point on its surface, in the directions of geographical north, geographical west, and vertically upwards respectively. The force is completely known when these are given, since it depends on three elements only. If H, δ, ι have the meanings formerly assigned (p. 220, 221, 227), we have of course

$$H=\sqrt{X^2+Y^2},\ \tan\delta=Y/X,\ \tan\iota=Z/\sqrt{X^2+Y^2}.$$

Again, if V be the magnetic potential of the earth, l the latitude, and λ the longitude of any point on its surface, then, supposing the earth to be a sphere of radius a, we have

$$X=-\frac{1}{a}\frac{dV}{dl},\ Y=-\frac{1}{a\cos l}\frac{dV}{d\lambda},\ Z=-\frac{dV}{dr},\quad . \quad (53),$$

r denoting the distance of any point from the centre of the earth. When V is known, therefore, the force is completely determined.

If now we suppose all the magnetized matter (or its equivalent—say, electric currents) to be within the earth, it follows, from the theory of spherical harmonics, that we can write down a convergent series for its potential at all external points, when the potential at every point of its surface is given.[4] In fact, if the expansion of this surface potential in terms of surface harmonics be

$$S_1+S_2+\ .\ .\ .\ +S_i+\ .\ .\ .\ ,$$

we have for all external points

$$V=S_1\left(\frac{a}{r}\right)^2+S_2\left(\frac{a}{r}\right)^3+\ .\ .\ .\ +S_i\left(\frac{a}{r}\right)^{i+1}+\ .\ .\ .\quad (54).^{5}$$

The number of terms of this series that must be retained in order to obtain a sufficiently accurate representation of the phenomena will of course depend on circumstances, and can only be ascertained by trial. $S_1, S_2, \ldots S_i$ are functions of known form, containing respectively 3, 5, . . . $2i+1$ constants; hence, if terms beyond the i^{th} order may be neglected, the expression for V will contain i^2+2i arbitrary constants. These must be determined by observation, and then the magnetic action at all points on the surface or outside the earth is known irrespective of the internal distribution of the magnetic causes.

Data sufficient to determine the earth's magnetic action.

If we look at the matter from the general point of view that V is determined when its surface value is known, we have the following propositions.

I. V is determined when the vertical force is known at every point of the earth's surface.

For, let the surface value of Z be expanded in a series of surface harmonics of which the i^{th} is Z_i; then, equating this to the i^{th} harmonic in the surface value of $Z=-dV/dr$ derived from (54), we have $(i+1)S_i=aZ_i$, which determines S_i. Thus the proposition is proved.

[1] *Quart. Jour. Math.*, 1860; and *Quaternions*, § 414.

[2] *Cf.* Riecke, *l.c.*

[3] *Res. d. Mag. Vereins*, 1838.

[4] See Thomson and Tait, vol. i. chap. 1, App. A and B.

[5] The term S_0 of course vanishes, since the sum of the positive and negative magnetism within the earth is zero.

II. The surface value of V, and hence its general value for external points, is determined if the northward component of the magnetic force be known at every point of the earth's surface.

This follows at once from the fact that the difference of the values of V at any two places is the line integral of the magnetic force along *any* line joining them; thus, if V_0 be the value of V at the geographical north pole, we have

$$V = -a\int_{\frac{\pi}{2}}^{l} Xdl + V_0 \quad . \quad . \quad . \quad . \quad . \quad . \quad (55).$$

But the constant V_0 does not affect the general value of V; hence the proposition is established.

III. The same conclusion follows if the westward horizontal component be known all over the earth's surface and the northward component along any one meridian.

In fact, if V be the potential at any place whose latitude is l and longitude λ, then

$$V = -a\int_{\frac{\pi}{2}}^{l} Xdl - a\int_{\lambda_0}^{\lambda} Y \cos l d\lambda + V_0 \,,$$

the first integration being performed along the given meridian, the second along the parallel of latitude corresponding to the place.

From I., II., and III. we have the remarkable conclusion that, if the vertical component be given all over the earth, or the northward component, or the westward component and the northward along one parallel, then in each case the other two elements are determined.

Approximation by means of the line integral of magnetic force.

Gauss gives another interesting application of the line integral of magnetic force. If this integral be taken all round any closed curve or polygon, the result is zero. Let us express this for any geodesic triangle ABC, at whose vertices the horizontal force has the values H_1, H_2, H_3. If the inclinations of H to $\overrightarrow{BC}$ at B and C be α and α', to $\overrightarrow{CA}$ at C and A β and β', to $\overrightarrow{AB}$ at A and B γ and γ', then, if the arcs BC, CA, AB be not too long, we may replace the component along BC at every point by the average of its values at B and C, and so on. We thus get

$$\tfrac{1}{2}BC\,(H_2\cos\alpha + H_3\cos\alpha') + \tfrac{1}{2}CA\,(H_3\cos\beta + H_1\cos\beta') + \tfrac{1}{2}AB\,(H_1\cos\gamma + H_2\cos\gamma') = 0 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (56).$$

If we suppose the values of H at B and C to be known, and the values of the declination to be known at all three places, the above equation determines the value of H at A. Calculating in this way from observed values at Göttingen, Milan, and Paris, Gauss found for H at Paris 0·51696, the observed value being 0·51804.

External and internal causes of earth's magnetic action.

It has been supposed hitherto that the magnetic causes are entirely internal to the earth. The foregoing theory enables us to test how far this assumption is correct.

If we suppose that there are external causes, then the potential at internal points due to these will be

$$T_0 + T_1\frac{r}{a} + T_2\left(\frac{r}{a}\right)^2 + \; . \; . \; . \; T_i\left(\frac{r}{a}\right)^i + \; . \; . \; . \; ,$$

$T_0, T_1, T_2 \ldots T_i$ being the different harmonics in the surface value of the part of the potential due to external causes. Suppose now the whole vertical force deduced from observation for all parts of the earth's surface, and expanded in a series of surface harmonics, the i^{th} of which is Z_i; then, since this is the sum of the i^{th} harmonics in the parts due to internal and to external causes, we have

$$-(i+1)S_i + iT_i = aZ_i \,. \quad . \quad . \quad . \quad . \quad . \quad (57).$$

Further, suppose the surface value of V determined from observations of horizontal force, and let the i^{th} harmonic in it be V_i, then we have

$$S_i + T_i = V_i \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (58).$$

From equations (57) and (58) we can determine S_i and T_i, and thus settle how much is due to external and how much to internal causes. It does not appear from observation that any sensible part of the *mean* value of V arises from causes external to the earth.

Gaussian distribution for a sphere.

We have seen already that the action of any body can be represented at external points by an ideal layer of positive and negative magnetism. Gauss finds for the surface density of the layer in the case of a spherical body like the earth, the expression $(V/a - 2Z)/4\pi$, which may be deduced immediately from the formulæ already given.

If we draw a series of equipotential surfaces corresponding to small equidifferent values of V, these will cut the earth's surface in a series of equipotential lines, which are called the "magnetic parallels." These lines obviously have the following properties. The horizontal force is everywhere perpendicular to them, and is at any point inversely proportional to the distance between two consecutive lines there. So that, if these lines were drawn upon a terrestrial globe, their crowding would indicate increase of horizontal force. The lines of horizontal force, or "magnetic meridians," the tangent at every point of which is parallel to the horizontal component, are everywhere orthogonal to the magnetic parallels, and their positive direction is from parallels of greater potential to parallels of less potential. If, as has been tacitly assumed hitherto in accordance with the results of observation, the potential on the earth's surface have but one maximum and one minimum, then the parallels will be closed curves expanding successively from the maximum point and then closing again round the minimum point, and the magnetic meridians will all run between these two points. It is clear that at each of these points the equipotential surface and the earth's surface touch; at the minimum point the line of total resultant force will pass *to* the earth, at the maximum point *from* it; at the former, therefore, the *north* end of a freely suspended needle will dip vertically downwards, at the latter the *south* end will do the same. This is the simplest possible case for a magnetized sphere. It is easy to see that, if we define a north pole[1] as a point on the earth's surface at which the horizontal intensity vanishes, and the dip is 90°, there might be more than one such point. Consider the series of equipotential surfaces 1, 2, 3, 4, 5, 6 in fig. 26,[2] each of which has two eminences with a depression

Magnetic parallels and meridians.

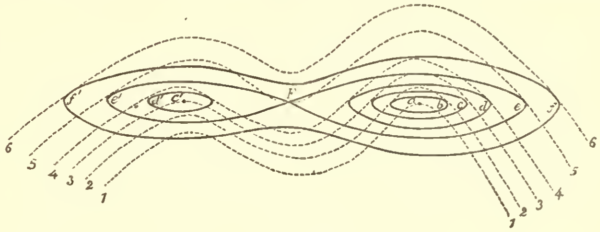

Fig. 26.

between them. The lines a, b, c, d, e, f are the sections of these by the earth's surface. 1 just touches the surface in a; and, if the potential increase in the order in which the surfaces are numbered, a will be a north pole. The section by 2 is the single oval b. 3 touches the surface in c', which is clearly another north pole, and also meets the surface in a single oval c equipotential with c'. The section by 4 is the double oval d, d'. The depression on 5 touches the surface at F, and meets it in a figure of 8, e, e', on which F is the double point. F is therefore yet another north pole according to our definition; it differs, however, from an ordinary north pole in one important respect; for the law that the north end of the compass points from parallel of greater to parallel of less potential shows at once that near F and *inside* the 8-shaped parallel the south end will point to F, whereas at a neighbouring point *outside* the north end will point to F. Such a point is called a false north pole, and we see that the existence of two true north poles necessitates the existence of a false north pole; and in general it may be established[3] that,

False poles.

[1] Of course pole as thus defined has nothing to do with pole in any of the former senses, *e.g.*, the line joining its N and S poles is not parallel to the earth's magnetic axis.

[2] Gauss, *l.c.*, § 12. *Cf.* Mascart and Joubert, *Leçons sur l'Électricité et sur le Magnétisme*, tom. i. § 436, 1882.

[3] See Gauss, *All. Theorie des Erdmagnetismus*, § 12; Maxwell, vol. i. § 113, vol. ii. § 468.

however many poles of the same kind there may be, true and false, the whole number must be odd. This of course disposes of the notion formerly held by some physicists that the earth actually had *two* north poles. As already indicated, Gauss concluded from his reduction of the magnetic observations at his disposal that, apart from purely local disturbances, the earth has, as a matter of fact, only one north and one south pole.

Local disturbances of magnetic parallels.

The effect of a deposit of magnetic ore, or other cause of the kind, might of course produce a disturbance, within a limited area, of the equipotential lines. It may assist the practical magnetist to indicate the nature of this disturbance in a particular case. Let us suppose that a magnet is placed some distance underground, vertical, with its north pole uppermost. Then, if its moment be sufficiently great, the equipotential lines will be as in fig. 27.[1] The upper side of the figure is supposed to be magnetic north, and it is supposed that the undisturbed

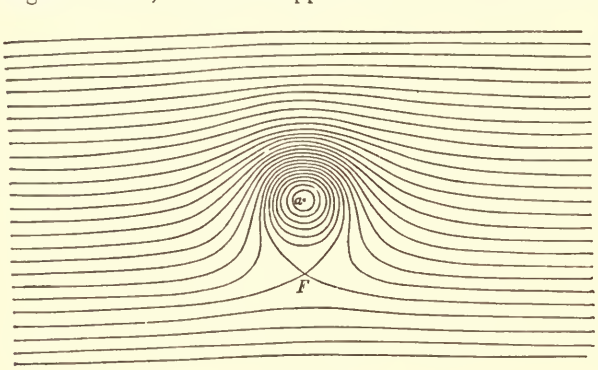

Fig. 27.

parallels would be straight lines running magnetic east and west, which is sufficiently near the truth in most cases. It should be observed that fig. 27 is in reality a transformation of figure 26, one of the poles being projected to infinity. The reader should notice that the double point F, due south of the point *a* vertically over the disturbing magnet, is a point of equilibrium at which the horizontal components of the forces of the earth and the magnet destroy each other; it will be a false pole, south or north according as the magnet or the earth prevails.

Experimental Foundation for the Law of the Inverse Square.

Difficulties of the question as to the elementary law.

From what has already been laid down, it will be seen that the determination of the elementary law of magnetic action is a very complex problem. The action between two magnets depends, not only on their distance apart, but also on their relative angular position. Then we have to distinguish force of translation, which varies inversely as the fourth power of the distance, and directive couple, which varies inversely as the third power. It must also be remembered that the elementary law results in part from an hypothesis as to the nature and distribution of the cause of the magnetic action, for, until some such hypothesis is made, no clear conception is possible of what is to be understood by elementary action. Lastly, we have the disturbance which arises from magnetic induction, the consequence of which is that magnetically speaking two magnets are not the same at different distances apart. When all these circumstances are considered, it is not surprising to find considerable uncertainty and difference of opinion among the earlier magnetic philosophers. The truth is that the law as now established owes quite as much to the development of magnetic theory as to the work of magnetic experimenters.

Huygens, Hooke, Newton.

The question attracted the notice of Huygens and Hooke, but Newton seems to have been one of the first who propounded any law on the subject. He says (*Principia*, lib. iii. prop. 6, cor. 5) that some rough experiments had led him to the conclusion that the magnetic force (vis magnetica) decreases according to the law of the inverse cube of the distance. No account of the experiments is extant, and it does not appear what he means exactly by vis magnetica. If the directive couple is meant, and the action of the *entire* magnet is intended, then, as we have seen, this is in agreement with modern theory. In a remarkable note in the annotated edition of the *Principia* by Le Sueur and Jacquier (assisted by Calandrini?) (1742) on the passage in question, a series of deflexion experiments are described, and an accurate discussion is given, from which results the law of the inverse cube for the deflecting couple. Hawksbee[2] made experiments with a view to determine the law of magnetic action, in which a deflecting magnet was moved at various distances round a compass, and the corresponding deflexions noted. A few years later Brook Taylor[3] and the same experimenter made a series of observations in which the "end on" method of deflexion still in use was adopted. But in neither case was any definite result arrived at. A similar uncertainty appeared in the experiments of Whiston, who indicates the inverse $\frac{3}{2}$th power of the distance as the law of decrease. Musschenbroek's experiments, which were extensive, also led to no final result. He used the method of Hooke, in which the attraction of a vertical bar magnet upon another suspended from one arm of a delicate balance is balanced by weights attached to the other arm. From some of his experiments he deduces as low a power as the inverse 1st, from others the $\frac{3}{2}$th, and so on; but no attempt is made to analyse the phenomena. Michell, in his treatise on artificial magnets (1750), however, deduces the law of the inverse square from Musschenbroek's results. Although Æpinus does not arrive at any definite result as to the elementary law, there can be no doubt that his *Tentamen Theoriæ Electricitatis et Magnetismi* (1759) contributed powerfully towards the solution of the question. Tobias Mayer seems to have been the first to publish the law of the inverse square as the actual result of an experimental investigation. His paper was read before the Royal Society of Göttingen, and was referred to in the *Göttinger Gelehrter Anzeiger* for 1760, but never fully published; it is best known from the criticism of Æpinus, "Examen Theoriæ Magneticæ a Tob. Mayero propositæ" (*Nov. Comm. Acad. Petrop.*, 1768).[4] The most important of the earlier contributions was undoubtedly that of Lambert.[5] He seems to have been the first to analyse the physical circumstances of the problem in a thorough manner, and to point out the various elements of disturbance to be provided for. We regret that we are unable to devote space to an exhaustive account of his memoirs,[6] which are most instructive reading even now. He showed that the effect of an oblique magnetic force on the needle varies as the sine of the inclination; and, making allowances for this, he deduced the law of the inverse square from deflexion experiments made at different distances. He also described the method of oscillations, but found difficulties in its practical application. It is upon his theoretical work, however, rather than upon his experiments, that his claim to be remembered rests. About the same time as Lambert,

Dalla Bella and Robison. we have Dalla Bella[1] and Robison,[2] the well-known professor of natural philosophy in the university of Edinburgh, working at the same subject. The former used the method of Hooke and Musschenbroek, but discussed more carefully the exact nature of the resultant action. His results indicated the law of the inverse square. Robison used both the method of deflexion and the method of oscillation, the peculiarity in his apparatus being the movable magnet, which was composed of two magnetized spheres connected by a slender rod, and suspended either in the field of the earth alone, or at different distances from a large magnet. He made several independent investigations, and seems to have arrived in each case at the law of the inverse square as his final result.

Coulomb. The researches of Coulomb,[3] from which many date the commencement of the modern theory, present many features of great interest. He used the improved form of Michell's torsion balance, which had served him so well in his electrical experiments. In order to realize as nearly as possible the ideal case of a linear solenoid, whose action can be represented by positive and negative magnetism concentrated at its ends, he worked with magnets made of thin steel wire magnetized longitudinally. The circumstances of the experiment are thus considerably simplified, for the acting magnet may be so arranged that the action of one of the poles may be neglected, or, failing that, the action of both can be easily calculated.

In one of his experiments he took a magnetized steel wire 25 inches long, and $1\frac{1}{3}$ lines thick, and placed it vertically in the magnetic meridian before a horizontal magnetic needle some 3 inches long, delicately suspended by a silk fibre. The rod was raised and lowered at a given distance from the needle until the attraction on the near pole of the needle, as tested by the rapidity of the vibrations, was a maximum; it was then found that the lower end of the bar was about 1 inch below the needle. Again, the rod being placed horizontal and perpendicular to the magnetic meridian on a level with the needle, it was displaced until the needle returned to the magnetic meridian; it was then found that the needle was directed to a point about 1 inch from the end of the bar. Both these experiments thus indicate that the magnetism at one end may be supposed concentrated at a point about an inch from the end of the bar. It is clear that, in these experiments, provided the rod is sufficiently long or the distance between it and the needle not too great, the action of the distant pole may be neglected, for the double reason that the pole is more distant and that the force exerted by it is nearly perpendicular to the direction in which it can be effective. Making this assumption, Coulomb observed the number of vibrations, when the vertical rod was absent, and when it was placed at various distances.

The forces thence deduced were found to vary very nearly as the inverse square of the distance. Statical experiments with the torsion balance led to a like result.

Later researches. Hansteen. Later than Coulomb we have the experiments of Bidone,[4] Hansteen,[5] Steinhauser,[6] and Scoresby.[7] By far the most important among these is Hansteen, whose methods were a great step towards the more complete treatment finally adopted by Gauss. He uses Taylor's "end on" method of deflexion, and also the method of Hooke and Musschenbroek. The acting magnet was a bar magnet, the action of which he represents by a distribution of positive and negative magnetism on its two halves whose density at a distance x from the centre is λx^r. The force at distance D due to an element $d\mu$ of positive magnetism he assumes to be $d\mu/D^n$. He finds that in all his experiments the value $n=2$ best represents the results obtained; but that various values of r may be adopted with almost equal advantage; he inclines, however, to the value $r=2$.

Gauss. In his classical memoir on the absolute measurement of the earth's magnetic force, Gauss took up the question in the most general manner yet attempted. Assuming that the force due to an element of positive magnetism varies as the inverse nth power of the distance, he showed that, when the distance between the magnets is sufficiently great compared with the greatest linear dimensions of either (more than four times as great in his own experiments), the deflexions ϕ and ϕ' for the "end on" and "broadside on" positions of the deflecting magnet are given by

$$\tan\phi = L_1 r^{-(n+1)} + L_3 r^{-(n+2)} + \text{\&c.},$$
$$\tan\phi' = L_1' r^{-(n+1)} + L_3' r^{-(n+2)} + \text{\&c.};$$

where $L_1/L'_1 = n$. He made a series of deflexion experiments, and found that his results could be represented with sufficient accuracy by the formulæ[8]

$$\tan\phi = 0{\cdot}086870 r^{-3} - 0{\cdot}002185 r^{-5},$$
$$\tan\phi' = 0{\cdot}043435 r^{-3} + 0{\cdot}002449 r^{-5}.$$

The following table shows the closeness of the agreement between theory and experiment (r is measured in metres; Φ and Φ' denote observed and ϕ and ϕ' calculated values):—

r	Φ	$\Phi-\phi$	Φ'	$\Phi'-\phi'$
	° ′ ″	″	° ′ ″	″
1·1			1 57 24·8	+2·8
1·2			1 29 40·5	−6·0
1·3	2 13 51·2	+ 0·8	1 10 19·3	+6·0

1·6	1 12 7·6	− 3·3	0 37 12·2	−3·2
1·7	1 0 9·9	− 5·0	0 30 57·9	−1·2
1·8	0 50 52·5	+ 4·2	0 25 59·5	−3·4
1·9	0 43 21·8	+ 7·8	0 22 9·2	+2·6
2·0	0 37 16·2	+10·6	0 19 1·6	+5·9
2·1	0 32 4·6	+ 0·9	0 16 24·7	+4·9
2·5	0 18 51·9	−10·2	0 9 36·1	−2·5
3·0	0 11 0·7	− 1·1	0 5 33·7	−0·2
3·5	0 6 56·9	− 0·2	0 3 28·9	−1·0
4·0	0 4 35·9	− 3·7	0 2 22·2	+1·7

We have here a double proof of the law of the inverse square,—first, in the fact that $\tan\phi$ and $\tan\phi'$ can be expressed so accurately by two terms of a series, the first of which contains r^{-3}; second, in the fact that the coefficient of the first term in $\tan\phi$ is exactly double that in $\tan\phi'$. These researches of Gauss are remarkable, not only for the great generality of the theory, but also for the novelty of the experimental method, and the exceeding accuracy and refinement of the observations. The law of the inverse square has in fact been regarded as settled ever since they were made. They are important from another point of view, to which we shall return presently.

Magnetic Measurements, Relative and Absolute.

Chief magnetic measurements. he mos. important magnetic determinations that have to be made are the direction of the axis of a magnet relatively to its mass, the magnetic moment of a magnet, the direction of a magnetic field, and the strength of a magnetic field, or its component in any given direction. In most of these cases the measurement may be either relative or absolute. For example, we may determine the moment of a magnet either relatively, in terms of the moment of some other magnet arbitrarily chosen, or absolutely, in terms of the fundamental units of space, mass, and time. The complete theory of measurements of the latter kind is due to Gauss, and the carrying of them into practice to him in conjunction with Weber and the *Magnetischer Verein*, of which these two German philosophers were the leading spirits. We shall discuss the

[8] *Intensitas Vis Magneticæ*, &c., § 21, 1833.

matter here only in so far as it concerns the work of a physical laboratory, the rest belonging more properly to the subject of Terrestrial Magnetism (see METEOROLOGY).

Determination of magnetic axis, and of the magnetic declination.

Axial Direction and Magnetic Declination.—The magnet is suspended, usually by means of one or more fibres of unspun silk, so as to be free to move about a vertical axis. We shall suppose, for simplicity, that the magnetic axis is in a horizontal plane. If this is not so, instead of determining the axial direction, we determine a vertical plane through it. In order to obtain a fixed line of reference in the magnet, two marks may be made on it as nearly in the direction of the axis as can be guessed to begin with ; this arrangement is used with dipping needles and also for horizontal needles when no great accuracy is required. For declination needles two contrivances of greater refinement are used.

Mirror method.

1. A mirror is rigidly attached to the magnet, so that the normal to its surface is nearly parallel to the magnetic axis. The image of a fixed horizontal scale in this mirror is observed by means of a fixed telescope, and the angular motion of the magnet deduced from the motion of the scale divisions over the wires of the telescope. This is called the mirror method.[1]

Collimator magnet.

2. A more compact arrangement is to attach to the magnet a small photographic scale and a lens, the former being placed at the principal focus of the latter, so that the line joining the middle division of the scale to the optical centre of the lens is nearly parallel to the axis of the magnet. The scale is viewed through the lens by means of a fixed telescope, and it is clear that the line just mentioned gives us a fixed direction in the magnet, and that the motion of the magnet can be followed by observing the apparent motion of the scale across the wires of the telescope. This may be called the collimator method.[2]

Unifilar magnetometer.

The apparatus usually employed in the United Kingdom for observing the magnetic declination,[3] and also for other absolute magnetic measurements, is the portable unifilar magnetometer, the upper part of which is shown in figs. 28, 29. The lower part consists simply of a tripod stand supporting three V-shaped groves, into which the points of the levelling screws attached to the fixed limb of the instrument are set. In making an observation of the declination the instrument is arranged as in fig. 28. The declination collimator magnet is suspended in the box A (the sides of which are removed to allow the interior to be seen) by means of the suspension fibre D, attached to the torsion head PH. The scale of the magnet is observed through the small telescope QBG. The first step is to remove the torsion as far as possible from the suspension fibre by hanging to it a brass plummet E of the same weight as the declination magnet. After this weight has come to rest, it is replaced by the declination magnet, so that the latter shall rest as nearly as possible in the magnetic meridian without introducing torsion of the fibre. The movable limb is now turned till some division of the magnet scale is on the cross wires of the telescope. It is then clamped. The magnet is now inverted, and the number of the scale division on the wires again read. The mean of these readings gives the point of the scale the line from which to the centre of the collimating lens is parallel to the axis of the magnet. This point of the scale (axial point) will remain the same so long as the magnetism of the magnet does not alter, or the adjustment of the scale and collimating lens is not interfered with. The tangent screw is now worked until the cross wires of the telescope are on the axial point of the scale. The verniers of the limb are then read. The next step is to observe the azimuth of the sun or of some other heavenly body, by means of which we can refer the azimuth of the magnetic meridian to the true north. For this purpose the instrument is provided with a small transit mirror NO, which has a motion in altitude so as to bring any object into the field of the telescope. To use it, the limb is unclamped, and it and the mirror moved until the sun or star comes into the field of the telescope ; the limb is then clamped and the time noted at which the heavenly body passes the intersection of the cross wires. The verniers are again read. The differences of the readings, added to the azimuth of the heavenly body found by means of the time from the *Nautical Almanac*, gives the declination at the time and place of observation.

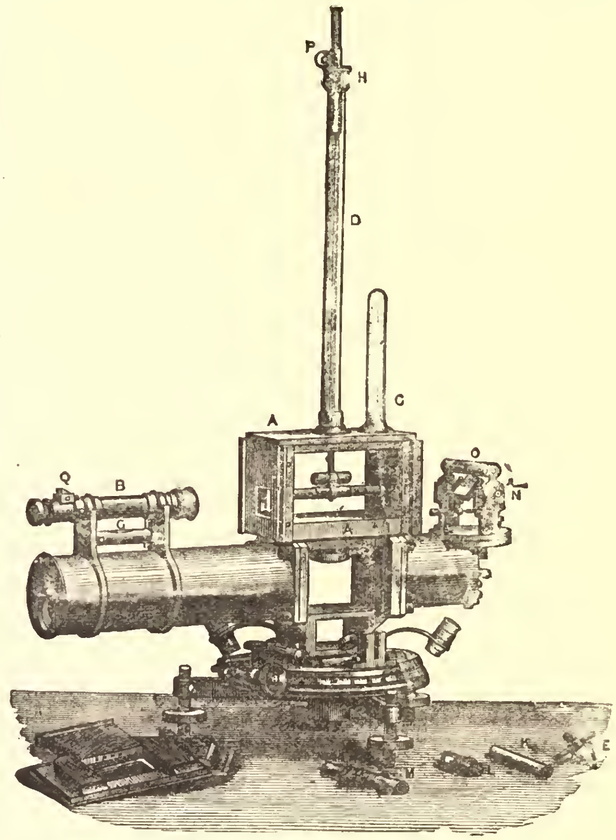

FIG. 28.—Unifilar Magnetometer, arranged to indicate declination.

There are several causes of error to be guarded against. (1) Torsion is reduced within as small limits as possible to begin with, and if there is reason to suspect any residual error we may test the apparatus by turning the torsion head of the suspension tube first 90° one way and then 90° the other. If the deflexion of the magnet is exactly the same and oppositely directed in the two cases, then we may conclude that the torsion is zero in the azimuth of equilibrium. If not, then we may turn the torsion head so as to reduce the error still further; or we may calculate its amount (assuming torsion to be proportional to twist) from the two observations, and allow for it. (2) If the axis of the magnet is not very nearly parallel to the line of collimation of the telescope to begin with, and consequently the two scale readings far apart, an error may arise[4] from the vertical axis of suspension not being exactly reversed by the inversion. This error is reduced by repeating the observation, after adjusting the axis of the magnet and telescope so as to be more nearly parallel. (3) If mean declination for a given day be desired, correction must be made for the diurnal variation, and under certain circumstances this variation may even produce disturbances in the course of a single observation.

Magnetic moment and horizontal intensity.

Magnetic Moment, Horizontal Intensity of the Earth's Force.—If merely relative measurements of the magnetic moment K of a given magnet, or of the horizontal intensity H of the earth's force, are desired, there are two methods of obtaining them. The first is the method of vibrations. Having found the moment of inertia A of the magnet M about its vertical axis of suspension, and the

[1] The mirror method was first suggested by Poggendorff (*Pogg. Ann.*, vii., 1826). It was carried out in practice by Gauss.

[2] There seems to be some doubt to whom the collimator method is due. Airy, Lloyd, Lamont, and Weber all did something for it. See Lamont, *Handb. d. Magnetismus*, p. 154.

[3] Want of space compels us to omit all but the leading points. Readers in search of full practical details must be referred to *The Admiralty Manual of Scientific Enquiry*, pp. 84 *sq.*; Maxwell, *Electricity and Magnetism*, §§ 449 *sq.* ; Lamont, *Handbuch der Magnetismus*, and *Erd-Magnetismus*, where references to all the authorities up to his time will be found. They should also study the classical memoirs of Gauss to be found in the fifth volume of his collected works.

[4] See Swan, *Trans. Roy. Soc. Edin.*, vol. xxi., 1855.

time T of its vibration under the earth's force, we obtain the product $KH, = p$, say. Secondly, by the method of deflexion, of which two varieties, tangent deflexion and sine deflexion, are in use, the value of the quotient $K/H, = q$, say, is found. In this method K is used as the *deflecting* magnet, and the moment K′ of the *deflected* magnet does not appear in the result.[1] It is obvious that, if we know the value of H, or may assume it constant, either of these methods will enable us to express the moment of any magnet in terms of that of another arbitrarily chosen as unit; and, reciprocally, if we operate with a magnet of known or of constant moment, we can determine the values of H at different times and places in terms of its value at an arbitrarily chosen time and place.

By combining two observations, in one of which a magnet K is the vibrating and in the other the deflecting magnet, we can obtain both K and H in absolute measure, for we have two equations $KH = p$, and $K/H = q$, which give

$$K = \sqrt{pq}\,, \quad \text{and } H = \sqrt{p/q}\,.$$

Unifilar magnetometer: vibration experiments.

Vibration Experiments.—If θ be the angle between the axis of the magnet and H at time t, γ the angle between the axis and H in the position of no torsion, τKH the coefficient of torsion, then the equation of motion of the magnet, when the arc of oscillation is very small, may be written

$$A\ddot{\theta} + KH\theta + \tau KH(\theta - \gamma) = 0 \quad . \quad . \quad . \quad . \quad . \quad (59).$$

This gives for the period of a complete vibration

$$T^2 = 4\pi^2 A/KH(1+\tau) \quad . \quad . \quad . \quad . \quad . \quad . \quad (60).$$

The observations are made with the magnetometer arranged as for the declination experiment. The swinging magnet is brought to rest, and the circle so clamped that the axial point of the magnet scale is on the cross wire of the telescope; the magnet is then slightly disturbed so as to oscillate through a small arc (16′ or so). The time of vibration is found first roughly, by taking the time of a single vibration, then more accurately by counting a large number of vibrations and timing the end of the last as accurately as possible. τ is found by observing the deflexion θ' and θ'' caused by turning the torsion head through an angle β in one direction and then through an angle β in the opposite direction; we thus get from equation (59)

$$KH\theta' + \tau KH(\theta' - \gamma - \beta) = 0\,,$$
$$KH\theta'' + \tau KH(\theta'' - \gamma + \beta) = 0\,;$$

and $\tau = (\theta' - \theta'')/(2\beta - \theta' + \theta'')$. From the same equation we may also determine γ when necessary.

The most troublesome part of the whole process still remains, viz., the determination of A. This is effected by attaching to the magnet a body whose moment of inertia B can be calculated from its dimensions. For this purpose Gauss fixed a cross bar of wood to the magnet, and attached to it at known equal distances from the axis of suspension two cylindrical weights of known mass and dimension. Sometimes a cylinder of gun metal is slung below the magnet by means of two loops. Perhaps the best method is to use a ring of gun metal attached to the magnet so that its plane is horizontal and its centre as nearly as possible in the line of suspension. The new time of vibration being T_1, and the new coefficient of torsion (if different) τ', we have the new equation

$$T_1^2 = 4\pi^2(A+B)/KH(1+\tau')\,.$$

From this and (60) we get

$$A = B\Big/\left(\frac{1+\tau}{1+\tau'}\cdot\frac{T_1^2}{T^2} - 1\right).$$

[1] This important fact was first noticed by Lambert.

There are several corrections which, although in general negligible, may sometimes require to be considered. (1) H may vary so much during the experiment as to cause a sensible error; (2) if the arc of vibration be too large, it may be necessary to apply the reduction to infinitely small arcs; (3) if the amplitude of the vibrations decrease too rapidly, account must be taken of the resistance to the motion arising from the viscosity of the air, &c.;[2] (4) a correction has to be made for the alteration of the moment of the magnet by the earth's induction,[3] and (5) a temperature correction for the magnetic moment and the moment of inertia.

Deflexion experiments with unifilar magnetometer.

Deflexion Experiments.—In Gauss's arrangement the deflecting magnet was placed in an east-west direction, *i.e.*, end on to the original position of the deflected magnet. The equation of equilibrium in this case is [see equation (51)]

$$K'H(1+\tau)\sin\theta = \cos\theta\left(\frac{2KK'}{r^3} - \frac{T_1}{r^4} + \frac{T_2}{r^5} + \ . \ . \ . \right)$$

or

$$r^3\frac{H(1+\tau)}{2K}\tan\theta = 1 - \frac{P_1}{r} + \frac{P_2}{r^2} + \ . \ . \ . \ . \ . \ . \ . \quad (61).$$

where $P_1 = T_1/2K'K$, $P_2 = T_2/2K'K$, &c.

In the method of sines the deflecting magnet is turned until it is perpendicular to the axis of the deflected magnet in its final position of equilibrium; the equation of equilibrium in this case is

$$\frac{r^3 H}{2K}\sin\theta = 1 - \frac{P_1}{r} + \frac{P_2}{r^2} + \&c. \quad . \quad . \quad . \quad . \quad . \quad (62).$$

The advantage of the method of tangents is that the moment of the deflector is not affected inductively by the earth's force. In the method of sines a correction has on this account to be made; but, on the other hand, there is no torsion, and, from the symmetry of the position of the two magnets, the approximate formulæ have a more exact application.

The new pattern of the unifilar magnetometer is adapted for the method of sines. The instrument arranged as in fig. 29 is first carefully levelled, and fitted with the graduated cross bar D, which is so set in its sockets as to be perpendicular to the line of collimation of the telescope A. The box is opened, and the torsion removed from the suspending fibre by means of a plummet as already explained. The deflected magnet is then suspended so as to be at the same height as the deflecting magnet when the latter is placed in its carriage on the cross bar. The sides of the box are now closed, and the circle of the instrument turned until the middle division of the scale B, seen by reflexion from a mirror attached to the deflected magnet, is on the cross wires of the telescope A; the circle is then clamped, and the verniers read. The deflecting magnet K (the same as that used in the vibration experiments) is next placed in its carriage L on the cross bar at a distance r_1 (30 cm. or so) east; the circle is then turned until the middle division of the scale is again on the cross wires; the verniers are read once more. The difference between the two readings being θ_1, we have

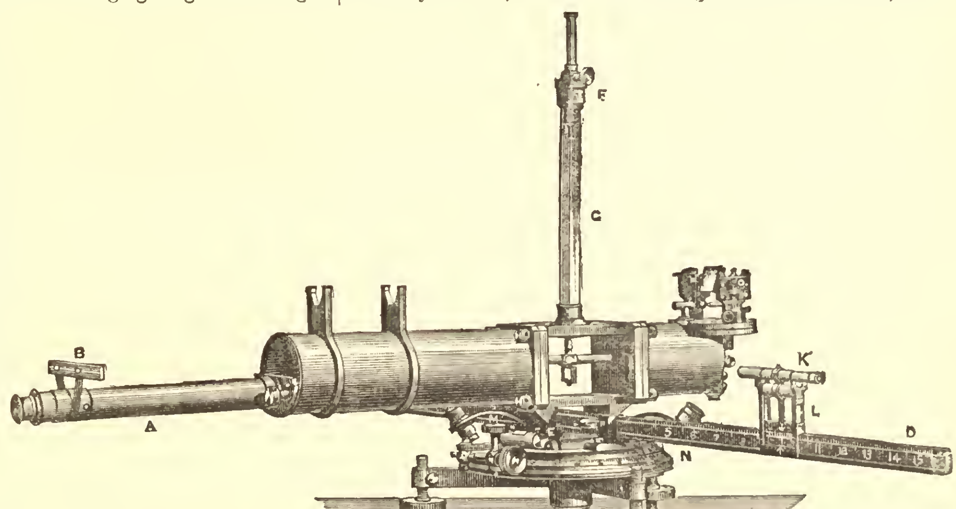

Fig. 29.—Unifilar Magnetometer, arranged to show deflexion.

[2] In this connexion see more especially Lamont. *Handb. d. Magnetismus*, pp. 282 *sq.*

[3] See Lamont, *Handb.*, p. 371; Maxwell, vol. iii. § 457.

$$\frac{r_1^3 H \sin\theta_1}{2K} = 1 - \frac{P_1}{r_1} + \frac{P_2}{r_1^2} + \ldots \quad (63).$$

The deflecting magnet is reversed in its carriage, and the whole operation repeated. If the deflexion now be θ_2, irrespective of sign, then

$$\frac{r_1^3 H}{2K} \sin\theta_2 = 1 + \frac{P_1}{r_1} + \frac{P_2}{r_1^2} + \ldots \quad (64).$$

The mean of these gives

$$\frac{r_1^3 H}{4K}(\sin\theta_1 + \sin\theta_2) = 1 + \frac{P_2}{r_1^2} + \ldots \quad (65).$$

The magnet is finally removed to a distance r_1 west, and the previous observations repeated; we thus get

$$\frac{r_1^3 H}{4K}(\sin\theta_3 + \sin\theta_4) = 1 + \frac{P_2}{r_1^2} + \ldots \quad (66).$$

The mean of (65) and (66) is then taken, and we get

$$\frac{r_1^3 H}{2K} S_1 = 1 + \frac{P_2}{r_1^2} \quad \ldots \quad (67),$$

where $S_1 = \frac{1}{4}(\sin\theta_1 + \sin\theta_2 + \sin\theta_3 + \sin\theta_4)$, or, what is practically the same, the sine of the mean of θ_1, θ_2, θ_3, and θ_4. The object in taking the mean of (65) and (66) is to eliminate any error arising from the non-coincidence of the middle point of the cross bar with the axis of suspension.

In order to eliminate P_2, another set of observations are made with a new distance r_2 (26 cm. or so), giving the equation

$$\frac{r_2^3 H}{2K} S_2 = 1 + \frac{P_2}{r_2^2} \quad \ldots \quad (68).$$

From (67) and (68) we have finally

$$\frac{K}{H} = \frac{r_1^5 S_1 - r_2^5 S_2}{2(r_1^2 - r_2^2)};$$

$$P_2 = \frac{r_1^2 r_2^2 (r_2^3 S_2 - r_1^3 S_1)}{r_1^5 S_1 - r_2^5 S_2}.$$

When great accuracy is required, several corrections have to be applied:—(1) the moment of the deflector must be corrected for induction; (2) the moment of the deflector must be corrected for temperature; (3) the lengths r_1 and r_2 on the cross bar must be corrected for temperature.

Statical instruments.

Statical Method.—There is another method by which we may determine the product KH, viz., we may oppose a statical couple to the couple exerted by the earth on the magnet in a given position, so that there may be equilibrium; the statical couple, which may arise from the torsion of a fibre, from a bifilar suspension, or other gravitational force, thus becomes the measure of the magnetic couple; and hence KH can be determined in absolute measure. Coulomb's torsion balance experiments are an example of this method. It finds numerous applications in the variation instruments of fixed magnetical observatories, and also in instruments for magnetic observations at sea, but it is very little used in the ordinary work of a physical laboratory.

Measurements by electromagnetic induction.

Magnetic Measurement by Electromagnetic Induction.—It has been explained in the article ELECTRICITY that, if, either owing to the variation of the magnetic field, or owing to the motion of a closed linear conductor in it, the number of lines of magnetic force N passing in the positive direction through the conductor vary, this variation will cause an electromotive force $-dN/dt$ in the positive direction round the circuit. Let us suppose, to take a simple case, that we have a coil of wire made up of a number of parallel plane circular windings, and that the sum of all the areas of the separate windings is A. If we place this in a field of uniform intensity R, so that the normal to the windings makes an angle θ with R, the number of lines of force passing through the coil will be $N_1 = AR\cos\theta$. If we now suddenly reverse the coil, by turning it through 180° about an axis perpendicular to its normal, the value of N in the new position is $N_2 = -AR\cos\theta$. Hence the *integral* electromotive force during the motion is $-\int dt dN/dt = N_2 - N_1 = -2AR\cos\theta$, and the whole quantity Q of electricity which passes will be $Q = -2AR\cos\theta/S$, where S is the resistance of the coil. If Q be found in absolute measure,[1] and A and S be known, we thus obtain the value of $R\cos\theta$. This is the principle of Weber's "earth inductor,"[2] by means of which the horizontal and vertical components of the earth's force can be measured, and in consequence the declination and inclination determined.

Weber's earth inductor.

Verdet's exploring coil.

If the test coil be made very small, so that the portion of the field which it occupies may be supposed uniform, this method may be applied to measure the intensity at different parts of a non-uniform field.[3] The small coil is placed with its windings perpendicular to the lines of force, and then suddenly reversed, or, if that be impossible, suddenly removed to a part of the field where the number of lines of force passing through it is zero. The integral electromotive force is of course in the latter case only half what it is in the former. This method is often of use where, owing to the great strength of the field and the consequent disturbances arising from induction, any other method would be utterly useless.

Magnetic moment determined by electro-magnetic induction.

The method of electromagnetic induction may also be applied to measure the component of the magnetic moment of any body parallel to a given line.

Let $aa'bb'$ (fig. 30) be the section of a uniform cylindrical coil of length $2l$, made up of a single layer of flat circular windings of radius b, n to the centimetre. Let the axis of the coil be taken for x-axis, and let K be any magnet within the coil, placed with

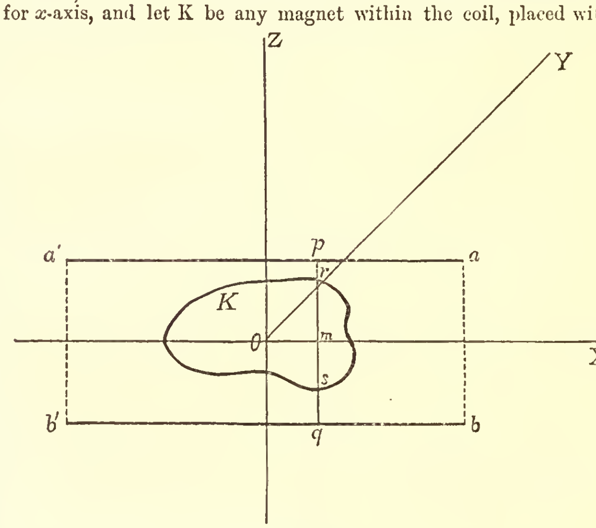

Fig. 30.

the given line parallel to the axis of the coil. Let pq be any single winding of the coil, then the surface integral of the magnetic induction for pq is given by $\iint a\,dydz$; hence the whole number of lines of force through the coil is given by

$$N = \int n dx \iint a\,dydz,$$

$$= n\iiint a\,dxdydz,$$

the integration being extended all over the cylindrical space $abb'a'$. Now, since $a = \alpha + 4\pi A = -dV/dx + 4\pi A$, we get

$$\left.\begin{aligned} N &= -n\iiint \frac{dV}{dx}dxdydz + 4\pi n\iiint A\,dxdydz, \\ &= -n\left(\iint V dydz - \iint V' dydz\right) + 4\pi n K, \\ &= +4\pi n K - n(S - S') \end{aligned}\right\} \quad (69),$$

where K is the component parallel to the axis of the coil of the moment of the magnet, and S and S′ the values of the surface integral of the potential of the magnet (derived from Poisson's distribution) over the two ends of the coil. When there are more layers than one, we must of course sum the different parts of N arising from the different layers.

The formulæ are quite general, and some applications will be given later. Meantime we see that, if the coil be

[1] See arts. ELECTRICITY and GALVANOMETER.
[2] *Pogg. Ann.*, xc., 1853.
[3] *Cf.* Verdet, *Ann. d. Chim. et d. Phys.*, xli., 1854.

so long that the magnetic potential of the body at its two ends may be neglected, then the integral electromotive force caused by the sudden removal of the body, or by the sudden destruction of its magnetism, is $4\pi n$ times the component of the magnetic moment parallel to the axis of the coil, n being the number of windings per unit of length of the coil.

[Early vibration observations.] *Historical Remarks on the Progress of Magnetic Measurements.*—The method of vibrations came very early into use in magnetic measurements. Whiston and Graham made vibration observations with a dipping needle. Musschenbrock and Mallet also used a horizontal needle. Lambert appears, however, to have been the first to thoroughly understand and appreciate the method. For long it was the only accurate process in use for obtaining relative measures of the earth's force. It was so used by Rossel, D'Entrecasteaux, and Humboldt. Coulomb, Hansteen, and Poisson, all contributed more or less to its improvement; and it finally reached perfection in the hands of Gauss,[1] who gave the experimental process for obtaining the moment of inertia, investigated the correction for resistance, and, by the introduction of the mirror and scale method, imparted astronomical accuracy to the determination of the period of vibration.

The method of deflexion, in one form or another, is very old. Its existence as a thoroughly scientific method, however, dates from Hansteen. The essential improvement of eliminating the constants depending on the magnetic distribution by observations at different distances is due to Gauss. The advantages of the sine method were first pointed out by Lamont in 1841.[2]

[Poisson first suggests absolute magnetic measurements.] Poisson seems to have been the first to conceive the idea of absolute magnetic measurement. In a short but luminous article at the end of the *Connaissance des Temps* for 1828, he describes a method for obtaining the value of H in absolute measure. Horizontal vibration experiments are to be made with two magnets A and A′, whose moments of inertia A and A′ are known. The times of vibration t and t' of A and A′, each suspended alone, are to be observed. Then both are to be placed in the magnetic meridian at a distance r apart in the same horizontal line, and the periods θ and θ' observed, of A when A′ is fixed, and of A′ when A is fixed. If r be very great compared with the linear dimensions of A and A′, then

$$H^2 = \frac{8\pi^2\theta\theta'\sqrt{AA'}}{r^3tt'\sqrt{(t^2-\theta^2)(t'^2-\theta'^2)}}.$$

He recommends, however, that comparatively small values of r be taken, and the constants of distribution eliminated by experimenting at different distances. His fundamental units are the gramme, metre, and second.

Nothing came of Poisson's proposal until Gauss took up the subject, both theoretically and experimentally, as above described. The first absolute measure of the earth's horizontal force was made by him at Göttingen on the 18th September 1832; the value found was 1·782[3] in millimetre milligramme second units. The magnet he used (about a foot long and weighing about 1 lb) had for its moment 100877000[4] in the same units.

[Determination of magnetic distribution.] *The determination of the distribution of magnetism within a body*, in other words, the determination of the magnetic moments of its individual elements, by observations of magnetic force at external points, is, as we have seen, an indeterminate problem. Nevertheless, a considerable part of the literature of magnetic science relates to it; and we must give some account of what has been done, although the results obtained are of comparatively slight physical interest, and of small practical value.

["Free magnetism," different uses of the phrase.] Experimenters have been somewhat slow in recognizing the essential indeterminateness of the problem. This no doubt has arisen from their imperfect analysis of the phenomena. Thus, although we cannot determine the actual internal distribution, yet the problem to determine the Gaussian surface distribution which will represent the magnetic action at all external points, however difficult, is quite determinate. This surface distribution has been called by some the "free magnetism" of the body; and some, all the powerful contrary evidence notwithstanding, have imagined that this distribution has a physical existence, and have even spoken of the depth to which the free magnetism penetrates into the magnet. Others have confounded the free magnetism of Gauss's distribution with that of Poisson's; and in many cases it is impossible to gather what the experimenter meant to indicate exactly by the phrase.

The case in which, from the circumstances, the variation of the internal distribution is confined within the narrowest limits is that of bar magnets, whose length considerably exceeds their lateral dimensions; and this is practically the only case that has been much studied. The most natural way of attempting to represent the action of such a magnet would be to suppose it replaceable by a fixed ideal magnet, and then to determine by experiment the strength and position of the poles of this magnet. The earliest notion was that the poles were situated exactly at the ends of the bar. It was soon found, however, that, if the poles did exist, they were not in general exactly at the ends. Lambert and Kupfer[5] concluded from their experiments that in many cases the poles lay outside the bar, while in weak magnets they lay inside. Coulomb, as we have seen, and also Dalla Bella, inferred from their results that the poles fell within. Recent experiments have been made by Pouillet,[6] by Benoit,[7] by Petruscheffsky,[8] and by others on the same subject; but it is needless to describe them here.

["Poles," different meanings of.] The word "pole," like the phrase "free magnetism," has been used by different writers in very different senses. Some have applied that name to the mass centres of the positive and negative magnetism of the actual molecules. But, although as a matter of convenience we have used these points in our theoretical development, they have, as far as physical observations are concerned, no existence. Others have defined the poles to be the mass centres of the positive and negative parts of Gauss's surface distribution. These might of course be determined, although the process would be extremely troublesome, and the result of no practical value whatever. In point of fact, if the magnet be in a uniform field, *i.e.*, at a very great distance from the system that acts on it, the action depends solely on the magnetic moment, and the magnetic distribution has nothing to do with it; the poles in this case are physically indeterminate. If, on the other hand, two magnets are within a moderate distance of each other, we may set to ourselves the problem to find two points in each of them such that the mutual action will be represented by quantities of positive and negative magnetism concentrated there. Then, in general, such points may or may not exist. Riecke has shown (see above, p. 233) that, if the distance between the magnets exceed a certain limit, then, as a matter of approximation, these equivalent poles, as he calls them, do exist. Except, however, in the case of magnets symmetrical about an axis, and also about an equatorial plane, they are not fixed in the magnets, but

depend upon their relative position. Although his results are extremely interesting from a mathematical and theoretical point of view, we do not see that much practical advantage would attend the use of these equivalent poles; and we are inclined to think that, except in the popular usage for distinguishing one end of a magnet from the other, and in the case of ideal magnets, the word pole had better be abandoned altogether.

Distribution in a linear magnet.

The idea of representing the action of a linear magnet by a continuous distribution of free magnetism, positive in one half and negative in the other, is very old. It appears in Bazin's work on the magnetic curves published in 1753; and Tobias Mayer, in his memoir above quoted, assumes that the density of the distribution is proportional to the distance from the middle of the bar. Four distinct methods have been used in attempting to determine the law of distribution.

1. The deflexions of a small needle in different positions near the magnet have been observed, and by means of these the constants in some formula assumed for the distribution have been calculated. This was the process adopted by Lambert and Hansteen, and, in some of his experiments, by Lamont.[1]

2. Instead of measuring deflexion, we may count the oscillations of the needle, and proceed as before. This method was used by Coulomb, Becquerel, and Kupfer, but it led to no satisfactory results, partly owing to the disturbances arising from induction and the force of translation upon the needle, partly owing to the difficulty of putting a satisfactory theoretical interpretation upon the results.

Different methods employed.

3. Some observers have measured the force required to detach a small armature of soft iron or steel from different parts of the bar, thinking thereby to obtain a direct measure of the free magnetism. It is not very easy to say what is measured by this process, but it is obvious, on a little consideration, that the effect is complex, depending greatly on the nature and extent of the surfaces in contact, and also upon the mutual induction between the magnet and the armature. Experiments of this kind have been made by Dub, Lamont, and others.

4. Another method frequently employed is to slide along the bar a small ring-shaped coil embracing it as closely as possible, and to measure the induction currents for a given displacement. The assumption usually made is that the integral electromotive force is proportional to the free magnetism on the portion of the bar passed over, or, what amounts to the same thing, to the difference between the magnetic moments per unit of length of the sections of the bar on which the coil rests at the beginning and end of the motion. This is, however, only an approximation to the truth, and the accuracy of this approximation is very difficult to estimate in the practical case where the lateral dimensions of the bar are finite. The following investigation will show the nature of the difficulty.

The integral electromotive force is $-(N_1 - N_2)$, where N_1 and N_2 are the surface integrals of magnetic induction taken over the coil in its initial and final positions. Let us take first a linear solenoid SN (fig. 31) of length l, and magnetic moment m, and a coil of a single winding PQ, which moves so that its centre R is always in the line SN, and its plane always perpendicular to SN; then

$$N = \iint a\,dydz = \iint \alpha\,dydz + 4\pi\iint A\,dydz ,$$

the former integral extending all over PQ, the latter over the infinitely small section of the solenoid at R, α being the force due to the end distribution at N and S. We thus get

$$N = \frac{2\pi m}{l}(\cos\theta - \cos\theta') \quad . \quad . \quad . \quad . \quad . \quad (70),$$

where θ and θ' are the angles PSX and PNX. This shows, in the first place (see equation (25) above), that if the coil PQ were to expand and contract as it moves, so as always to remain a section of the same tube of force, there would be no variation of N, and no electromotive force, which is as it should be. If we were at liberty to suppose PQ infinitely small, then, when R is between S and N, $\cos\theta - \cos\theta'$ would be the sum of two unities, and, when R is outside, the difference. In such a case, so long as PQ moved on the magnet, there would be no electromotive force, but if we suddenly move it over the end, there would be an electromotive force

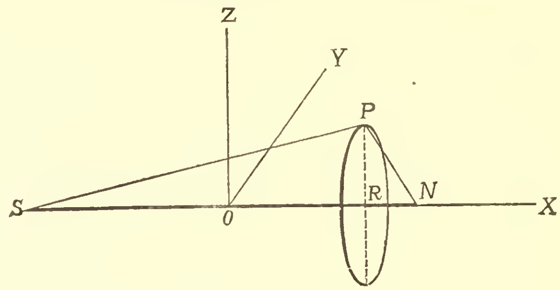

Fig. 31.

$-4\pi m/l$, which is proportional to the moment of the bar. When PQ is not infinitely small, there is a variable part of N, depending on the dimensions of PQ, which will give rise to an electromotive force, even when the coil is moved along a uniformly magnetized bar, where there is no free magnetism except at the ends.

It is now easy to form a conception of what happens in the case of an ordinary complex solenoidal bar. We may suppose such a bar made up of a number of simple linear solenoids. A certain number of these, corresponding to the end parts of Poisson's distribution, will have the same length as the bar; the others, corresponding to the lateral surface and volume parts of the distribution, will be of continuously diminishing lengths. If we were at liberty to suppose the lateral dimensions of the bar and the radius of the coil to be infinitely small, then, as the coil moves along the bar, we should have an electromotive force due to passage over the ends of the short solenoids, and, as it moves over the end, an electromotive force due to passage over the ends of the long solenoids. We might in this way by a sufficient number of observations determine the distribution of the free magnetism throughout the bar and at its ends; and in this case no distinction would be necessary between the volume and the surface distribution in any section.

If, however, the dimensions of the section of the bar, and consequently of the coil, be finite, a correction would have to be applied, depending, not only on the dimensions of the bar and coil, but also on the magnetic distribution. All that we can then do is to assume a formula for Gauss's surface distribution and determine its constants. We thus get Gauss's distribution, and a formula that will account for the electrical observations; *but we obtain no information as to the actual internal distribution of the magnetism in the bar.*

Lenz and Jacobi[2] appear to have been the first to apply the method of induction currents to the measurement of the magnetic distribution in bar magnets. They attempted no theoretical analysis of their results, although they assigned a law of distribution. Van Rees,[3] who questioned their conclusions, gave an imperfect theory, and made some careful researches of his own. Rothlauf[4] made further experiments, and entered more fully into the theory, though still with insufficient generality. The most recent experiments of the kind we are aware of are those of Schaper,[5] who discusses the theory with complete generality, taking account of the ends of the bar.

Different laws assigned.

After what has been said, the reader will scarcely be surprised to find that the different experimenters assigned very different formulæ for the distribution in bar magnets. Lambert deduces from his experiments a distribution whose density is Ax,—A being a constant, and x the distance from the ends of the bar. Brugmans, V. Swinden, and Lenz and Jacobi adopt the law Ax^2; Hansteen, as we have seen, the law Ax^r, where $r = 2$ or 3. Biot deduced from Coulomb's experiments the law $A(\mu^x - \mu^{-x})$ for the density of the free magnetism, which would give for the moment per unit of length of the bar the law $a - b(\mu^x + \mu^{-x})$, see above, p. 231. Becquerel,

[1] See also Airy and Stuart, *Phil. Mag.*, 1873.

[2] *Pogg. Ann.*, lxi., 1844.

[3] *Over de Verdeeling van het Magnetismus in Magneten*, Amst., 1847.

[4] *Pogg. Ann.*, cxvi., 1862.

[5] *Wied. Ann.*, ix., 1880.

Van Rees, Lamont, and Rothlauf favour this last formula; but none of these experimenters give any proper account of the ends, which must be specially represented in all but those cases where the magnetic moment is zero there. Schaper finds that the results of experiment can be adequately represented by means of end distributions, and a lateral surface distribution following the law $Ax+Bx^3$. See his paper above quoted, p. 242.[1]

[Theory of carrying power; experiments on it.] *Carrying Power of a Magnet.*—It is obvious that the magnetization of a piece of iron must affect its force of cohesion. The most familiar case is that of a magnet to which an armature is fitted. If the surfaces of the pole and armature be carefully ground flat, so as to fit, we may regard the magnet and the armature as continuations of each other. The force of cohesion here is mainly due to the magnetism; and the force required to separate the two is called the "carrying power" of the magnet. To simplify the question, let us consider a cylindrical bar of section ω, uniformly magnetized in the direction of its length with intensity I. Suppose the bar cut so that the normal to the plane of section makes an angle θ with I, and let the surfaces of section be separated infinitely little, then the surface density of Poisson's distribution will be $I\cos\theta$ on each surface. Assuming that the cohesion is caused solely by the attraction of these surface layers, we get for the carrying power $P=2\pi I\cos\theta\times I\cos\theta\,\omega\sec\theta$, *i.e.*, $P=2\pi I^2\omega\cos\theta$. The carrying power is therefore greatest, viz., $2\pi\omega I^2$, when the surface of the pole is perpendicular to the lines of magnetization.

A great variety of experiments have been made on this subject by Joule, Dub, Tyndall, Lamont, and others, mostly, however, under circumstances that do not admit of the application of the above theory. For an account of what has been done, the reader should consult Wiedemann's *Galvanismus*, ii. § 425 *sq.* The most recent investigations on the subject will be found in the papers of Rowland, quoted below, p. 255, and in papers by Stefan and Wassmuth in the *Monatsberichte der Weiner Akademie* for 1880 and 1882.[2] The facts are not so simple as the above theory would indicate; but Wassmuth finds a modified form of it to agree sufficiently well with observation.

Mathematical Theory of Magnetic Induction.

[Axioms of magnetic induction.] The two fundamental axioms of this theory are the following:—

1. The induced magnetism in any element of a body depends merely on the magnitude and direction of the resultant magnetic force ($\mathfrak{H}$) at the element.

2. The magnetic moment induced by any force $\mathfrak{H}$ is the resultant of the magnetic moments induced separately by any forces of which $\mathfrak{H}$ is the resultant.

With reference to axiom 1 it is to be remarked that account must be taken of the physical condition of the body as to temperature, and so forth; but it is implied that no account is to be taken of its magnetic state, except in so far as that affects the resultant magnetic force. In other words, it is asserted that the moment induced by any force does not depend upon any pre-existing magnetic moment in the element, and is the same whatever forces may have acted on the element previously. The full significance of these statements will be better appreciated when we come to consider the exceptions to them in case of strongly magnetic bodies. It should also be noticed that it is supposed that the body has reached a state of magnetic equilibrium, and that by whole resultant magnetic force is understood, not only that arising from the given inducing system, including pre-existing magnetism in the body itself, but also that arising from induced magnetism.

In the mathematical theory no distinction is drawn between the part of the induced magnetism which disappears when the inducing force is removed, and that which remains. If anywhere we contemplate what happens after the removal of the force, it is assumed that *all* the induced magnetism disappears. This important restriction must be borne in mind in applying the results in practice.

Axiom 2 enables us to assign at once the law connecting the components of induced magnetization A_1, B_1, C_1 with the components α, β, γ of the resultant force. If r_1, q_3, p_2 be the components parallel to the three coordinate axes of the induced magnetization caused by a unit resultant force parallel to the axis of x, then, by the axiom, the components of magnetization induced by a force α in the same direction will be $r_1\alpha$, $q_3\alpha$, $p_2\alpha$; similarly, if p_3, r_2, q_1 be the components due to unit force parallel to the y axis, then the components due to β will be $p_3\beta$, $r_2\beta$, $q_1\beta$; and finally, if q_2, p_1, r_3 be components due to unit force parallel to z axis, the components due to γ will be $q_2\gamma$, $p_1\gamma$, $r_3\gamma$. Compounding all these, according to the axiom, we get

[General law of induction.]

$$\left.\begin{aligned}A_1&=r_1\alpha+p_3\beta+q_2\gamma\\B_1&=q_3\alpha+r_2\beta+p_1\gamma\\C_1&=p_2\alpha+q_1\beta+r_3\gamma\end{aligned}\right\}\quad\quad(71).$$

Hence the most general expressions for the components of magnetization compatible with our axioms are three linear functions of the components of the resultant force.

Here it is necessary to introduce a classification of bodies according to their magnetic properties.

[Homogeneity and heterogeneity.] If equal, similar, and *similarly situated* elements cut from different parts of a body have identical magnetic properties, it is said to be "magnetically homogeneous," if not, "heterogeneous."

[Isotropy and æolotropy.] If equal and similar elements cut around the same point *in different directions* be identical in their magnetic properties, the body is said to be magnetically "isotropic"; if not, "æolotropic."

These are not cross classifications; for a body (*e.g.*, Iceland spar) may be æolotropic and yet homogeneous, and it might be heterogeneous and yet isotropic. We must regard the coefficients p, q, r of (71) as belonging to a point of the body; and we see that in a homogeneous body they will be the same for all points, whereas in a heterogeneous body they will vary from point to point, *i.e.*, they will be functions continuous or discontinuous of the position of the point.

[Law of induction for isotropics.] In the case of an isotropic body it is obvious *a priori* that the induced magnetization must be coincident in direction with the resultant force; the conditions for this are that the coefficients p and q should all vanish, and that $r_1=r_2=r_3=\kappa$. The equations (71) thus reduce to

$$A_1=\kappa\alpha\,,\ B_1=\kappa\beta\,,\ C_1=\kappa\gamma\quad\quad(72).$$

In an æolotropic body, on the other hand, the coefficients may be all different from zero and from one another; but, as we shall see, at all events in the ideal case contemplated by the mathematical theory, the conservation of energy reduces the number of independent constants by three; while a proper choice of axes reduces it by three more; so that the magnetic properties of any element of an æolotropic body depend virtually on three independent constants.

The theory here given is the generalization of Poisson's theory due to Sir William Thomson. It aims at giving the simplest possible exposition of the results of experiment with the fewest assumptions as to the molecular structure of bodies. We first discuss specially a few of the cases

[1] Various experimenters have attempted to determine the "indifference zone" of magnets under different circumstances, *i.e.*, the line separating the positive and negative parts of the surface distribution. For information as to this and other matters under the present head omitted for want of space, see Wiedemann, *Galvanismus*, ii. §§ 277, 356, 396, 401; and Lamont, *Handbuch*, §§ 6, 27, 63, 64, 65.

[2] Abstracted in *Wied. Beibl.* 1880 and 1882; see also Von Waltenhofen, *Wien. Ber.*, 1870, and Siemens, *Berl. Monatsber.*, 1881.

more important in practice, and then give a brief account of the general theory with a view to establish some general principles to guide us in the subsequent account of the (often very complex) phenomena observed by experimenters.

Synthetic solution for a sphere in uniform field.

Homogeneous Æolotropic Sphere in a Uniform Field of Inductive Force.—We suppose that the sphere, to begin with, is not magnetized. If the sphere were uniformly magnetized,[1] with components A_1, B_1, C_1, then (see above, p. 232) the force inside the sphere due to this magnetization would have for its components

$$\alpha_1 = -\tfrac{4}{3}\pi A_1\,,\ \beta_1 = -\tfrac{4}{3}\pi B_1\,,\ \gamma_1 = -\tfrac{4}{3}\pi C_1\,.$$

This uniform force combined with the given uniform force $(\alpha_0, \beta_0, \gamma_0)$ of the inductive field would result in a uniform force

$$\alpha = \alpha_0 - \tfrac{4}{3}\pi A_1\,,\ \beta = \beta_0 - \tfrac{4}{3}\pi B_1\,,\ \gamma = \gamma_0 - \tfrac{4}{3}\pi C_1 \quad . \quad . \quad (73).$$

It is obvious therefore that the assumption of uniform magnetization will enable us to satisfy the law of induction.

In point of fact, substituting in (71) and transposing, we get three linear equations to determine A_1, B_1, C_1 in terms of α_0, β_0, γ_0, viz.,

$$(1 + \tfrac{4}{3}\pi r_1)A_1 + \tfrac{4}{3}\pi p_3 B_1 + \tfrac{4}{3}\pi q_2 C_1 = r_1\alpha_0 + p_3\beta_0 + q_2\gamma_0\,,\ \&c. \ . \quad (74).$$

Reduction in the number of induction coefficients.

It is easy, by means of these and formulæ given above, to calculate the couple exerted on the inductively magnetized sphere. If we put $\alpha_0 = 0$, $\beta_0 = F\cos\theta$, $\gamma_0 = F\sin\theta$, we can calculate the work done on the sphere in turning through 180° about an axis perpendicular to the direction of the field. This, by the conservation of energy, ought to vanish, and we thus get the conditions $p_1 = q_1$, $p_2 = q_2$, $p_3 = q_3$. The equations (74) therefore reduce to

$$\left.\begin{aligned} A_1 &= r_1\alpha + p_3\beta + p_2\gamma \\ B_1 &= p_3\alpha + r_2\beta + p_1\gamma \\ C_1 &= p_2\alpha + p_1\beta + r_3\gamma \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad . \quad . \quad (75).$$

Hence, if α, β, γ be parallel to a radius of the central quadric

$$r_1x^2 + r_2y^2 + r_3z^2 + 2p_1yz + 2p_2zx + 2p_3xy = 1\,,$$

A_1, B_1, C_1 will be normal to the diametral plane of that radius. We have, therefore, by the theory of surfaces of the second degree, the following conclusions.

Three principal magnetic axes.

1. The induced magnetization is not in general in the direction of the inducing force; but there are in general at every point three directions, called the three principal magnetic axes, mutually at right angles to each other, for which the directions of the induced magnetization and of the inducing force coincide. If the axes of coordinates be parallel to these principal axes, the equations (75) reduce to

$$A_1 = r_1\alpha\,,\ B_1 = r_2\beta\,,\ C_1 = r_3\gamma \quad . \quad . \quad . \quad . \quad (76).$$

Principal magnetic inductive susceptibilities.

The values of r_1, r_2, r_3 in this case are called the "principal magnetic inductive susceptibilities." Bodies for which these coefficients are all positive are called paramagnetic or ferromagnetic. Bodies for which they are all negative are called diamagnetic. No substance is known for which some are positive and others negative, although this is a mathematically possible case. Since intensity of magnetization and resultant magnetic force are of the same dimension $[L^{-\frac{1}{2}}M^{\frac{1}{2}}T^{-1}]$, r_1, r_2, r_3 are pure numbers; for all substances except iron, nickel, and cobalt, they are extremely small. The value of the coefficients r and p for any other axes can be expressed in terms of the three principal susceptibilities by means of simple formulæ which we need not stop to deduce.

A physical meaning can be given to r_1, as follows. Let the body be homogeneous, and let us cut from it a cylindrical piece whose axis is parallel to the principal axis of susceptibility r_1. Place this cylinder in the direction of the lines of force in a uniform field of unit strength, then, provided the cylinder be infinitely thin, and of longitudinal dimensions infinitely great compared with its lateral, the internal force due to the induced magnetization will be zero (see above, p. 229), and it will be magnetized inductively with a uniform intensity r_1. Similarly for r_2, r_3.

Principal permeabilities.

The three coefficients

$$\varpi_1 = 1 + 4\pi r_1\,,\ \varpi_2 = 1 + 4\pi r_2\,,\ \varpi_3 = 1 + 4\pi r_3\,,$$

used later on, are called by Thomson the three principal permeabilities of the body at any point. These are of course pure numbers, and they are positive for all known substances.

2. If the susceptibilities for any two principal axes be equal, then every axis in the plane of these two is a principal axis.

3. If all three principal susceptibilities be equal at any point, then every axis through that point is a principal axis, and the susceptibility for every such axis is the same. The body is therefore isotropic at that point, and the direction of the induced magnetization coincides with the direction of the inductive force for every direction of the latter.

Magnetization and couple for sphere in uniform field.

Returning to the problem of the æolotropic sphere, let us simplify our equations by taking the coordinate axes parallel to the common directions of the principal axes throughout the homogeneous sphere. We then get for the components of magnetization

$$A_1 = \frac{r_1}{1 + \frac{4}{3}\pi r_1}\alpha_0\,,\ B_1 = \frac{r_2}{1 + \frac{4}{3}\pi r_2}\beta_0\,,\ C_1 = \frac{r_3}{1 + \frac{4}{3}\pi r_3}\gamma_0 \quad . \quad (77).$$

Using these formulæ, we get, by means of (22), for the components of the couple acting on the sphere (of volume v),

$$\left.\begin{aligned} \mathfrak{L} &= v\frac{r_2 - r_3}{(1 + \frac{4}{3}\pi r_2)(1 + \frac{4}{3}\pi r_3)}\beta_0\gamma_0 \\ \mathfrak{M} &= v\frac{r_3 - r_1}{(1 + \frac{4}{3}\pi r_3)(1 + \frac{4}{3}\pi r_1)}\gamma_0\alpha_0 \\ \mathfrak{N} &= v\frac{r_1 - r_2}{(1 + \frac{4}{3}\pi r_1)(1 + \frac{4}{3}\pi r_2)}\alpha_0\beta_0 \end{aligned}\right\} \quad . \quad . \quad . \quad (78).$$

There is of course no force of translation. As a special case let us suppose r_1, r_2, and r_3 to be in descending order of algebraical magnitude, and suspend the sphere with the axis of r_1 perpendicular to the lines of force. We may put $\beta_0 = F\cos\theta$, $\gamma_0 = F\sin\theta$, where θ is the angle between the axis of γ (r_2) and the direction of the field, then we have

$$\mathfrak{L} = \tfrac{1}{2}vF^2(r_2 - r_3)\sin 2\theta/(1 + \tfrac{4}{3}\pi r_2)(1 + \tfrac{4}{3}\pi r_3).$$

Hence the sphere tends to turn so as to place the axis of algebraically greatest susceptibility parallel to the lines of force. It will be in equilibrium when either principal axis is parallel to the lines of force; but in stable equilibrium only when the axis of greatest permeability is in that position. It is to be noticed that the couple is proportional to the square of the strength of the field.

There is another way of expressing these results more in accordance with the ideas of Faraday.

If N be the surface integral of magnetic induction taken over the meridian section (ω) of the sphere perpendicular to the direction of the vector $\mathfrak{B}$ inside, or, as we may call it, the number of lines of force that pass through the sphere, then we have

$$N = 3F\omega\left\{\left(\frac{\varpi_2}{\varpi_2 + 2}\right)^2\cos^2\theta + \left(\frac{\varpi_3}{\varpi_3 + 2}\right)^2\sin^2\theta\right\}^{\frac{1}{2}},$$

$$\mathfrak{L} = -\frac{1}{24\pi^2 R}\,\frac{(\varpi_2 + 2)(\varpi_3 + 2)}{\varpi_2 + \varpi_3 + \varpi_2\varpi_3}\,\frac{d(N^2)}{d\theta}\,,$$

R being the radius of the sphere.

Deduction of Faraday's laws.

From these formulæ we can draw the following conclusions:—

1. *The number of lines of force that pass through the sphere is greatest, viz.,* $3F\omega\varpi_2/(\varpi_2 + 2)$, *when the axis of greatest permeability is parallel to the direction of the undisturbed field, and least, viz.,* $3F\omega\varpi_3/(\varpi_3 + 2)$, *when the axis of least permeability is in the same position.*

2. *In any position the number of lines passing through the spherical space is greater for a paramagnetic body, and*

[1] Here and in future the suffix 0 denotes components of magnetizing force, &c., due to given or pre-existent magnetization; while the suffix 1 denotes those due to induced magnetization. Letters without suffixes denote totals; *e.g.*, $\alpha = \alpha_0 + \alpha_1$, $A = A_0 + A_1$, and so on.

less for a diamagnetic body, than it would be if the sphere were absent.

3. *The sphere is in equilibrium when the number of lines of force passing through it is a maximum or a minimum, the equilibrium being stable in the former case, and unstable in the latter.*

duced agnet- ition of otropic here.

Homogeneous Isotropic Sphere in Uniform Field.—This case is obtained by putting $r_1 = r_2 = r_3 = \kappa$ in the above formulæ. The magnetization is parallel to the undisturbed field; and the couple vanishes, so that the sphere is in equilibrium in all positions. If the strength of the field be F, we get for the intensity of magnetization

$$I = \frac{\kappa}{1+\frac{4}{3}\pi\kappa}F = \frac{3}{4}\frac{(\varpi-1)}{\varpi+2}F\ ;$$

also

$$\mathfrak{N} = \frac{3\varpi}{\varpi+2}F\omega .$$

In order to familiarize the reader with this important case, we give two figures of the lines of force from Sir W. Thomson's *Reprint*, pp. 490, 491,—one for a paramagnetic

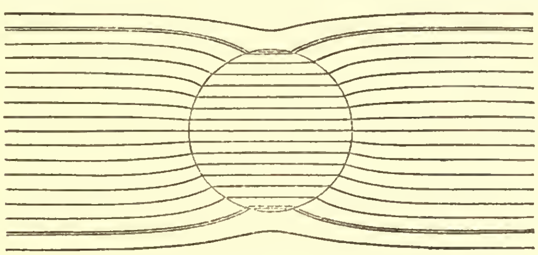

FIG. 32.—Lines of Force for a Paramagnetic Sphere.

(fig. 32) having $\varpi = 2{\cdot}8$, and another for a diamagnetic (fig. 33) having $\varpi = {\cdot}48$. The former represents a paramagnetic whose susceptibility is something like $\frac{1}{440}$th of the maximum observed for the best Norway iron. The latter corresponds to a diamagnetic having a susceptibility some 16,000 times that of bismuth, which is the most powerfully diamagnetic substance known.

The reader should observe that, although the field inside the isotropic sphere is uniform, this is not the case outside,

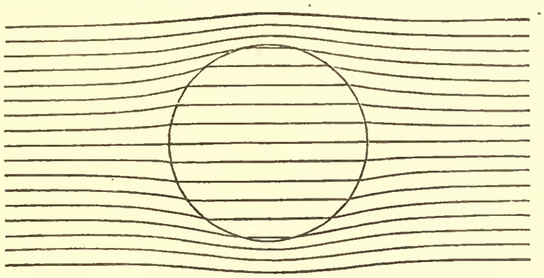

FIG. 33.—Lines of Force for a Diamagnetic Sphere.

a fact sometimes forgotten by experimenters. Of course the disturbance in the case of a bismuth sphere would be infinitesimal.

Eolotro- ic ellip- oid in niform eld.

Homogeneous Æolotropic Ellipsoid in a Uniform Field.—In the case of a sphere the tendency to set in a uniform field is wholly dependent on the æolotropy of the sphere, and is independent of its form. It is important, in order to get a complete picture of the behaviour of inductively magnetized bodies, to obtain a solution for some case where the form has an effect upon the result. A solid bounded by a surface of the second degree affords such a case.

If an ellipsoid be uniformly magnetized so that the components of magnetization parallel to its three principal axes a, b, c be A_1, B_1, C_1, this magnetization gives rise to a force

$$\alpha_1 = -A_1L\,,\quad \beta_1 = -B_1M\,,\quad \gamma_1 = -C_1N\ ;$$

when L, M, N have the values given above, p. 232. If we now place this ellipsoid in a uniform field $(\alpha_0, \beta_0, \gamma_0)$, the force inside will be given by

$$\alpha = \alpha_0 - A_1L\,,\quad \beta = \beta_0 - B_1L\,,\quad \gamma = \gamma_0 - C_1L \quad . \quad . \quad (79).$$

It is obvious, therefore, that the equations (75) of induction can, as in the case of a sphere, be satisfied by the assumption of uniform magnetization.

There is no difficulty in dealing with the general case in which the principal magnetic axes are not parallel to the principal axes of figure; we shall content ourselves, however, with the case in which the principal magnetic axes r_1, r_2, r_3 are parallel respectively to a, b, c. Equations (76) then give at once

$$A_1 = r_1(\alpha_0 - A_1L)\,,\quad B_1 = r_2(\beta_0 - B_1M)\,,\quad C_1 = r_3(\gamma_0 - C_1N) \quad (80);$$

whence

$$A_1 = \frac{r_1\alpha_0}{1+r_1L}\,,\quad B_1 = \frac{r_2\beta_0}{1+r_2M}\,,\quad C_1 = \frac{r_3\gamma_0}{1+r_3N} \quad . \quad . \quad (81).$$

The components of the magnetic moment are of course obtained at once from these by multiplying by the volume.

For the components of couple, $\mathfrak{L}, \mathfrak{M}, \mathfrak{N}$, tending to turn the ellipsoid about the axes a, b, c, we get

$$\left.\begin{array}{l}\mathfrak{L} = \frac{4}{3}\pi abc\,\dfrac{r_2 - r_3 + r_2r_3(N-M)}{(1+r_2M)(1+r_3N)}\beta_0\gamma_0 \\ \mathfrak{M} = \&c., \qquad \mathfrak{N} = \&c.\end{array}\right\} \quad . \quad . \quad . \quad (82).$$

From these equations we can draw the following important conclusions,—first as to the magnetization of the ellipsoid.

1. When r_1, r_2, r_3 are so small that their squares may be neglected, as in fact is the case with all bodies except iron, nickel, and cobalt, the components of magnetization reduce to $r_1\alpha_0$, $r_2\beta_0$, $r_3\gamma_0$. A glance at equations (79) will show that what happens is simply that the part of the internal inducing force which depends on the squares of the susceptibilities is not sensible. In other words, the *form* of the body is without influence on the induced magnetization. Or, what is again equivalent to the same thing, the induced magnetism may be supposed to produce no disturbance in the inducing field. With weakly magnetic substances the form does not affect the induced magnetization.

These conclusions are of course not limited to the ellipsoidal form in particular; but we have the general result that, *if the squares of the susceptibilities are negligible, then the form of the body has no effect on the induced magnetism.*

2. On the other hand, *when the susceptibilities* (and consequently the permeabilities) *are very great*, since $A_1 = \alpha_0/(1/r_1 + L)$, &c., it is clear that *the influence of the form of the body predominates.* The extreme case is that of a body of infinite permeability, in which the induced magnetism is wholly determined by the form. With strongly magnetic bodies the influence of form predominates.

3. If, however, the ellipsoid be very elongated in the direction of a, then L will be very small, and r_1L may be very small, notwithstanding the largeness of r_1. In that case $A_1 = r_1\alpha_0$. Exception.

4. From 1, 2, and 3 we have the following most important results. In experimenting with weakly magnetic bodies in a uniform field—in order, say, to determine their susceptibility—the form of the body is indifferent. On the other hand, with strongly magnetic bodies an elongated form must be used, because in that case only does the induced magnetism depend mainly on the susceptibility of the material. With bodies approaching the spherical form differences in form produce far more effect on the experimental results than differences in the susceptibility of the material, so that in such cases the experimenter really measures the accuracy of his instrument maker [1] more than the magnetic susceptibility of his material. Best form for determination of susceptibility.

5. For a flat disk (infinitely oblate ellipsoid), having its r_1 axis parallel to the lines of force, $L = 4\pi$, and $A_1 = r_1\alpha_0/(1+4\pi r_1) = \alpha_0(\varpi_1 - 1)/4\pi\varpi_1$. If such a body were diamagnetic, and had $r_1 = -1/4\pi$, *i.e.*, had zero Flat disk.

[1] As a matter of history, Riecke did unwittingly obtain in this way a tolerable approximation to the ratio of the circumference of a circle to the diameter. See Stoletow, *Phil. Mag.*, 1874, p. 202.

permeability, the normal magnetization would be infinite for any finite force.

Magnetic couple, two parts of.

Next, we have the following conclusions as to the magnetic couple. Let us suppose the ellipsoid free to move about its a axis, and let the direction of the field be perpendicular to a, so that $\beta_0 = \mathrm{F}\cos\theta$, $\gamma_0 = \mathrm{F}\sin\theta$; the couple tending to turn the b axis parallel to the undisturbed direction of the field is the sum of two parts:—

$$\mathfrak{L}_1 = \tfrac{2}{3}\frac{\pi abc\mathrm{F}^2(r_2 - r_3)}{(1 + r_2\mathrm{M})(1 + r_3\mathrm{N})}\sin 2\theta \quad . \quad . \quad . \quad . \quad (83),$$

and

$$\mathfrak{L}_2 = \tfrac{2}{3}\frac{\pi abcr_2r_3(\mathrm{N} - \mathrm{M})}{(1 + r_2\mathrm{M})(1 + r_3\mathrm{N})}\sin 2\theta \quad . \quad . \quad . \quad . \quad (84).$$

For small susceptibilities the effect of æolotropy predominates.

1. *If the susceptibilities are so small that their squares and products are negligible*, then $\mathfrak{L}$ reduces to

$$\mathfrak{L}_1 = \tfrac{2}{3}\pi abc\mathrm{F}^2(r_2 - r_3)\sin 2\theta.$$

In other words, *the form of the body has no effect*, and it behaves exactly like an æolotropic sphere of the same volume; *i.e.*, it will tend to turn its axis of greatest permeability parallel to the lines of force.

For large susceptibilities the effect of form predominates.

2. *If the susceptibilities be very large*, then the most important part of $\mathfrak{L}$ will be $\mathfrak{L}_2$. Now a glance at the values of M and N (34) shows that N − M has the same sign as $b^2 - c^2$; hence *the ellipsoid will tend to place its longest dimension parallel to the lines of force.*[1] This is the general effect of the influence of *form* in the case of strongly magnetic bodies, or, if we choose to put it so, the effect of the disturbance of the field by the induced magnetism.

3. It is of course possible in the case of strongly magnetic bodies that both parts of $\mathfrak{L}$ may be sensible, so that the resultant action would be affected both by form and by the magnetic structure, either predominating according to circumstances; for by properly shaping the ellipsoid we can give N − M any value positive or negative from 0 to 2π. In this way, given an æolotropic body for which $1/r_3 - 1/r_2$ is not greater than 2π, we might so shape it that it would turn its longest dimensions parallel to the lines of force, or so that it would turn its shortest dimensions parallel to the lines of force, the shortest axis in the second case being the axis of greatest permeability; or we might so shape it that the equilibrium would be neutral.

And, in general, given a body æolotropic within certain limits, we might shape it in such a manner that the effect of its form would exactly neutralize the effect due to its structure, so that, as far as setting in a uniform field is concerned,[2] it would behave like an isotropic sphere.

Isotropic ellipsoid.

Homogeneous Isotropic Ellipsoid in a Uniform Field.—The formulæ for this case are of course at once obtained by putting $r_1 = r_2 = r_3 = \kappa$ in the above formulæ. We thus get

$$\mathrm{A}_1 = \frac{\kappa\alpha_0}{1 + \kappa\mathrm{L}}, \quad \mathrm{B}_1 = \frac{\kappa\beta_0}{1 + \kappa\mathrm{M}}, \quad \mathrm{C}_1 = \frac{\kappa\gamma_0}{1 + \kappa\mathrm{N}} \quad . \quad . \quad . \quad (85);$$

$$\mathfrak{L} = \tfrac{4}{3}\frac{\pi abc\kappa^2(\mathrm{N} - \mathrm{M})\beta_0\gamma_0}{(1 + \kappa\mathrm{M})(1 + \kappa\mathrm{N})}, \quad \mathfrak{M} = \&\mathrm{c.}, \quad \mathfrak{N} = \&\mathrm{c.} \quad (86).$$

The following conclusions are worthy of notice:—

1. *The resultant magnetization will not, as in the case of an isotropic sphere, be parallel to the resultant magnetic force.*

Influence of form the same for a diamagnetic as for a paramagnetic body.

2. *The ellipsoid will tend to set its longest dimension parallel to the lines of force*; and, since κ is involved in the numerator in the form κ^2, *this conclusion is the same for a diamagnetic as for a paramagnetic body.* Of course we exclude the mathematically possible case of one of the factors $1 + \kappa\mathrm{M}$ or $1 + \kappa\mathrm{N}$ vanishing or becoming negative. For all weakly magnetic bodies, however, κ is so small that the tendency of an elongated isotropic body to set in a *uniform* field is insensible.

Tore.

Ring Electromagnet.—A simple case,[3] which has recently acquired practical importance, is that of an electromagnet having a soft iron core shaped like an anchor ring, whose mean diameter is R, and radius of section a, wound uniformly with n turns of a primary coil in which flows a current i. The lines of force and the lines of magnetization will evidently be circles, and, since the Poisson's surface and volume distributions vanish, the whole magnetic force $\mathfrak{H}$ will be simply that due to the current. At a distance ρ from the axis of the ring $\mathfrak{H} = 2ni/\rho$; for the whole work done on a unit pole in passing round any coaxial circle of radius ρ is $\mathfrak{H} \times 2\pi\rho = 4\pi ni$.[4] The intensity of magnetization is, therefore, $\mathrm{I} = 2n\kappa i/\rho$, and $\mathfrak{B} = 2ni(4\pi\kappa + 1)/\rho = 2n\varpi i/\rho$. Hence it appears that the total induction through a secondary coil of n' windings is $2nn'i(4\pi\kappa\int d\mathrm{S}/\rho + \int d\mathrm{S}'/\rho)$, where $\int d\mathrm{S}/\rho$ is taken over the section of the core, and $\int d\mathrm{S}'/\rho$ over the section of the coil. In the case of an anchor ring of circular section, if we neglect the difference between the radius of the primary coil and the radius of the core, the expression for the total induction through the secondary is $4\pi nn'\varpi i(\mathrm{R} - \sqrt{\mathrm{R}^2 - a^2})$.

Small sphere non-uniform field.

In a *non-uniform field* the problem of magnetic induction becomes very difficult for bodies of finite size. If, however, we deal with infinitely small bodies we may suppose the field uniform throughout the body, and apply the results already obtained to find the induced magnetism.

Small Æolotropic Sphere in a Non-uniform Field.—Let $\mathrm{A}_1, \mathrm{B}_1, \mathrm{C}_1$ be the components of the induced magnetization parallel to the principal magnetic axes of the sphere, $\alpha_0, \beta_0, \gamma_0$ the components of the strength of the undisturbed field at the centre of the sphere in the same direction; then, denoting $r_1/(1 + \frac{4}{3}\pi r_1)$ by s_1, and so on, we have $\mathrm{A}_1 = s_1\alpha_0$, $\mathrm{B}_1 = s_2\beta_0$, $\mathrm{C}_1 = s_3\gamma_0$. If the magnetization of the small sphere (of volume v) were rigid, its potential energy W′ would be $\mathrm{W}' = -v(\mathrm{A}_1\alpha_0 + \mathrm{B}_1\beta_0 + \mathrm{C}_1\gamma_0)$. The actual potential energy, W, of the inductively magnetized sphere is different, because its magnetism varies as it passes from one part of the field to another. In any infinitely small displacement, however, we may calculate the work on the supposition that the magnetism is temporarily rigid. In other words, we may put $d\mathrm{W} = d\mathrm{W}'$, where the latter is taken on the supposition that $\mathrm{A}_1, \mathrm{B}_1, \mathrm{C}_1$ do not vary, while on the other hand $\alpha_0, \beta_0, \gamma_0$ do vary, because the resultant force both alters its magnitude and its direction relative to the principal axes of the sphere. We thus get

$$d\mathrm{W} = -v(\mathrm{A}_1 d\alpha_0 + \mathrm{B}_1 d\beta_0 + \mathrm{C}_1 d\gamma_0).$$

In integrating we must take account of the fact that $\mathrm{A}_1, \mathrm{B}_1, \mathrm{C}_1$ are variable. Substituting their values, we get

$$d\mathrm{W} = -v(s_1\alpha_0 d\alpha_0 + s_2\beta_0 d\beta_0 + s_3\gamma_0 d\gamma_0),$$

whence

$$\mathrm{W} = -\frac{v}{2}(s_1\alpha_0^2 + s_2\beta_0^2 + s_3\gamma_0^2) \quad . \quad . \quad . \quad (87).$$

This important formula contains the whole of the theory of the movement of small spherical masses of inductively magnetizable matter in any field of force. We can deduce from it at once the position of equilibrium of an æolotropic sphere suspended in a uniform magnetic field, with freedom to rotate about a given diameter.

Faraday's magnecrystallic law deduced from the principle of least potential energy.

Let λ, μ, ν and l, m, n be the direction cosines of the given diameter and of the direction of the field relative to the principal magnetic axes of the sphere, and R the strength of the field; then $\mathrm{W} = -\frac{1}{2}v\mathrm{R}^2(s_1l^2 + s_2m^2 + s_3n^2)$. For stable equilibrium W must be a minimum, and for unstable equilibrium a maximum, *i.e.*, there is stable or unstable equilibrium according as $s_1l^2 + s_2m^2 + s_3n^2$ is a maximum or a minimum under the given kinematical conditions, which will be expressed by a relation between λ, μ, ν and l, m, n. It is needless to work out the analytical solution; for it leads to results easily obtainable from formulæ already given. It is important, however, to show the identity of this method of treatment

[1] Assuming, as is always the case in nature, that r_2 and r_3 have the same sign.

[2] In other respects it would not in general behave as if it were isotropic.

[3] See art. ELECTRICITY, vol. viii. p. 68.

[4] Kirchhoff, *Pogg. Ann.*, Ergbd. v. 1870. In the same paper he discusses the effect of a rectilinear current in a cylindrical iron wire, and finds that the circular magnetization in a wire of length L gives rise to an apparent increase of the coefficient of self-induction equal to $2\pi\kappa\mathrm{L}$.

with Faraday's view of the matter. If a, b, c be the components of the magnetic induction parallel to the principal axes of the sphere, then we get $a=(1+\frac{8}{3}\pi s_1)Rl$, $b=$&c., $c=$&c. Whence if N denote the total induction through the sphere[1] in the direction of the undisturbed field, we have, ω being the area of its meridian section,

$$N=\omega(al+bm+cn)$$
$$=R+\frac{8}{3}\pi R(s_1l^2+s_2m^2+s_3n^2).$$

N is thus a maximum or a minimum when $s_1l^2+s_2m^2+s_3n^2$ is a maximum or a minimum.

We have therefore established quite generally Faraday's law that *an æolotropic sphere suspended in a uniform field with freedom to rotate about any diameter will be in stable or unstable equilibrium according as the number of lines of force that pass through it is a maximum or a minimum.* A particular case of this theorem has already been proved above (p. 245) for strongly magnetic bodies.

We next apply the formula (87) to deduce the force of *translation* in a heterogeneous field.

1. We see that in a uniform field W is constant so long as there is translation merely without rotation, *i.e.*, there is no tendency in an æolotropic or isotropic sphere to move bodily in a uniform field.

Faraday's law of translational force deduced. Isotropic sphere.

2. If we suppose the sphere isotropic (*i.e.*, $s_1=s_2=s_3=\tau$), then $W=-\frac{1}{2}\tau v(\alpha_0^2+\beta_0^2+\gamma_0^2)=-\frac{1}{2}\tau vR^2$. Hence the force tending to move the sphere in the direction of ds is

$$-\frac{dW}{ds}=\frac{1}{2}\tau v\frac{d(R^2)}{ds}=\tau vR\frac{dR}{ds} \quad . \quad . \quad . \quad (88).$$

In other words, the small sphere is subject to a force of which the scalar potential is $\frac{1}{2}\tau vR^2$. If then we draw the isodynamic surfaces $R^2=$const., the force on an inductively magnetized isotropic sphere will be everywhere at right angles to these; that is, the direction of this force at every point will be tangential to the *lines of slope* of the resultant force, viz., in the direction in which that force varies most rapidly. In the case of paramagnetic bodies, for which τ is positive, *the spheres will tend to move from places of weaker to places of stronger resultant force*; in the case of diamagnetic bodies, for which τ is negative, *from places of stronger to places of weaker force.* This is the famous law found experimentally by Faraday, and afterwards theoretically established by Sir William Thomson.

Isodynamic surfaces and lines of slope.

It must be carefully borne in mind that the lines of slope of the field are not necessarily coincident with the lines of force, *but may cross them at any degree of obliquity.*

As strange mistakes have been made in this matter,[2] it may be well to illustrate this statement by a few examples.

In the case of an isolated north pole the lines of slope coincide with the lines of force, which are straight lines radiating from the pole. In this case a paramagnetic sphere would approach and a diamagnetic sphere recede from the pole *along the lines of force.*

The lines of force for a rectilinear electric current are circles of which it is the axis; the lines of slope are straight lines radiating from the current. A paramagnetic sphere would therefore move towards, a diamagnetic sphere away from the current in a direction *perpendicular to the lines of force.*

In the case of an infinitely small magnet, whose lines of force are given by $r=c\sin^2\theta$, the lines of slope are given by $r=c'\sin^4\theta/\cos\theta$; and the angle between the line of force and the line of slope at the point (r,θ) is $\tan^{-1}\{\tan\theta(1+\cos^2\theta)/(3+5\cos^2\theta)\}$

The theory of isodynamics and lines of slope in the case of plane fields of force, *i.e.*, those for which the potential is given by the equation $d^2V/dx^2+d^2V/dy^2=0$, is remarkably simple. If $\xi=x+iy$, $\eta=x-iy$, we know that $V=\phi(\xi)+\psi(\eta)$, ϕ and ψ being functions depending on the particular case. When these are known the isodynamics are given by

$$\phi'(\xi)\psi'(\eta)=\text{const.}$$

and the lines of slope by

$$\frac{\phi'(\xi)}{\psi'(\eta)}=\text{const.}$$

Æolotropic sphere.

3. Next suppose an æolotropic sphere allowed to move without rotation in any direction ds. Let the direction cosines of the field relative to its principal magnetic axes be l,m,n, then these are constant during the displacement; and, if R be the intensity of the field, $\alpha_0=Rl$, $\beta_0=Rm$, $\gamma_0=Rn$; whence

$$-\frac{dW}{ds}=\frac{1}{2}v(s_1l^2+s_2m^2+s_3n^2)\frac{d(R^2)}{ds} \quad . \quad . \quad . \quad (89).$$

Hence, as before, *the resultant force of translation on the sphere is along the line of slope, in the direction in which the force increases if the body be wholly paramagnetic, in the opposite direction if it be wholly diamagnetic.*

Besides depending on the nature of the field, the force of translation, on account of the factor $s_1l^2+s_2m^2+s_3n^2$, depends on the position of the body relative to the lines of force. Bearing in mind the theory of the radii of an ellipsoid, we have the following proposition:—

The force of translation on an æolotropic sphere is greatest when its axis of (numerically) greatest magnetic susceptibility is parallel to the lines of force, and least when the axis of (numerically) least susceptibility is in the same position.

Or, using permeability instead of susceptibility,—

The force of translation is greatest for a paramagnetic sphere when its axis of greatest permeability is parallel to the lines of force, for a diamagnetic sphere when the axis of least permeability is parallel to the lines of force, and vice versa.

Or, yet again, in the words of Faraday:—

The force of translation exerted upon a paramagnetic sphere is greatest when it is so placed that the greatest number of lines of force pass through it, whereas in the case of a diamagnetic sphere the force is greatest when it is so placed that the least number of lines of force pass through it, and vice versa.

Approximate theory for bodies of finite size.

Approximate Theory of the Action on Bodies of Finite Size in a Non-Uniform Field.—We have seen that, if the square of the susceptibility be negligible, the effect of the form of the body and the disturbance of the field arising from the induced magnetism may be neglected. In that case we may replace the spheres of the foregoing discussion by cubes, and determine the action on a body of finite size by integrating the action on the elementary cubes of which it is composed. Thus the potential energy will be $-\frac{1}{2}\iiint(s_1\alpha_0^2+s_2\beta_0^2+s_3\gamma_0^2)dv$, and the body need not necessarily be homogeneous. From this expression we can deduce the force under given circumstances.

It is quite easy to see, without any mathematical calculation, what will happen in a field of force which diminishes in intensity outwards from an axial line. If we suspend an elongated paramagnetic body with its centre in the axis of the field, it will evidently be in stable equilibrium with its longest dimension placed axially; for if it were slightly displaced every little cube of it would move into a place of weaker force, and would therefore tend to return. If, on the other hand, the body were diamagnetic, it would be in stable equilibrium in an equatorial position; for any displacement from that position would bring every little cube nearer the axis of the field, *i.e.*, into a place of stronger force, and therefore each such cube would tend to return.

General Problem of Magnetic Induction.—It will be instructive to consider for a little the theory of induced magnetism in its most general form.

We shall suppose the induction to arise from given magnetic force $(\alpha_0,\beta_0,\gamma_0)$, arising from pre-existing magnetism (A_0,B_0,C_0) or otherwise. Letters with suffix 1 denote components of induced magnetism, of force arising therefrom, and so on. Letters without suffix denote components of total force, total magnetization, &c. Thus V_0, V_1, V denote the potentials due to pre-existent, induced, and total magnetism respectively; and we have $V=V_0+V_1$, and the like relation in other cases.

We suppose all the media within the field to have definite permeability; but there may be æolotropy and heterogeneity to any extent, and discontinuity along given surfaces.

[1] That is, the number of lines of force passing through the sphere (see above, p. 244).

[2] See Wiedemann, *Galvanismus* (ed. 1874), ii. 665; Todhunter, *Natural Philosophy for Beginners*, pt. i. § 387.

General problem of magnetic induction.

Resolving along the principal magnetic axes at (x, y, z), we get, by the law of induced magnetism, (l_1, m_1, n_1), (l_2, m_2, n_2), (l_3, m_3, n_3) being the direction cosines of the axes $\varpi_1, \varpi_2, \varpi_3$,

$$al_1 + bm_1 + cn_1 = \varpi_1(\alpha l_1 + \beta m_1 + \gamma n_1) + 4\pi(A_0 l_1 + B_0 m_1 + C_0 n_1),$$

and two similar equations.

Multiplying these by l_1, l_2, l_3, adding and so on, we get

$$\left.\begin{aligned} a &= s_1\alpha + t_3\beta + t_2\gamma + 4\pi A_0 \\ b &= t_3\alpha + s_2\beta + t_1\gamma + 4\pi B_0 \\ c &= t_2\alpha + t_1\beta + s_3\gamma + 4\pi C_0 \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad . \quad . \quad (90),$$

where

$$s_1 = \varpi_1 l_1^2 + \varpi_2 l_2^2 + \varpi_3 l_3^2, \quad t_1 = \varpi_1 m_1 n_1 + \varpi_2 m_2 n_2 + \varpi_3 m_3 n_3,$$

&c. ;—that is to say, given functions of x,y,z.

Besides these, we have the conditions of normal continuity for $\mathfrak{B}$, viz.,

$$\frac{da}{dx} + \frac{db}{dy} + \frac{dc}{dz} = 0,$$

and at a surface of discontinuity, λ, μ, ν being the direction cosines of the normal at any point from the first medium to the second,

$$(a - a')\lambda + (b - b')\mu + (c - c')\nu = 0,$$

dashed letters referring to values on the first side of the surface, undashed letters to values on the second.

From these we get finally, for the determination of V,

$$\frac{d}{dx}\left(s_1\frac{dV}{dx} + t_3\frac{dV}{dy} + t_2\frac{dV}{dz}\right) + \&c. + \&c. + 4\pi\rho_0 = 0 \quad . \quad (91).$$

and

$$\left\{ s_1'\frac{dV'}{dx} - s_1\frac{dV}{dx} + t_3'\frac{dV'}{dy} - t_3\frac{dV}{dy} + t_2'\frac{dV'}{dz} - t_2\frac{dV}{dz} \right\}\lambda$$
$$+ \left\{ \&c. \right\}\mu + \left\{ \&c. \right\}\nu + 4\pi\sigma_0 = 0 \quad . \quad . \quad (92).$$

Here

$$\rho_0 = -\left(\frac{dA_0}{dx} + \frac{dB_0}{dy} + \frac{dC_0}{dz}\right),$$

$$\sigma_0 = (A_0 - A_0')\lambda + (B_0 - B_0')\mu + (C_0 - C_0')\nu;$$

i.e., they are Poisson's volume and surface densities for the pre-existing magnetization.

It may be shown by a method[1] essentially the same as that used in the article ELECTRICITY, vol. viii. p. 27, that equations (91) and (92), with the condition that V be continuous everywhere and vanish at infinity, lead to a unique determination of V. When V is known, A_1, B_1, C_1 can be found at once from (90).

Case of homogeneous isotropic medium with no pre-existing magnetization.

In what follows we shall confine ourselves to homogeneous isotropic media, and we shall suppose that in parts of the medium inductively magnetizable there is no pre-existing magnetism. The equations (91) and (92) then reduce to

$$\frac{d^2V}{dx^2} + \frac{d^2V}{dy^2} + \frac{d^2V}{dz^2} = 0 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (93),$$

and

$$\varpi\frac{dV}{d\nu} + \varpi'\frac{dV'}{d\nu'} = 0 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (94),$$

$d\nu, d\nu'$ being elements of normals drawn inwards in the two media. Equations (90) reduce to

$$a = \varpi\alpha, \quad b = \varpi\beta, \quad c = \varpi\gamma;$$

whence

$$A_1 = -\frac{\varpi - 1}{4\pi}\frac{dV}{dx}, \quad B_1 = -\frac{\varpi - 1}{4\pi}\frac{dV}{dy}, \quad C_1 = -\frac{\varpi - 1}{4\pi}\frac{dV}{dy} \quad (95).$$

Induced magnetization in this case both solenoidal and lamellar.

From these last, combined with (93), we have the important consequence that the induced magnetization is both solenoidal and lamellar. This is true only for homogeneous isotropic media in which the pre-existing magnetism, if any there be, is solenoidal.

In all cases such as we are now considering, the part of the magnetic potential due to induced magnetism may be calculated wholly from surface distributions at the surfaces of discontinuity. If σ_1 be this surface density, we have

$$\frac{dV}{d\nu} + \frac{dV'}{d\nu'} + 4\pi\sigma_1 = 0 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (96).$$

From equations (94) and (96)

$$\sigma_1 = \kappa_1\frac{dV}{d\nu} = \kappa_1'\frac{dV'}{d\nu'},$$

where $\kappa_1 = (\varpi - \varpi')/4\pi\varpi', \quad \kappa_1' = (\varpi' - \varpi)/4\pi\varpi.$

Let us suppose that a body A of permeability ϖ is suspended in a medium of permeability ϖ'. If the susceptibilities be small, the forces arising from the induced magnetism will be so small that the direction of the normal force at the surface of A will be the same as if the field were undisturbed by its presence.

Differential action.

First, let the medium be vacuum, for which we suppose $\varpi' = 1$, then, if A be paramagnetic (*i.e.*, $\varpi > 1$), κ_1 will be positive, and the surface magnetism will be positive where the lines of force leave the body, and negative where they enter it. If A be diamagnetic (*i.e.*, $\varpi < 1$), κ_1 will be negative, and the magnetic polarity of the body as a whole will be opposite to what it was in the former case.

Secondly, let the surrounding medium have permeability ϖ', then κ_1 is positive or negative according as $\varpi >$ or $< \varpi'$; in the former case A will behave like a paramagnetic body in vacuo, in the latter like a diamagnetic body in vacuo.

It appears then that, *by virtue of differential action, a body may behave paramagnetically or diamagnetically according as it is placed in a less or in a more permeable medium than itself.*

Poisson's equation.

In practice it is most convenient in general to determine V_1 instead of V. The above equations can be easily modified to admit of this. In fact we get at once, remembering that $dV_0'/d\nu' = -dV_0/d\nu$, since V_0 has no discontinuity at the surface of the media,

$$\frac{d^2V_1}{dx^2} + \frac{d^2V_1}{dy^2} + \frac{d^2V_1}{dz^2} = 0 \quad . \quad . \quad . \quad . \quad . \quad . \quad (97);$$

$$\varpi\frac{dV_1}{d\nu} + \varpi'\frac{dV_1'}{d\nu'} + (\varpi - \varpi')\frac{dV_0}{d\nu} = 0 \quad . \quad . \quad . \quad . \quad (98).$$

These equations, together with the condition that V_1 be finite and continuous and vanish at infinity, determine V_1 completely. Since the induced magnetization is lamellar, we may write $A_1 = d\phi_1/dx$ &c., we then get by (95)

$$\phi_1 = -\frac{\varpi - 1}{4\pi}(V_0 + V_1) = -\kappa(V_0 + V_1) \quad . \quad . \quad . \quad (99),$$

which give the components of moment in terms of the known function V.

J. Neumann's transformation theorem.
